HPLC analyses of the ammonia and enzyme solubilizates from the RRR of straw revealed similar to the water extracts, several components eluting in the range between 15 min and 30 min (both labels, HPLC method LC05). These components were characterized by their elution behavior (each below or equal to 2.8% TRR).

A summary of all identified components in rice matrices after foliar treatment with ^{14}C-pyraclostrobin (chlorophenyl label and tolyl label) is given in Table 6.2.1-24.

Table 6.2.1-24: Summary of identified components in rice matrices after foliar treatment with ^{14}C-BAS 500 F (chlorphenyl label and tolyl label)

Metabolite	Structure	Forage		Straw		Grain	
		Chloro-phenyl Label mg/kg (% TRR)	Tolyl Label mg/kg (% TRR)	Chloro-phenyl Label mg/kg (% TRR)	Tolyl Label mg/kg (% TRR)	Chloro-phenyl Label mg/kg (% TRR)	Tolyl Label mg/kg (% TRR)
BAS 500 F		1.165 (60.7)	1.189 (73.3)	3.794 (44.3)	4.356 (41.5)	1.060 (54.4)	1.091 (51.6)
500M07 (BF500-3)		0.312 (16.3)	0.140 (8.6)	1.477 (17.3)	0.839 (8.0)	0.288 (14.8)	0.218 (10.3)

3. Proposed metabolic pathway

Metabolism of pyraclostrobin in rice occurred mainly by N-desmethoxylation. Unchanged parent compound was the main constituent in all matrices of both labels, representing 41.5 - 73.3% TRR. The N-desmethoxy metabolite 500M07 (BF 500-3) represented the second most abundant component accounting for 8.0% - 17.3% TRR. Some further polar and medium polar components were characterized by their HPLC elution behavior and were all clearly below 10% TRR. Parts of non-extractables found in straw and grain, are partially incorporated in or associated with cellulose, lignin, starch or protein.

Figure 6.2.1-11: Proposed metabolic pathway of BAS 500 F in rice

Bound Residues:
Cellulose, lignin, starch

4. Extractability of residues according to residue analytical methods

Rice matrices of the chlorophenyl label were extracted following the protocol of BASF residue method 535/1 and QuEChERS method. Compared to the solvent extractions of the metabolism investigations, similar amounts of the parent compound and 500M07 were extracted using BASF residue method 535/1. The concentrations of both metabolites ranged from 83%-105% compared to the values found during metabolism investigations. QuEChERS method extracted somewhat lower amounts of parent compound and 500M07 from forage and straw (46%-92%). From grain it extracted 75% of pyraclostrobin and 114% of metabolite 500M07.

Table 6.2.1-25: Amounts of BAS 500 F and 500M07 extracted from rice samples with different extraction methods (chlorophenyl label)

Matrix	**Forage**			**Straw**			**Grain**		
Extraction Method	Metabolism Investigation	BASF Method 535/1	QuEChERS Method	Metabolism Investigation	BASF Method 535/1	QuEChERS Method	Metabolism Investigation	BASF Method 535/1	QuEChERS Method
Metabolite	[mg/kg]								
BAS 500 F	1.165 (100%)	1.228 (105%)	0.697 (59.8%)	3.794 (100%)	3.331 (87.8%)	1.728 (45.5%)	1.059 (100%)	0.875 (82.6%)	0.799 (75.4%)
500M07	0.312 (100%)	0.319 (102%)	0.287 (92.0%)	1.477 (100%)	1.355 (91.7%)	0.713 (48.3%)	0.288 (100%)	0.285 (99.0%)	0.329 (114%)

5. Storage stability

Storage stability investigations were performed in the rice extracts at the beginning and at the end of the study. For all matrices a reanalysis of stored extracts was performed. Initial analyses of rice forage, straw and grain for quantification were carried out within a maximum of 176 days after sampling for the methanol extracts and within 262 days for the water extracts. The stored extracts were reanalyzed approximately 11 month after extraction. In all cases, the chromatograms obtained from the stored extracts were in very good accordance with the initial analyses.

III. CONCLUSION

The highest levels of total radioactive residues (TRR) were found in rice straw (8.564 mg/kg chlorophenyl label and 10.503 mg/kg tolyl label). In rice grain, lower levels were detected for both labels (1.948 mg/kg chlorophenyl label, 2.112 mg/kg tolyl label). The lowest values were found in rice forage, sampled one day before the second application, amounting to 1.921 mg/kg (chlorophenyl label) and 1.622 mg/kg (tolyl label).

The extractability with methanol and water was high in rice forage (chlorophenyl label: 86.5% TRR, tolyl label: 83.5% TRR). For rice straw, the extractability was lower with 68.5% TRR (chlorophenyl label) and 64.8% TRR (tolyl label). From rice grain 75.6% TRR (chlorophenyl label) and 71.4% TRR (tolyl label) were extracted by solvent extraction. From all matrices the major part of the radioactivity was extracted with methanol.

The nature of the residues was examined by HPLC analysis of the methanol and water extracts. Metabolites were identified by mass spectrometric analysis and/or co-chromatography experiments. The predominant residues of ^{14}C-pyraclostrobin in rice consisted of the unchanged parent compound and its desmethoxy metabolite 500M07 (BF 500-3). In rice forage, straw and grain of both labels pyraclostrobin was the main component identified, ranging from 41.5% - 73.3% TRR. Metabolite 500M07 was found in all matrices as the second most prominent compound (from 8.0% to 17.3% TRR). Some further polar and medium polar components were characterized by their HPLC elution behavior and were all clearly below 10% TRR.

The Residual Radioactive Residue (RRR) after solvent extraction was characterized using a sequential solubilization procedure with aqueous ammonia solution and enzymes that released further portions of 4.9% - 16.7% TRR. The ammonia and enzyme solubilizates of straw (both labels) were analyzed by HPLC. Like in the water extracts several components eluting in the range between 15 min and about 30 min were detected and characterized by their HPLC elution behavior. Higher levels of non-extractables found in straw and grain, are partially incorporated in or associated with cellulose, lignin, starch or protein.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: chlorophenyl-U-C14- pyraclostrobin and tolyl-U-C14

Description:	carbon-14 chlorophenyl ring labelled (6.8 MBq/mg) and carbon-14 tolyl ring labelled (7.09 MBq/mg) pyraclostrobin
Lot/Batch #:	^{14}C-BAS 500 F (chlorophenyl): 579-4007 ^{14}C-BAS 500 F (tolyl): 566-4101
Purity:	^{14}C-BAS 500 F (chlorophenyl): 98.6% (radiochemical) ^{14}C-BAS 500 F (tolyl): 99.8% (radiochemical)
CAS#:	175013-18-0
Development code:	BAS 500 F
Stability of test compound	Storage stability investigations were not performed

2. Test Commodity: Cereals

Crop:	Wheat
Type:	Spring wheat
Variety:	WS Thasos 661
Botanical name:	*Triticum aestivum L.*
Crop parts(s) or processed	
Commodity:	Forage, Hay, Straw, Grain
Sample size:	Forage: 500.7 g (chlorophenyl) and 508.8 g (tolyl) Hay: 297.9 g (chlorophenyl) and 260.3 g (tolyl) Straw: 1957.6 g (chlorophenyl) and 2894.7 g (tolyl) Grain: 2917.1 g (chlorophenyl) and 1823.6 g (tolyl)

3. Soil: A sandy loam soil was used. The soil physicochemical properties are described below (see Table 6.2.1-26).

B. STUDY DESIGN AND METHODS

1. Test procedure

Two experiments were performed using either chlorophenyl-^{14}C-labelled or tolyl-^{14}C-labelled pyraclostrobin. The active substance was applied to the seeds using a blank formulation (BAS 662 XI F), for each label at a nominal rate of 1 x 0.010 kg as/ha.

Figure 6.2.1-12: Structural formula of ^{14}C-BAS 500 F labelled at the chlorophenyl ring

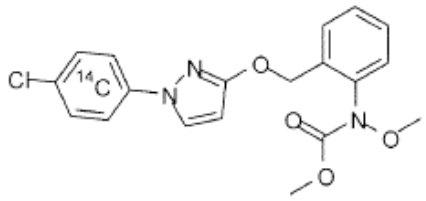

Figure 6.2.1-13: Structural formula of ^{14}C-BAS 500 F labelled at the tolyl ring

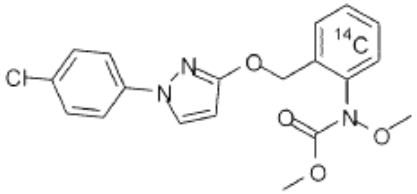

The treated seeds were sown into plastic containers and filled with loamy sand soil (Bruch West; German scheme DIN 4220: loamy sand, USDA scheme sandy loam). Physical and chemical properties of sandy loam soil are given in Table 6.2.1-26.

Table 6.2.1-26: Soil characteristics: soil used for sowing

USDA classification	
clay	11.9%
silt	21.7%
sand	66.4%
soil class	sandy loam
DIN classification	
clay	11.9%
silt	25.8%
sand	62.3%
soil class	loamy sand
Other soil parameters	
total nitrogen	0.13%
total organic carbon	1.48%
total carbon	3.33%
pH ($CaCl_2$)	7.2
pH (H_2O)	7.8
effective cation exchange capacity	11.8 cmol/kg
max. water holding capacity	30.2 g/100 g dry soil
microbial biomass	37.8 mg C/100 g dry soil
microbial C / organic C	2.6%
bulk density	1220 g/L
dry matter	90.6%

Samples of wheat matrices were collected at growth stage 59 (forage), GS 73-75 (hay) and GS 89 (grain and straw) for the chlorophenyl and tolyl label.

2. Description of analytical procedures

All samples (forage, hay, straw and grain) were homogenized with a knife mill along with dry ice. After sublimation of the dry ice, the samples were weighed, mixed, divided into aliquots and radioassayed.

The total radioactive residues (TRR) were determined by direct combustion analysis of small aliquots of homogenized sample material. The sample material was combusted by means of an automatic sample oxidizer. The $^{14}CO_2$ was trapped by an absorption and scintillation liquid, and the collected radioactivity was measured by liquid scintillation counting. Aliquots of liquid samples were mixed with a sufficient volume of a suitable scintillator prior to measurement.

Due to the low radioactivity levels of all wheat matrices, a solvent extraction was only performed for straw samples to get information about potential metabolites formed.

The homogenized straw samples were extracted with methanol and water. Subsequently the methanol extracts were partitioned with cyclohexane and ethyl acetate. The cyclohexane phases were fractionated using a SPE column and the fractions containing the highest radioactivity amount were investigated by HPLC using two different HPLC methods.

For metabolite assignment, the retention times of peaks in the HPLC runs of the isolated straw fractions were compared to those of authentic reference compounds that were analyzed with the same HPLC methods.

For straw the TRR was also calculated by summarizing the Extractable Radioactive Residues (ERR) and the Residual Radioactive Residues (RRR) after solvent extraction.

II. RESULTS AND DISCUSSION

A. TOTAL RADIOACTIVE RESIDUES (TRRs)

The levels of total radioactive residues (TRR) of pyraclostrobin found in wheat forage, hay, straw and grain are reported in Table 6.2.1-27.

Table 6.2.1-27: Total radioactive residues in wheat samples

Wheat matrix	Sampling Interval (DAT[1])	TRR determined [mg/kg]	TRR calculated [2] [mg/kg]
Chlorophenyl Label			
Forage	65	0.0008 [3]	n.p.
Hay	76	0.0015 [3]	n.p.
Straw	104	0.0051 [3]	0.0043
Grain	104	0.0008	n.p.
Tolyl Label			
Forage	63	0.0005	n.p.
Hay	74	0.0014	n.p.
Straw	103	0.0045	0.0038
Grain	103	0.0011	n.p.

[1)] DAT = Days After Treatment (sowing of the treated seed)
[2)] TRR was calculated as the sum of ERR + RRR
[3)] mean value of the two measurements
[4)] n.p. = not performed

All residue levels were below 0.010 mg/kg in all matrices. The TRR values of forage accounted for 0.0008 mg/kg (chlorophenyl label) and 0.0005 mg/kg (tolyl Label). In wheat hay the TRR amounted to 0.0015 mg/kg (chlorophenyl label) and 0.0014 mg/kg (tolyl label). The highest radioactivity levels were found in straw with 0.0051 mg/kg (chlorophenyl label) and 0.0045 mg/kg (tolyl label). In grain the TRR amounted to 0.0008 mg/kg (chlorophenyl label) and 0.0011 mg/kg (tolyl label).
For straw the TRR was also calculated by summarizing the Extractable Radioactive Residues (ERR) and the Residual Radioactive Residues (RRR) after solvent extraction. The values amounted to 0.0043 mg/kg for the chlorophenyl label and to 0.0038 mg/kg for the tolyl label. The calculated TRR values of wheat straw were in good accordance to those obtained by direct combustion analysis. The calculated TRR values of straw samples were set to 100% TRR in the workups for further sample calculations.

B. EXTRACTION, CHARACTERIZATION AND IDENTIFICATION OF RESIDUES

1. Extraction of residues

Since the amount of radioactive residues was below 0.010 mg/kg in all matrices, no further investigations regarding identification, characterization and quantification were performed for forage, hay and grain.
In spite of the also very low radioactive residues, straw samples were extracted with methanol and water to obtain information about potential metabolites formed.
The extractability of the radioactive residues from straw with methanol and water is summarized in Table 6.2.1-28. Altogether, 63.3% TRR were extracted for the chlorophenyl label and 46.4% TRR for the tolyl label. The major part of the residues was extracted with methanol (chlorophenyl label: 44.1% TRR, tolyl label: 37.4% TRR).

Table 6.2.1-28: Extractability of radioactive residues in wheat samples

Matrix	Combined methanol extracts		Combined water extracts		ERR		RRR		TRR calculated [1]
	[mg/kg]	[% TRR]	[mg/kg]	[% TRR]	[mg/kg]	[% TRR]	[mg/kg]	[% TRR]	
Chlorophenyl Label									
Straw	0.0019	44.1	0.0008	19.3	0.0027	63.3	0.0016	36.7	0.0043
Tolyl Label									
Straw	0.0014	37.4	0.0003	9.0	0.0018	46.4	0.0021	53.6	0.0038

[1)] TRR was calculated as the sum of ERR + RRR

2. Identification, characterization and quantitation of extractable residues

Due to the low amounts of radioactive residues, the background noise of the chromatograms was comparatively high. Nevertheless, one peak was detected for both labels when analyzed according to both HPLC methods.
Retention time comparison with reference items suggested that this peak represents the parent compound pyraclostrobin and / or the metabolite 500M07 (BF 500-3). Since pyraclostrobin and 500M07 have similar retention times in both HPLC methods, the peak may contain one or both of the compounds. The identical retention times in the second HPLC method were confirmed by a co-chromatography experiment performed with the unlabelled reference items pyraclostrobin and 500M07. The isolated SPE fractions probably containing pyraclostrobin and / or 500M07 represented about 0.0005 mg/kg or 12.7% TRR for the chlorophenyl label and about 0.0004 mg/kg or 9.6% TRR for the tolyl label. The results of the analysis of wheat straw are summarized in Table 6.2.1-29 (chlorophenyl label) and Table 6.2.1-30 (tolyl label).

Table 6.2.1-29: Summary of characterized residues of wheat straw and final residue (chlorophenyl label)

Designation	[mg/kg]	[% TRR]
Total radioactive residues in wheat straw	0.0043	100
Characterized in the methanol extract

Ethyl acetate phase	0.0007	17.1
Water phase	0.0004	8.2
Total characterized in the methanol extract (sum fractions 1-6 + ethyl acetate and water phase)	**0.0019**	**44.9**
Total characterized in the water extract	**0.0008**	**19.3**
Total characterized from ERR	**0.0028**	**64.1**
Final residue (RRR)	0.0016	36.7
Total characterized (ERR) + final residue	**0.0043**	**100.8**

In the ERR of the chlorophenyl label, 12.7% of the total radioactive residues were characterized by HPLC analysis of the isolated SPE fraction of the methanol extract (Fraction 5, as described above), most probably containing pyraclostrobin and / or 500M07. Additionally, 51.4% TRR were characterized by means of their extractability and elution properties. The RRR amounted to 0.0016 mg/kg or 36.7% TRR and was not further investigated due to the low residue concentration.

Table 6.2.1-30: Summary of characterized residues of wheat straw and final residue (tolyl label)

Designation	[mg/kg]	[% TRR]
Total radioactive residues in wheat straw	0.0038	100
Characterized in the methanol extract		
Radioactive residues in the cyclohexane phase	0.0006	15.1
Characterized in the cyclohexane phase by SPE fractionation		
Fraction 1	<0.0001	0.1
Fraction 2	<0.0001	0.3
Fraction 3	<0.0001	0.6
Fraction 4	<0.0001	1.1
Fraction 5: Containing BAS 500 F and / or 500M07	0.0004	9.6
Fraction 6	0.0001	2.7
Sum of characterized residues in the cyclohexane Phase (sum fractions 1-6)	0.0006	14.4
Ethyl acetate phase	0.0005	13.6
Water phase	0.0003	8.7
Total characterized in the methanol extract (sum fractions 1-6 + ethyl acetate and water phase)	**0.0014**	**36.7**
Total characterized in the water extract	**0.0003**	**9.0**
Total characterized from ERR	**0.0018**	**45.7**
Final residue (RRR)	0.0021	53.6
Total characterized (ERR) + final residue	**0.0038**	**99.3**

In the ERR of the tolyl label, 9.6% of the total radioactive residues were again characterized by HPLC analysis of the isolated SPE fraction of the methanol extract (Fraction 5), most probably containing pyraclostrobin and / or 500M07. Another 36.1% TRR were characterized upon their extractability and elution characteristics. The RRR amounted to 0.0021 mg/kg or 53.6% TRR and was also not further investigated due to its low residue concentration.

3. Proposed metabolic pathway

In all wheat matrices the total radioactive residues were below 0.010 mg/kg. Nevertheless, a solvent extraction was performed to get information about potential metabolites formed and it was possible to isolate one metabolite fraction from the methanol extract of straw from both labels. Retention time comparison with reference compounds suggest, that the isolated fraction contains the unchanged parent compound pyraclostrobin and / or the desmethoxylated metabolite 500M07. These results are in good agreement with those obtained from a wheat metabolism study (Reinhardt, K.: Metabolism of 14C-BAS 500 F in Wheat, BASF DocID 1999/11137) and a rotational crop study (Veit, P.: Confined Rotational Crop Study with 14C-BAS 500 F, BASF DocID: 1999/11829), in which unchanged parent compound and 500M07 were also detected.

4. Storage stability

Storage stability investigations on pyraclostrobin and its metabolites were already performed within a wheat metabolism study (Reinhardt, K.: Metabolism of 14C-BAS 500 F in Wheat, BASF DocID 1999/11137) and within a rotational crop study (Veit, P.: Confined Rotational Crop Study with 14C-BAS 500 F, BASF DocID: 1999/11829). Additionally, the HPLC analyses performed in this study were carried out within two month after extraction. Therefore, concerning the current study no further storage stability investigations were necessary.

III. CONCLUSION

The levels of total radioactive residues (TRR) were very low (<0.010 mg/kg) in all wheat matrices. The highest levels of total radioactive residues (TRR) were found in wheat straw (0.0051 mg/kg and 0.0045 mg/kg, chlorophenyl and tolyl label, respectively) followed by hay (0.0015 mg/kg and 0.0014 mg/kg, chlorophenyl and tolyl label). In wheat forage the TRR amounted to 0.0008 mg/kg (chlorophenyl label) and 0.0005 mg/kg (tolyl label). The TRR values of grain were 0.0008 mg/kg (chlorophenyl label) and 0.0011 mg/kg (tolyl label).
Due to the low radioactivity levels only straw samples were extracted with solvent. The extractability of the radioactive residues from straw with methanol and water was moderate for both labels (63.3% TRR chlorophenyl label and 46.4% tolyl label). For both labels, the major part of the residues (about 40% TRR) was extracted with methanol. Due to low levels of radioactivity in the Residual Radioactive Residues (RRR) after solvent extraction no further solubilization steps were performed.
The nature of the residues was examined by HPLC analyses of fractions isolated from the methanol extracts of straw (both labels). These fractions were obtained from the methanol extracts by liquid /liquid partition and subsequent fractionation of the cyclohexane phases by SPE fractionation on a silica gel column. The isolated fractions were further investigated by HPLC. Retention time comparison with authentic reference compounds suggest that the only significant peak detected most probably represents the parent compound pyraclostrobin and/or its desmethoxylated metabolite 500M07 (BF 500-3), that are co-eluting using the applied HPLC methods.

CA 6.2.2 Poultry

A poultry metabolism study conducted with tolyl-^{14}C and chlorophenyl-^{14}C labeled pyraclostrobin was evaluated during the previous Annex I inclusion process.

Pyraclostrobin (BAS 500 F) is rapidly absorbed, distributed and excreted. In hens dosed with 12 mg/kg feed, the residues in muscle were below 0.010 mg/kg. Consequently, no further investigations were carried out. In fat and eggs, pyraclostrobin and the desmethoxy metabolite 500M07 (BF 500-3) formed the major part of the residue whereas in liver hydroxylation reactions were predominant. As in plant matrices, cleavage products (as 500M04 and 500M49) have been identified in tissues and eggs. The study is still meeting today's requirements. Therefore, no new study has been performed.

CA 6.2.3 Lactating ruminants

A goat metabolism study conducted with tolyl-^{14}C and chlorophenyl-^{14}C labeled pyraclostrobin was evaluated during the previous Annex I inclusion process.

The following conclusion is copied from the EFSA Reasoned Opinion on the re-evaluation of established MRLs:
Studies of the metabolism of pyraclostrobin in goats showed that residues in products of animal origin derive from the parent compound as well as from its desmethoxy metabolite (500M07). After five consecutive daily oral administrations of ^{14}C-pyraclostrobin at a nominal dosage of 12 or 50 mg/kg DM feed, there was rapid absorption from the gastrointestinal tract. Radioactivity was excreted mainly via the faeces. The radiolabel in milk accounted for only 0.1–0.5% of the total applied radioactivity. There was no indication of accumulation of ^{14}C-pyraclostrobin in tissues. The parent compound was found in fat, muscle and, at lower amounts, in liver. Metabolites are formed in liver and kidney by hydroxylation of the chlorophenyl and tolyl rings and by cleavage of the molecule. Little extraction was seen in liver. Pyraclostrobin was present in all tissues and in milk and was the main residue component in muscle and in fat (log Pow = 3.9).

The study is still meeting today's requirements. Therefore, no new study has been performed.

Upon request of the Australian authority, an in-vitro comparison study was performed for goat and cow cell cultures. In order to allow a comprehensive overview, the study summary of these supplemental investigations are provided. Goat and cow microsomes and hepatocytes were incubated with the chlorophenyl-^{14}C labeled test substance.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Pyraclostrobin (unlabelled, 14C-labeled)

Description:	unlabelled BAS 500 F (pyraclostrobin, methyl N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl] oxymethyl}phenyl) N-methoxycarbamate), 14C-labeled BAS 500 F (pyraclostrobin, methyl N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl] oxymethyl}phenyl) N-methoxycarbamate, labeled at chlorophenyl-U-C14); (specific activity: 91.4 MBq/mg)
Lot/Batch #:	unlabelled pyraclostrobin: 01815-183 labelled pyraclostrobin: 579-2202
Purity:	unlabelled pyraclostrobin: 99.9% (HPLC) labelled pyraclostrobin: 99.4% (RHPLC)
CAS#:	unlabelled/labelled pyraclostrobin: 175013-18-0
Development code:	not applicable
Spiking levels:	100 µM (high dose), 10µM (low dose)
Stability of test compound:	no storage stability investigations were necessary

2. Test Commodity:

Cell cultures: Liver microsomes from male goats (purchased from In Vitro Technologies GmbH Leipzig, Germany) and male cows (purchased from In Vitro Technologies GmbH Leipzig, Germany), all preparations contained 20 mg microsomal protein per mL.

In vitro assay: The test solutions (mix of unlabeled and 14C-labeled test item pyraclostrobin) were incubated at approximately 100 µM for high dose or approximately 10 µM for low dose conditions with goat or cow microsomes. The radioactivity per incubation mixture was approximately 100000 dpm. Each sample (2 mL total volume) comprised 1 mg of microsomal protein, a NADPH generating system and potassium phosphate buffer (approximately 90 mM, pH 7.4). The reactions were performed at 37°C for 3 h in a shaker and stopped by addition of 2 mL acetone (resulting in a final volume of 4 mL for each sample). All experiments (goat high dose, goat low dose, cow high dose and cow low dose) were carried out as triplicates. For every condition one additional experiment (not as a triplicate) was done with heat inactivated microsomes (incubated for 10 min in boiling water).

B. STUDY DESIGN AND METHODS

The present study including the analytical phase was performed at the BASF Agricultural Center Limburgerhof, Germany.

1. Test procedure

The aim of the study was to compare the metabolism of BAS 500 F (pyraclostrobin) in cell cultures of the ruminants goat and cow. The *in vitro* metabolism investigations with pyraclostrobin were performed with a mixture of unlabelled and ^{14}C-labeled (chlorophenyl-U-C14) test item. The active substance was incubated at 100 µM (high dose) or 10 µM (low dose) with goat or cow liver microsomes (1 mg microsomal protein per incubation mixture). The incubations were carried out for 3 h at 37°C and stopped by addition of acetone. For each experimental condition a control experiment with heat inactivated microsomes was performed.

Figure 6.2.3-1: Structural formula of unlabelled BAS 500 F

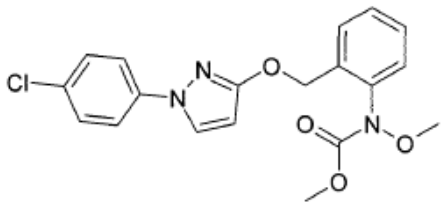

Figure 6.2.3-2: Structural formula of ^{14}C-BAS 500 F labelled at the chlorophenyl ring

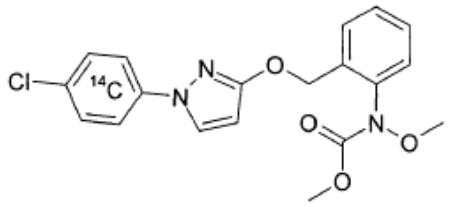

2. Description of analytical procedures

2 mL of each stopped incubation mixture were pooled and stored at -18°C until further processing. The samples from the incubations with inactivated microsomes were directly stored at -18°C. An aliquot of the pooled workup sample from the high dose incubations with cow microsomes was concentrated and stored at -18°C until HPLC-MS analysis. For quantitative HPLC analysis, aliquots of each sample were taken and were evaporated with nitrogen. The volume was adjusted with water and the samples were stored at -18°C until HPLC analysis.
For fractionation, an aliquot of the pooled sample from the high dose incubations with goat microsomes was concentrated. Aliquots of the concentrated sample were sequentially fractionated by HPLC (HPLC method LC04). Three fractions per HPLC run were manually cut and the corresponding fractions were pooled. The pooled fractions were adjusted to an end volume of 5 mL for LSC measurement. Then, the solvent was completely evaporated, the residues resuspended in HPLC eluent A (water/acetonitrile/acetic acid, 950/50/1, v/v/v) and stored at -18°C until HPLC-MS analysis.

II. RESULTS AND DISCUSSION

A. TOTAL RADIOACTIVE RESIDUES (TRRs)

Total radioactive residues were quantified in stopped incubation mixtures and pooled samples. The total radioactive residues were also measured in the stopped incubates with heat inactivated microsomes, which served as controls. The recoveries of both experiments were compared. The found total residual levels per incubation mixture corresponded approximately to the intended value of 100000 dpm.
Additionally, no significant difference of the total radioactive residues in incubates with active or inactivated microsomes were observed. This finding excluded a possible generation of volatile components in the presence of active microsomal enzymes.

B. EXTRACTION, CHARACTERIZATION AND IDENTIFICATION OF RESIDUES

1. Extraction and hydrolysis of residues

All control experiments with heat inactivated microsomes yielded 100.0% TRR of the unmodified parent compound pyraclostrobin indicating that no hydrolytical degradation is taking place under the conditions applied.

2. Identification, characterization and quantitation of extractable residues

The identification of the metabolites was based on HPLC-MS analyses of HPLC fractions from high dose incubations with goat microsomes (fraction 1 to 3) and HPLC-MS analysis of the concentrated sample from high dose incubations with cow microsomes. Peak assignment in the other samples was done by comparison of the HPLC retention times and metabolite patterns with those of the fractions investigated by HPLC-MS and reference items.

Goat

In the sample from the **high dose** incubations with goat microsomes, the unchanged parent compound pyraclostrobin (fraction 3) was the most abundant component, accounting for 6.994 mg/kg (43.4% TRR). The metabolite 500M04 (fraction 1) was detected at a concentration of 4.210 mg/kg (26.1% TRR). Additionally, the metabolites 500M35, 500M86, 500M87, 500M34 and 500M88 were identified by HPLC-MS (fraction 2). In total, 16.128 mg/kg (100.0% TRR) of radioactive residues were identified in samples from the high dose incubations with goat microsomes. In the sample from **low dose** incubations with goat microsomes, the metabolite 500M04 was the most abundant component, accounting for 1.473 mg/kg (90.3% TRR). The parent compound pyraclostrobin was found at 0.159 mg/kg (9.7% TRR). Accordingly, 1.632 mg/kg (100.0% TRR) of the radioactive residues were identified.

Table 6.2.3-1: Identified components in the workup samples from incubations with goat microsomes

Designation	[mg/kg]	[µg/mg Protein]	[% TRR]
HIGH dose incubation with goat microsomes			
Total radioactive residue (TRR)	**16.128**	**64.511**	**100.0**
Identified in stopped and pooled incubation mixtures			
500M04	4.210	16.841	26.1
500M88, 500M34, 500M35, 500M86 and 500M87	1.526	6.104	9.5
	1.744	6.976	10.8
	1.653	6.614	10.3
BAS 500 F	6.994	27.975	43.4
Total identified	**16.128**	**64.511**	**100.0**
LOW dose incubation with goat microsomes			
Total radioactive residue (TRR)	**1.632**	**6.529**	**100.0**

500M04	1.473	5.894	90.3
BAS 500 F	0.159	0.636	9.7
Total identified	**1.632**	**6.529**	**100.0**

Cow

In the sample from the **high dose** incubations with cow microsomes, the parent compound pyraclostrobin was the most abundant component, accounting for 15.007 mg/kg (90.3% TRR). The metabolite 500M04 was present at a concentration of 1.610 mg/kg (9.7% TRR). Additionally, the metabolites 500M34 and 500M88 were identified by HPLC-MS, but present only in trace amounts. In total, 16.617 mg/kg (100.0% TRR) of the radioactive residues were identified. In the sample from **low dose** incubations with cow microsomes, the parent compound pyraclostrobin was also the most abundant component, accounting for 0.553 mg/kg (29.7% TRR). The metabolite 500M04 was present at a comparable concentration of 0.462 mg/kg (24.8% TRR). Moreover, peaks corresponding to metabolites of fraction 2 (500M35, 500M86, 500M87, 500M34 and 500M88) were detected in the quantitative HPLC chromatogram. Hence, 1.015 mg/kg (54.6% TRR) of radioactive residues were identified and additional 0.845 mg/kg (45.4% TRR) were characterized in samples from the low dose incubations with cow microsomes.

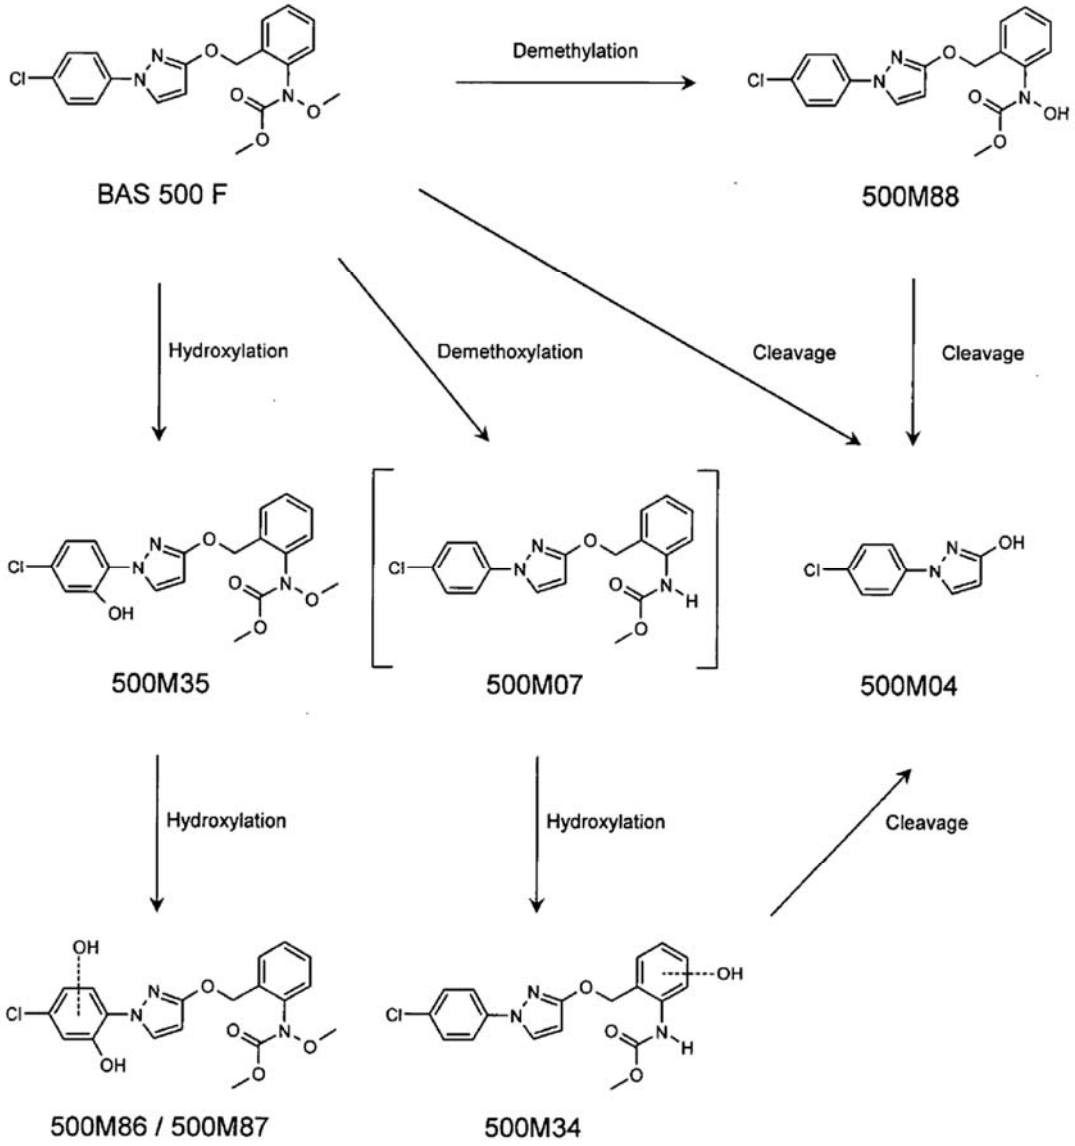
3. Proposed metabolic pathway

Pyraclostrobin was similarly metabolized by goat and cow microsomes. After low dose incubation of pyraclostrobin at 10 µM with goat microsomes the parent compound was detected in portions below 10% TRR. The transformation of pyraclostrobin was not as complete when incubated at 100 µM (portion of parent compound at 43.4% TRR), which indicates that under these conditions the responsible microsomal enzymes were saturated. A similar tendency was observed for the incubations of pyraclostrobin with cow microsomes. Whereas only 29.7% TRR of the parent compound were detected when incubated at 10 µM, a portion of 90.3% TRR of pyraclostrobin remained in samples from high dose incubations at 100 µM.

Pyraclostrobin was metabolized by five transformation reactions:
• Cleavage of the ether bond
• Demethylation of the N-methoxycarbamate group
• Desmethoxylation of the N-methoxycarbamate group
• Hydroxylation of the tolyl moiety
• Hydroxylation of the chlorophenyl moiety

The cleavage product 500M04 (1-(4-chlorophenyl)-1H-pyrazole-3-ol) is the central metabolite in the *in vitro* biotransformation route of pyraclostrobin through goat and cow microsomes. This compound was also found in a previous *in vivo* study in goat as one of the key metabolites of pyraclostrobin. The metabolite 500M04 can be generated by direct cleavage of the parent compound pyraclostrobin, but also by cleavage of the metabolites 500M88 or 500M34, because their chlorophenyl-pyrazole moiety remains unaltered. The latter path is supported by the observation that after low dose incubations with goat microsomes pyraclostrobin was almost completely transformed to 500M04 (>90% TRR), whereas in samples from high dose incubations the metabolites 500M88 and 500M34 were also present.
The metabolite 500M88 results from demethylation of the N-methoxycarbamate group of pyraclostrobin and appeared in samples from incubations with goat and cow microsomes. Desmethoxylation of the N-methoxycarbamate group leads to metabolite 500M07, which was not detected in the course of this study, but previously observed in the goat study mentioned above. 500M07 is the putative precursor of metabolite 500M34, which was found in the present study (goat and cow microsomes) and results from hydroxylation of 500M07 at the benzylic ring. As mentioned above, both metabolites (500M88 and 500M34) were possibly cleaved to the main metabolite 500M04.
The metabolite 500M35 results from hydroxylation and the metabolites 500M86 / 500M87 result from twofold hydroxylation of the chlorophenyl residue of pyraclostrobin. In the previous *in vivo* goat study, both hydroxylation of the benzylic and the chlorophenyl residue was observed.
The metabolic pathway of pyraclostrobin incubated with goat and cow microsomes is shown in Figure 6.2.3-3.

Figure 6.2.3-3: Metabolic pathway of BAS 500 F incubated with goat and cow microsomes



4. Comparison of *in vitro* metabolism in goat and cow

All metabolites identified in samples from incubations with cow microsomes were also found when using goat microsomes. Incubation of pyraclostrobin with microsomes from either origin preferentially led to cleavage of the ether bond, yielding metabolite 500M04. The amount of the cleavage product 500M04 was 90.3% TRR in samples from incubations with goat microsomes and 24.8% TRR in samples from incubations with cow microsomes, both under non-saturated low dose conditions.

Demethylation and desmethoxylation of the N-methoxycarbamate group of pyraclostrobin was also observed with goat and cow microsomes, leading to metabolite 500M88 and the putative precursor 500M07, respectively. Hydroxylation of this precursor at the benzylic ring led to metabolite 500M34, in samples from goat and cow microsomes. The metabolites 500M88 and 500M34 are both precursors of the main metabolite 500M04.

Hydroxylation of the chlorophenyl moiety of pyraclostrobin led to the metabolites 500M35 and 500M86 / 500M87. These metabolites were identified by HPLC-MS in the sample from high dose incubations with goat microsomes and a corresponding peak group was identified by HPLC in the sample from low dose incubations with cow microsomes. However, hydroxylation of the chlorophenyl moiety played only a minor role in the *in vitro* biotransformation route of pyraclostrobin.

5. Storage stability

All samples were stored at approximately -18°C during the course of the study. The pattern and the main peaks in the quantitative HPLC chromatogram of the sample from high dose incubations with goat microsomes and the HPLC chromatogram of the fractionation of the same sample showed no significant difference. Since the quantitative HPLC analyses of all samples in this study were performed six days after sampling, no storage stability investigations were necessary.

III. CONCLUSION

The investigation of the *in vitro* metabolism of pyraclostrobin in goat and cow was conducted by incubation experiments of the test item (mix of unlabeled and ^{14}C-Iabeled pyraclostrobin) at 100 µM (high dose) or 10 µM (low dose) with the corresponding microsomes, followed by qualitative and quantitative analysis of the residues.

Pyraclostrobin was similarly metabolized by goat and cow microsomes. All metabolites identified in samples from incubations with cow microsomes were also found in the experiments with goat microsomes. The appearance of the main metabolite 500M04 (BF 500-5) was independent from the microsome‘s origin and resulted from cleavage of the ether bond. lt was already identified in a previous *in vivo* goat study as one of the key degradation products of pyraclostrobin. The metabolite 500M88 (demethylation of the N-methoxycarbamate group) and 500M34 (desmethoxylation of the N-methoxycarbamate group and hydroxylation of the benzylic ring) were further common metabolites found after the incubation of pyraclostrobin with goat or cow microsomes. Both are putative precursors of the main metabolite 500M04. Hydroxylation of the chlorophenyl moiety played only a minor role in the *in vitro* biotransformation route of pyraclostrobin.

In samples from the control experiments with heat inactivated microsomes only the unmodified parent compound pyraclostrobin was detected, demonstrating that the transformation of pyraclostrobin was dependent on the presence of active microsomal enzymes.

CA 6.2.4 Pigs

According to Reg. 283/2013, pig metabolism studies shall be provided where the plant protection product is used in crops whose parts or products, also after processing, are fed to pigs and where it becomes apparent that metabolic pathways differ significantly in the rat as compared to ruminants and where the intake is expected to exceed 0.004 mg/kg bw/day.

For pyraclostrobin, no metabolism study was performed in pigs, since the metabolite patterns in rodents (rats) and ruminants (goats) did not differ significantly.

CA 6.2.5 Fish

A bioaccumulation study has been performed in 1999. The study has been already submitted in context of the previous Annex I inclusion process. However, in the previous evaluation it has not been assessed within the residue section. In the study the tolyl-^{14}C and chlorophenyl-^{14}C labeled test substance was applied to water. The study includes the identification of metabolites in edible and inedible portions of bluegill sunfish.

As a new data requirement according to Regulation 283/2013, metabolism studies on fish may be required where the plant protection product is used in crops whose parts or products, also after processing, are fed to fish and where residues in feed may occur from the intended applications. Pyraclostrobin is registered in the majority of crops being intended as fish feed item. In most of these crops residue levels above LOQ occur. The working document on the study conduct was published in II/2013. In order to meet these new data requirements, a fish metabolism study (dosing via diet) has been performed.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 F (Pyraclostrobin, Reg. No. 304428)
[Tolyl-U-^{14}C]-BAS 500 F; specific activity 4.62 MBq/mg,
[Chlorophenyl-U-^{14}C]-BAS 500 F; specific activity 4.32 MBq/mg,
Lot/Batch #: BAS 500 F: 00937-128
[Tolyl-U-^{14}C]-BAS 500 F: 566-2101
[Chlorophenyl-U-^{14}C]-BAS 500 F: 579-1201
Purity: BAS 500 F: 99.8% (Chemical purity)
[Tolyl-U-^{14}C]-BAS 500 F: > 98% (Radiochemical purity)
[Chlorophenyl-U-^{14}C]-BAS 500 F: > 98% (Radiochemical purity)
CAS#: 175013-18-0
Development code: not applicable
Stability of test compound: The test item was stable for up to 3 months.

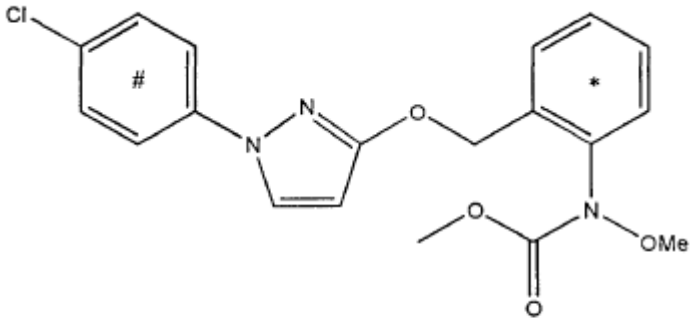
2. Test animals: Fish
Test species: Bluegill Sunfish (*Lepomis macrochirus*)
Body weight: 0.883 – 1.211 g/animal (wet, at the start of exposure, used for bioaccumulation and metabolism study)
Age: ca. 12 months (at the start of exposure)

B. STUDY DESIGN

1. Test procedure

Test fish were exposed to 300 ng as/L (nominal concentration) in a flow-through system. The test concentration was derived from acute toxicity data of pyraclostrobin for bluegill sunfish (ca. 1% of the 96 h LC_{50}). Since this concentration was already very low, a test with a second lower concentration could not be conducted, as results would have been below analytical limits of determination.
The active substance was dissolved in N,N-dimethyl formamide (DMF) and this stock solution was pumped into a mixing vessel supplied with a diluent stream of water. From there, the treated water flowed through the tanks at rates of 12.1 – 13.0 L/hour. Test fish (*ca*. 150 of *ca.* 1 g size for each label at day 0) were exposed for 37 days. Subsequently fish were exposed to a continuous flow of dilution water alone for either 14 days (chlorophenyl label) or 21 days (tolyl label). A control experiment with ca. 150 fish was conducted where fish were exposed to DMF and diluent water alone.

Figure 6.2.5-1: Structural formula of ^{14}C-BAS 500 F labelled at the chlorophenyl ring and the tolyl ring



= [^{14}C]-BAS 500F Chlorophenyl label
* = [^{14}C]-BAS 500F Tolyl label

2. Description of analytical procedures

Water and fish were sampled at suitable intervals. Fish were dissected into edible (muscle) and inedible (viscera) tissue fractions. Total radioactivity was determined in tissue and water samples.
Extracts of water, edibles and inedibles were analyzed by radio-HPLC. Unchanged parent compound and degradation products were identified by chromatographic comparison with reference compounds and metabolites previously identified in the course of a rat metabolism study.

II. RESULTS AND DISCUSSION

A. TOTAL RADIOACTIVE RESIDUES (TRRs)

1. Test item concentration in the water

Chlorophenyl label
During the uptake phase the actual concentration of total radioactivity in water was in the range of 263 – 344 ng/L with a mean concentration of 305 ng/L. Water sampled at the first day of depuration contained 14% of the nominal concentration used in the uptake phase and thereafter the concentration dropped to levels below the limit of determination. The only radioactive component in water was unchanged pyraclostrobin.

Tolyl label
During the uptake phase the actual concentration of total radioactivity in water was in the range of 278 - 336 ng/L with a mean concentration of 300 ng/L. Water sampled at the first day of depuration contained 22% of the nominal concentration used in the uptake phase and thereafter the concentration dropped to levels below the limit of determination. The only radioactive component in water was unchanged pyraclostrobin.

2. Test item concentration in fish

Chlorophenyl label
Mean concentrations of radioactivity in the total fish reached an apparent steady state of 0.184 - 0.235 mg/kg after 4 days of exposure. Mean concentrations of radioactivity in the fillet increased from 0.047 mg/kg on day 1 of the exposure period to a plateau of 0.066 - 0.071 mg/kg. Mean concentrations of radioactivity in the inedible fraction (viscera) increased from 0.180 mg/kg on day 1 to a plateau of 0.314 - 0.404 mg/kg during days 4 - 35 of the exposure period.

Tolyl label
Mean concentrations of radioactivity in the total fish reached an apparent steady state of 0.192 - 0.243 mg/kg after 4 days of exposure. Mean concentrations of radioactivity in the fillet increased from 0.07 mg/kg on day 1 of the exposure period to a plateau of 0.074 - 0.084 mg/kg. Mean concentrations of radioactivity in the inedible fraction (viscera) increased from 0.197 mg/kg on day 1 to a plateau of 0.331 - 0.425 mg/kg during days 4 - 35 of the exposure period.

3. Bioconcentration factor

Chlorophenyl label
The bioconcentration factors and kinetic parameters based on total radioactivity concentrations were derived from Non-Linear-Regression Analysis using a 2-Compartment Model and are summarized in Table 6.2.5-1. The depuration half-life in whole fish was 0.9 day. Accordingly, the time to reach 90% depuration is 3.0 days. The bioconcentration factor calculated directly from the ratio of the ^{14}C-concentrations in water and tissue fractions (mean of days 4 – 35) was 673 for whole fish, 232 for edible tissues and 1169 for viscera (Table 6.2.5-2). The values were in good accordance with those obtained by kinetic modelling.

Tolyl label
The bioconcentration factors and kinetic parameters based on total radioactivity concentrations were derived from Non-Linear-Regression Analysis using a 2-Compartment Model and are summarized in Table 6.2.5-1. The depuration half-life in whole fish was 0.9 days. Accordingly, the time to reach 90% depuration is 2.8 days. The bioconcentration factor calculated directly from the ratio of the ^{14}C-concentrations in water and tissue fractions (mean of days 4 – 35) was 719 for whole fish, 262 for edible tissues and 1221 for viscera (Table 6.2.5-2). The values were in good accordance with those obtained by kinetic modelling.

The BCF values for unchanged BAS 500 F were 379 for whole fish, 191 for edibles and 574 for inedibles. The BCF values are shown in Table 6.2.5-3.

Table 6.2.5-3: Bioconcentration factors for unchanged parent compound calculated from the ratio of the BAS 500 F concentrations in tissues and water

Treatment	BCF		
	Edibles	Inedibles	Whole Fish
Chlorophenyl label	191	574	379
Tolyl label	178	853	507

B. EXTRACTION, CHARACTERIZATION AND IDENTIFICATION OF RESIDUES

1. Extraction of residues

Most of the radioactivity (>80.6% and >81.6% with the chlorophenyl label and tolyl label, respectively) was recovered in the methanol extracts. A further 2.3-5.3% (chlorophenyl label) and 2.4 - 4.8% (tolyl label) were extracted by water. The Residual Radioactive Residues (RRR) after solvent extraction were in the range of 3.9 to 9.9% (chlorophenyl label) and in the range of 5.5 to 11.2% (tolyl label) of the total radioactive residue. The residual radioactive residues from edible tissue (8.2 - 11.2%) were consistently higher than that from inedible tissue (3.9 - 7.6%). There were no obvious differences between the 2 sites of radiolabel.

Extractability data in fish tissue is shown in Table 6.2.5-4.

Table 6.2.5-4: Recovery during the extraction of fish tissue for chromatography

Treatment	Matrix type	Initial Sample [%]	Extract 1 [%]	Extract 2 [%]	RRR [%]	Total Recovery [%]
Uptake Day 21						
Chlorophenyl label	Edible	100.0	80.6	5.3	8.2	94.0
	Inedible	100.0	90.1	2.3	3.9	96.2
Tolyl label	Edible	100.0	88.4	4.2	11.2	103.8
	Inedible	100.0	101.1	2.4	5.5.	109.0
Uptake Day 28						
Chlorophenyl label	Edible	100.0	88.7	5.2	9.9	103.8
	Inedible	100.0	84.7	3.0	5.6	93.4
Tolyl label	Edible	100.0	81.9	4.8	11.2	98.0
	Inedible	100.0	81.6	4.5	7.6	93.7

Extract 1 = Methanol, Extract 2 = Water

In the experiment with the chlorophenyl label, between 82.1 and 99.4% of the total radioactivity in water was extracted by solid phase extraction leaving 1.2 - 7.5% in the aqueous residue. With the tolyl label, between 82.9 and 95.4% of the total radioactivity was extracted and 1.1 - 7.0% recovered in the aqueous residue. In both experiments, quantities of radioactivity recovered in the aqueous residue were lower in the pre-equilibration phase than after addition of the fish. This indicates the presence of unextracted polar components, possibly eliminated from the fish. Overall recoveries of radioactivity exceeded 85% and, considering the low levels of radioactivity in water from this study, were considered quantitative.

2. Identification, characterization and quantitation of extractable residues

In edible tissue, 62.8 - 73.7% (0.051 - 0.052 mg/kg) showed chromatography consistent with unchanged pyraclostrobin, 6.5 - 9.4% (0.005 - 0.007 mg/kg) with 500M07 and 2.5 - 3.6% (0.002 - 0.003 mg/kg) with 500M08. In the experiment conducted with the chlorophenyl label, 2.0% (0.001 mg/kg) of 500M04 was detected, whilst with the tolyl label, 4.1% (0.003 mg/kg) of 500M45 was detected. In the experiment with the tolyl label, 2 components of a highly polar nature, Unknowns 4 and 5, were detected at 2.0% (0.002 mg/kg) and 4.0% (0.003 mg/kg), respectively. Radioactivity in the water extract accounted for 4.8 - 5.2% (0.004 mg/kg) to leave residual radioactive residues of 9.9 - 11.2% (0.007 - 0.009 mg/kg), so these fractions were not characterized further.

Inedible tissue contained 38.6 - 57.4% (0.156 - 0.244 mg/kg) unchanged pyraclostrobin and 3.4 - 7.3% (0.014 - 0.029 mg/kg) 500M07. In the experiment with the chlorophenyl label, 4.5% (0.018 mg/kg) of 500M08 and 9.0% (0.036 mg/kg) of 500M04 were detected together with 5.3% (0.021 mg/kg) each of 2 unidentified components (Unknowns 1 and 2) and 14.7% (0.059 mg/kg) Unknown 3. In the experiment with the tolyl label, 16.1% (0.068 mg/kg) of Unknown 3 and 4.6% (0.012 mg/kg) of Unknown 5 were detected. Radioactivity in the water extract accounted for 3.0 - 4.5% (0.012 - 0.019 mg/kg), leaving residual radioactive residues of 5.6 - 7.6% (0.023 - 0.032 mg/kg), so these fractions were not characterized further.

It appeared that pyraclostrobin was initially metabolized to form metabolite 500M07. Subsequent hydroxylation yielded metabolites 500M08 and 500M45. In addition, cleavage of the ether link between the pyrazole and tolyl rings lead to separation of the molecule into 500M04 and unidentified components (possibly the highly polar Unknowns 4 and 5). Up to 5 unidentified components were observed in fish tissues during the study. However, the major component in all tissue fractions was unchanged pyraclostrobin which comprised 39% - 74% of the Total Radioactive Residue (TRR).
A summary of identified metabolites in fish fractions from the steady-state period (28 days of exposure) is shown in Table 6.2.5-5. The structures of identified metabolites are presented in Table 6.2.5-6.

Table 6.2.5-5: Summary of Identified and Characterized Radioactivity Results in Fish Tissues - Day 28

Table 6.2.5-6: Structures of identified metabolites

Metabolite	Structure
BAS 500 F	500M07 (BF 500-3)	500M08	500M45	500M04 (BF 500-5)	
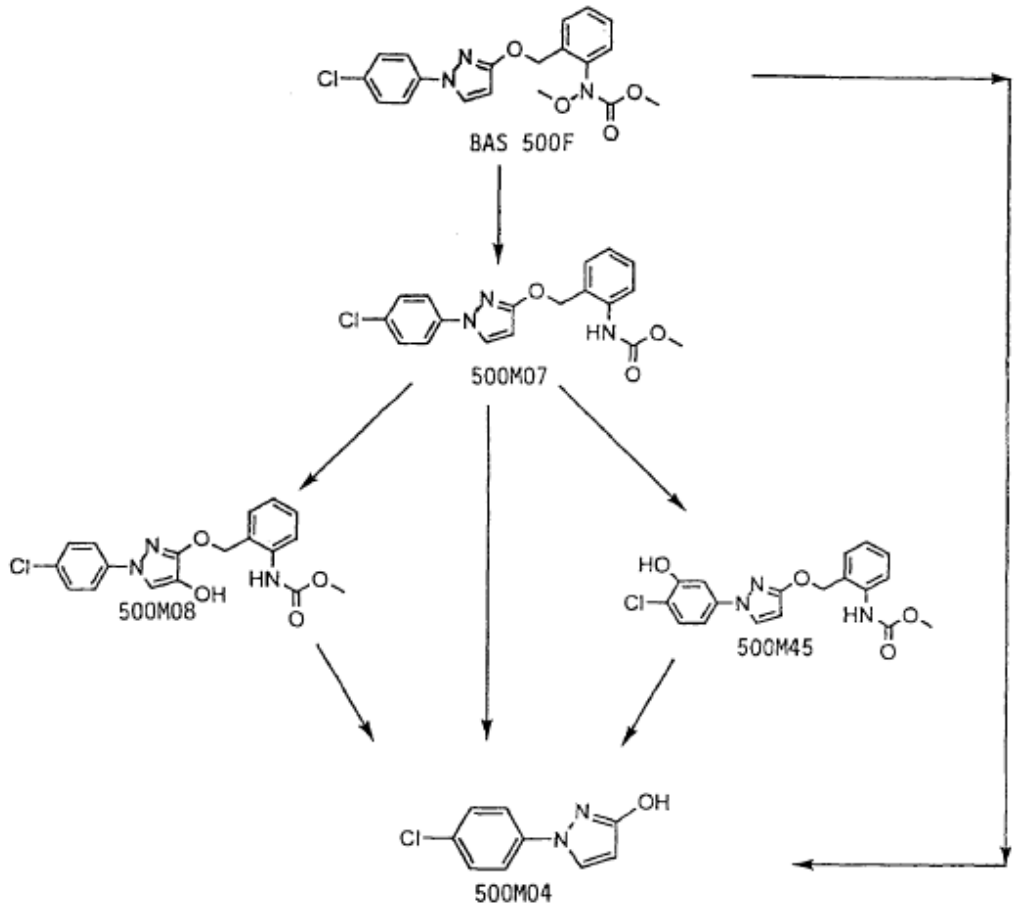
3. Proposed metabolic pathway

The proposed pathway for the metabolism of pyraclostrobin in bluegill sunfish is presented in Figure 6.2.5-2.

Figure 6.2.5-2: Proposed pathway for the metabolism of pyraclostrobin in Bluegill Sunfish



6. Storage Stability

BAS 500 F and the radioactive components detected in fish are stable in fish tissue during storage at ca. -20°C for up to 3 months.

III. CONCLUSION

After exposure of fish to pyraclostrobin at a nominal exposure level of 300 ng/L, apparent steady state was reached after 2 - 4 days. After termination of the exposure, radioactivity levels in fish tissues decreased rapidly with a half-life of *ca.* 0.7 – 1.0 days. Bioconcentration factors based on total radioactivity were relatively low in edibles (232 - 262) and relatively high in inedibles (1169 - 1221). For unchanged parent compound, the BCF values were considerably lower in all tissues. This is an indication for an intensive metabolic clearance of pyraclostrobin. Only minor differences were observed between the two labelled forms of the test compound with regard to the kinetic parameters. In the edible tissues pyraclostrobin formed the major part of the residue, followed by 500M07 (BF 500-3). Cleavage of the ether bond resulting in the formation of the metabolite 500M04 (BF 500-5) occurred to a minor extent and mainly in the inedible portion of fish.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 F (Pyraclostrobin, Reg No. 304428)
Description: Chlorophenyl-U-^{14}C-pyraclostrobin, specific activity 6.15 MBq/mg
Tolyl-^{14}C-BAS 500 F, specific activity 6.6 MBq/mg
^{13}C-BAS 500 F
Lot/Batch #:[Chlorophenyl-U-^{14}C]-Label: 579-6301
[Tolyl-^{14}C]-Label: 566-5101
^{13}C-BAS 500 F: 1026-1018
Purity: [Chlorophenyl-U-^{14}C]-Label: 99.2% (CoA), radiochemical purity
[Tolyl-^{14}C]-Label: 566-5101: 99.9% (CoA), radiochemical purity
^{13}C-BAS 500 F: 99.8%
CAS#: 175013-18-0
Development code: not applicable
Stability of test compound: analysis of storage stability was not performed

2. Test animals: Fish
Test species: Rainbow Trout (Oncorhynchus mykiss)
Body weight: 330 – 465 g (at the start of exposure)
Body length: not applicable

B. STUDY DESIGN AND METHODS

1. Test procedure

Before starting the exposure phase, the fish were allowed to acclimatize to the laboratory environment for at least 14 days in de-chlorinated tap water. The experimental animals were fed a non-enriched diet for at least two weeks prior to the start of the experiment.
The experiment was carried out in two experimental tanks, each filled with approximately 1400 L of pre-conditioned tap-water under flow-through conditions with a flow rate of approximately 120 L/h. Each tank was stocked with 5 experimental animals. Water in the tank was constantly recirculated through two filter columns to avoid the accumulation of dissolved test item and metabolites. The water temperature was kept constant at around 15ºC (±2°C) throughout the experiment. Fish were housed under a 16 hour light/8 hour dark cycle throughout the experiment.

For the chlorphenyl label ^{14}C-labelled and ^{13}C-labelled test item were mixed in a ratio of 2:1 (specific activity: 3.72 MBq/mg). The tolyl label comprised a mixture of ^{14}C-labelled test item and non-labelled test items in a ratio of 5:3 (specific activity: 4.33 MBq/mg).

Figure 6.2.5-3: Structural formula of ^{14}C-BAS 500 F labelled at the chlorophenyl ring

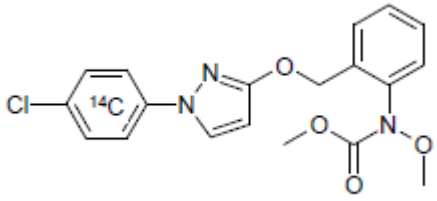

Figure 6.2.5-4: Structural formula of ^{14}C-BAS 500 F labelled at the tolyl ring

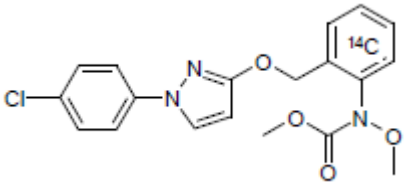

Figure 6.2.5-5: Structural formula of Carbon-13 labelled pyraclostrobin

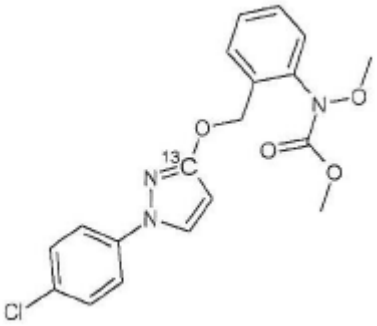

Figure 6.2.5-6: Structural formula unlabelled pyraclostrobin

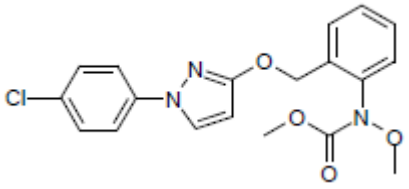

During the study, the test item was dosed to the fish for 10 consecutive days for both labels at a nominal level of 10 mg/kg. The daily dose administered was 11.07 mg [Chlorophenyl-U-14C]-pyraclostrobin and 10.54 mg [Tolyl-14C]-pyraclostrobin respectively per kg food consumed. The daily ration was distributed on the surface of the water. Fish were fed at approximately 2.3% of wet body weight per day. The ration was adjusted weekly to account for the estimated weight gain of the experimental animals.

A pre-test showed that radioactivity in tissue reached a maximum plateau 10 days after the first dose. So the sacrifice time was set to the 10th day 6 h following the 10th dose. The fish were killed and edible tissues (liver, filet and filet skin) and pyloric caeca removed post mortem.
Samples not analyzed immediately were stored frozen (-20°C) until analysis. After analysis, samples were returned to storage at -20°C.

2. Description of analytical procedures

Extraction

Aliquots of the homogenized filet, the entire homogenized filet skins and unmodified livers were extracted with acetonitrile. The number of acetonitrile extractions depended on the sample weight. Liver samples were extracted with water after acetonitrile extraction.
Aliquots of pooled extracts containing significant amounts of radioactivity (A-extracts) were concentrated and were centrifuged; the supernatant was analyzed by HPLC, TLC and LC-MS. The radioactivity was determined by LSC.

Treatment of Residual Radioactive Residues (solubilization procedures)

Residual Radioactive Residues remaining in liver accounted for >10% TRR were further investigated following treatment of the post extraction tissue debris with digestive enzymes.
The samples were mixed with TRIS buffer to give a non-viscous suspension. Protease enzymes (from Streptomyces griseus) were added. Following incubation, solids were separated by centrifugation and decanting of the supernatant. The pellet was dried and an aliquot of remaining solids was determined by combustion/LSC. The supernatant was determined by LSC.
The residues after protease treatment were pooled and further digested with pepsin. Therefore, artificial gastric juice was added to the residue and the sample was incubated. After centrifugation, the supernatant was determined by LSC.
Artificial chyle (containing pancreatin) was added to the residue. The sample was incubated at a pH of 7.5. After centrifugation, the supernatant was determined by LSC.

The solid debris was dried and combusted. Radioactivity was determined via LSC.

Fat precipitation

The sample extracts were stored in a freezer (-20°C) directly after extraction. During storage, fat precipitation occurred in all samples. Fat was separated from extracts and dissolved in dichloromethane. The radioactive content of the fat was determined by LSC analysis.

Quantification and identification of residues

Pooled extracts of filet, filet skin and liver were analyzed with radio thin layer chromatography (radio TLC) on silica gel plates to identify radioactive residues. [Tolyl-14C]-pyraclostrobin and [Chlorophenyl-U-14C]-pyraclostrobin, as well as 10 known metabolites (certified reference items) were used to analyze the composition of the radioactive residues in the extracts.
As confirmatory method, an HPLC method with online radio detection was used to analyze the composition in pooled extracts. The identity of radiolabelled components was based on co-chromatography with certified reference items. HPLC was used to quantify the test item in the dose formulation as well as in homogeneity and stability tests. For HPLC separation, gradient elution on reversed-phase columns was applied.

In addition to HPLC analysis, the identity of components was confirmed by mass spectrometry in MRM mode. Two transitions were established for each component.

II. RESULTS AND DISCUSSION

A. TOTAL RADIOACTIVE RESIDUES (TRRs)

Edible Tissues
Radioactive residue data for the tissues are provided in Table 6.2.5-7. Residues in the filet, filet skin and liver were for [Chlorophenyl-U-14C]-pyraclostrobin 0.282, 0.229 and 0.556 mg/kg, and for [Tolyl-14C]-pyraclostrobin 0.239, 0.232 and 0.479 mg/kg, respectively.

Faeces
TRR data for faeces are provided in Table 6.2.5-7. Residues were analyzed for [Chlorophenyl-U-14C]-pyraclostrobin 7.33 mg/kg (6.42% TRR), and for [Tolyl-14C]-pyraclostrobin 4.87 mg /kg (5.28% TRR), respectively.

Table 6.2.5-7: Total radioactive residues (TRR) in tissues and faeces from rainbow trout following oral administration of ^{14}C-BAS 500 F

Total radioactive residues (TRR) [mg/kg]		
Label position	**Chlorophenyl label**	**Tolyl label**
Filet	0.282	0.239
Filet skin	0.229	0.232
Liver	0.556	0.479
Faeces	7.33	4.87

B. EXTRACTION, CHARACTERIZATION AND IDENTIFICATION OF RESIDUES

1. Extraction of residues

Filet
The homogenized filet was extracted with acetonitrile, resulting in extraction of 97.7% TRR (0.276 mg/kg) for chlorophenyl label and 97.2% TRR (0.232 mg/kg) for tolyl label. The solid debris was analyzed by combustion analysis and contained 2.2% TRR (0.006 mg/kg) for chlorophenyl label and 2.8% TRR (0.007 mg/kg) for tolyl label.

Filet Skin
The homogenized filet skin was extracted with acetonitrile, resulting in extraction of 97.8% TRR (0.225 mg/kg) for chlorophenyl label and 98.0% TRR (0.228 mg/kg) for tolyl label. The solid debris was analyzed by combustion analysis and contained 2.2% TRR (0.004 mg/kg) for chlorophenyl label and 2.0% TRR (0.005 mg/kg) for tolyl label.

Liver
The homogenized liver samples were extracted with acetonitrile and water, resulting in extraction of 84.5% TRR (0.470 mg/kg) for chlorophenyl label and 83.3% TRR (0.399 mg/kg) for tolyl label.

A summary of the extractability of residues of ^{14}C-pyraclostrobin in rainbow trout matrices is presented in Table 6.2.5-8.

Table 6.2.5-8: Extractability of residues of ^{14}C-BAS 500 F in rainbow trout matrices

Matrix	ERR[1]		PES[2]		TRR
	mg/kg	% TRR	mg/kg	% TRR	mg/kg
Chlorophenyl label					
Filet	0.276	97.7	0.006	2.2	0.282
Filet skin	0.225	97.8	0.004	2.2	0.229
Liver	0.470	84.5	0.086	15.5	0.556
Tolyl label					
Filet	0.232	97.2	0.007	2.8	0.239
Filet skin	0.228	98.0	0.005	2.0	0.232
Liver	0.399	83.3	0.080	16.7	0.479

1 ERR = Extractable Radioactive Residue (acetonitrile extracts, fat precipitate, for liver: water extract)
[2] PES = Post-Extraction Solid

2. Identification, characterization and quantitation of extractable residues

Filet

For identification of labeled components, concentrated filet extract was analyzed with TLC directly without further purification. The analysis led to a pattern of 2 peaks, 1 main and 1 trace peak in both labels, which were identified as unchanged pyraclostrobin and 500M89 (Reg. No. 334089) by co-chromatography.

The residues were quantified by LSC analysis in combination with radio TLC. Unchanged pyraclostrobin accounted for 93.1% TRR (0.262 mg/kg) for chlorophenyl and 92.3% TRR (0.220 mg/kg) for tolyl label. Metabolite 500M89 (Reg. No. 334089) accounted for 2.6% TRR (0.007 mg/kg) for chlorophenyl and 3.0% TRR (0.007 mg/kg) for tolyl label. A small amount of radioactivity, representing the polar fraction, remained unidentified at the start point (0.005 mg/kg, 2.0% TRR for chlorophenyl and 0.004 mg/kg, 1.4% TRR for tolyl label).

The sum of identified residue from extractable radioactivity in filet samples was for chlorophenyl label 95.7% TRR (0.269 mg/kg) and for tolyl label 95.3% TRR (0.227 mg/kg). The sum of characterized residue in filet sample was for chlorophenyl label 2.0% TRR (0.005 mg/kg) and for tolyl label 1.8% TRR (0.005 mg/kg) from extractable radioactivity.
The sum of identified and characterized residue in extractable radioactivity in filet samples was for chlorophenyl label 97.7% TRR (0.274 mg/kg) and for tolyl label 97.1% TRR (0.232 mg/kg).

LC-MS analysis of the filet extracts confirmed the identification of only unchanged pyraclostrobin and 500M89 (Reg. No. 334089) in the samples 2 specific MRM transitions for each component were established and where these were detected in tissue extract, were used to confirm the assignments made by co-chromatography. MRM ion chromatograms for transitions A and B for compounds pyraclostrobin (Reg. No. 304428) and 500M89 (Reg. No. 334089) show peaks at 8.47 and 11.15 min, respectively, which confirms the presence of these compounds in this extracts.

Analysis of filet extract with HPLC method 2 led to only 1 peak of unchanged pyraclostrobin. Other residues were not detectable (below detection limit).

A summary of identified, characterized and final radioactive residues in fish filet sample is presented in Table 6.2.5-9.

[1] Identified metabolites were resolved and quantified using LSC in combination with radio TLC and qualitative confirmation was performed by LC-MS

Filet Skin
For identification of labeled components, concentrated filet skin extract was analyzed with TLC directly without further purification. The analysis led to a pattern of 2 peaks, 1 main and 1 trace peak in both labels, which were identified as unchanged pyraclostrobin and 500M89 (Reg. No. 334089) by co-chromatography.

The residues were quantified by LSC analysis in combination with radio TLC. Unchanged pyraclostrobin accounted for 91.6% TRR (0.210 mg/kg) for chlorophenyl and 90.5% TRR (0.210 mg/kg) for tolyl label. Metabolite 500M89 (Reg. No. 334089) accounted for 3.7% TRR (0.008 mg/kg) for chlorophenyl and 4.3% TRR (0.010 mg/kg) for tolyl label. A small amount of radioactivity, representing the polar fraction, remained unidentified at the start point 2.2% TRR (0.006 mg/kg) for chlorophenyl and 2.6% TRR (0.006 mg/kg) for tolyl label.

The sum of identified residue from extractable radioactivity in filet skin samples was for chlorophenyl label 95.3% TRR (0.218 mg/kg) and for tolyl label 94.8% TRR (0.220 mg/kg). The sum of characterized residue in filet skin sample was for chlorophenyl label 2.6% TRR (0.007 mg/kg) and for tolyl label 3.0% TRR (0.007 mg/kg) from extractable radioactivity.
The sum of identified and characterized residue in extractable radioactivity in filet skin samples was for chlorophenyl label 97.9% TRR (0.225 mg/kg) and for tolyl label 97.8% TRR (0.227 mg/kg).

A summary of identified, characterized and final radioactive residues in fish filet skin sample is presented in Table 6.2.5-10.

Table 6.2.5-10: Summary of identified and characterized ^{14}C-residues extracted from filet skin (after 10 daily doses of ^{14}C-BAS 500 F at 10 mg/kg feed nominal)

[1] Identified metabolites were resolved and quantified using LSC in combination with radio TLC and qualitative confirmation was performed by LC-MS

LC-MS analysis of the filet skin extracts confirmed the identification of only unchanged pyraclostrobin and 500M89 (Reg. No. 334089) in the samples. 2 specific MRM transitions for each component were established and where these were detected in tissue extract, were used to confirm the assignments made by co-chromatography. MRM ion chromatograms for transitions A and B for compounds pyraclostrobin (Reg. No. 304428) and 500M89 (Reg. No. 334089) show peaks at 8.47 and 11.15 min, respectively, which confirms the presence of these compounds in these extracts.

Analysis of filet skin extract with HPLC method 2 led to only 1 peak of unchanged pyraclostrobin. Other residues were not detectable (below detection limit).

Liver
For identification of labeled components, concentrated liver extract was analyzed by TLC directly without further purification. The analysis led to a pattern of 2 peaks, 1 main and 1 trace peak in both labels, which were identified as unchanged pyraclostrobin and 500M89 (Reg. No. 334089) by co-chromatography.

The residues were quantified by LSC analysis in combination with radio TLC. Unchanged pyraclostrobin accounted for 73.6% TRR (0.409 mg/kg) for chlorophenyl and 70.4% TRR (0.337 mg/kg) for tolyl label. Metabolite 500M89 (Reg. No. 334089) accounted for 1.0% TRR (0.006 mg/kg) for chlorophenyl and 2.3% TRR (0.011 mg/kg) for tolyl label. A small amount of radioactivity, representing the polar fraction, remained unidentified at the start point (0.037 mg/kg, 6.7% TRR for chlorophenyl and 0.032 mg/kg, 6.9% TRR for tolyl label).

The sum of identified residue from extractable radioactivity in liver sample was for chlorophenyl label 74.6% TRR (0.415 mg/kg) and for tolyl label 72.7% TRR (0.348 mg/kg). The sum of characterized residue in liver sample was for chlorophenyl label 9.9% TRR (0.055 mg/kg) and for tolyl label 10.5% TRR (0.049 mg/kg) from extractable radioactivity, for chlorophenyl label 8.1% TRR (0.044 mg/kg) and for tolyl label 11.2% TRR (0.054 mg/kg) were released from post-extraction solids.
So the sum of identified and characterized residue in liver sample was for chlorophenyl label 92.6% TRR (0.514 mg/kg) and for tolyl label 94.4% TRR (0.451 mg/kg).
LC-MS analysis of the liver extracts confirmed the identification of only unchanged pyraclostrobin and 500M89 (Reg. No. 334089) in the samples.

A summary of identified, characterized and final radioactive residues in fish liver sample is presented in Table 6.2.5-11.

Table 6.2.5-11: Summary of identified and characterized ^{14}C-residues extracted from liver (after 10 daily doses of ^{14}C-BAS 500 F at 10 mg/kg feed nominal)

[1] Identified metabolites were resolved and quantified using LSC in combination with radio TLC and qualitative confirmation was performed by LC-MS

The nature of residual radioactive residues in the liver was investigated by treatment with digestive enzyme (protease). The process resulted in a further 6.1% TRR (0.034 mg/kg) for chlorophenyl and 10.0% TRR (0.048 mg/kg TRR) for tolyl being liberated. The digestion with pepsin enzyme resulted in liberation of 0.4% TRR (0.002 mg/kg) for chlorophenyl and 0.4% TRR (0.002 mg/kg TRR) for tolyl.
The digestion with pancreatin enzyme resulted in liberation of 1.4% TRR (0.008 mg/kg) for chlorophenyl and 0.8% TRR (0.004 mg/kg TRR) for tolyl.

A summary of characterized residues released from residual radioactive residues of fish liver is presented in Table 6.2.5-12.

Table 6.2.5-12: Summary characterized ^{14}C-residues released from residual radioactive residues of liver (after 10 daily doses of ^{14}C-BAS 500 F at 10 mg/kg feed nominal)

Designation	Post Extraction Solid (PES) Fractions			
	PES of liver		Sum of fractions	
	mg/kg	% TRR	mg/kg	% TRR
Chlorophenyl label PES of liver 0.086 mg/kg, 15.5% TRR				
Characterized				
Extractable following treatment with protease enzyme	0.034	6.1	0.034	6.1
Extractable following treatment with pepsin enzyme	0.002	0.4	0.002	0.4

Total identified and/or characterized radioactivity released from post-extraction solids			**0.044**	**8.1**
Tolyl label PES of liver 0.080 mg/kg, 16.7% TRR				
Characterized				
Extractable following treatment with protease enzyme	0.048	10.0	0.048	10.0
Extractable following treatment with pepsin enzyme	0.002	0.4	0.002	0.4
Extractable following treatment with pancreatin enzyme	0.004	0.8	0.004	0.8
Total characterized in released radioactivity			**0.054**	**11.2**
Total identified and/or characterized radioactivity released from post-extraction solids			**0.054**	**11.2**

Note: No meaningful chromatogram was obtained for the liver extract following treatment of post extraction solids with protease enzyme. The radioactive residues in the extract were characterized as extractable following treatment with protease, pepsin or pancreatin enzyme.

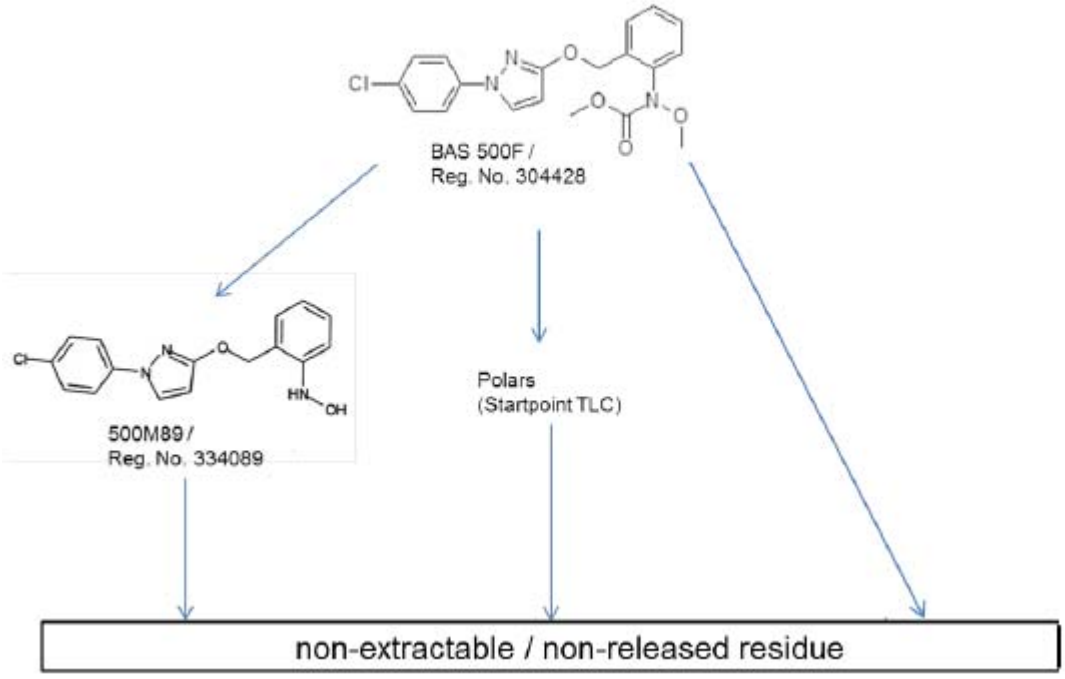
Two specific MRM transitions for each component were established and where these were detected in tissue extract, were used to confirm the assignments made by co-chromatography. MRM ion chromatograms for transitions A and B for compounds pyraclostrobin (Reg. No. 304428) and 500M89 (Reg. No. 334089) show peaks at 8.47 and 11.15 min, respectively, which confirms the presence of these compounds in this extracts.

Analysis of liver extract with HPLC method 2 led to only 1 peak of unchanged pyraclostrobin. Other residues were not detectable (below detection limit).

3. Proposed metabolic pathway

In all matrices (liver, filet skin, filet) and in both labels (chlorophenyl and tolyl) most of the extracted residues consisted only of unchanged parent (70.4-93.1% TRR). The metabolite 500M89 (Reg. No. 334089) occurred in minor amounts (1-4% TRR). An amount of 1.6 to 2.6% TRR in filet and filet skin were characterized as polar transformation products by TLC analysis. In liver samples 6.7 and 6.9% TRR can be assigned to this polar not identified fraction.
Thus, one metabolic transformation could be identified: cleavage of the amide yielding the metabolite 500M89 (Reg. No. 334089). Reactions leading to a cleavage of the molecule did not occur. Not identifiable residues in a range of 1-7% TRR were characterized by TLC as very polar compounds. In liver ca. 8-11% TRR were incorporated in the tissue and just releasable with digestive enzymes.

Figure 6.2.5-7: Pathway for the metabolism of pyraclostrobin in rainbow trout



4. Storage stability

All extraction, fractionation and HPLC analysis was completed within 6 months of sacrifice, therefore storage stability analysis was not performed.

III. CONCLUSION

The daily dose administered was 11.07 mg [Chlorophenyl-U-14C]-pyraclostrobin and 10.54 mg [Tolyl-14C]-pyraclostrobin respectively per kg food consumed.

The radioactive residues in filet accounted for 0.282 mg/kg (chlorophenyl label) and 0.239 mg/kg (tolyl label). In filet skin 0.229 mg/kg (skin chlorophenyl label) and 0.232 mg/kg (skin tolyl label) were found. Radioactive residues in liver accounted for 0.556 mg/kg (liver chlorophenyl label) and 0.479 mg/kg (liver tolyl label).

Approximately 99.40% of the [Chlorophenyl-U-14C]-pyraclostrobin dose and 85.79% of the [Tolyl-14C]-pyraclostrobin were recovered as a total mass balance, the majority of which was present in the active coal (ca 55%, respectively 46%).

The recovery of radioactivity in filet was relatively high compared to filet skin and liver. In the filet samples 4.21% for chlorophenyl label and 3.84% for tolyl label were recovered. In filet skin 0.20% for chlorophenyl label and 0.31% for tolyl label, in liver 0.39% for chlorophenyl label and 0.37% for tolyl label were recovered.

The extractability of the filet and filet skin was high, for filet 97.7% TRR (0.276 mg/kg; chlorophenyl) and 97.2% TRR (0.232 mg/kg; tolyl label) as well as for filet skin 97.8% TRR (0.225 mg/kg; chlorophenyl) and 98.0% TRR (0.228 mg/kg; tolyl), respectively. The extractability of liver accounted for 84.5% TRR (0.470 mg/kg; chlorophenyl) and 83.3% TRR (0.399 mg/kg; tolyl). The residue after extraction of liver was 15.5% (0.086 mg/kg) TRR for chlorophenyl and 16.7% TRR (0.080 mg/kg) for tolyl and was further hydrolyzed with digestive enzymes, whereby an additional 8.1% TRR (0.044 mg/kg) for chlorophenyl and 11.2% TRR (0.054 mg/kg) for tolyl was released.

The identification of 1 metabolite was based on co-chromatography in a radio TLC system and confirmation by LC-MS/MS in MRM mode.

In all matrices (filet, filet skin, liver) and in both labels (chlorophenyl and tolyl) most of the extracted residues consisted mainly of unchanged parent (70.4-93.1% TRR; 0.210-0.409 mg/kg). Only minor amounts of the metabolite 500M89 (Reg. No. 334089) were detected in extracted residue (1-4% TRR; 0.006-0.011 mg/kg). Taking the actual feed burden and the overdosing factor (8 x) into account, no significant residues of 500M89 will occur when fish are fed with commodities being treated with pyraclostrobin.

Only one metabolic transformation could be identified: Cleavage of the amide residue yielding the metabolite 500M89 (Reg. No. 334089). Reactions leading to a cleavage of the molecule between the ring systems did not occur. Therefore, both labels are comparable with respect to the overall result regarding metabolite formation of both studies. A degradation to polar residues occurred in a range of 1-7% TRR (0.005-0.037 mg/kg), as characterized by TLC. In liver ca. 8-11% TRR (0.044-0.054 mg/kg) were incorporated in the tissue and just releasable with digestive enzymes.

The results achieved in analysis of the chlorophenyl and tolyl label were very well comparable. The amounts of residues in the same tissues of both labels were very similar and in both labels the main identified residue consisted of unchanged pyraclostrobin. The results are in accordance with those obtained during the BCF study.

Although not requested by guideline, it was intended to conduct an in vitro metabolism study in rainbow trout cryopreserved hepatocytes and microsomes as supplementary information in comparison to the full metabolism study. However, due to so far insufficient metabolic activity in the cells reliable results are currently not available. The study will be continued to find out if this approach can principally be used in this context.
Due to the situation described above, the study is not part of the supplemental dossier, although it was included in the study list of the application for renewal of approval as data point KCA 6.2.5/3 (BASF DocID 2014/1001602).

CA 6.3 Magnitude of residues trials in plants

Pyraclostrobin is registered in multiple crops belonging to different EU crop groups. Within this dossier residue data are only provided for the representative uses supporting the renewal of approval. The solo EC formulation BAS 500 06 F and the mixed formulation BAS 516 07 F (containing pyraclostrobin and boscalid) have been selected as representative formulations.

Consequently, in this dossier section the relevant data for the following crops are summarized:

- Potatoes (BAS 516 07 F)
- Cereals (BAS 500 06 F)
- Maize including sweet corn (BAS 500 06 F)

In order to increase the readability of the dossier, the data for mixing partners are not shown in this dossier. The studies provided below for potatoes and cereals have been submitted before in context of national or zonal product registration dossiers. They have not been evaluated within the MRL re-evaluation process according to Reg. 396/2005, Art. 12. Consequently, they are not considered as peer-reviewed.

In case of maize/sweet corn and driven by the high importance of maize silage as feed item, parts of the studies had been provided to EFSA in context of the MRL evaluation process. The studies which had been assessed before are indicated accordingly by a remark above the study header so that a differentiation between “old” and new data should be possible without problems.

In M-CA 6.7 the residue levels found in samples destined for human food or for animal feed are compared with the data that have already been evaluated by EFSA. The relevant residue levels for parent are underlined. For the desmethoxy metabolite the codes 500M07 and BF 500-3 are used synonymously.

CA 6.3.1 Potatoes

The formulation BAS 516 07 F is registered in the Northern part of the EU. Due to the favorable residue behavior in potatoes with residues consistently below the LOQ of 0.02 mg/kg at all sampling intervals, only a reduced number of residue data is required.

In order to allow a more comprehensive evaluation in potatoes, the residue trials with the formulation BAS 536 01 F are additionally summarized. As shown in the table below, the mixed formulation containing pyraclostrobin and dimethomorph is registered at higher rates (100 g pyraclostrobin/ha compared to 17 g pyraclostrobin/ha), but is also registered in additional countries. The results obtained confirm the favorable residue behavior since even at the higher rates the residues found in tuber were well below the LOQ of 0.02 mg/kg.

Table 6.3.1-1: Summary of the critical GAP for the proposed use in potatoes for BAS 516 07 F

I. MATERIAL AND METHODS

A. MATERIALS

1.	**Test Material:**	BAS 516 00 F
	Description:	BAS 516 00 F: 6.7% of BAS 500 F (pyraclostrobin), 26.7% of BAS 510 F (boscalid), WG formulation
	Lot/Batch #:	2002-1
	Purity:	Not relevant
	CAS#:	Pyraclostrobin: 175013-18-0 Boscalid: 188425-85-6
	Development code:	not applicable
	Spiking levels:	Pyraclostrobin: 0.02 and 0.2 mg/kg
2.	**Test Commodity:**	Root and tuber vegetables
	Crop:	Potato tuber
	Type:	not applicable
	Variety:	Astate, Gloria, Sava, Europa, Agatha, Victoria
	Botanical name:	*Solanum tuberosum* L.
	Crop parts(s) or processed Commodity:	tuber
	Sample size:	min. 2.0 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

In 2003, a total of 6 residue trials were conducted in potatoes in The Netherlands, Germany, United Kingdom, Denmark and France (North and South). The formulation BAS 516 00 F was applied 4 times at a rate of 0.02 kg as/ha of pyraclostrobin. The applications took place at 33 (±1), 23 (±1), 13 (±1) and 3 (±1) days before harvest with a spray rate of 150 L/ha. Samples were taken immediately after application and 3 ±1, 7 ±1 and 13 ±1 days thereafter. The samples were stored until analysis. The maximum storage interval from harvest until extraction was 162 days.

2. Description of analytical procedures

The specimens were analysed for residues of pyraclostrobin and its metabolite BF 500-3 using BASF method No. 445/0 which quantifies the relevant residues with a limit of quantitation (LOQ) of 0.02 mg/kg for pyraclostrobin and its metabolite BF 500-3 in all of the specimen material. The mean recovery results for pyraclostrobin and its metabolite BF 500-3 were 87.7 ± 27.0% and 83.0 ± 14.5%, respectively, at fortification levels of 0.02 and 0.20 mg/kg.
Pyraclostrobin and BF 500-3 residues were extracted from the homogenized specimens with methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned against cyclohexane. The final determination of pyraclostrobin and BF 500-3 was performed by HPLC-MS/MS.

II. RESULTS AND DISCUSSION

In none of the samples analysed, any pyraclostrobin or BF 500-3 residues were found above the limit of quantitation of 0.02 mg/kg.

A summary of residues is presented in Table 6.3.1-4. Details are shown in Table 6.3.1-5.

Table 6.3.1-4: Summary of pyraclostrobin and BF 500-3 residues in potatoes after 4 applications of BAS 516 00 F

Matrix	Year	DALA[1]	Range of residues (mg/kg)		
			BAS 500 F	BF 500-3	BAS 500 F, total [2, 3]
Potato tuber	2003	0	<0.02	<0.02	<0.04
		3-4	<0.02	<0.02	<0.04
		6-8	<0.02	<0.02	<0.04
		12-14	<0.02	<0.02	<0.04

1 days after last application
2 as pyraclostrobin equivalent (conversion factor is 1.08)
3 for calculation purposes, "< 0.02" is set 0.02

III. CONCLUSION

No residues of pyraclostrobin or its metabolite BF 500-3 (500M07) above the limit of quantitation of 0.02 mg/kg were found in any of the analysed specimens.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 536 01 F

Description:	BAS 536 01 F: 40 g/L BAS 500 F (pyraclostrobin), 72 g/L BAS 550 F (dimethomorph), EC formulation
Lot/Batch #:	5041
Purity:	Not relevant
CAS#:	Pyraclostrobin: 175013-18-0 Dimethomorph: 110488-70-5
Development code:	not applicable
Spiking levels:	Pyraclostrobin: 0.02 and 0.02 mg/kg

2. Test Commodity: Root and tuber vegetables

Crop:	Potato tuber
Type:	Not relevant
Variety:	Dailfa, Gliceta, Primura, Kuras, Agata, Cesar, Vitesse, Cherie, Bintje, Hamlet
Botanical name:	*Solanum tuberosum* L.
Crop parts(s) or processed Commodity:	tuber
Sample size:	min. 2 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2005 growing season, a total of 10 field trials were conducted in potatoes in order to determine the magnitude of the residues of active ingredient(s) in or on Raw Agricultural Commodities (RAC). BAS 536 01 F, an EC formulation of pyraclostrobin (40 g/L) and dimethomorph (72 g/L) was foliar applied 3 times at a rate of 2.5 L/ha of formulated product (0.1 kg as/ha of pyraclostrobin) to potatoes beginning about 21 days before expected harvest with a spray interval of 7 days. The spray volume used was 300 L/ha.
Potato tuber specimens were collected directly after the last application (DALA) from each plot at all locations as well as 3, 7 and 14 days thereafter.
The samples were stored frozen until analysis. The maximum storage interval from harvest until extraction was 234 days.

2. Description of analytical procedures

All samples were analysed with BASF method no. 445/0, which quantifies the residues of pyraclostrobin and its metabolite BF 500-3 with a limit of quantitation of 0.02 mg/kg each in all sample materials. Procedural recoveries obtained with the analytical series averaged at 87.3% for pyraclostrobin and at 85.6% for BF 500-3 at fortification levels of 0.02 and 0.20 mg/kg.
Pyraclostrobin and BF 500-3 residues were extracted from the homogenized specimens with methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned against cyclohexane. The final determination of pyraclostrobin and BF 500-3 was performed by HPLC-MS/MS.

II. RESULTS AND DISCUSSION

The analysis for pyraclostrobin and its metabolite BF 500-3 showed that in none of the potato tuber samples analysed any residues above limit of quantitation could be determined.

A summary of residues is presented in Table 6.3.1-6. Details are shown in Table 6.3.1-7.

Table 6.3.1-6: Summary of pyraclostrobin and BF 500-3 residues in potatoes after 3 applications of BAS 536 01 F

Matrix	Year	DALA[1]	Range of residues (mg/kg)		
			BAS 500 F	BF 500-3	BAS 500 F, total [2, 3]
Tuber	2005	0-15	<0.02	<0.02	<0.04

[1] days after last application
[2] as BAS 500 F equivalent (conversion factor is 1.084)
[3] for calculation purposes, "< 0.02" is set 0.02

III. CONCLUSION

No residues of pyraclostrobin or its metabolite BF 500-3 (500M07) above the limit of quantitation were found in any of the analysed specimens.

I. MATERIAL AND METHODS

A. MATERIALS

1.	**Test Material:**	BAS 516 07 F
	Description:	BAS 516 07 F: 6.7% of BAS 500 F (pyraclostrobin), 26.7% of BAS 510 F (boscalid), WG formulation
	Lot/Batch #:	FRE-001182
	Purity:	Not relevant
	CAS#:	Pyraclostrobin: 175013-18-0 Boscalid: 188425-85-6
	Development code:	not applicable
	Spiking levels:	Pyraclostrobin: 0.01 and 0.1 mg/kg

2.	**Test Commodity:**	Root and tuber vegetables
	Crop:	Potato
	Type:	not applicable
	Variety:	Actrice, Jearla, Spunta, El Mundo
	Botanical name:	*Solanum tuberosum* L.
	Crop parts(s) or processed Commodity:	tuber
	Sample size:	1.0 - 5.0 kg/24 tubers

B. STUDY DESIGN AND METHODS

1. Test procedure

During 2015, a total of 4 residue trials were conducted in potatoes in representative potato growing areas in South Europe to determine the residue level of pyraclostrobin (BAS 500 F) and boscalid (BAS 510 F) in/on potato tubers after application of BAS 516 07 F. Each field consisted of one untreated (plot 1) and one treated plot (plot2).

In this summary only the results of residues of pyraclostrobin were reported. Results and conclusions of the other active substance (boscalid) are not considered as relevant in this summary.

The test item was foliar applied four times at 18 (±1), 12 (±1), 8 (±1) and 3 (±1) days before harvest at a rate of 16.75 g as/ha of pyraclostrobin and 66.75 g as/ha boscalid with a water volume of 300 L/ha. Plot 1 remained untreated.

Untreated and treated specimen of potato (tuber) were sampled at 0, 3, 7, and 13 - 14 DALA (days after last application). Control (untreated) specimens were collected prior to the treated specimens to avoid any contamination. All samples were double bagged.

The maximum storage interval from sampling to extraction for pyraclostrobin (BAS 500 F) and its metabolite 500M07 and boscalid (BAS 510 F) was 234 days. Storage stabilities of boscalid and pyraclostrobin and its metabolite were shown for 24 months.

2. Description of analytical procedures

Specimen from all trials were analyzed for pyraclostrobin (BAS 500 F) and its metabolite 500M07 (BF 500- 3) and boscalid (BAS 510 F) according to BASF analytical method No. 535/1 (L0076/01), which quantifies the relevant residues with a limit of quantitation (LOQ) of 0.01 mg/kg for all analytes.

The overall mean recovery for pyraclostrobin was at 92.6% (n=6) and for its metabolite 500M07 at 99.6% (n=6), respectively, at fortification levels of 0.01 and 0.10 mg/kg.

Pyraclostrobin and 500M07 residues were extracted from the homogenized specimens with methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned against cyclohexane. The final determination of pyraclostrobin and 500M07 was performed by LC-MS/MS.

The results of procedural recovery experiments are summarised in Table 6.3.1-8.

Table 6.3.1-8 Summary of recoveries of pyraclostrobin and its metabolite in potato tuber specimen in Southern Europe

Matrix	Fortification level (mg/kg)	Summary recoveries							
		n	Mean (%)	SD (+/-)	RSD (%)	n	Mean (%)	SD (+/-)	RSD (%)
Method No. 535/1		Pyraclostrobin				500M07			
Potato tuber	0.01	3	96.5	8.7	9.0	3	102	9.2	9.0
	0.1	3	88.7	5.8	6.6	3	97.6	8.4	8.7
overall		**6**	**92.6**	**7.9**	**8.5**	**6**	**99.6**	**8.2**	**8.2**

II. RESULTS AND DISCUSSION

In none of the analysed samples any pyraclostrobin or 500M07 residues were found above the limit of quantitation of 0.01 mg/kg.

A summary of residues is presented in Table 6.3.1-4. Details are shown in Table 6.3.1-5.

Table 6.3.1-9: Summary of pyraclostrobin and 500M07 residues in potatoes after four applications of BAS 516 07 F

[1] expressed as parent equivalent, conversion factor for calculation of 500M07 to parent is 1.08
[2] for residues < 0.01 mg/kg (for 500M07 < 0.011 mg/kg), value was set to 0.01 mg/kg (for 500M07 to 0.011 mg/kg) for calculation of sum

CA 6.3.2 Cereals (wheat, barley)

Multiple residue studies have been performed in cereals for the active substance pyraclostrobin in solo and mixed formulations in cereal crops. The residue data were evaluated during the previous Annex I inclusion process, various national submissions, but also in context of the EU MRL re-evaluation according to Reg. 396/055 Art. 12. They were considered as suitable for establishing an EU MRL for wheat, rye, barley and oats. Between 1998 and 2005 more than 70 trials were conducted in representative growing areas of the Northern and Southern part of Europe. In the trials, two applications were performed at 250 g as/ha.

Despite the broad coverage, new residue trials in cereals have been performed between 2009 and 2012. The purpose of these trials was to provide a consistent residue data package for the formulation BAS 500 06 F, but also to ensure that the residue levels in grain are covered by the established EU MRLs. The trials were performed in accordance with the most critical registered GAP (see Table 6.3.2-1). The distribution of these trials is shown in Table 6.3.2-2.

Table 6.3.2-1: Summary of the critical GAP for the proposed use in cereals for BAS 500 06 F

Crop	Outdoor/ Protected	Growth stage (BBCH)	Maximum number of applications	Minimum application interval (days)	Maximum		Minimum PHI (days)**
					Rate* (kg as/ha)	Water (L/ha)	
Barley	O	25 -69	2	21	0.25	100 – 400	35
Oat	O	25 -69	2	21	0.25	100 – 400	35
Wheat	O	25 -69	2	21	0.25	100 – 400	35
Triticale	O	25 -69	2	21	0.25	100 – 400	35
Rye	O	25 -69	2	21	0.25	100 – 400	35

* amount of pyraclostrobin per ha and application
** for cereal crops the actual preharvest interval is defined by the latest growth stage of application (which is BBCH 69)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 06 F

Description:	BAS 500 06 F: pyraclostrobin (BAS 500 F), 200.0 g/L nominal content, EC
Lot/Batch #:	0003223026
Purity:	99.9%
CAS#:	Pyraclostrobin: 175013-18-0 BF 500-3: 512165-96-7
Development code:	not applicable
Spiking levels:	0.01-10 mg/kg

2. Test Commodity: Cereals

Crop:	Barley
Type:	not applicable
Variety:	Marthe, Laverda, Lomerit, Cervoise, Franzi, Moutso, Mattina, Caballar
Botanical name:	*Hordeum vulgare L.*
Crop parts(s) or processed Commodity:	Whole plant w/o roots, ears, rest of plant w/o roots, grain, straw
Sample size:	Whole plant w/o roots: ≥0.5 mg/kg, ears: ≥1.0 mg/kg, rest of plant w/o roots ears: ≥0.7 mg/kg, grain: ≥1.0 mg/kg, straw: ≥0.5 mg/kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2011 growing season, 8 field trials were conducted in Northern and Southern Europe in order to determine the magnitude of residues of pyraclostrobin in barley after two applications of BAS 500 06 F. Each field trial consisted of a control and a treated plot. BAS 500 06 F (200 g/L pyraclostrobin), was applied twice with an application rate of 0.25 kg as/ha and a spray volume of 200 L/ha at growth stages BBCH 49 and 69. Whole plant no roots specimens were taken directly after the last application. Depending on the maturity ears and "rest of plant without roots" or grain and straw specimens were taken at 28 ± 1, 35 ± 1 and 42 ± 1 days after last application. If crop stage BBCH 89 was not reached at 42 ± 1 DALA, an additional sampling of grain and straw was made.
The samples were stored deep frozen until analysis. The maximum storage interval from harvest until analysis for plant samples was 385 days.

Table 6.3.2-3: Application and sampling details for trials conducted in 2011

Region	No. of trials	No. of appl.	F, P, or G	Test item	Active substance	Application		Target timing	
						Rate as (kg/ha)	Water vol. (L/ha)	Application	Sampling (DALA)[1]
Northern and Southern Europe	8	2	F	BAS 500 06 F (EC)	BAS 500 F	0.25	200	BBCH 49 BBCH 69	0 28 +/- 1 35 +/- 1 42 +/- 1 BBCH 89

[1] days after last application

2. Description of analytical procedures

All specimens were analysed for pyraclostrobin and its metabolite BF 500-3 using BASF method 535/1 (synonym: L0076/01).
The analytes were extracted with a mixture of methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned at alkaline conditions against cyclohexane. The final determination was performed by HPLC-MS/MS. The limit of quantitation (LOQ) of the method for pyraclostrobin and its metabolite BF 500-3 was 0.01 mg/kg.
The results of procedural recovery experiments were 88% for pyraclostrobin and 85% for BF 500-3 at fortification levels between 0.01 and 10 mg/kg.

II. RESULTS AND DISCUSSION

At pre harvest interval (PHI) of 34-35 days residues of pyraclostrobin ranged between 0.06 and 0.24 mg/kg in ears, 1.02 and 3.08 mg/kg in rest of plant without roots, 0.02 and 0.22 mg/kg in grain and 0.50 and 7.68 mg/kg in straw.
The residues of the metabolite BF 500-3 ranged between 0.05 and 0.21 mg/kg in ears, 0.14 and 0.92 mg/kg in rest of plant without roots, 0.01 and 0.09 mg/kg in grain and 0.26 and 2.89 mg/kg in straw. In the control samples no residues at or above the limit of quantitation were found.

A summary of residues is presented in Table 6.3.2-4. Details are shown in Table 6.3.2-5.

III. CONCLUSION

At pre harvest interval (PHI) of 34-35 days residues of pyraclostrobin ranged between 0.06 and 0.24 mg/kg in ears, 1.02 and 3.08 mg/kg in rest of plant without roots, 0.02 and 0.22 mg/kg in grain and 0.50 and 7.68 mg/kg in straw.
The residues of the metabolite BF 500-3 (500M07) ranged at pre harvest interval (PHI) of 34-35 days between 0.05 and 0.21 mg/kg in ears, 0.14 and 0.92 mg/kg in rest of plant without roots, 0.01 and 0.09 mg/kg in grain and 0.26 and 2.89 mg/kg in straw.

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2010 growing season, a total of 8 field trials were conducted in Northern and Southern Europe in order to determine the magnitude of residues of pyraclostrobin in barley after two applications of BAS 500 06 F. Each field trial consisted of a control and a treated plot. BAS 500 06 F (200 g/L pyraclostrobin), was foliar applied twice with an application rate of 0.25 kg as/ha and a spray volume of 200 L/ha at growth stages BBCH 49 and 69. "Whole plant without roots" specimens were taken directly after the last application. Depending on the maturity ears and "rest of plant without roots" or grain and straw specimens were taken at 28 ± 1, 35 ± 1 and 42 ± 1 days after last application. If crop stage BBCH 89 was not reached at 42 ± 1 DALA, an additional sampling was made.
The samples were stored deep frozen until analysis. The maximum storage interval from harvest until analysis for plant samples was 406 days.

[1] days after last application

2. Description of analytical procedures

All specimens were analysed for pyraclostrobin and its metabolite BF 500-3 using BASF method 535/1 (synonym: L0076/01).
The analytes were extracted with a mixture of methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned at alkaline conditions against cyclohexane. The final determination was performed by HPLC-MS/MS. The limit of quantitation (LOQ) of the method for pyraclostrobin and its metabolite BF 500-3 was 0.01 mg/kg.
The results of procedural recovery experiments were 89.1% for pyraclostrobin and 87.3% for BF 500-3 at fortification levels between 0.01 and 1.0 mg/kg.

II. RESULTS AND DISCUSSION

At pre harvest interval (PHI) of 34-36 days residues of pyraclostrobin ranged between 0.10 and 2.66 mg/kg in ears, 0.59 and 7.13 mg/kg in rest of plant without roots, 0.13 and 0.54 mg/kg in grain and 3.79 and 4.24 mg/kg in straw. The residues of the metabolite BF 500-3 ranged between 0.02 and 0.98 mg/kg in ears, 0.10 and 1.69 mg/kg in rest of plant without roots, 0.09 and 0.35 mg/kg in grain and 1.09 and 1.59 mg/kg in straw.
In untreated specimens residues were always below 0.01 mg/kg with two exceptions. One grain specimen contained 0.02 mg/kg of pyraclostrobin and 0.01 mg/kg of the metabolite BF 500-3. One straw specimen contained 0.11 mg/kg of pyraclostrobin and 0.04 mg/kg of the metabolite BF 500-3. The residues in the control sample are most likely caused by an unknown contamination.

A summary of residues is presented in Table 6.3.2-7. Details are shown in Table 6.3.2-8.

Table 6.3.2-7: Summary of pyraclostrobin and BF 500-3 residues in the treated barley specimens after application of BAS 500 06 F

Crop	Year	Appl.	DALA[1]	Growth stage (BBCH)	Residues found (mg/kg)			
					Matrix	BAS 500 F	BF 500-3[3]	Total[4]

III. CONCLUSION

At pre harvest interval (PHI) of 34-36 days, residues of pyraclostrobin ranged between 0.10 and 2.66 mg/kg in ears, 0.59 and 7.13 mg/kg in rest of plant without roots, 0.13 and 0.54 mg/kg in grain and 3.79 and 4.24 mg/kg in straw.
The residues of the metabolite BF 500-3 (500M07) ranged in specimens, sampled at the PHI of 34-36 days, between 0.02 and 0.98 mg/kg in ears, 0.10 and 1.69 mg/kg in rest of plant without roots, 0.09 and 0.35 mg/kg in grain and 1.09 and 1.59 mg/kg in straw.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 702 01 F, BAS 700 00 F, BAS 500 06 F, BAS 480 38 F

Description:	BAS 702 01 F (BAS 700 F, BAS 500 F, BAS 480 F), BAS 700 00 F (BAS 700 F), BAS 500 06 F (BAS 500 F), BAS 480 38 F (BAS 480 F)	
Lot/Batch #:	205005, BAS 700 F: 42 g/L, BAS 500 F: 67 g/L, BAS 480 F: 42 g/L (BAS 702 01 F) 201149, BAS 700 F: 62.5 g/L (BAS 700 00 F) 8265, BAS 500 F: 200 g/L (BAS 500 06 F) 15146, BAS 480 F: 83 g/L (BAS 480 38 F)	
Purity:	not relevant	
CAS#:	Pyraclostrobin (BAS 500 F): 175013-18-0 Fluxapyroxad (BAS 700 F): 907204-31-3 Epoxiconazole (BAS 480 F): 133855-98-8	
Development code:	not applicable	
Spiking levels:	Pyraclostrobin:	0.01 – 10.0 mg/kg
	Fluxapyroxad:	0.01 – 10.0 mg/kg
	Epoxiconazole:	0.01 – 10.0 mg/kg

2. Test Commodity: Cereals

Crop:	Barley
Type:	not relevant
Variety:	Marthe, Prestige, Cecilia, Otis
Botanical name:	*Hordeum vulgare* L.
Crop parts(s) or processed Commodity:	whole plant (no roots), rest of plant (no roots), ears, grain, straw
Sample size:	min. 1.0 kg (straw min. 0.5 kg)

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2009 growing season, 4 trials in barley were conducted in different representative growing areas in France, Spain, Italy and Germany to determine the residue level of fluxapyroxad, pyraclostrobin and epoxiconazole in or on raw agricultural commodities (RAC). Therefore, the new fungicidal formulation BAS 702 01 F (fluxapyroxad, pyraclostrobin and epoxiconazole) was compared to the solo formulations BAS 700 00 F (fluxapyroxad), BAS 500 06 F (pyraclostrobin) and BAS 480 38 F (epoxiconazole).
All trials consisted of five plots: plot 1 (control), plot 2 (treated with BAS 702 01 F), plot 3 (treated with BAS 700 00 F), plot 4 (treated with BAS 500 06 F) and plot 5 (treated with BAS 480 38 F).
BAS 702 01 F (42 g/L fluxapyroxad + 67 g/L pyraclostrobin + 42 g/L epoxiconazole, EC) was applied twice at a single rate equivalent to 0.126 kg as/ha of epoxiconazole, 0.201 kg as/ha of pyraclostrobin and 0.126 kg as/ha of fluxapyroxad on plot 2.
BAS 700 00 F (62.5 g/L fluxapyroxad, EC) was applied twice at a single rate equivalent to 0.125 kg as/ha of fluxapyroxad on plot 3.
BAS 500 06 F (200 g/L pyraclostrobin, EC) was applied twice at a single rate equivalent to 0.250 kg as/ha of pyraclostrobin on plot 4.
BAS 480 38 F (83 g/L epoxiconazole, EC) was applied twice at a single rate equivalent to 0.125 kg as/ha of epoxiconazole on plot 5.
In all trials the applications were made at crop stages BBCH 39-49 and 69 (exception: in trial L090027: the 1st application was carried out at BBCH 71). The spray volume used was 200 L/ha.
Barley "whole plant without roots" specimens were collected directly after the last application.
After 28 (±1), 35 (±1) and 42 (±1) days, either ears and rest of plant or grain and straw were taken depending on the crop maturity (exception: trial L090027 4th sampling was not carried out).
Commercial harvest (BBCH 89) was reached in two trials at 35 DALA (L090027, L090028), and in two trials at 41 DALA.
The samples were stored frozen until analysis. The maximum storage interval from harvest until analysis was 406 days.

2. Description of analytical procedures

All specimens of plot 2 and 4 were analysed for pyraclostrobin and its metabolite BF 500-3 using BASF method 535/1 (synonym: L0076/01), which has a limit of quantitation of 0.01 mg/kg. The results of procedural recovery experiments at fortification levels between 0.01 and 10 mg/kg averaged at about 100% for pyraclostrobin and 95% for BF 500-3.
Pyraclostrobin and its metabolite BF 500-3 were extracted with a mixture of methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned at alkaline conditions against cyclohexane. The final determination of the analytes was performed by HPLC-MS/MS.

II. RESULTS AND DISCUSSION

Although the application rate of pyraclostrobin was 24% higher in the application of the solo formulation on plot 4 (2 x 0.250 kg as/ha) compared to the mixed formulation on plot 2 (2 x 0.201 kg as/ha), the residues levels found in both variants were comparable at all times.
Directly after the last application, the pyraclostrobin residues in barley "whole plant no roots" specimens ranged between 3.44 and 6.40 mg/kg in plot 2 (mixed formulation) and between 3.54 and 6.60 mg/kg in plot 4 (solo formulation).
In barley grain collected at 29 DALA residues decreased and were at 0.06 mg/kg in plot 2 and 0.08 mg/kg in plot 4. At about 35 DALA residues ranged from 0.02 - 0.21 mg/kg (plot 2) and from 0.01 - 0.09 mg/kg (plot 4). After longer PHI residues up to 0.07 mg/kg were found.
Residues found in ears were higher than the results for grain. At 27 - 29 DALA the residues in ears in plot 2 reached 0.21 - 0.99 mg/kg and in plot 4 0.17 - 1.01 mg/kg.
The residues in straw are dependent on the ripening stage / water content of the matrix and at 29 DALA residues of 2.02 mg/kg for plot 2 and 2.23 mg/kg for plot 4 were found. After longer PHI's the maximum residues, found in straw, were comparable for the mix and the solo formulation (about 35 DALA: 1.63 to 2.42 mg/kg in plot 2 and 0.79 - 2.50 mg/kg in plot 4; 41 - 42 DALA: 1.19 to 2.09 mg/kg in plot 2 and 0.46 to 2.87 mg/kg plot 4).
At 34-42 DALA, residues of metabolite BF 500-3 in barley grain ranged between 0.02 - 0.09 mg/kg after application of the mixed formulation and 0.02 – 0.07 mg/kg after application of the solo formulation. At 34-42 DALA, residues of metabolite BF 500-3 in barley straw ranged between 0.26 - 0.81 mg/kg after application of BAS 702 01 F and 0.22 – 1.08 mg/kg after application of BAS 500 06 F.

None of the analyzed untreated specimens did contain any residues of pyraclostrobin or BF 500-3 above LOQ.

A summary of residues is presented in
Table 6.3.2-9. Details are shown in Table 6.3.2-10.

Table 6.3.2-9: Summary of pyraclostrobin and BF 500-3 residues in barley after 2 applications of BAS 702 01 F and BAS 500 06 F

Matrix	Year	DALA[1]	Range of residues (mg/kg)

III. CONCLUSION

The results of the study show that the residue behaviour of pyraclostrobin in/on barley specimens after application of mixed formulation BAS 702 01 F is in correspondence to the behaviour found after use of the respective solo formulation BAS 500 06 F.
At harvest maturity, the pyraclostrobin residues in barley grain (34-42 DALA: BAS 702 01 F → 0.02 – 0.21 mg/kg; BAS 500 06 F → 0.01 – 0.09 mg/kg) and in barley straw are at a comparable level (34-42 DALA: BAS 702 01 F → 1.19 – 2.42 mg/kg; BAS 500 06 F → 0.46 – 2.50 mg/kg).
At 34-42 DALA, residues of metabolite BF 500-3 in barley grain ranged between 0.02 and 0.09 mg/kg after application of the mixed formulation and between 0.02 and 0.07 mg/kg after application of the solo formulation. At 34-42 DALA, residues of metabolite BF 500-3 in barley straw ranged between 0.26 and 0.81 mg/kg after application of BAS 702 01 F and between 0.22 and 1.08 mg/kg after application of BAS 500 06 F.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 556 03 F, BAS 500 06 F or BAS 555 00 F

Description:	BAS 556 03 F: BAS 500 F (pyraclostrobin, 130 g/L), BAS 555 F (metconazole, 80 g /L), EC BAS 500 06 F: BAS 500 F (pyraclostrobin, 200 g/L), EC BAS 555 00 F: BAS 555 F (metconazole, 60 g/L), EC
Lot/Batch #:	BAS 556 03 F: 380009, BAS 500 06 F: 0003223026, BAS 555 00 F: 0003255328
Purity:	not applicable
CAS#:	Pyraclostrobin: 175013-18-0, metconazole: 125116-23-6
Development code:	not applicable
Spiking levels:	whole plant w/o roots: 0.01 and 25 mg/kg, ears: 0.01 and 1.0 mg/kg, grain: 0.01 and 1.0 mg/kg, straw: 0.01, 1.0 and 10 mg/kg

2. Test Commodity: Cereals

Crop:	Barley
Type:	not relevant
Variety:	Souleyka, Cavia, Azurel, Amorosa
Botanical name:	*Hordeum vulgare* L.
Crop parts(s) or processed	
Commodity:	whole plant (no roots), rest of plant (no roots), ears, grain, straw
Sample size:	whole plant (no roots): ≥0.5 kg, rest of plant (no roots) ≥1.0 kg, ears ≥1.0 kg, grain, straw ≥0.5 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2011 growing season, four field trials were conducted at representative winter barley growing areas in Germany, UK, Southern France and Italy to determine the residue level of pyraclostrobin and metconazole (BAS 555 F) in or on Raw Agricultural Commodities (RAC).
Plot 2 was treated with **BAS 556 03 F**, an EC formulation of metconazole (80 g/L) and pyraclostrobin (130 g/L) and was foliar applied twice at a rate of 0.143 kg as/ha pyraclostrobin and 0.088 kg as/ha metconazole to barley at BBCH 49 and BBCH 69-73. The nominal spray volume used was 200 L/ha.
Plot 3 was treated with **BAS 500 06 F**, an EC formulation of pyraclostrobin (200 g/L) and was foliar applied twice at a rate of 0.25 kg as/ha pyraclostrobin to barley at BBCH 49 and BBCH 69-73. The nominal spray volume used was 200 L/ha.
Plot 4 was treated with BAS 555 00 F, an EC formulation of metconazole (60 g/L) and was foliar applied twice at a rate of 0.09 kg as/ha metconazole to barley at BBCH 49 and BBCH 69-73. The nominal spray volume used was 200 L/ha.
Whole plant specimens were collected directly before (plot 1) and after (plot 2 to 4) the last application. At 28-29 days after last application (DALA), 34-36 DALA and 41-42 DALA either, ears and "rest of plant without roots", or grain and straw specimens were taken depending on the maturity.
The samples were stored frozen until analysis. The maximum storage interval from harvest until analysis was 406 days.

Table 6.3.2-11: Application and sampling details for trials conducted in 2011

Region	No. of trials	No. of appl.	F, P, or G	Test item	Active substance	Application		Target timing

					pyraclostrobin	0.143			
				BAS 500 06 F	pyraclostrobin	0.25			
				BAS 555 00 F	metconazole	0.09			

[1] days after last application

2. Description of analytical procedures

All specimens were analysed for pyraclostrobin and its metabolite BF 500-3 using BASF method No. 535/1 (synonym: L0076/01):
Pyraclostrobin and its metabolite BF 500-3 were extracted with a mixture of methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned at alkaline conditions against cyclohexane. The final determination of the analytes was performed by HPLC-MS/MS. The limit of quantification of the method was 0.01 mg/kg.
The results of procedural recovery experiments were 81-94% for pyraclostrobin and 80-96% for BF 500-3 at fortification levels between 0.01 and 25 mg/kg.

II. RESULTS AND DISCUSSION

Residues of pyraclostrobin parent analysed in whole plant specimens, taken 0 days after last application, ranged between 2.3 - 5.1 mg/kg in plot 2 and 1.9 - 9.2 mg/kg in plot 3. At 28-29 DALA residues in ear specimens ranged between 0.049 - 0.26 mg/kg in plot 2; 0.066 - 0.39 mg/kg in plot 3, while residues in "rest of plant w/o roots" ranged between 0.25 - 2.0 mg/kg in plot 2; 0.39 - 3.5 mg/kg in plot 3. At BBCH 83-89, residues in grain ranged between 0.019 - 0.059 mg/kg in plot 2; 0.029 - 0.065 mg/kg in plot 3, and residues in straw specimens ranged between 0.42 - 3.2 mg/kg in plot 2; 0.46 - 4.1 mg/kg in plot 3.
Residues of metabolite BF 500-3 analyzed in barley grain were found in maximum up to 0.042 mg/kg. In rest of plant and straw samples maximum residues of 1.9 mg/kg in plot 2 and of 2.4 mg/kg in plot 4 were found.

No residues of pyraclostrobin and its metabolite BF 500-3 above the limit of quantitation (0.01 mg/kg) were detected in the untreated specimens of this study.
All specimens, apart from the S1 whole plant, S2 rest of plant and S3 ear specimens from trial S11-00713-02 (L110193) and the S3 rest of plant specimen from trial S11-00713-04 (L110195), showed that the new formulation BAS 556 03 F does not lead to higher pyraclostrobin residues than the solo formulation BAS 500 06 F.

A summary of residues is presented in Table 6.3.2-12 and
Table 6.3.2-13. Details are shown in Table 6.3.2-14.

III. CONCLUSION

Residues of pyraclostrobin parent analysed in whole plant specimens, taken 0 days after last application, ranged between 2.3 and 5.1 mg/kg in plot 2 (treated with the mixed formulation BAS 556 03 F) and between 1.9 and 9.2 mg/kg in plot 3 (treated with BAS 500 06 F). At BBCH 83-89, residues in grain ranged between 0.019 and 0.059 mg/kg in plot 2 and between 0.029 and 0.065 mg/kg in plot 3; residues in straw specimens ranged between 0.42 and 3.2 mg/kg in plot 2 and between 0.46 and 4.1 mg/kg in plot 3.
Residues of metabolite BF 500-3 analysed in barley grain were found in maximum up to 0.042 mg/kg. In rest of plant and straw samples maximum residues of 1.9 mg/kg in plot 2 and of 2.4 mg/kg in plot 3 were found.
In general, it was proven with only a few exceptions that a double treatment with formulation BAS 556 03 F at of 0.143 kg as/ha leads to lower pyraclostrobin residues compared to the corresponding treatment with solo formulation BAS 500 06 F at 0.25 kg as/ha.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 703 04 F, BAS 700 00 F, BAS 500 06 F

Description: BAS 703 04 F: 150 g/L of BAS 500 F (pyraclostrobin) and 75 g/L of BAS 700 F (fluxapyroxad), EC
BAS 500 06 F: 200 g/L of BAS 500 F (pyraclostrobin), EC
BAS 700 00 F: 62.5 g/L of BAS 700 F (fluxapyroxad), EC

Lot/Batch #: BAS 703 04 F: 208088
BAS 700 00 F: 201454
BAS 500 06 F: 0004863761

Purity: 99.9%

CAS#: BAS 500 F: 175013-18-0
BAS 700 F: 907204-31-3

Development code: not applicable

Spiking levels: 0.01-100 mg/kg

2. Test Commodity: Cereals

Crop: Barley

Type: not applicable

Variety: Propino, Cervoise, Pewter, Arta

Botanical name: *Hordeum vulgare L.*

Crop parts(s) or processed

Commodity: Whole plant without roots, ears, grain, rest of plant without roots, straw

Sample size: 0.5-1.0 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2012 growing season, 4 trials in barley were conducted in different representative growing areas in Northern France, Spain, Greece and Germany to determine the residue level of fluxapyroxad and pyraclostrobin in or on raw agricultural commodities (RAC).
Therefore, the fungicidal formulation BAS 703 04 F (fluxapyroxad and pyraclostrobin) was compared to the solo formulations BAS 700 00 F (fluxapyroxad) and BAS 500 06 F (pyraclostrobin). All trials consisted of four plots: plot 1 (control), plot 2 (treated with BAS 703 04 F), plot 3 (treated with BAS 700 00 F) and plot 4 (treated with BAS 500 06 F).

BAS 703 04 F (75 g/L fluxapyroxad and 150 g/L pyraclostrobin, EC) was applied twice at a single rate equivalent to 0.1125 kg as/ha of fluxapyroxad and 0.225 kg as/ha of pyraclostrobin on plot 2.
BAS 700 00 F (62.5 g/L fluxapyroxad, EC) was applied twice at a single rate equivalent to 0.125 kg as/ha of fluxapyroxad on plot 3. **BAS 500 06 F** (200 g/L pyraclostrobin, EC) was applied twice at a single rate equivalent to 0.250 kg as/ha of pyraclostrobin on plot 4.

In all trials the applications were made at crop stages BBCH 49 and 69. The spray volume used was 200 L/ha. "Whole plant without roots" specimens were collected directly after the last application. After 28±1, 35±1 and 42±1 days, either ears or "rest of plant" or grain and straw were taken depending on the crop maturity. Commercial harvest (BBCH 89) was reached at 36 to 47 days after the last application (DALA).

The specimens were shipped under deep-frozen conditions from the field stations to the specimen management side, homogenized using dry ice and stored deep frozen until analysis. Maximum storage interval from harvest until analysis was about 12 months.

Table 6.3.2-15: Application and sampling details for trials conducted in 2012

Region	No. of trials	No. of appl.	F, P, or G	Test item	Active substance	Application		Target timing	
						Rate as (kg/ha)	Water vol. (L/ha)	Appl.	Sampling (DALA)[1]

					BAS 500 F	0.225			
				BAS 700 00 F (EC)	BAS 700 F	0.125			
				BAS 500 06 F (EC)	BAS 500 F	0.250			

[1] days after last application

2. Description of analytical procedures

All specimens were analysed for pyraclostrobin and its metabolite BF 500-3 using BASF method No. 535/1 (synonym: L0076/01):
Pyraclostrobin and its metabolite BF 500-3 were extracted with a mixture of methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned at alkaline conditions against cyclohexane. The final determination of the analytes was performed by HPLC-MS/MS. The limit of quantification of the method was 0.01 mg/kg.
The results of procedural recovery experiments were 93.6% for pyraclostrobin and 95.2% for BF 500-3 at fortification levels between 0.01 and 100 mg/kg.

II. RESULTS AND DISCUSSION

Although the application rate of pyraclostrobin was higher in the application of the BAS 500 06 F formulation (2 x 250 g as/ha) compared to the mixed formulation BAS 703 04 F (2 x 225 g as/ha), the residue levels found in both variants were very comparable in barley matrices.

Directly after the last application, the residues of pyraclostrobin in barley "whole plant without roots" specimens ranged between 3.6 and 5.1 mg/kg (mixed formulation) and between 4.4 and 6.0 mg/kg (solo formulation).

In barley grain collected at 34 to 36 DALA residues of pyraclostrobin ranged between 0.04 and 0.25 mg/kg (mixed formulation) and between 0.056 and 0.33 mg/kg (solo formulation). Residues of metabolite BF 500-3 ranged from 0.020 to 0.089 mg/kg (mixed formulation) and 0.03 to 0.16 mg/kg (solo formulation). At 41-47 DALA parent pyraclostrobin residues in barley grain ranged between <0.01 - 0.27 mg/kg (mixed formulation) and between <0.01 - 0.35 mg/kg (solo formulation), residues of the metabolite ranged between <0.01 - 0.082 mg/kg (mixed formulation) and for the solo formulation between <0.01 - 0.15 mg/kg.

The residues of pyraclostrobin in barley straw collected at 34 to 36 DALA ranged between 0.80 and 1.9 mg/kg (mixed formulation) and between 1.2 and 2.8 mg/kg (solo formulation), while residues of metabolite BF 500-3 ranged from 0.20 to 0.46 mg/kg (mixed formulation) and from 0.44 to 0.99 mg/kg (solo formulation). At 41 - 47 DALA parent pyraclostrobin residues in barley straw ranged between <0.01 - 1.7 mg/kg (mixed formulation) and between 0.56 - 2.9 mg/kg (solo formulation), residues of the metabolite ranged between <0.01 - 0.50 mg/kg (mixed formulation) and for the solo formulation between 0.22 - 0.85 mg/kg.

No residues equal or above the limit of quantitation (0.01 mg/kg) of pyraclostrobin and its metabolite BF 500-3 were present in control specimens.

The summarized results are given in
Table 6.3.2-16. The detailed results are given in Table 6.3.2-17.

Table 6.3.2-16: Summary of pyraclostrobin and BF 500-3 residues in the treated barley specimens after application of BAS 703 04 F and BAS 500 06 F

[1] days after last application
[2] BBCH stage at respective sampling
[3] conversion factor for calculation of BF 500-3 (500M07) to parent equivalent is 1.08
[4] for residues <0.01 mg/kg, value was set to 0.01 mg/kg for calculation of sum
[5] without roots

The values of trial L120231 (L1202310028 and L1202310029, DALA 42, GS 89) are not considered for any further evaluation, due to an obvious mix up of sample material most likely during the threshing process.
There are no further consequences on the trial L120231, previous samplings showed residues equal to the other trial.

III. CONCLUSION

In barley grain collected at 34 to 36 DALA, residues of pyraclostrobin ranged between 0.04 and 0.25 mg/kg (mixed formulation) and between 0.056 and 0.33 mg/kg (solo formulation). Residues of metabolite BF 500-3 ranged from 0.020 to 0.089 mg/kg (mixed formulation) and from <0.01 to 0.16 mg/kg (solo formulation).
At 41-47 DALA, parent pyraclostrobin residues in barley grain ranged between <0.01 - 0.27 mg/kg (mixed formulation) and between <0.01 - 0.35 mg/kg (solo formulation), residues of the metabolite BF 500-3 ranged between <0.01 - 0.082 mg/kg (mixed formulation) and for the solo formulation between <0.01 and 0.15 mg/kg.

The residues of pyraclostrobin in barley straw collected at 34 to 36 DALA ranged between 0.80 and 1.9 mg/kg (mixed formulation) and between 1.2 and 2.8 mg/kg (solo formulation), while residues of metabolite BF 500-3 ranged from 0.20 to 0.46 mg/kg (mixed formulation) and from 0.44 to 0.99 mg/kg (solo formulation).
At 41 - 47 DALA, parent pyraclostrobin residues in barley straw ranged between <0.01 and 1.7 mg/kg (mixed formulation) and between 0.56 and 2.9 mg/kg (solo formulation), residues of the metabolite BF 500-3 ranged between <0.01 and 0.50 mg/kg (mixed formulation) and for the solo formulation between 0.22 and 0.85 mg/kg.

A. MATERIALS

1. Test Material: BAS 500 06 F

Description:	BAS 500 06 F (BAS 500 F, 200 g/L pyraclostrobin), EC formulation
Lot/Batch #:	BAS 500 06 F: 0003223036
Purity:	99.9%
CAS#:	BAS 500 F: 175013-18-0 BF 500-3: 512165-96-7
Development code:	not applicable
Spiking levels:	0.01 - 1.0 mg/kg

2. Test Commodity: Cereals

Crop:	Wheat
Type:	not applicable
Variety:	Cubus, Solstice, Mercato, Frument, Euclide, Svevo, Aubusson, Prospero
Botanical name:	*Triticum L.*
Crop parts(s) or processed	
Commodity:	Whole plant without roots, ears, grain, rest of plant without roots, straw
Sample size:	whole plant (no roots): ≥0.5 kg, rest of plant (no roots) ≥1.0 kg, ears ≥1.0 kg, grain, straw ≥0.5 kg

B. STUDY DESIGN AND METHODS

During the 2010 growing season, a total of 8 field trials were conducted in Northern and Southern Europe in order to determine the magnitude of residues of pyraclostrobin after two applications of BAS 500 06 F. Each trial consisted of a control and a treated plot. BAS 500 06 F (200 g/L pyraclostrobin, EC), was applied twice with an application rate of 0.250 kg as/ha and a spray volume of 200 L/ha at growth stages BBCH 49 and 69. "Whole plant no roots" specimens were taken directly after the last application. Depending on the maturity ears and "rest of plant without roots" or grain and straw specimens were taken at 28±1, 35±1 and 42±1 DALA.
The samples were stored deep frozen until analysis. The maximum storage interval from harvest until analysis for plant samples was 334 days.

Table 6.3.2-18: Application and sampling details for trials conducted in 2010

Region	No. of trials	No. of appl.	F, P, or G	Test item	Active substance	Application		Target timing	
						Rate as (kg/ha)	Water vol. (L/ha)	Appl.	Sampling (DALA)[1]
Northern and Southern Europe	8	2	F	BAS 500 06 F	BAS 500 F	0.250	200	BBCH 49 BBCH 69	0 28±1 35±1 42±1

[1] days after last application

2. Description of analytical procedures

The specimens were analysed for residues of pyraclostrobin and its metabolite BF 500-3 using BASF method 535/1 (synonym: L0076/01), which quantifies the relevant residues with a limit of quantitation (LOQ) of 0.01 mg/kg for pyraclostrobin and its metabolite BF 500-3 in all of the specimen material. The results of procedural recovery experiments were 89% for pyraclostrobin and 86% for BF 500-3 at fortification levels between 0.01 and 1.0 mg/kg.
Pyraclostrobin and BF 500-3 residues were extracted from the homogenized specimens with methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned against cyclohexane. The final determination of pyraclostrobin and BF 500-3 was performed by HPLC-MS/MS.

II. RESULTS AND DISCUSSION

At pre harvest interval (PHI) of 34-36 days residues of pyraclostrobin ranged between 0.18 and 0.49 mg/kg in ears, 1.89 and 5.59 mg/kg in rest of plant without roots, <0.01 and 0.02 mg/kg in grain and 4.08 and 5.76 mg/kg in straw.

The residues of the metabolite BF 500-3 ranged between 0.06 and 0.37 mg/kg in ears, 0.63 and 1.90 mg/kg in rest of plant without roots, <0.01 mg/kg in grain and 1.72 and 1.93 mg/kg in straw.

No residues of either pyraclostrobin or its metabolite BF 500-3 above the respective limits of quantitation were found in any of the analysed untreated specimens.

A summary of residues is presented in
Table 6.3.2-19. Details are shown in Table 6.3.2-20.

Table 6.3.2-19: Summary of pyraclostrobin and BF 500-3 residues in the treated wheat specimens after application of BAS 500 06 F

Crop	Year	Appl.	DALA[1]	Growth stage (BBCH)	Residues found (mg/kg)			
					Matrix	BAS 500 F	BF 500-3[3]	Total[4]

III. CONCLUSION

At PHI of 34-36 days, residues of pyraclostrobin ranged between 0.18 and 0.49 mg/kg in ears, between 1.89 and 5.59 mg/kg in rest of plant without roots, between <0.01 and 0.02 mg/kg in grain and between 4.08 and 5.76 mg/kg in straw.

The residues of the metabolite BF 500-3 (500M07) ranged in specimens sampled at 34 to 36 DALA between 0.06 and 0.37 mg/kg in ears, between 0.63 and 1.90 mg/kg in rest of plant without roots, between <0.01 mg/kg in grain and between 1.72 and 1.93 mg/kg in straw.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 06 F

Description:	BAS 500 06 F (BAS 500 F, 200 g/L pyraclostrobin), EC formulation
Lot/Batch #:	BAS 500 06 F: 0003223036
Purity:	99.9%
CAS#:	BAS 500 F: 175013-18-0 BF 500-3: 512165-96-7
Development code:	not applicable
Spiking levels:	0.01 - 10 mg/kg

2. Test Commodity: Cereals

Crop:	Wheat
Type:	not applicable
Variety:	Asano, Solstice, Tabasco, Quality, Svevo, Aubusson, Califa Sur
Botanical name:	*Triticum L.*
Crop parts(s) or processed	
Commodity:	Whole plant without roots, ears, grain, rest of plant without roots, straw
Sample size:	whole plant (no roots): ≥0.5 kg, rest of plant (no roots) ≥0.65 kg, ears ≥1.0 kg, grain, straw ≥0.5 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2011 growing season, a total of 8 field trials were conducted in Northern and Southern Europe in order to determine the magnitude of residues of pyraclostrobin after two applications of BAS 500 06 F. Each trial consisted of a control and a treated plot. The fungicidal formulation BAS 500 06 F (200 g/L pyraclostrobin), was applied twice with an application rate of 0.25 kg as/ha and a spray volume of 200 L/ha at growth stages BBCH 49 and 69. "Whole plant no roots" specimens were taken directly after the last application. Depending on the maturity ears and "rest of plant without roots" or grain and straw specimens were taken at 28 ± 1, 35 ± 1, 42 ± 1 DALA. If crop stage BBCH 89 was not reached, an additional sampling was made.

The samples were stored deep frozen until analysis. The maximum storage interval from harvest until analysis for plant samples was 408 days.

Table 6.3.2-21: Application and sampling details for trials conducted in 2011

Region	No. of trials	No. of appl.	F, P, or G	Test item	Active substance	Application		Target timing	
						Rate as (kg/ha)	Water vol. (L/ha)	Appl.	Sampling (DALA)[1]
Northern and Southern Europe	8	2	F	BAS 500 06 F	BAS 500 F	0.25	200	BBCH 49 BBCH 69	0 28±1 35±1 42±1 BBCH 89

[1] days after last application

2. Description of analytical procedures

The specimens were analysed for residues of pyraclostrobin and its metabolite BF 500-3 using BASF method 535/1 (synonym: L0076/01), which quantifies the relevant residues with a limit of quantitation (LOQ) of 0.01 mg/kg for pyraclostrobin and its metabolite BF 500-3 in all of the specimen material. The results of procedural recovery experiments were 87% for pyraclostrobin and 83% for BF 500-3 at fortification levels between 0.01 and 10 mg/kg.

Pyraclostrobin and BF 500-3 residues were extracted from the homogenized specimens with methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned against cyclohexane. The final determination of pyraclostrobin and BF 500-3 was performed by HPLC-MS/MS.

II. RESULTS AND DISCUSSION

At PHI of 34-36 days residues of pyraclostrobin ranged between 0.05 and 0.54 mg/kg in ears, 0.23 and 5.32 mg/kg in rest of plant without roots, <0.01 and 0.02 mg/kg in grain and 4.18 and 4.40 mg/kg in straw.
The residues of the metabolite BF 500-3 ranged between 0.02 and 0.29 mg/kg in ears, 0.11 and 1.66 mg/kg in rest of plant without roots, <0.01 mg/kg in grain and 1.53 and 1.79 mg/kg in straw.
In two untreated 'rest of plant without root' samples residues of 0.01 mg/kg and 0.06 mg/kg of pyraclostrobin and 0.02 mg/kg of BF 500-3 were found. In the respective untreated straw samples residues of 0.01 and 0.03 mg/kg of pyraclostrobin and 0.01 mg/kg of BF 500-3 were found. The detected residues in the control samples are caused by unknown contamination. In all other than the above mentioned control samples no residues at or above the limit of quantitation were found.

A summary of residues is presented in Table 6.3.2-22. Details are shown in Table 6.3.2-23.

Table 6.3.2-22: Summary of pyraclostrobin and BF 500-3 residues in the treated wheat specimens after application of BAS 500 06 F

I. MATERIAL AND METHODS

A. MATERIALS

1.	**Test Material:**	BAS 556 03 F, BAS 500 06 F, BAS 555 00 F
	Description:	BAS 556 03 F: BAS 500 F (pyraclostrobin, 130 g/L) and BAS 555 F (metconazole, 80 g/L), EC BAS 500 06 F: BAS 500 F (pyraclostrobin, 200 g/L), EC BAS 555 00 F: BAS 555 F (metconazole, 60 g/L), EC
	Lot/Batch #:	BAS 556 03 F: 380009, BAS 500 06 F: 0003223026, BAS 555 00 F: 0003255328
	Purity:	not relevant
	CAS#:	Pyraclostrobin: 175013-18-0 Metconazole: 125116-23-6
	Development code:	not applicable
	Spiking levels:	whole plant (no roots): 0.1 and 20 mg/kg, ears: 0.01 and 2.0 mg/kg, grain: 0.01 and 1.0 mg/kg, straw: 0.01 and 8.0 mg/kg

2. Test Commodity: Cereals

Crop:	Wheat
Type:	not relevant
Variety:	Julius, Oakley, PR22 R58, Bologna
Botanical name:	*Triticum L.*
Crop parts(s) or processed	
Commodity:	whole plant (no roots), rest of plant (no roots), ears, grain, straw
Sample size:	whole plant (no roots): ≥0.5 kg, rest of plant (no roots) ≥1.0 kg, ears ≥1.0 kg, grain, straw ≥0.5 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2011 growing season, four field trials were conducted at representative winter wheat growing areas in Germany, the UK, Southern France and Italy to determine the residue level of pyraclostrobin (BAS 500 F) and metconazole (BAS 555 F) in or on Raw Agricultural Commodities (RAC).

Plot 2 was treated with **BAS 556 03 F**, an EC formulation of metconazole (80 g/L) and pyraclostrobin (130 g/L) and was foliar applied twice at a rate of 0.143 kg as/ha pyraclostrobin and 0.088 kg as/ha metconazole to wheat at BBCH 49-51 and BBCH 69. The nominal spray volume used was 200 L/ha.

Plot 3 was treated with **BAS 500 06 F**, an EC formulation of pyraclostrobin (200 g/L) and was foliar applied twice at a rate of 0.250 kg as/ha pyraclostrobin to wheat at BBCH 49-51 and BBCH 69. The nominal spray volume used was 200 L/ha.

Plot 4 was treated with BAS 555 00 F, an EC formulation of metconazole (60 g/L) and was foliar applied twice at a rate of 0.090 kg as/ha metconazole to wheat at BBCH 49-51 and BBCH 69. The nominal spray volume used was 200 L/ha.

Whole plant specimens were collected directly before (plot 1) and after (plot 2 to 4) the last application. At 27-29 days after last application (DALA), 34-36 DALA and 39-43 DALA either ears and "rest of plant without roots", or grain and straw specimens were taken depending on the maturity. At trials S11-00711-01 and 02 (L110188 and L110189) where BBCH 89 was not reached at 42 (±) DALA, grain and straw specimens were taken 57 DALA when BBCH 89 was reached. The samples were stored frozen until analysis. The maximum storage interval from harvest until extraction was 343 days.

2. Description of analytical procedures

All specimens of plot 2 and 3 were analysed for pyraclostrobin and its metabolite BF 500-3 using BASF method 535/1 (synonym: L0076/01), which has a limit of quantitation of 0.01 mg/kg. The results of procedural recovery experiments at fortification levels between 0.01 and 20 mg/kg were between 85 - 98% for pyraclostrobin and 75 - 91% for BF 500-3.

Pyraclostrobin and its metabolite BF 500-3 were extracted with a mixture of methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned at alkaline conditions against cyclohexane. The final determination of the analytes was performed by HPLC-MS/MS.

II. RESULTS AND DISCUSSION

Residues of parent pyraclostrobin analysed in whole plant specimens, taken 0 days after last application, ranged between 2.0 - 3.8 mg/kg in plot 2; 3.9 – 10 mg/kg in plot 3. At 27-29 DALA residues in ear specimens ranged between 0.11 - 0.31 mg/kg in plot 2; 0.19 - 0.36 mg/kg in plot 3, while residues in "rest of plant w/o roots" ranged between 0.57 - 3.0 mg/kg in plot 2; 1.3 - 6.1 mg/kg in plot 3. At BBCH 85-89, residues in grain ranged between <0.01 - 0.020 mg/kg in plot 2; <0.01 - 0.039 mg/kg in plot 3, and residues in straw specimens ranged between 0.49 - 1.9 mg/kg in plot 2; 0.95 - 5.5 mg/kg in plot 3.

Residues of metabolite BF 500-3 analysed in whole plant specimens, taken 0 days after last application, ranged between 0.069 – 0.24 mg/kg in plot 2; 0.14 – 0.46 mg/kg in plot 3. At 27-29 DALA residues in ear specimens ranged between 0.044 - 0.12 mg/kg in plot 2; 0.078 - 0.17 mg/kg in plot 3, while residues in "rest of plant w/o roots" ranged between 0.22 - 1.1 mg/kg in plot 2; 0.38 – 1.6 mg/kg in plot 3. At BBCH 85-89, residues in grain were <0.01 mg/kg in plot 2; <0.01 - 0.023 mg/kg in plot 3, and residues in straw specimens ranged between 0.30 - 0.97 mg/kg in plot 2; 0.42 - 2.0 mg/kg in plot 3.

No residues of pyraclostrobin and its metabolite BF 500-3 above the limit of quantitation (0.01 mg/kg) were detected in the untreated specimens of this study. All specimens, apart from the S3 straw specimen from trial S11-00711-02 (L110189), showed that the new formulation BAS 556 03 F does not lead to higher pyraclostrobin residues than the solo formulation BAS 500 06 F.

A summary of residues is presented in Table 6.3.2-24. Details are shown in Table 6.3.2-25.

III. CONCLUSION

At BBCH 85-89, residues of parent pyraclostrobin analysed in grain ranged between <0.01 - 0.020 mg/kg in plot 2 (treated with the mixed formulation BAS 556 03 F) and between <0.01 and 0.039 mg/kg in plot 3 (treated with BAS 500 06 F); residues in straw specimens ranged between 0.49 and 1.9 mg/kg in plot 2 and were in the range of 0.95 to 5.5 mg/kg in plot 3.

At BBCH 85-89, residues of metabolite 500M07 (BF 500-3) analysed in grain were at <0.01 mg/kg in plot 2 and between <0.01 and 0.023 mg/kg in plot 3; residues in straw specimens ranged between 0.30 and 0.97 mg/kg in plot 2 and ranged between 0.42 and 1.2 mg/kg in plot 3.

Report:	CA 6.3.2/10 Meyer M., 2013b Study on residue behaviour of Fluxapyroxad (BAS 700 F), Pyraclostrobin (BAS 500 F) in wheat after treatment with either BAS 703 04 F, BAS 700 00 F or BAS 500 06 F under field conditions, Germany, United Kingdom, Spain, Southern France, 2012 2013/1336790
Guidelines:	EC 1107/2009 of the European Parliament and of the Council of 21 Oct 2009, EEC 79/117, EEC 91/414, EEC 91/414 Annex II (Part A Section 6), EEC 91/414 Annex III (Part A Section 8), EEC 1607/VI/97 rev. 2 10.06.1999, EEC 7029/VI/95 rev. 5 Appendix B (July 22 1997), EEC 7525/VI/95 rev. 9 (March 2011)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 703 04 F (EC), BAS 700 00 F (EC), BAS 500 06 F (EC)

Description:	BAS 703 04 F (75 g/L of BAS 700 F and 150 g/L of BAS 500 F, EC) BAS 500 06 F (Pyraclostrobin: 200 g/L of BAS 500 F,EC) BAS 700 00 F (Fluxapyroxad: 62.5 g/L of BAS 700 F, EC)
Lot/Batch #:	BAS 703 04 F: 208088 BAS 500 06 F: 0004863761
Purity:	99.9%
CAS#:	BAS 500 F: 175013-18-0 BF 500-3: 512165-96-7
Development code:	not applicable
Spiking levels:	0.01 - 10 mg/kg

2. Test Commodity: Cereals

Crop:	Wheat
Type:	not applicable
Variety:	Asano, JB Diego, Gallareta, Ingenio
Botanical name:	*Triticum L.*
Crop parts(s) or processed	
Commodity:	Whole plant without roots, ears, grain, rest of plant without roots, straw
Sample size:	0.1-1.0 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2012 growing season, 4 trials in wheat were conducted in different representative growing areas in Southern France, Spain, UK and Germany to determine the residue level of fluxapyroxad (BAS 700 F) and pyraclostrobin (BAS 500 F) in or on raw agricultural commodities (RAC).

Therefore, the fungicidal formulation BAS 703 04 F (fluxapyroxad and pyraclostrobin) was compared to the solo formulations BAS 700 00 F (fluxapyroxad) and BAS 500 06 F (pyraclostrobin). All trials consisted of four plots: plot 1 (control), plot 2 (treated with BAS 703 04 F), plot 3 (treated with BAS 700 00 F) and plot 4 (treated with BAS 500 06 F).

BAS 703 04 F (75 g/L fluxapyroxad and 150 g/L pyraclostrobin, EC) was applied twice at a single rate equivalent to 0.1125 kg as/ha of fluxapyroxad and 0.225 kg as/ha of pyraclostrobin on plot 2. BAS 700 00 F (62.5 g/L fluxapyroxad, EC) was applied twice at a single rate equivalent to 0.125 kg as/ha of fluxapyroxad on plot 3. **BAS 500 06 F** (200 g/L pyraclostrobin, EC) was applied twice at a single rate equivalent to 0.250 kg as/ha of pyraclostrobin on plot 4.

In all trials the applications were made at crop stages BBCH 49 and 69. The spray volume used was 200 L/ha. Wheat “whole plant without roots" specimens were collected directly after the last application. After 28±1, 35±1 and 42±1 days, either ears or rest of plant or grain and straw were taken depending on the crop maturity. In case BBCH growth stage 89 was not yet reached after 42 days, a further sampling was done.

For trial L120235, additional separate samples of grain and straw from the 42 DALA time point were processed and analysed since the absence of fluxapyroxad residues in the straw specimen indicated a possible mix-up in sample labelling. The results from the newly processed specimens were in line with the first indicating that a mislabelling of the straw sample occurred prior to processing.

Commercial harvest (BBCH 89) was reached at 42 to 50 days after the last application (DALA).

The specimens were stored frozen until analysis. The maximum storage interval from harvest until analysis was about 12 months.

Table 6.3.2-26: Application and sampling details for trials conducted in 2012

Region	No. of trials	No. of appl.	F, P, or G	Test item	Active substance	Application		Target timing	
						Rate as (kg/ha)	Water vol. (L/ha)	Appl.	Sampling (DALA)[1]
Northern and Southern Europe	4	2	F	BAS 703 04 F (EC)	BAS 700 F	0.1125	200	BBCH 49 BBCH 69	0 28±1 35±1 42±1 BBCH 89
					BAS 500 F	0.225			
				BAS 700 00 F (EC)	BAS 700 F	0.125			
				BAS 500 06 F (EC)	BAS 500 F	0.250			

[1] days after last application

2. Description of analytical procedures

The specimens were analysed for residues of pyraclostrobin and its metabolite BF 500-3 using BASF method 535/1 (synonym: L0076/01), which quantifies the relevant residues with a limit of quantitation (LOQ) of 0.01 mg/kg for pyraclostrobin and its metabolite BF 500-3 in all of the specimen material. The results of procedural recovery experiments were 84.6% for pyraclostrobin and 83.2% for BF 500-3 at fortification levels between 0.01 and 10 mg/kg.
Pyraclostrobin and BF 500-3 residues were extracted from the homogenized specimens with methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned against cyclohexane. The final determination of pyraclostrobin and BF 500-3 was performed by HPLC-MS/MS.

II. RESULTS AND DISCUSSION

Although the application rate of pyraclostrobin was higher in the application of the BAS 500 06 F formulation (2 x 0.250 kg as/ha) compared to the mixed formulation BAS 703 04 F (2 x 0.225 kg as/ha), the residues levels found in both variants were very comparable in wheat matrices.
Directly after the last application, the residues of pyraclostrobin in whole plant without roots ranged between 3.7 and 4.2 mg/kg (mixed formulation) and between 3.0 and 6.7 mg/kg (solo formulation). The residues of pyraclostrobin in wheat grain collected at 36 DALA and later, were between <0.01 and 0.015 mg/kg (mixed formulation) and <0.01 and 0.017 mg/kg (solo formulation). Residues of metabolite BF 500-3 were <0.01 mg/kg.

In wheat straw residues of pyraclostrobin ranged from 0.29 to 1.6 mg/kg (mixed formulation) and 0.29 to 1.5 mg/kg (solo formulation) whereas residues of metabolite BF 500-3 ranged between 0.10 and 0.56 mg/kg (mixed formulation) and from 0.12 to 0.45 mg/kg (solo formulation).

No residues at or above the LOQ of 0.01 mg/kg of pyraclostrobin and its metabolite were present in control specimens.

A summary of residues is presented in Table 6.3.2-27. Details are shown in Table 6.3.2-28.

Table 6.3.2-27: Summary of pyraclostrobin and BF 500-3 residues in the treated wheat specimens after application of BAS 703 04 F and BAS 500 06 F

III. CONCLUSION

Directly after the last application, the residues of pyraclostrobin in whole plant without roots ranged between 3.7 and 4.2 mg/kg (mixed formulation) and between 3.0 and 6.7 mg/kg (solo formulation). The residues of pyraclostrobin in wheat grain collected at 36 DALA and later, were between <0.01 and 0.015 mg/kg (mixed formulation) and between <0.01 and 0.017 mg/kg (solo formulation). Residues of metabolite BF 500-3 were in grain always <0.01 mg/kg.
In wheat straw, residues of pyraclostrobin ranged from 0.29 to 1.6 mg/kg (mixed formulation) and from 0.29 to 1.5 mg/kg (solo formulation) whereas residues of metabolite BF 500-3 ranged between 0.10 and 0.56 mg/kg (mixed formulation) and from 0.12 to 0.45 mg/kg (solo formulation).

CA 6.3.3 Maize, sweet corn

The use in maize was not part of the previous Annex I inclusion process, it was submitted for the first time in Europe in summer 2010. The dRR was intended to achieve the registration of the mixed formulation BAS 512 16 F (containing the active ingredients pyraclostrobin and epoxiconazole) in maize. Subsequently to this submission, further draft Registration Reports were provided to countries acting as zonal RMS. The trials supporting a registration of the solo formulation BAS 500 06 F were partly included since the trials were performed side-by-side at the same locations.

After submission, Germany has prepared an evaluation report on the MRLs for maize, which was provided to EFSA in summer 2011. Based on the evaluation report EFSA has published a Reasoned Opinion (Feb 2012) in which the use in maize and its impact on the dietary feed burden calculations were investigated.

In order to allow a comprehensive evaluation of the formulation BAS 500 06 F, the old and the new data are summarized in this chapter.

Report:	CA 6.3.3/1 Aitken A., 2013a Study on the residue behaviour of Pyraclostrobin (BAS 500 F) in maize following one application of BAS 500 06 F to 8 trials in 2012 - SEU and NEU 2013/1308888
Guidelines:	EC 1107/2009 of the European Parliament and of the Council of 21 Oct 2009, EEC 79/117, EEC 91/414, EEC 7525/VI/95 rev. 9 (March 2011), EEC 7029/VI/95 (22 July 1997)
GLP:	yes (certified by Department of Health of the Government of the United Kingdom, United Kingdom)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 06 F

Description:	BAS 500 06 F (200 g/l BAS 500 F, pyraclostrobin), EC
Lot/Batch #:	0004863761
Purity:	Not relevant
CAS#:	Pyraclostrobin (BAS 500 F): 175013-18-0 500M07 (BF 500-3): 51265-96-7
Development code:	not applicable
Spiking levels:	0.01 – 20 mg/kg

2. Test Commodity: Cereals

Crop:	Maize
Type:	not relevant
Variety:	Athlet, NK Bull, Pioneer P 8000, LG 30222, Octet, AS 72, Antiss, PR33Y-7U

Crop parts(s) or processed

Commodity:	whole plant without roots, cobs without husks, cobs with husks, rest of plant without roots, grain and straw
Sample size:	> 0.5 kg (12 plants)

B. STUDY DESIGN AND METHODS

1. Test procedure

During the growing season of 2012, eight field trials with maize (field conditions) were conducted in Germany, United Kingdom, The Netherlands, Belgium, South France, Greece, Italy and Spain, in order to determine the magnitude of the residues of pyraclostrobin after a single treatment with BAS 500 06 F.

Each trial consisted of two plots: plot 1 (untreated control) and plot 2 (treated with BAS 500 06 F). The test item BAS 500 06 F (200 g/L pyraclostrobin, EC), was applied to maize once at BBCH 65 at a rate of 0.200 kg as/ha of pyraclostrobin with a water volume of 400 L/ha (with 10% of variation). Whole plant (without roots) specimens were taken at 0 days after the application, cobs without husks, cobs with husks, and the rest of the plant were taken at BBCH 75 and BBCH 85 and grain and straw were taken at BBCH 89. The samples were frozen until analysis. The maximum storage interval was 260 days (the interval from sampling until completion of the analytical phase).

Table 6.3.3-3: Application and sampling details for trials conducted in 2012

Region	No. of trials	No. of appl.	F, G, I[2]	Test item	Active substance	Application		Target timing

[2] Field, Glasshouse or Indoor

2. Description of analytical procedures

All specimens were analysed for pyraclostrobin and its metabolite BF 500-3 using the BASF method No. 535/1 (L0076/01), which quantifies residues of pyraclostrobin and its metabolite analyte with a limit of quantitation (LOQ) of 0.01 mg/kg per analyte.

The results of procedural recovery experiments obtained with the analytical series averaged at about 93% for pyraclostrobin and at about 92% for BF 500-3 at fortification levels between 0.01 and 20.0 mg/kg.

According to method No. 535/1, the analytes are extracted with a mixture of methanol, water and hydrochloric acid. An aliquot of the extract is centrifuged and partitioned at alkaline conditions against cyclohexane. The final determination is performed by HPLC-MS/MS.

II. RESULTS AND DISCUSSION

Pyraclostrobin

"Whole plant without roots" specimens collected at 0 DALA (BBCH 65) showed pyraclostrobin residues between 1.5 and 4.2 mg/kg.

At BBCH 75 cobs without husks showed pyraclostrobin residues from <0.010 to 0.021 mg/kg, cobs with husks showed pyraclostrobin residues from <0.010 to 0.075 mg/kg and residues of the rest of plant (without roots) specimens were between 0.15 and 0.71 mg/kg.

At BBCH 85 cobs without husks showed pyraclostrobin residues between <0.010 and 0.039 mg/kg, cobs with husks showed pyraclostrobin residues from <0.010 to 0.052 mg/kg and residues of the rest of plant (without roots) specimens were between 0.20 and 0.76 mg/kg.

Maize straw specimens collected at BBCH 89 showed pyraclostrobin residues between <0.010 and 0.30 mg/kg. The pyraclostrobin residues in maize grain specimens from all trials taken at BBCH 89 were below the LOQ (<0.010 mg/kg).

No residues of pyraclostrobin above the limit of quantitation (0.010 mg/kg) were found in the majority of the untreated specimens of this study. For two whole plants without roots specimens contaminations of pyraclostrobin occurred up to 0.031 mg/kg and in 4 "rest of plant without roots" specimens up to 0.16 mg/kg. In addition, pyraclostrobin was detected in one straw specimen at the limit of quantitation (0.01 mg/kg).

BF 500-3

"Whole plant without roots" specimens collected at BBCH 65 showed BF 500-3 residues between <0.010 and 0.11 mg/kg.

Cobs without husks and cobs with husks specimens collected at BBCH 75 showed BF 500-3 residues below the LOQ (<0.010 mg/kg). Rest of plant (without roots) specimens collected at BBCH 75 showed BF 500-3 residues between 0.038 and 0.23 mg/kg.

Cobs without husks and cobs with husks specimens collected at BBCH 85 showed BF 500-3 residues below the LOQ (<0.010 mg/kg). Rest of plant (without roots) specimens collected at BBCH 85 showed BF 500-3 residues between 0.032 and 0.17 mg/kg.

Maize straw specimens collected at BBCH 89 showed BF 500-3 residues between <0.010 and 0.15 mg/kg. The BF 500-3 residues in maize grain specimens from all trials taken at BBCH 89 were below the LOQ (<0.010 mg/kg).

No residues of BF 500-3 above the limit of quantitation (0.010 mg/kg) were found in the untreated specimens of this study.

Summaries of residues of pyraclostrobin and its metabolite BF 500-3 are given in Table 6.3.3-4, details in Table 6.3.3-5.

Table 6.3.3-4: Summary of pyraclostrobin and BF 500-3 residues in the treated maize specimens after one application of BAS 500 06 F

Region	Matrix	Timing (DALA[1])	Range of residues[4] (mg/kg)		
			BAS 500 F	BF 500-3[2]	Total residue[3]
EU North & South	Whole plant w/o roots	0	1.5 – 4.2	<0.010 – 0.11	1.6 – 4.2
	Cobs without husks	15 - 36	<0.010 – 0.021	<0.010	<0.020 – 0.031
	Cobs with husks		<0.010 – 0.075	<0.010	<0.020 – 0.085
	Rest of plant w/o roots		0.15 – 0.71	0.038 – 0.23	0.22 – 0.92
	Cobs without husks	26 - 56	<0.010 – 0.039	<0.010	<0.020 – 0.049
	Cobs with husks		<0.010 – 0.052	<0.010	<0.020 – 0.062
	Rest of plant w/o roots		0.20 – 0.76	0.032 – 0.17	0.25 – 0.89
	Grain[5]	34 - 82	<0.010	<0.010	<0.020
	Straw[5]		<0.010 – 0.30	<0.010 – 0.15	<0.020 – 0.40

[1] days after last application
[2] conversion factor for calculation of BF 5003 to parent BAS 500 F is 1.084
[3] sum of pyraclostrobin and BF 500-3
[4] for calculation purposes < 0.01 was set to 0.01
[5] In error the farmer harvested the trial plots before the final (S4) sampling could be conducted. Therefore no harvest grain and straw samples were available for analysis.

III. CONCLUSION

The results show, that immediately after the application of formulation BAS 500 06 F at a rate of 0.200 kg as/ha, residues of pyraclostrobin were in "whole plant without root" specimens between 1.5 and 4.2 mg/kg. Residues of metabolite BF 500-3 ranged in those samples from <0.010 to 0.11 mg/kg.
Pyraclostrobin as well as the BF 500-3 (500M07) residues in maize grain specimens from all trials taken at BBCH 89 were below the LOQ (<0.010 mg/kg).

In "cobs without husks" specimens sampled at BBCH 85 (being relevant for extrapolation to sweet corn), pyraclostrobin residues up to 0.039 mg/kg were determined. Residues of metabolite BF 500-3 were in those specimens always below the LOQ of the analytical method applied (0.01 mg/kg).

A. MATERIALS

1.	**Test Material:**	BAS 500 06 F
	Description:	BAS 500 06 F (200 g/l BAS 500 F, pyraclostrobin), EC
	Lot/Batch #:	0005018890
	Purity:	Not relevant
	CAS#:	175013-18-0
	Development code:	not applicable
	Spiking levels:	0.01 – 10 mg/kg
2.	**Test Commodity:**	Cereals
	Crop:	Maize
	Type:	not relevant
	Variety:	Pomeri
	Botanical name:	*Zea mays L.*
	Crop parts(s) or processed	
	Commodity:	whole plant without roots, cobs without husks, cobs with husks, rest of plant without roots, grain and straw
	Sample size:	min. 12 plants (grain: 2.0 kg, straw 0.5 kg, other matrices: 1.0 kg)

B. STUDY DESIGN AND METHODS

1. Test procedure

During the growing season of 2013, one field trial with maize (field conditions) was conducted in Northern France, in order to determine the magnitude of the residues of pyraclostrobin and its metabolite BF 500-3 after a single treatment with BAS 500 06 F. The trial consisted of two plots: plot 1 (control), plot 2 (treated with BAS 500 06 F).

The test item BAS 500 06 F (200 g/L pyraclostrobin), an emulsifiable concentrate (EC), was applied to maize once at BBCH 65 at a rate of 0.200 kg as/ha of pyraclostrobin. The water volume used was 400 L/ha. Whole plant (no roots) specimens were taken at 0 days before application in plot 1 and 0 days after the application in plot 2 (BBCH 65), cobs without husks, cobs with husks and rest of plant were taken at BBCH 75 and BBCH 85 and maize grain and straw were taken at BBCH 89. In order to ensure that the data regarding the residue are as reliable as possible, a minimum of 12 plants were taken.

2. Description of analytical procedures

All specimens were analysed for pyraclostrobin and its metabolite BF 500-3 using the BASF method 535/1 (synonym: L0076/01), which quantifies residues of pyraclostrobin and its metabolite analyte with a limit of quantitation (LOQ) of 0.01 mg/kg per analyte.
The results of procedural recovery experiments obtained with the analytical series were at 94.2% for pyraclostrobin and at 99.6% for BF 500-3 at fortification levels between 0.01 and 10.0 mg/kg.
According to method No. 535/1, the analytes are extracted with a mixture of methanol, water and hydrochloric acid. An aliquot of the extract is centrifuged and partitioned at alkaline conditions against cyclohexane. The final determination is performed by HPLC-MS/MS.

II. RESULTS AND DISCUSSION

Pyraclostrobin:
"Whole plant without roots" specimens collected at 0 DALA (BBCH 65) showed pyraclostrobin residues of 1.6 mg/kg. At BBCH 75 cobs without husks showed pyraclostrobin residues below the LOQ (<0.010 mg/kg), cobs with husks showed pyraclostrobin residues 0.028 mg/kg and the rest of plant (no roots) specimen 0.26 mg/kg. At BBCH 85, cobs without husks showed pyraclostrobin residues below the LOQ (<0.010 mg/kg), cobs with husks showed pyraclostrobin residues of 0.016 mg/kg and the rest of plant (no roots) specimen 0.44 mg/kg. Maize straw specimen collected at BBCH 89 showed pyraclostrobin residues of 0.19 mg/kg. The pyraclostrobin residues in maize grain specimen taken at BBCH 89 were below the LOQ (<0.010 mg/kg). No residues of pyraclostrobin above the limit of quantitation (0.010 mg/kg) were found in the untreated specimens of this study.

Metabolite BF 500-3:
"Whole plant without roots" specimen collected at BBCH 65 showed BF 500-3 residues below the LOQ (<0.010 mg/kg). Cobs without husks and cobs with husks specimens collected at BBCH 75 showed BF 500-3 residues below the LOQ (<0.010 mg/kg). Rest of plant (no roots) specimen collected at BBCH 75 showed BF 500-3 residues of 0.066 mg/kg. Cobs without husks and cobs with husks specimens collected at BBCH 85 showed 500M07 residues below the LOQ (<0.010 mg/kg). Rest of plant (no roots) specimen collected at BBCH 85 showed BF 500-3 residues of 0.071 mg/kg. Maize straw specimens collected at BBCH 89 showed BF 500-3 residues of 0.047 mg/kg. The BF 500-3 residues in Maize grain specimens taken at BBCH 89 were below the LOQ (<0.010 mg/kg). No residues of BF 500 -3 above the limit of quantitation (0.010 mg/kg) were found in the untreated specimens of this study.

Summaries of residues of pyraclostrobin and its metabolite BF 500-3 are given in Table 6.3.2-7, details in Table 6.3.2-8.

Table 6.3.3-7: Summary of pyraclostrobin and BF 500-3 residues in the treated maize specimens after one application of BAS 500 06 F

Region	Matrix	Timing (DALA[1])	Growth stage	Range of residues (mg/kg)		
				BAS 500 F	BF 500-3[2]	Total residue[3]
Northern Europe	Whole plant w/o roots	0	65	1.6	<0.01	1.6
	Cobs without husks	29	75	<0.010	<0.01	<0.020
	Cobs with husks			0.028	<0.01	0.038

	Grain	85	89	<0.010	<0.01	<0.020
	Straw			0.19	0.047	0.24

[1] days after last application
[2] conversion factor for calculation of BF 5003 to parent BAS 500 F is 1.084
[3] sum of pyraclostrobin and BF 500-3, for calculation purposes < 0.01 was set to 0.01

III. CONCLUSION

Immediately after the application of formulation BAS 500 06 F, "whole plant without root" specimens showed pyraclostrobin residues of 1.6 mg/kg, BF 500-3 residues were below the LOQ (<0.010 mg/kg).
Maize straw specimen collected at BBCH 89 showed pyraclostrobin residues of 0.19 mg/kg and BF 500-3 residues of 0.047 mg/kg. The pyraclostrobin and metabolite BF 500-3 residues in maize grain specimens taken at BBCH 89 were below the LOQ (<0.01 mg/kg).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 512 04 F

Description:	BAS 512 04 F (pyraclostrobin: 133 g/L, epoxiconazole: 50 g/L), SE
Lot/Batch #:	FRE-000369
Purity:	Not relevant
CAS#:	Pyraclostrobin: 175013-18-0 Epoxiconazole: 133855-98-8
Development code:	not applicable
Spiking levels:	Pyraclostrobin: 0.01/1/5 mg/kg

2. Test Commodity: Cereals

Crop:	Maize
Type:	not applicable
Variety:	Delitop, PR 39T13, Justina, Adenzo, 66-77 Dekalb, 3441 Pioneer, Mitic, Tardio 130.
Botanical name:	*Zea mays*
Crop parts(s) or processed	
Commodity:	whole plant (no roots), rest of plant (no roots), cobs with husks, grain
Sample size:	1 kg (12 plants) of whole plant without roots; 1 kg (12 pieces) of cob with husks; 2 kg of grain.

B. STUDY DESIGN AND METHODS

1. Test procedure

During the growing season 2008, eight field trials were conducted in Germany, Northern France, United Kingdom, The Netherlands, Italy, Greece, Southern France and Spain in order to determine the residue levels of pyraclostrobin, its metabolite BF 500-3 and epoxiconazole in maize. The trials were performed with the formulation BAS 512 04 F, a SE formulation containing 133 g/L of pyraclostrobin and 50 g/L of epoxiconazole. BAS 512 04 F was applied once at a rate of 0.1995 kg as/ha of pyraclostrobin and 0.075 kg as/ha of epoxiconazole. The application took place at BBCH 65 with a spray volume of 400 L/ha.
Whole plants without roots were collected from the treated plots immediately after the treatment at BBCH 65. Thereafter specimens consisting of cob with husks or rest of plant without roots were sampled at 7 - 28 DALA (BBCH 71 – 73), at 16 - 42 DALA (BBCH 75 – 79) and at 30 - 70 DALA (BBCH 85). Grain and rest of plant without roots were collected at harvest at 63 - 99 DALA at BBCH 89. All samples were stored deep frozen until analysis. The maximal storage interval was 260 days.

2. Description of analytical procedure

For the analysis of pyraclostrobin and its metabolite BF 500-3 the BASF method no. 535/1 was used. The results of procedural recovery experiment averaged at about 92.5% for pyraclostrobin and 88.5% for BF 500-3 at fortification levels between 0.01 and 5.0 mg/kg. The method achieves a limit of quantitation (LOQ) of 0.01 mg/kg.
The residues of pyraclostrobin and its metabolite BF 500-3 were extracted with a mixture of methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned at alkaline conditions against cyclohexane. The final determination was performed by HPLC-MS/MS.

II. RESULTS AND DISCUSSION

Directly after the application (0 DALA) of BAS 512 04 F, pyraclostrobin residues were between 1.93 mg/kg and 3.49 mg/kg in maize whole plant without roots. In the course of the study, the residues of pyraclostrobin declined. At harvest time (66 - 99 DALA) the pyraclostrobin residues in the rest of the plants were between 0.03 mg/kg and 0.27 mg/kg. In grain, no pyraclostrobin residues above the LOQ were obtained.
At 0 DALA, BF 500-3 residues were between 0.01 - 0.14 mg/kg in maize whole plant without roots. At harvest time (66 - 99 DALA) the BF 500-3 residues in the rest of the plants were between 0.01 mg/kg and 0.16 mg/kg. In grain, BF 500-3 residues were between < 0.01 and 0.01 mg/kg.

The results from trial number L080330 showed a different behaviour and are therefore presented separately. Directly after the application (0 DALA) the residues of pyraclostrobin were <0.01 mg/kg in whole plants without roots. At BBCH 89 (63 DALA), pyraclostrobin residues were <0.01 mg/kg in maize grain. In the rest of the plants without roots, pyraclostrobin residues were 0.15 mg/kg.

Summaries of residues of pyraclostrobin and its metabolite BF 500-3 are given in Table 6.3.3-9 and Table 6.3.3-10, details are provided in Table 6.3.2-11.

III. CONCLUSION

After the application at BBCH 65, the residues of pyraclostrobin were <0.01 (LOQ), BF 500-3 residues were between <0.01 and 0.01 mg/kg at crop maturity (BBCH 89).

Study on the residue behaviour of BAS 480 F, BAS 500 F and BF 500-3 (500M07) in corn after treatment with BAS 512 04 F under field conditions in Germany, 2011
2013/1065883
Guidelines: None
GLP: no

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 512 04 F
Description: BAS 512 04 F: 133 g/L pyraclostrobin (BAS 500 F) and 50 g/L epoxiconazole (BAS 480 F), SE
Lot/Batch #: 3191342
Purity: not applicable
CAS#: not applicable
Development code: not applicable
Spiking levels: 0.01-10 mg/kg

2. Test Commodity: Cereals
Crop: Maize
Type: not applicable
Variety: not applicable
Botanical name: *Zea mays*
Crop parts(s) or processed
Commodity: whole plant (no roots), cobs with / without husks, husks
Sample size: not applicable

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2011 growing season, one field trial was conducted in Germany in order to determine the magnitude of residues of pyraclostrobin, BF 500-3 and BAS 480 F in maize after one application of BAS 512 04 F.
The test item BAS 512 04 F (133 g/L BAS 500 F, pyraclostrobin and 50 g/L BAS 480 F epoxiconazole, SE), was foliar applied once with an application rate of 0.2 kg as/ha of pyraclostrobin and 0.075 kg as/ha of epoxiconazole and a spray volume of 400 L/ha at growth stages BBCH 71. “Whole plant no roots” specimens were taken directly after application. Cobs were taken at BBCH 75, 79, 85 and were separated into the portions “cobs with husks”, “cobs without husks” and “husks”.
Samples were stored frozen until analysis. The maximum storage interval from harvest until analysis was 174 days.

Table 6.3.3-12: Application and sampling details for trials conducted in 2011

Region	No. of trials	No. of appl.	F, P, or G	Test item	Active substance	Application		Target timing	
						Rate as (kg/ha)	Water vol. (L/ha)	Application	Sampling (DALA)[1]
Northern Europe	1	1	F	BAS 512 04 F (SE)	BAS 500 F	0.2	400	BBCH 71	BBCH 75 BBCH 79 BBCH 85
					BAS 480 F	0.075			

[1] days after last application

2. Description of analytical procedures

All specimens were analysed for pyraclostrobin and its metabolite BF 500-3 (500M07) using BASF method 535/1 (synonym: L0076/01).
The analytes were extracted with a mixture of methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned at alkaline conditions against cyclohexane. The final determination was performed by HPLC-MS/MS. The limit of quantitation (LOQ) of the method for pyraclostrobin and its metabolite BF 500-3 was 0.01 mg/kg.
The results of procedural recovery experiments were 91.6% for pyraclostrobin and 87.6% for BF 500-3 at fortification levels between 0.01 and 10 mg/kg.

II. RESULTS AND DISCUSSION

Directly after the application (0 DALA) of BAS 512 04 F, pyraclostrobin residues were 0.98 mg/kg and BF 500-3 residues were 1.02 mg/kg in maize whole plant without roots. The unusual finding of the metabolite immediately after application can be just explained by a contamination in the lab or during sample processing.
In the course of the study, the residues of pyraclostrobin and BF 500-3 declined. In the edible portion “cobs without husks” none of the analytes was found above LOQ throughout the study.

Details of residues are shown in Table 6.3.3-13.

III. CONCLUSION

In the edible portion “cobs without husks” none of the analytes is found above LOQ throughout the study.

Crop:	Maize
Type:	not relevant
Variety:	Nescio, Maxxis Duo, Ohio, LG 3218, Dekalb 66-77, PR-3345, Anadon, Castellano.
Botanical name:	*Zea mays*
Crop parts(s) or processed Commodity:	whole plant (no roots), rest of plant (no roots), cobs with husks, grain
Sample size:	1 kg (12 plants) of whole plant without roots; 1 kg (12 pieces) of cob with husks; 2 kg of grain.

B. STUDY DESIGN AND METHODS

1. Test procedure

During the growing season 2009, eight field trials were conducted in Germany, Northern France, United Kingdom, The Netherlands, Italy, Greece, Southern France and Spain in order to determine residue levels of pyraclostrobin, its metabolite BF 500-3 and epoxiconazole in maize.
The trials were performed with the formulations BAS 512 04 F (133 g/L of pyraclostrobin and 50 g/L of epoxiconazole, SE). In four out of the eight trials also a treatment with BAS 500 06 F (200 g/L of pyraclostrobin, EC) was included.
Plot 2 of trials L090168, L090170, L090172 and L090174 were treated once with **BAS 512 04 F** at a rate of 1.5 L/ha (0.1995 kg as/ha of pyraclostrobin and 0.075 kg as/ha of epoxiconazole), while on plot 3 of the same trials **BAS 500 06 F** was applied once at a rate of 1 L/ha (0.2 kg as/ha of pyraclostrobin). Consequently, it was possible to compare both treatments in these four trials.
In four additional trials (L090169, L090171, L090173 and L090175) plot 2 were also treated once with BAS 512 04 F at a rate of 1.5 L/ha, but in these trials BAS 500 06 F was not applied.
The application took place at BBCH 65 - 67 with a spray volume of 400 L/ha.
Whole plants without roots were collected from the treated plots immediately after the treatment at BBCH 65 - 67. Thereafter specimens consisting of cob with husks or rest of plant without roots were sampled at 6 - 17 DALA (BBCH 71), at 19 - 36 DALA (BBCH 75 – 77) and at 30 - 64 DALA (BBCH 85). Grain and rest of plant without roots were collected at harvest at 49 - 91 DALA (BBCH 89). The samples were stored until analysis. The maximum storage interval from harvest until analysis was 222 days.

2. Description of analytical procedures

BASF method 535/1 (synonym: L0076/01) was used for the analysis of pyraclostrobin, its metabolite BF 500-3 (500M07) and epoxiconazole. The method achieves a limit of quantitation (LOQ) of 0.01 mg/kg.
Pyraclostrobin, BF 500-3 and BAS 480 F were extracted from plant matrices using a mixture of methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned at alkaline conditions against cyclohexane. An aliquot of the organic phase was evaporated to dryness and dissolved in a mixture of methanol and water. The final determination was performed by HPLC-MS/MS.

II. RESULTS AND DISCUSSION

Trials L090168, L090170, L090172 and L090174
Directly after the last application (0 DALA) of BAS 512 04 F, the pyraclostrobin residues ranged from 1.6 - 2.4 mg/kg in the "whole plant (no roots)" specimens. The residues declined significantly at BBCH 71 to 0.026 - 0.072 mg/kg in "cob with husks" and to 0.18 - 0.66 mg/kg in "rest of plant (no roots)". This decline continued over the remaining sampling stages until at the last one, where <0.01 mg/kg were found in the "grain" and a range of 0.079 - 0.50 mg/kg in the "rest of plant (no roots)" specimens.
Directly after the last application (0 DALA) of BAS 500 06 F, the pyraclostrobin residues ranged from 1.4 - 4.3 mg/kg in the "whole plant (no roots)" specimens. The residues declined significantly at BBCH 71 to 0.025 - 0.053 mg/kg in "cob with husks" and to 0.25 - 0.89 mg/kg in "rest of plant (no roots)". This decline continued over the remaining sampling stages until at the last one, where <0.01 mg/kg were found in the "grain" and a range of 0.083 - 0.50 mg/kg in the "rest of plant (no roots)" specimens.
In the trials which were treated with BAS 512 04 F and BAS 500 06 F, the decline of the residues of pyraclostrobin was similar.

Trials L090169, L090171, L090173 and L090175
In these trials with just one treated plot (treated with BAS 512 04 F), the pyraclostrobin residues ranged from 2.2 - 3.6 mg/kg in the "whole plant (no roots)" specimens at 0 DALA. The residues declined significantly at BBCH 71 to < 0.01 - 0.076 mg/kg in "cob with husks" and to 0.090 - 0.72 mg/kg in "rest of plant (no roots)". This decline continued over the remaining sampling stages until at the last one <0.01 mg/kg were found in the "grain" and a range of 0.045 - 0.67 mg/kg in the "rest of plant (no roots)" specimens.

No residues of the metabolite BF 500-3 (500M07) were found in any of the grain samples.

No residues above the limit of quantitation were found in any of the untreated specimens.

Summaries of residues of pyraclostrobin and its metabolite BF 500-3 are given in Table 6.3.2-14 and Table 6.3.2-15 for trials L090168, L090170, L090172 and L090174. In
Table 6.3.2-16 they are given for trials L090169, L090171, L090173 and L090175, details are shown for all trials in Table 6.3.2-17.

Table 6.3.3-14: Summary of results for BAS 500 F and its metabolite BF 500-3 from plot 2, treated with BAS 512 04 F (Trials L090168, L090170, L090172 and L090174)

III. CONCLUSION

At harvest maturity, the residues of pyraclostrobin and its metabolite BF 500-3 (500M07) were always below the LOQ (0.01 mg/kg)
The results of the study show that the residue behaviour of pyraclostrobin in/on maize specimens after application of BAS 512 04 F is in correspondence to the behaviour found after use of the respective solo formulation BAS 500 06 F.

CA 6.3.4 Supplemental study supporting the dietary exposure assessment for the metabolite 500M04 (plus conjugates)

Report: CA 6.3.4/1
Morgenthal K., 2014b
500M79: Residue analysis in plant matrices by LC-MS/MS
2014/1001661

Guidelines: EU Regulation Regulation 544/2011 (10 June 2011) implementing Regulation No 1107/2009, EU Regulation 1107/2009 with Regulation 545/2011 (former Annex III), OECD Guidance Document on Pesticide Residue Analytical Methods (ENV/JM/MONO(2007)17 - 13-Aug-07, SANCO/825/00 rev. 8.1 (16 November 2010), EEC 91/414 Annex II (Part A Section 4), SANCO/3030/99 rev. 4 - Guidance for generating and reporting methods of analysis in support of pre- and post-registration data requirements for Annex II (part A Section 4) and Annex III (part A Section 5) of 91/414/EEC, EEC 91/414 Annex III (Part A Section 5), EPA 860.1340: Residue Chemistry Test Guidelines - Residue Analytical Method

GLP: yes
(certified by Swiss Federal Office of Public Health, Berne, Switzerland)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Pyraclostrobin
Description: BAS 536 01 F: 72 g/L BAS 550 F and 40 g/L pyraclostrobin (EC), BAS 516 07 F: 26.7% BAS 510 F and 6.7% pyraclostrobin (WG)
Lot/Batch #: not applicable
Purity: not applicable
CAS#: not applicable
Development code: not applicable
Spiking levels: 0.01-0.1 mg/kg

2. Test Commodity: Brassica vegetables, leaf vegetables and fresh herbs, legume vegetables (fresh), stem vegetables (fresh)
Crop: Broccoli, cauliflower, lettuce, cabbage, leek, spinach, bean
Type: not applicable
Variety: not applicable
Botanical name: Brassica oleracea var. botrytis L., Brassica oleracea italica Plenck , Brassica oleracea var. capitata, Lactuca sativa L., Allium ampeloprasum L., Spinacia oleracea L., Phaseolus vulgaris
Crop parts(s) or processed
Commodity: Broccoli (inflorescences), cauliflower (inflorescences), lettuce (head), cabbage (white, heads), leek (whole plant, no roots), spinach (leaves), bean (pods with seeds, seeds)
Sample size: not applicable

B. STUDY DESIGN AND METHODS

1. Test procedure

The study was conducted to determine residues of 500M79 (Reg. No. 5937091) and 500M04 (BF 500-5, Reg. No. 298327) in plant matrices (broccoli, cauliflower, lettuce, leek cabbage, spinach and bean) derived from the BASF projects No. 365214, 365220_1, 365222, 35216, 365219, 309344 and 309370.

Study Code 365214:
The formulation BAS 536 01 F (EC) was foliar applied in broccoli and cauliflower three times (17±1, 10±1 and 3±1 days before harvest) at a rate of 0.100 kg as/ha pyraclostrobin and 0.180 kg as/ha dimethomorph with a water volume of 400 L/ha. Samples taken 3-4 and 6-8 days after last application (DALA) were analysed for residues of 500M04 and 500M79 in inflorescences.

Study Code 365220_1:
The formulation BAS 536 01 F (EC) was foliar applied three times at a rate of 0.180 kg as/ha dimethomorph and 0.100 kg as/ha pyraclostrobin to lettuce at 28-29, 21 and 14 days before harvest. The nominal spray volume used was 200 L/ha. Samples taken 14 and 20 DALA were analysed for residues of 500M04 and 500M79 in lettuce heads.

Study Code 365222:
The formulation BAS 536 01 F (EC) was foliar applied to lettuce three times at 21±1, 14±1 and 7±1 days before harvest at a rate of 2.5 L/ha of formulated product (0.1 kg as/ha of pyraclostrobin and 0.18 kg as/ha of dimethomorph). The water volume used was 200 L/ha. Samples taken 7 and 13-14 DALA were analysed for residues of 500M04 and 500M79 in lettuce heads.

Study Code 35216:
The formulation BAS 536 01 F (EC) was foliar applied in cabbage (white) three times (17±1, 10±1 and 3±1 days before harvest) at a rate of 0.100 kg as/ha pyraclostrobin and 0.180 kg as/ha dimethomorph in a spray volume of 600 L/ha. Samples taken 3-4 and 7-8 DALA were analysed for residues of 500M04 and 500M79 in cabbage heads.

Study Code 365219:
The formulation BAS 536 01 F (EC) was foliar applied in leek three times (17±1, 10±1 and 3±1 days before harvest) at a rate of 0.100 kg as/ha pyraclostrobin and 0.180 kg as/ha dimethomorph in a spray volume of 200 L/ha. Samples taken 2-3 and 7-8 DALA were analysed for residues of 500M04 and 500M79 in leek whole plants (no roots).

Study Code 309344:
The formulation BAS 516 07 F (WG) was foliar applied in spinach twice at a rate of 0.4005 kg as/ha for boscalid and 0.1005 kg as/ha for pyraclostrobin in a spray volume of 400 L/ha. Application timings were 21 (±1) days before harvest (DBH) for the first and 14 (±1) DBH for the second application. Samples taken 13-14 and 21 DALA were analysed for residues of 500M04 and 500M79 in spinach leaves.

Study Code 309370:
Green beans were treated twice with BAS 516 07 F (WG). In trials L100423 to L100426, BAS 516 07 F was foliar-applied at a rate of 2 x 0.4005 kg as/ha of boscalid and 2 x 0.1005 kg as/ha of pyraclostrobin. For trial L100591 the study plan stated 2 x 0.481 kg as/ha of BAS 510 F and 2 x 0.121 kg as/ha of pyraclostrobin (actual rate was 1 x 0.378 and 1 x 0.396). The application rate of spray solution was 400 L/ha for trials L100423 to L100426 and 150 L/ha for trial L100591. The applications were conducted 14 and 7-8 days before harvest. Residues of 500M04 and 500M79 were analysed in bean pods with seeds taken 3, 7-8 and 13-15 DALA and in seeds taken 7-8 and 13-15 DALA.

2. Description of analytical procedures

Metabolite 500M79 was extracted from plant matrices using a mixture of methanol, Milli-Q water and hydrochloric acid. An aliquot of the extract was evaporated to dryness and re-dissolved in Milli-Q water. The analyte was hydrolysed using enzymatic cleavage to 500M04. Following reversed phase C18 SPE-column clean-up, the final determination of 500M04 was performed by LC-MS/MS.

The results are expressed as 500M04 and as 500M79 equivalent with a Limit of Quantification (LOQ) of 0.005 mg/kg (500M04) and 0.01 mg/kg (500M79).

II. RESULTS AND DISCUSSION

The Limit of Quantitation is 0.005 mg/kg for 500M04 and 0.01 mg/kg for 500M79 in all plant matrices described below. For better readability it is not repeated for each of the plant matrices.

Broccoli

The residues of 500M04 and 500M79 in broccoli inflorescences were investigated in six samples. The residue range in two samples collected 3 days after the last application (DALA) was < 0.005 – 0.007 mg/kg (500M04) and < 0.010 – 0.013 mg/kg (500M79). In two samples collected at 6 DALA, the residue levels were at < 0.005 – 0.026 mg/kg (500M04) and at < 0.010 – 0.047 mg/kg (500M79).
In two untreated samples, no residues of 500M04 or 500M79 above the Limit of Quantitation were present.

Cauliflower

The residues of 500M04 and 500M79 in cauliflower inflorescences were investigated in six samples. The residue range in two samples collected 3 – 4 DALA was < 0.005 – 0.009 mg/kg (500M04) and < 0.010 – 0.017 mg/kg (500M79). In two samples collected 7 – 8 DALA, the residue range increased to < 0.005 – 0.012 mg/kg (500M04) and < 0.010 – 0.022 mg/kg (500M79).
In two untreated samples, no residues of 500M04 or 500M79 above the Limit of Quantitation were present.

Lettuce

The residues of 500M04 and 500M79 in lettuce heads were investigated in fourteen samples. The residue range in four samples collected at 7 DALA was 0.011 – 0.024 mg/kg (500M04) and 0.019 – 0.044 mg/kg (500M79). In six samples collected at 13 – 14 DALA, the residue range was < 0.005 – 0.019 mg/kg (500M04) and < 0.010 – 0.035 mg/kg (500M79). The maximum residues were found in two samples collected at 20 DALA (500M04: 0.009 – 0.018 mg/kg, 500M79: 0.017 – 0.033 mg/kg).
In two untreated samples, no residues of 500M04 or 500M79 above the Limit of Quantitation were present.

Cabbage (White)
The residues of 500M04 and 500M79 in cabbage (white) heads were investigated in nine samples. The residue range in four samples collected at 3 – 4 DALA was < 0.005 – 0.019 mg/kg (500M04) and at < 0.010 – 0.034 mg/kg (500M79). In four samples collected at 7 – 8 DALA, no residues were present at or above the Limit of Quantitation (500M04: < 0.005 mg/kg, 500M79: < 0.010 mg/kg).
In one untreated sample, no residues of 500M04 or 500M79 above the Limit of Quantitation were present.

Leek
The residues of 500M04 and 500M79 in leak whole plants (no roots) were investigated in five samples. The residue range in two samples collected at 2 – 3 DALA was 0.020 – 0.041 mg/kg (500M04) and 0.037 – 0.074 mg/kg (500M79). In two samples collected at 7-8 DALA, the residue range decreased to 0.012 – 0.018 mg/kg (500M04) and to 0.022 – 0.032 mg/kg (500M79).
In one untreated sample, no residues of 500M04 or 500M79 above the Limit of Quantitation were present.

Spinach
The residues of 500M04 and 500M79 in spinach leaves were investigated in seven samples. The residue range in three samples collected at 13 – 14 DALA was 0.026 – 0.039 mg/kg (500M04) and 0.047 – 0.070 mg/kg (500M79). In three samples collected at 21 DALA, the residues ranged between 0.020 and 0.030 mg/kg (500M04) and between 0.036 and 0.055 mg/kg (500M79).
In one untreated sample, no residues of 500M04 or 500M79 above the Limit of Quantitation were present.

Bean
The residues of 500M04 and 500M79 in *bean pods with seeds* were investigated in ten samples. In one sample collected at 3 DALA, no residues of 500M04 or 500M79 at or above the Limit of Quantitation (500M04: 0.005 mg/kg, 500M79: 0.010 mg/kg) were present. The residue range in four samples collected at 7-8 DALA was at < 0.005 – 0.012 mg/kg (500M04) and at < 0.100 – 0.019 mg/kg (500M79). In four samples collected at 13-15 DALA, the residues were found to range between < 0.005 and 0.014 mg/kg (500M04) and between < 0.010 and 0.026 mg/kg (500M79).

The residues of 500M04 and 500M79 in *bean seeds* were investigated in seven samples. The residues ranged in samples collected at 7 DALA between < 0.005 and 0.005 mg/kg (500M04) and were < 0.010 mg/kg (500M79). In samples collected at 13 – 15 DALA, no residues of 500M04 or 500M79 at or above the Limit of Quantitation (500M04: 0.005 mg/kg, 500M79: 0.010 mg/kg) were present.

In none of the untreated samples (total: 2 samples), residues of 500M04 and 500M79 above the Limit of Quantitation were determined.

Residues of 500M04 and 500M79 are summarised in
Table 6.3.4-1, details are shown in Table 6.3.4-2.

Table 6.3.4-1: Summary of Field Specimen Residues

Matrix	Portion analyzed	DALA[1)]	Growth stage	n	Range of 500M04 residues [mg/kg]	Range of 500M79 residues [mg/kg]
Broccoli	Inflorescences	3	49	2	< 0.005 – 0.007	< 0.010 – 0.013

[1] days after last application

III. CONCLUSION

In broccoli inflorescences, the residue range of 500M04 and 500M79 in samples collected at 3 days after the last application (DALA) was determined to be < 0.005 – 0.007 mg/kg (500M04) and < 0.010 – 0.013 mg/kg (500M79). In samples collected at 6 DALA, the residues were between < 0.005 and 0.026 mg/kg (500M04) and between < 0.010 and 0.047 mg/kg (500M79).

In cauliflower inflorescences, the residue range of 500M04 and 500M79 in samples collected at 3 - 4 DALA was determined to be < 0.005 – 0.009 mg/kg (500M04) and < 0.010 – 0.017 mg/kg (500M79). In samples collected at 7 – 8 DALA, the residues were on a comparable level with values of < 0.005 – 0.012 mg/kg (500M04) and of < 0.010 – 0.022 mg/kg (500M79).

In lettuce heads, the residue range of 500M04 and 500M79 in samples collected at 7 DALA was determined to be 0.011 – 0.024 mg/kg (500M04) and 0.019 – 0.044 mg/kg (500M79). In samples collected at 20 DALA, the residues were slightly lower with values in the range of 0.009 to 0.018 mg/kg (500M04) and in the range of 0.017 to 0.033 mg/kg (500M79).

In heads of cabbage (white) the residue range of 500M04 and 500M79 in samples collected at 3 – 4 DALA was determined to be < 0.005 - 0.019 mg/kg (500M04) and < 0.010 – 0.034 mg/kg (500M79). In samples collected at 7 – 8 DALA, the residues were always below the Limit of Quantification (LOQ, 500M04: < 0.005 mg/kg, 500M79: < 0.010 mg/kg) in all samples.

In leek samples (whole plants, no roots), the residue range of 500M04 and 500M79 in samples collected at 2 – 3 DALA was determined to be 0.020 – 0.041 mg/kg (500M04) and 0.037 – 0.074 mg/kg (500M79). In samples collected at 7 – 8 DALA, the residues were slightly lower with values in the range of 0.012 to 0.018 mg/kg (500M04) and in the range of 0.022 to 0.032 mg/kg (500M79).

In spinach leaves, the residue range of 500M04 and 500M79 in samples collected at 13 – 14 DALA was determined to be 0.026 – 0.039 mg/kg (500M04) and 0.047 – 0.070 mg/kg (500M79). In samples collected at 21 DALA, the residues were on a comparable level with values ranging between 0.020 and 0.030 mg/kg (500M04) and between 0.036 and 0.055 mg/kg (500M79).

In "bean pods with seed" specimens sampled at 3 DALA, no residues at or above the LOQ (500M04: 0.005 mg/kg, 500M79: 0.010 mg/kg) could be detected. In samples collected at 13 – 15 DALA, the residue range of 500M04 and 500M79 was determined to be < 0.005 – 0.014 mg/kg (500M04) and < 0.010 – 0.026 mg/kg (500M79).

In bean seed specimens sampled at 7 DALA, no residues at or above the LOQ (500M04: 0.005 mg/kg, 500M79: 0.010 mg/kg) could be detected. In samples collected at 13 – 15 DALA, residues of 500M04 were determined to be below or at the LOQ (0.005 mg/kg), residues of 500M79 were in all those samples below the LOQ (0.001 mg/kg).

CA 6.4 Feeding studies

Data/information on poultry and lactating ruminant feeding studies for pyraclostrobin were reviewed during the Annex I inclusion process and were considered to be acceptable. The following section was copied from the Draft Assessment Report, which was prepared by RMS Germany.

Table 6.4-1: Residues from livestock feeding studies (Annex IIA, point 6.4, Annex IIIA, point 8.3)

Intakes by livestock ≥ 0.1 mg/kg diet/day:	Ruminant: yes/~~no~~	Poultry: yes/~~no~~	Pig: yes/~~no~~
Muscle	< 0.05	< 0.05	< 0.05
Liver	< 0.05	< 0.05	< 0.05
Kidney	< 0.05	< 0.05	< 0.05
Fat	< 0.05	< 0.05	< 0.05
Milk	< 0.01	Not applicable	Not applicable
Eggs	Not applicable	< 0.05	Not applicable

For the Annex I inclusion process data were submitted covering the safe uses in cereals, grapes and banana (import tolerance). Due to the favourable residue behaviour of pyraclostrobin, where even at the 10 x dose level no residues above LOQ were found, the revised feed burden covering the use in cereals did not result in any new MRL proposal. This was re-confirmed by RMS Germany and in the EFSA publication from February 2012 (see EFSA journal 2012; 10(3): 2606).

CA 6.4.1 Poultry

A hen feeding study is submitted and summarized below, which was performed for registration purposes in the US using the common moiety approach. The study is considered as supplemental information. Based on the results of the poultry metabolism study, no residues above the LOQ of the analytical methods (common moiety, parent) can be expected. This assumption was finally confirmed within the poultry feeding study.

Report:	CA 6.4.1/1 [redacted] 2000a A meat and egg magnitude of the residue study with BAS 500 F in laying hens 2000/5005
Guidelines:	EPA 860.1480
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

I. MATERIAL AND METHODS

Test system
Fifty-six white leghorn laying hens (*Gallus gallus*) aged approximately 64 weeks and in the weight range of 1.404 to 1.770 kg prior to dosing were used in the study. The feeding was performed at Southwest Bio-Labs Animal Carte Facility. Animals were selected for use in the study on the basis of overall health, egg production and body weight. The animals were quarantined for a period of 14 days and then acclimated for two weeks to adjust the hens to laboratory conditions and to determine each hen's suitability for testing.

Feeding and husbandry
The animals were housed individually in 18" x 12" x 16" metabolism cages in a temperature controlled study room. The lighting control was set to a photoperiod of 18 hours light and 6 hours dark and was utilized for the duration of the study. The animals were individually fed a commercial concentrate (EverLay 2000 Crumbles) daily. Additionally, animals in test groups II to IV were dosed with encapsulated pyraclostrobin (solved in methanol) via a balling gun once a day for 30 consecutive days at a target rate equivalent to a dietary exposure of 0.3 (1x), 0.9 (3x) and 3.0 (10x) mg/kg feed, respectively. The control group animals received placebo capsules containing cellulose powder concurrently with the treated animals. The animals were allowed ad libitum access to feed and to fresh potable tap water daily.

Derivation of detected dose levels
The feeding levels were estimated by taking into account the preliminary residue data available at the beginning of this study. The anticipated residues were worst case estimations. The main contributions to the dietary burden were from barley grain and wheat milled by-products. The calculation shown in Table 6.4.1-1 is performed for the estimation of the feeding levels according to US EPA guidelines. The actual US tolerances are very similar to the estimated values and are 0.4 mg/kg for barley grain and 0.04 mg/kg for wheat milled by-products, which leads to a dietary burden of 0.301 mg/kg feed.

Table 6.4.1-1: Calculation of the feed burden for hen

Feed item	% in diet	Tolerance (mg/kg)	Feed burden (mg/kg)
Barley grain	75	0.3	0.225
Wheat milled by-products	25	0.1	0.025
Total diet (mg/kg)			0.250

Therefore, it was concluded that a feeding level of 0.3 mg/kg would reflect a realistic 1x residue situation in feed, leading to feeding levels of 0.9 mg/kg for the 3x level and 3.0 mg/kg for the 10x level.

According to the most recent feed and dietary burden calculations using the EU methodology (see M-CA 6.7.2 for poultry), a maximum dietary burden of about 0.65 mg/kg feed dry matter is calculated. Therefore, based on this calculation the chosen feeding levels 0.3, 0.9 and 3.0 mg/kg feed would represent about 0.5x, 1.5x and 5x of the target rate.

Dose preparation
In order to obtain an accurate dose rate for pyraclostrobin equivalent to the ingested amount of feed, the weight of the feed consumed over a seven-day period was converted from a fresh weight to a dry weight. The appropriate amount of pyraclostrobin was weighed for each test group into a volumetric flask and the flask filled to volume with methanol for dissolving the test substance. The amount of test substance weighed into each flask for the 1x dose (EU: 0.5x), 3x dose (EU: 1.5x) and 10x dose (EU: 5x) was 0.0298 g, 0.0799 g and 0.2896 g, respectively. For each test group 100 µL of the respective solution were pipetted into the capsules.
In addition to the capsules prepared for dosing, two extra capsules were made for analysis (for each dose group and for each week).

Dose administration
Animals in test groups were dosed once per day in the afternoon (AM) following egg collection. The capsules (containing pyraclostrobin solved in methanol) were administered using a balling gun according to the manufacturer's instructions. These animals were dosed over a 30-day period at a target rate equivalent to 0.3, 0.9 and 3.0 mg/kg in the feed (test groups II, III and IV, respectively. Group IV consisting of five sub-groups a-e). The animals in group I served as the control and received placebos (containing cellulose) concurrently with the treated animals.

Egg sampling
Eggs were collected twice daily (AM and PM) beginning on study day -15 and continuing until the scheduled termination for each animal. At each collection period, the number of eggs was recorded. Eggs from PM collection were refrigerated overnight until the next morning when they were pooled with the AM collection for each subgroup. The eggs were removed from their shells, placed into labelled containers, thoroughly mixed using a Tekmar® Tissumizer®, weighed and the weights recorded. The unshelled homogenized eggs from each subgroup were divided into two labelled containers and the weight of the eggs in each container was recorded. All samples were stored frozen at less than -15°C on dry ice.

Terminal procedures
All animals were sacrificed approximately 6.5 hours following the final dose, except for two subgroups which were terminated at three and seven days post dosing to determine residue decline. At sacrifice, a composite of muscle, the entire liver and a composite of mesenteric peripheral fat samples were collected. The tissues were then pooled by subgroup and placed into separate labeled Ziplock® storage bags and transferred to a freezer immediately after collection. All hen tissue samples were processed at Southwest Bio-Labs. After homogenization, samples remained in frozen storage (< -15°C).

Bodyweight
Individual bodyweights were obtained on study days -15, -1, 16 and at scheduled termination for each animal. Prior to dosing, the animals weighed between 1.404 and 1.770 kg. At termination, the animals weighed between 1.376 and 1.837 kg. Many animals lost weight over the course of the treatment period. However, this occurred in treated and in control groups.

Residue analysis
Analyses of the egg and hen tissue samples were carried out with BASF method Number D9902. Method D9902 is a common moiety method and was developed to determine the residues of pyraclostrobin and BF 500-16 (500M77) in hen related matrices (egg, liver, fat and muscle). As part of the method, pyraclostrobin and BF 500-16 are hydrolyzed into BF 500-5 (500M04) and BF 500-9 (Reg.No. 402733, a derivative used for determination only and therefore not included in the metabolite list), respectively, and these analytes are determined by LC/MS/MS. The limit of quantitation of the method is 0.05 mg/kg for each analyte and for all matrices.

II. RESULTS AND DISCUSSION

As shown in Table 6.4.1-2 and Table 6.4.1-3, all pyraclostrobin and BF 500-16 (500M77) residues in eggs or hen tissues at the 5x dose level (EU) were below 0.05 mg/kg for each component of the residue and thus < 0.10 mg/kg for the total residue.

Table 6.4.1-2: Summary of BAS 500 F residues in eggs

Treatment Day	Average residue (mg/kg) 3.0 mg/kg dose (group IV)		
	BAS 500 F	BF 500-16	Total
-1	< 0.05	< 0.05	< 0.10
1	< 0.05	< 0.05	< 0.10
2	< 0.05	< 0.05	< 0.10
4	< 0.05	< 0.05	< 0.10
7	< 0.05	< 0.05	< 0.10
10	< 0.05	< 0.05	< 0.10
14	< 0.05	< 0.05	< 0.10
17	< 0.05	< 0.05	< 0.10
21	< 0.05	< 0.05	< 0.10
24	< 0.05	< 0.05	< 0.10
28	< 0.05	< 0.05	< 0.10
30	< 0.05	< 0.05	< 0.10
32	not analysed [1]		
33	not analysed [1]		
34	not analysed [1]		
36	not analysed [1]		
37	not analysed [1]		

[1] all residues were below LOQ therefore depuration data was not needed

Since there were no detectable residues at the 5x dose level (EU) samples from groups II (EU: 0.5x) and III (EU: 1.5x) and both depuration sub-groups were not analyzed.

Table 6.4.1-3: Summary of BAS 500 F residues in hen tissues

Tissue / Matrix	Average residue (mg/kg) 3.0 mg/kg (group IV)		
	BAS 500 F	BF 500-16	Total
Liver	< 0.05 [1]	< 0.05 [1]	< 0.10
Muscle	< 0.05 [1]	< 0.05 [1]	< 0.10
Fat	< 0.05 [1]	< 0.05 [1]	< 0.10

[1] all residues were below LOQ therefore depuration data was not needed

The efficiency of the analytical method number D9902 was determined by fortifying control samples with pyraclostrobin and its metabolite BF 500-16 (500M77) for each matrix. The average recoveries were 101±16% and 98±14% for pyraclostrobin in eggs and hen tissues, respectively. For BF 500-16, average recoveries were 68%±7 and 76%±22 in eggs and hen tissues, respectively. The detailed recovery results are given in Table 6.4.1-4.

Table 6.4.1-4: Recovery results of BAS 500 F and BF 500-16 in eggs and hen tissues

Matrix	Fortification level [mg/kg]	Average recovery level (%) ± S.D.	
		BAS 500 F (determined as BF 500-5)	BF 500-16 (determined as BF 500-9)
Eggs			
Eggs	0.05	101 ±16	68 ±7
Hen tissues			
Liver	0.05	85	96
Muscle	0.05	112	52
Fat	0.05	96	80
Average recovery [%] ± S.D.		98 ±14	76 ±22
Overall average recovery [%] ± S.D.		100 ±15	71 ±13

III. CONCLUSION

At the 3.0 mg/kg dose level (EU: 5x) residues of pyraclostrobin and its metabolite BF 500-16 (500M77) in eggs and hen tissues were below the method's limit of quantitation (LOQ, 0.05 mg/kg). Based on these results, samples from the 0.3 and the 0.9 mg/kg dose level (EU: 0.5x and 1.5x) as well as the depuration groups were not analyzed.

CA 6.4.2 Ruminants

Data/information on cow feeding studies for pyraclostrobin were reviewed during the Annex I inclusion process and were considered to be acceptable (see M-CA 6.4). No further data have been generated. In order to support the existing study, additional method validation experiments were performed for metabolites being detected in higher amounts in the goat metabolism study. From the fortification experiments performed with 500M04 and 500M85 (see M-CA 4.1), it can be concluded that the common moiety method is suitable for data generation purposes.

CA 6.4.3 Pigs

In case of pyraclostrobin, the metabolism in rats and ruminants are similar. Therefore, no pig feeding study is required.

CA 6.4.4 Fish

According to the Commission Regulations (EU) No 283/2013 (active substances) and 284/2013 (plant protection products) as of 1 March 2013, metabolism studies on fish and fish feeding studies might be required in future (latest by 31 Dec 2015), if residues occur in crops that are intended as feed items for fish. As pyraclostrobin is used in several crops being fed to fish, a fish metabolism study was performed. The study is reported in M-CA 6.2. It is considered as suitable for deriving a MRL proposal despite MRLs for fish matrices will not be set in close future. Due to this fact, but also driven by the lack of any suitable EU guideline / guidance document for the conduct of fish feeding studies, a respective study was not performed.

CA 6.5 Effects of Processing

CA 6.5.1 Nature of the residue

Data/information on processing studies were reviewed during the Annex I inclusion process and were considered acceptable.

The following conclusion was copied from the Draft Assessment Report (section 3, B.7) prepared by RMS Germany according to Directive EEC 91/414.

> Pyraclostrobin (BAS 500 F) was not degraded neither during the simulation of pasteurisation (pH 4, 90°C) nor during the simulation of baking, boiling, brewing (pH 5, 100°C) or during sterilisation (pH 6, 120°C). Because no degradation occurred, no degradation products were observed.

The assessment of Germany was recently confirmed by EFSA during the re-evaluation of established EU MRLs according to 396/2005. The following paragraph is directly copied from the relevant Reasoned Opinion:

The effect of processing on the nature of pyraclostrobin residues was investigated in the framework of the peer review. A study was conducted simulating representative hydrolytic conditions for pasteurization (20 minutes at 90°C, pH 4), boiling/brewing/baking (60 minutes at 100°C, pH 5) and sterilization (20 minutes at 120°C, pH 6). This study demonstrates that food processes such as brewing, cooking, sterilization or pasteurization, will not impact the nature of pyraclostrobin residues. The relevant residue for enforcement and risk assessment in processed commodities is therefore expected to be the same as for primary crops (Germany, 2001).

In 2013, BASF submitted a draft Registration Report to Italy covering the intended uses of the formulation BAS 500 02 F in citrus, kaki (persimmon) and olives. In context of this dRR and for supporting the use in oil olives, a processing study (magnitude of residues, BASF Doc ID 2013/1243223) had been performed. In the study, the relevant process fractions (raw oil, refined oil), but also intermediates and waste products were taken and analyzed for pyraclostrobin and the metabolite 500M07 (BF 500-3). In the final purification step from raw oil to refined oil ("deodorization"), higher temperatures are typically applied than during those steps which are covered by investigations according to OECD 507. As an accumulation of the metabolite 500M07 was observed during this step, the zRMS Italy required the conduct of a ^{14}C processing study simulating oil purification.

Report:	CA 6.5.1/1 Hueben M., 2014a High temperature hydrolysis - Simulated processing of 14C-Pyraclostrobin (14C-BAS 500 F) 2014/1136542
Guidelines:	OECD Test Guideline 507 - Nature of the residues in processed commodities - High temperature hydrolysis, EPA 860.1520, EEC 91/414 Annex II (Part A Section 6), EEC 91/414 Annex III (Part A Section 8), EEC 7035/VI/95 rev. 5
GLP:	yes (certified by Ministerium fuer Arbeit, Integration und Soziales des Landes Nordrhein-Westfalen, Duesseldorf)

Note: This study was not contained in the application. The reason for submission is described above.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1.	**Test Material:**	BAS 500 F (Pyraclostrobin, Reg No. 304428)
	Description:	[Chlorophenyl-U-^{14}C]-BAS 500 F, specific activity 6.15 MBq/mg [Tolyl-U-^{14}C]-BAS 500 F, specific activity 6.6 MBq/mg
	Lot/Batch #:	[Chlorophenyl-U-^{14}C]-Label: 579-6301 [Tolyl-U-^{14}C]-Label: 566-5101
	Purity:	[Chlorophenyl-U-^{14}C]-Label: 99.2% (radiochemical, CoA) [Tolyl-U-^{14}C]-Label: 99.9% (radiochemical, CoA)
	CAS#:	175013-18-0
	Development code:	not applicable

B. STUDY DESIGN AND METHODS

1. Test procedure

The hydrolytic degradation of pyraclostrobin was investigated at high temperatures in an olive oil / water mixture to simulate the process of olive oil raffination (deodorization step from raw oil to refined oil). The study was performed with ^{14}C-pyraclostrobin labeled at the chlorophenyl or at the tolyl ring.

Figure 6.5.1-1: Structural formula of ^{14}C-BAS 500 F labeled at the chlorophenyl ring

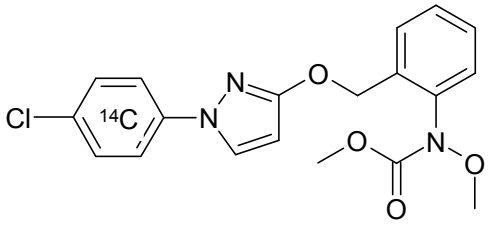

Figure 6.5.1-2: Structural formula of ^{14}C-BAS 500 F labeled at the tolyl ring

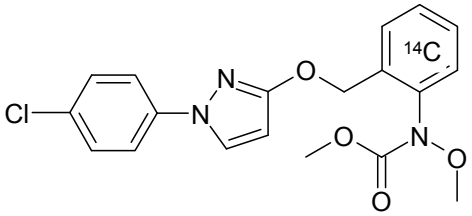

The test substance was applied into a mixture of olive oil and aqueous sodium chloride solution (in a ratio of 2:1) at a rate of 1 mg/mL and heated up to 190°C ± 5°C and 240°C ± 5°C for 30 minutes. After the incubation, the mixture was analyzed for the parent compound and possible transformation products. The conditions for the hydrolysis study are shown in Table 6.5.1-1.

Table 6.5.1-1: Simulated conditions for the hydrolysis study

Temperature (°C)	Time (min)	Remarks
190	30	Olive oil / water (2:1)
240	30	Olive oil / water (2:1)

2. Description of analytical procedures

Preparation of Samples for Total Radioactive Analysis

After separation of the phases, an aliquot of the aqueous phase was measured by LSC.

The olive oil phase was extracted four times with acetonitrile and an aliquot of the acetonitrile phase was measured by LSC. A smaller volume of the extracted oil phase was dissolved in acetone and measured by LSC.

In order to release and characterize further radioactivity from the oil phase, a lipase digestion was performed with the extracted oil phases. For phase separation cyclohexane was added to the reaction mixture. The phases were measured by LSC.

Some aliquots of the oil phase were subject to pancreatin and pepsin digestion in order to verify the bioavailability of the test item and its metabolites.

Liquid Chromatography/Mass Spectrometry (HPLC-MS/MS)
Acetonitrile extracts and the aqueous phases were analyzed by HPLC-MS/MS in MRM mode (HPLC Method 2) to scan for parent, known metabolites and to confirm the identification based on radio-TLC analysis. In addition, aqueous phases after enzyme digestion were analyzed to scan for released parent and/or metabolites.
For HPLC Method 2, the column used was a Hypersil Green ENV, the eluent system consisted of 2 mobile phases (A: 0.1% formic acid in water & B: 0.1% formic acid in acetonitrile), which were used applying gradient elution. HPLC Method 3 was used for the analysis of samples by HPLC/MS/MS. A Xevo TQS (Waters) mass spectrometer was used. Two transitions were established for parent and each reference item. Parent pyraclostrobin and 10 reference items were used to tune the HPLC-MS/MS to confirm or to exclude the presence of known metabolites. For HPLC Method 3, the column used was a Waters ACQUITY UPLC BEH C18, the eluent system consisted of 2 mobile phases (A: 0.1% formic acid in water/methanol (90:10, v:v) & B: 0.1% formic acid in methanol), which were used applying gradient elution.

Radio Thin Layer Chromatography (radio TLC)
All sample matrices were analyzed by radio TLC to determine the distribution of the radioactivity and to identify radioactive residues in the extracts. Samples were separated on pure silica with diisopropylether/dichloromethane/acetic acid (50/50/1, v/v/v). Radio-TLC was finally used for quantitation purposes.

II. RESULTS AND DISCUSSION

1. Extraction of residues

The majority of the radioactivity stayed in the olive oil phase during hydrolysis. In the aqueous phase less than 3% AR were found, except the tolyl 240°C samples where 15.77% AR and 13.26% AR were found.
In the 190°C experiments most of the radioactivity was extractable from the oil phase with acetonitrile. In the oil phase after acetonitrile extraction only 0.29% to 2.70% remained. In the 240°C experiments the radioactivity from the oil phase was less extractable. 4.28% to 28.71% of the applied radioactivity stayed in the oil phase after extraction with acetonitrile.
The mass balance for the chlorophenyl-label experiments were close to or above 90% AR. From the tolyl-label all samples were below but very close to 90%. The distribution of radioactivity after incubation is shown in Table 6.5.1-2. Only the results of the replicates 1 and 4 are included in the table below as they were further analyzed.

Table 6.5.1-2: Distribution of radioactivity after incubation at 190°C and 240°C

Sample	Acetonitrile extract oil [% AR]	Aqueous phase [% AR]	oil after extraction [% AR]	Mass balance [% AR]
1 Chloro 240°C	79.58	2.49	8.36	90.4
4 Chloro 240°C	89.56	1.20	4.28	95.0
1 Chloro 190°C	100.11	0.26	1.21	101.6
4 Chloro 190°C	84.73	0.33	2.70	87.8
1 Tolyl 240°C	49.19	15.77	22.09	87.1
4 Tolyl 240°C	45.61	13.26	28.71	87.6
1 Tolyl 190°C	85.20	1.83	2.02	89.0
4 Tolyl 190°C	88.84	0.77	0.29	89.9

2. Identification, characterization and quantitation of extractable residues

At 190°C:
At 190°C pyraclostrobin is degrading. As a major degradation product the metabolite 500M07 was identified at 190°C up to 50.4% AR. Hydrolysis of the parent was not complete at 190°C as residues of up to 46.6% AR of unchanged parent were found. Metabolite 500M07 was further degraded to 500M04 and 500M49. All peaks exceeding 10% AR were identified. The identification of one peak being present in amounts close to 10% AR in both labels failed despite multiple attempts were undertaken. Taking the actual levels of residues in oilseed and oil fruit crops into account (see M-CA 6.7: maximum STMRs at 0.053 mg/kg for oilseeds, 0.065 mg/kg for future use in oil olives), no significant contribution to the dietary risk can be expected.

The high variation of the degradation product composition in the replicates might be caused by even small variations of the test temperatures (± 5°C). The distribution pattern of radioactivity at 190°C is shown in Table 6.5.1-3.

Table 6.5.1-3: Distribution pattern of radioactivity at 190°C, incubation time 30 min

Substance	Replicate	Chlorophenyl-label [% AR]	Tolyl-label [% AR]
BAS 500 F	1	46.6	27.5
	4	0.0	42.2
	mean	23.3	34.8
500M07	1	32.1	36.1
	4	50.4	35.4
	mean	41.3	35.7
500M04	1	13.4	Not detectable
	4	24.6	
	mean	19.0	
500M49	1	Not detectable	10.3
	4		5.7

not further characterized	1	1.2	2.0
	4	3.0	1.1
	mean	2.1	1.5

*not detected or below detection limit

At 240°C:

At 240°C the degradation of pyraclostrobin is almost complete (only 5% AR were found in one tolyl-label replicate). Metabolite 500M07 is also subject to extensive degradation and only 23.4% AR (compared to 50.4% at 190°C) were found as a maximum concentration. In the chlorophenyl label, the degradation product 500M04 seems to be stable at 240°C and was found in amounts up to 82.3% AR. In contrast, the other cleavage products 500M49 is further degraded under these conditions and was detectable in minor amounts of 4.6% AR.

The terminal products of the high temperature hydrolysis of the tolyl label could only be characterized by chromatographic behavior (SPE, TLC), but was also subjected to enzymatic digestion reactions. None of these characterization reactions revealed distinct peaks. The distribution pattern of radioactivity at 240°C is shown in Table 6.5.1-4.

Table 6.5.1-4: Distribution pattern of radioactivity at 240°C, incubation time 30 min

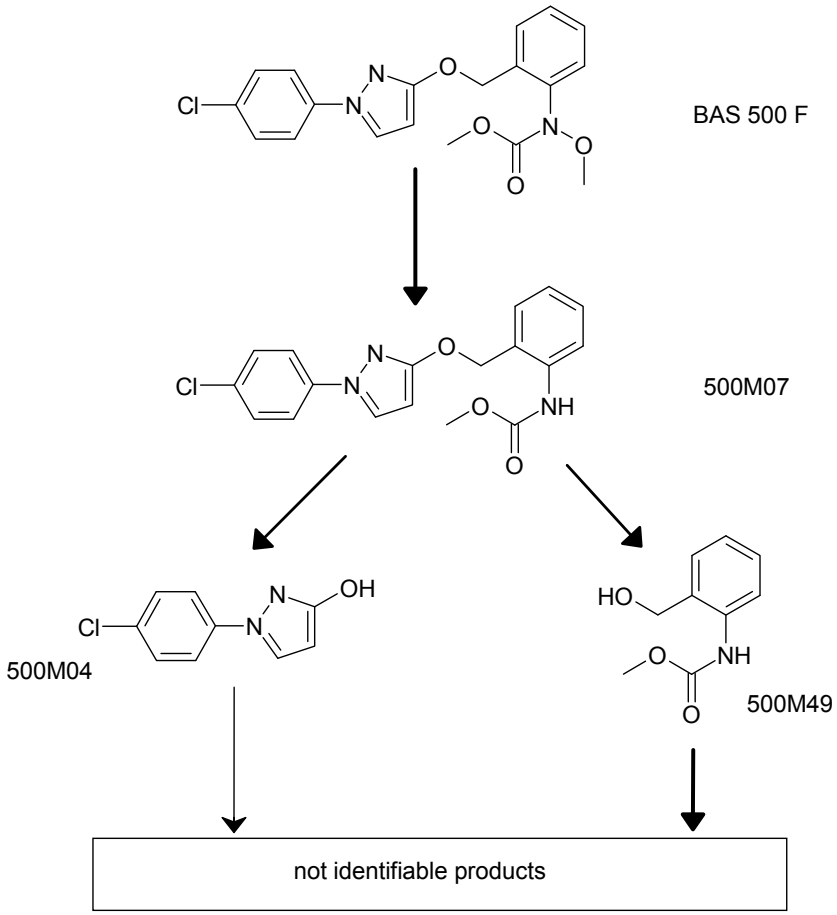
3. Proposed degradation pathway

In almost all samples the same metabolites were found in different compositions. Hydrolytic degradation at higher temperatures resulted in the formation of the metabolite 500M07 which is then further degraded to 500M49 and 500M04. Other degradation pathways seem to be of minor importance. At 240°C, the major product is 500M04. At 240°C, the degradation of the tolyl labelled test compound is leading to products which could be only characterized. By enzymatic cleavage reactions it was unambiguously proven this radioactivity is not resulting in pyraclostrobin related metabolites causing consumer concerns.

The proposed degradation pathway is given in Figure 6.5.1-3.

Figure 6.5.1-3: Proposed Degradation Pathway at 190°C and 240°C



4. Storage stability

All extraction, fractionation and HPLC analysis was completed within 30 days, therefore storage stability analysis was not performed.

III. CONCLUSION

In the study, an extensive degradation of the test item was observed at both temperatures. In almost all samples the same metabolites were found in different compositions. Hydrolytic degradation of the parent compound at 190°C resulted in the formation of the metabolite 500M07 which was then degraded to 500M49 and 500M04. At 240°C further degradation occurred; parent and the metabolite 500M07 were only found in minor amounts whereas in the chlorophenyl label, major component was the metabolite 500M04. In the tolyl label, most of the radioactivity present could be only characterized. Intensive characterization attempts were undertaken using different enzymes (lipase, pepsin, pancreatin), but also chromatographic techniques. They did not indicate the presence of any individual or distinct metabolite. The metabolite 500M07 was still the most abundant peak which could be identified followed by metabolite 500M49.

CA 6.5.2 Distribution of the residue in inedible peel and pulp

All representative uses to be evaluated in this dossier (potatoes, cereals and maize) are crops with edible peel only. Therefore, studies on the distribution between peel and pulp are not required.

CA 6.5.3 Magnitude of residues in processed commodities

During the past 15 years, multiple processing studies have been performed with pyraclostrobin containing products covering industrial production, but also household preparations. For the crops listed in Table 6.5.3-1, processing studies exist. The information on the processing steps covered (third column) is limited to those steps being considered as relevant for human consumption. The table does not include the studies submitted in context of this dossier.

Table 6.5.3-1: Overview on available processing studies supporting registered uses of pyraclostrobin containing formulations

EU Crop Group	Crops	Processing steps covered
Citrus fruits	Oranges	Peeling, canning, juice and marmalade production
Pome fruits	Apples	Washing, juice and sauce production
Stone fruits	Cherries	Washing, canning, juice and fruit syrup production
	Plums	Washing, puree and prune production
Berries and small fruits	Grapes	Wine, juice, raisins
	Strawberries	Washing, canning, jam, fruit syrup and distillate production
	Currants	Washing, canning, juice, jam and jelly production
Root and tuber vegetables	Carrots	Washing, peeling, cooking, juice production, canning
Fruiting vegetables	Tomatoes	Washing, canning, juice, puree and paste production
	Melons	Peeling
Brassica vegetables	Cabbage	Washing, cooking, Sauerkraut production, juice production
Leaf vegetables and fresh herbs	Lettuce, spinach	Washing, blanching, cooking
Legume vegetables	Peas	Washing, canning
Oilseeds and oilfruits	Soybean, oilseed rape, cotton, sunflower	Oil production (raw, refined)
Cereals	Barley	Pot barley, beer production
	Wheat	Flour, bran and germ production
Tea, coffee, herbal infusions and cocoa	Coffee	Roasting, brewing of coffee
Hops	Hops	Beer production
Sugar plants	Sugar cane	Sugar production (brown, refined)

Some of the studies were conducted according to the EU guidance document whereas the investigations performed in the USA are following US EPA OPPTS guidelines. The more recent studies are fulfilling the relevant OECD GD and GL. The majority of processing factors is included in the data bases of the German BfR and Dutch RIVM (BfR webpage: BfR compilation of processing factors for pesticide residues (October 2011), http://chemkap.rivm.nl/groente-fruit/processing-factors/). In almost all studies, pyraclostrobin residues did not show any accumulation in food destined for human consumption. Exceptions are prunes and raisins which can be explained by loss of water.

In context of this dossier, only studies for the intended uses are considered. Summaries of the new studies in wheat, oats and maize are provided below. The barley study submitted in the previous Annex I inclusion process is considered as peer reviewed. The results are also included in the EFSA Reasoned Opinion (Review of the existing maximum residue levels (MRLs) for pyraclostrobin according to Article 12 of Regulation (EC) No 396/2005. EFSA Journal 2011;9(8):2344. [92 pp.] doi:10.2903/j.efsa.2011.2344).

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Pyraclostrobin, 500M07, BAS 500 06 F

Description:	BAS 500 06F: BAS 500 F (Pyraclostrobin)
Lot/Batch #:	0003223026, Pyraclostrobin: 200.0 g/L
Purity:	BAS 500 F: 99.9% 500M07 (BF 500-3): 99.9%
CAS#:	BAS 500 F: 175013-18-0 500M07 (BF 500-3): 512165-96-7
Development code:	not applicable
Spiking levels:	BAS 500 F: 0.01 – 100 mg/kg 500M07 (BF 500-3): 0.01 – 20 mg/kg

2. Test Commodity: Cereals

Crop:	Wheat
Type:	not applicable
Variety:	JB Asano, Cubus, Akteur
Botanical name:	*Triticum L.*
Crop parts(s) or processed Commodity:	whole plant no roots, wet silage, wilted silage, grain, bran, flour, germ, middlings, shorts, gluten, gluten feed meal, starch, whole meal flour, whole grain bread
Sample size:	For analysis: >0.05 kg For processing: Whole plant no roots >7 kg, grain >40 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2011 growing season, four field trials in Germany were conducted in order to investigate the residue behaviour of BAS 500 F (pyraclostrobin) in wheat and its processed products previously treated with the test item BAS 500 06 F.
Each field trial consisted of a treated plot. Two field trials (L110166 and L110168) also included a control plot. The test item BAS 500 06 F, a 200 g/L EC formulation of pyraclostrobin, was foliar applied twice at an exaggerated target rate of 6.25 L product/ha (1.25 kg a.s./ha) for each application. The applications were made at crop stages BBCH 49 and BBCH 69 using a spray volume of 200 L/ha. Wheat specimens for analysis were sampled on the day of last application as well as at crop stages BBCH 71 and BBCH 89 (on the field). RAC specimens for analysis were taken from the treated specimens directly before the start of processing. The processing of wheat was conducted with specimens taken at crop stages BBCH 71 and BBCH 89. After processing, twelve different fractions of wheat products or intermediates were collected for analysis, namely wet silage, wilted silage, bran, flour, germ, middlings, shorts, gluten, gluten feed meal, starch, whole meal flour and whole grain bread.

2. Description of analytical procedures

The specimens were analysed for residues of BAS 500 F (pyraclostrobin) and its metabolite 500M07 (BF 500-3) using BASF method No. L0076/01 (535/1), which has a limit of quantitation of 0.01 mg/kg for each of the analytes. Pyraclostrobin and 500M07 are extracted with a mixture of methanol, water and hydrochloric acid. An aliquot of the extract is centrifuged and partitioned at alkaline conditions against cyclohexane. The final determination of pyraclostrobin and 500M07 is performed by HPLC-MS/MS. The mean recovery results for pyraclostrobin and its metabolite 500M07 were 94.6 ± 9.5% and 91.0 ± 13.2%, respectively, at fortification levels of 0.01 and 100 mg/kg (pyraclostrobin) and 0.01 and 20 mg/kg (metabolite 500M07).

II. RESULTS AND DISCUSSION

The residue levels of pyraclostrobin determined in the treated specimens and its processed fractions as well as the calculated transfer factors are presented in Table 6.5.3-2. The mean transfer factors representing the different processing steps were below 1 for pyraclostrobin in wet silage, flour, germ, gluten feed meal, starch, whole meal flour and whole grain bread. Therefore, it can be concluded, that pyraclostrobin is not being accumulated in these processed fractions. The mean transfer factors of wilted silage, bran, middlings, shorts and gluten greater than 1 for pyraclostrobin residues are most likely based on the weight ratio and different water contents between RAC and processing fractions.

Table 6.5.3-2: Summary of BAS 500 F residues in wheat, processed fractions and transfer factors

Matrix	Residue BAS 500 F (mg/kg)				Transfer factor[1] BAS 500 F				Mean transfer factor
Trial [2)]	1	2	3	4	1	2	3	4

Whole grain bread	0.01	0.01	0.03	0.03	1.00	1.00	0.75	0.75	0.88

[1] Transfer factor = residue in PF / residue in RAC
[2] Trial 1: L110166, Trial 2: L110167, Trial 3: L110168, Trial 4: L110169
[3] Specimens were taken directly before start of processing
[4] Residues expressed as parent equivalents, conversion factor for calculation of 500M07 (BF 500-3) to parent equivalent is 1.084.

III. CONCLUSION

Pyraclostrobin was concentrated in wilted silage, bran, middlings, shorts and gluten, whereas the metabolite 500M07 (BF 500-3) was concentrated in wet silage, wilted silage, bran, germ, middlings, shorts, gluten and whole meal flour. The concentration is most likely based on the weight ratio and different water contents between RAC and processing fractions. In all further matrices the residues declined during processing.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Fluxapyroxad, pyraclostrobin, M700F002, M700F048, M700F008, 500M07 (BF 500-3)

Description:	BAS 703 04 F: BAS 700 F (fluxapyroxad) and BAS 500 F (pyraclostrobin)
Lot/Batch #:	208088, fluxapyroxad: 73.3 g/L; pyraclostrobin: 147.5 g/L
Purity:	BAS 500 F: 99.9% 500M07 (BF 500-3): 99.9%
CAS#:	BAS 500 F: 175013-18-0 500M07 (BF 500-3): 512165-96-7
Development code:	not applicable
Spiking levels:	0.01 – 20 mg/kg

2. Test Commodity: Cereals

Crop:	Oat
Type:	not applicable
Variety:	Flocke
Botanical name:	*Avena sativa* L.
Crop parts(s) or processed Commodity:	Whole plant, grain, flour, groats/rolled oats, husks, dust, bran
Sample size:	For analysis: 0.15-1.84 kg For processing: 21.78-40.01 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2012 growing season, a total of 4 field trails were conducted in Germany to determine the magnitude of the residues of fluxapyroxad (BAS 700 F) and pyraclostrobin (BAS 500 F) in or on oat and processed products.
The formulation BAS 703 04 F was foliar applied twice at an exaggerated rate of 0.450 kg a.s./ha for fluxapyroxad and of 0.900 kg a.s./ha for pyraclostrobin. Application timings were at BBCH 49 and BBCH 69. Oat specimens were collected directly after the application (0 DALA) and at growth stage BBCH 89. Sampling of BBCH 89 specimens was performed twice. One specimen was used for processing into flour, groats/rolled oats, husks, dust and bran.

2. Description of analytical procedures

All specimens were analysed for pyraclostrobin and its metabolite 500M07 (BF 500-3) using BASF Method No. L0076/01 (535/1). The method has a limit of quantitation of 0.01 mg/kg for all analytes.
Pyraclostrobin and its metabolite 500M07 were extracted with a mixture of methanol, water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned at alkaline conditions against cyclohexane. The final determination of the analytes was performed by HPLC-MS/MS. Mean procedural recoveries were 95.3% for pyraclostrobin and 91.9% for the metabolite 500M07.

II. RESULTS AND DISCUSSION

In the grain specimens used for processing, residues of pyraclostrobin ranged between 0.20 and 0.46 mg/kg and residues of metabolite 500M07 (BF 500-3) ranged between 0.044 and 0.14 mg/kg.
In flour specimens, residues of pyraclostrobin ranged between 0.022 and 0.085 mg/kg and residues of the metabolite 500M07 ranged between <0.01 and 0.023 mg/kg. In groats/rolled oats residues of pyraclostrobin ranged between 0.01 and 0.042 mg/kg and residues of the metabolite 500M07 were between <0.01 and 0.011 mg/kg. Residue data are shown in Table 6.5.3-4.
The transfer factors for parent pyraclostrobin and metabolite 500M07 are shown in Table 6.5.3-5 and Table 6.5.3-6. In husks and dust, pyraclostrobin and its metabolite 500M07 were concentrated (pyraclostrobin: TF 2.34 and 5.23; 500M07: TF 2.42 and 5.45), whereas in all further matrices the residues declined during processing.
No residues of the analytes above the respective limits of quantitation were found in any of the analyzed untreated oat specimens or their processed products.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Pyraclostrobin, epoxiconazole, 1,2,4-triazole, triazolylalanine, triazole acetic acid, triazole lactic acid, 500M07 (BF 500-3)

Description: BAS 512 04 F: BAS 500 F (pyraclostrobin), BAS 480 F (epoxiconazole), SE formulation

Lot/Batch #: FRE-000369, pyraclostrobin: 133.4 g/L, epoxiconazole: 50.9 g/L

Purity: BAS 500 F: 99.9%,
500M07 (BF 500-3): 99.9%

CAS#: BAS 500 F: 175013-18-0
500M07 (BF 500-3): 512165-96-7

Development code: not applicable

Spiking levels: 0.01 – 20 mg/kg

2. Test Commodity: Cereals

Crop: Maize

Variety: BKC 2949, DK 243, Ronaldinho, DK 2949

Botanical name: *Zea mays*

Crop parts(s) or processed

Commodity: Whole plant, grain, chopped fodder, silage, refined oil, flour, meal, starch, bran, middlings, gluten, gluten feed meal, steepwater, germs, presscake

Sample size: For processing: 5 kg of whole plant; 20 kg of grain

B. STUDY DESIGN

1. Test procedure

During the growing season 2008, four field trials were conducted in Germany to determine the residue levels of pyraclostrobin and epoxiconazole in maize and their processed products. The trials were performed with the formulation BAS 512 04 F (0.133 kg pyraclostrobin/L and 0.05 kg epoxiconazole/L, SE). The formulation was foliar applied once at BBCH 65 at a rate of 7.5 L/ha (0.9975 kg as/ha of pyraclostrobin and 0.375 kg as/ha of BAS 480 F). Maize specimens for analysis were sampled directly after the last application and in addition 67 and 90 days after last application for trial L080338, 62 and 94 days after last application for trial L080339, 43 and 83 days after last application for trial L080340 as well as 70 and 88 days after last application for trial L080341. The processing of maize was conducted with maize taken at the second sampling event (BBCH 85, sampled as whole plant) and last sampling event (BBCH 89, sampled as grain). After processing, thirteen different fractions of maize products or intermediates were collected for analysis: chopped fodder, silage, refined oil, flour, meal, starch, bran, middlings, gluten, gluten feed meal, steep water, germs and press cake.

2. Description of analytical procedures

All samples were analyzed with BASF method no. 535/1 which quantifies the residues of pyraclostrobin, its metabolite 500M07 (BF 500-3) and epoxiconazole with a limit of quantitation of 0.01 mg/kg each for all matrices.
Pyraclostrobin, 500M07 and epoxiconazole were extracted using a mixture of methanol, water and HCl 2 mol/L. For clean-up a liquid/liquid partition against cyclohexane was used. The final determination of pyraclostrobin, 500M07 and epoxiconazole was performed by HPLC/MS/MS.
Some deviations were proceeded to the BASF Method No 535/1 for refined oil. For pyraclostrobin and 500M07 analysis, in the extraction step the Shaker was used during 50 minutes, instead of Ultra Turrax during 2 minutes. In the partition step, 10 mL of cyclohexane was used and an aliquot of 4 mL was taken. The factor aliquot did not change.
Average procedural recoveries in all sample materials ranged for pyraclostrobin between 73 and 113%, for 500M07 between 73 and 107% and for epoxiconazole between 81 and 109% at fortification levels of 0.01, 0.1, 1.0 and 20 mg/kg.

II. RESULTS AND DISCUSSION

For pyraclostrobin, chopped fodder and silage showed very similar residue levels and only a slight increase compared to whole plant was seen most likely resulting out of some water losses. The mean transfer factors representing the different processing steps were 1 for pyraclostrobin in refined oil, starch, bran, middlings, gluten, gluten feed meal, steep water, germs and press cake, because the residues in all 4 trials in the RAC grain samples were ≤ LOQ. The residue levels of pyraclostrobin determined in the treated specimens and its processed fractions as well as the calculated transfer factors are presented in Table 6.5.3-7.

According to 500M07 (BF 500-3), the transfer factor of chopped fodder and silage indicates that there was a slight increase compared to the residue levels in whole plant, most likely because of a water loss in the samples. The mean transfer factors representing the different processing steps were 1 for BF 500-3 in refined oil, flour, starch, bran, middlings, gluten, gluten feed meal, steep water, germs and press cake, because the residues in the RAC grain samples for all 4 trials were ≤ LOQ. The residue levels of BF 500-3 determined in the treated specimens and its processed fractions as well as the calculated transfer factors are presented in Table 6.5.3-8.

III. CONCLUSION

Concentration factors of process fractions obtained from maize grain were 1 for pyraclostrobin and its metabolite BF 500-3, because the residues in the RAC grain samples were ≤ LOQ.

CA 6.6 Residues in Rotational Crops

A confined rotational crop study (BASF DocID 1999/11829) was submitted and evaluated during the previous Annex I inclusion process. The residue levels and the nature of residues were investigated in three different succeeding crops (radish, lettuce, wheat) at an application rate of 900 g as/ha. In the study the ^{14}C-chlorophenyl and ^{14}C-tolyl labelled pyraclostrobin was applied to bare soil. The study is considered to be still scientifically valid and it is meeting the requirements included in OECD guideline 502.

For pyraclostrobin, the following conclusion was made by the RMS Germany in the course of the Annex I inclusion process. The relevant endpoint was copied from the Draft Assessment Report (2001).

Residues in succeeding crops (Annex IIA, point 6.6, Annex IIIA, point 8.5)

30, 120, 365 days plant back interval after application of 0.9 kg as/ha: TRR in the edible parts for human consumption are very low (radish roots, lettuce: < 0.040 mg/kg; wheat grain: < 0.089 mg/kg). No accumulation of pyraclostrobin or its degradation products [radish, lettuce: < 0.0106 mg/kg; wheat straw: < 0.0147 mg/kg; wheat grain: not detectable].

In context of the EU MRL review according to Article 12 (EFSA Journal 2011;9(8):2344) the assessment of Germany way confirmed by EFSA: The following paragraphs were directly copied from the relevant Reasoned Opinion.

Preliminary considerations

The use of pyraclostrobin in permanent crops or in third countries is not considered relevant with regard to the potential occurrence of residues in rotational crops. Within Europe, however, pyraclostrobin is also authorised for use in crops which may be grown in rotations, thus further consideration of pyraclostrobin residues in rotational crops is required. According to the soil degradation studies performed in the framework of the peer review, the highest DT90 value of pyraclostrobin, based on the field and laboratory studies, is 230 and 163 days, respectively. The desmethoxy metabolite (500M07) shows higher persistency in the soil with a DT90f value amounting to 529 days (Germany, 2001).

Nature of residues

In the peer review the metabolism of pyraclostrobin in rotational crops was studied in lettuce, radish and wheat with [tolyl-U-^{14}C]-pyraclostrobin and [chlorophenyl-U-^{14}C]-pyraclostrobin (Germany, 2001). The radiolabelled active substance was applied on a bare soil once at an application rate of 0.9 kg a.s./ha and respective crops were sown or planted at 30, 120 and 365 DAT.

The peer review concluded that the metabolic pathway of pyraclostrobin in rotational crops is similar to that in primary crops and no formation of new metabolites was observed. There is no accumulation of pyraclostrobin or its degradation products (including 500M07) in the parts of plants used for human or animal consumption. The relevant residue in rotational crops therefore should be defined as parent pyraclostrobin.

Magnitude of residues

According to the study results of the ^{14}C study, the total radioactive residues in the edible parts of succeeding crops were very low for all plant back intervals: radish roots, lettuce ≤ 0.04 mg/kg and wheat grain ≤0.089 mg/kg. No accumulation of pyraclostrobin or its residues was observed in rotational crops.

Application rates supported in the framework of this review range between 0.05 and 0.67 kg a.s./ha. Considering the overdosing factor of the above study and the fact that pyraclostrobin was applied to a bare soil (interception of pyraclostrobin by the plants is expected in practice), it is expected that residues of pyraclostrobin resulting from soil uptake will not exceed 0.01 mg/kg. Specific plant-back restrictions related to the use of pyraclostrobin are therefore not required, provided that pyraclostrobin is applied in compliance with the GAPs evaluated in the framework of this review.

CA 6.6.1 Metabolism in rotational crops

In order to prove that no metabolite consisting solely of the pyrazole moiety is formed in soil (see M-CA 7) and taken up by plants, preliminary investigations with the ^{14}C-pyrazole labelled pyraclostrobin were performed. ^{14}C-pyrazole labelled pyraclostrobin was applied at the maximum seasonal rate of 500 g as/ha to bare soil. After an aging period of 30 DAT crops were planted / sown. The use rate of 500 g as/ha corresponds to a realistic worst case GAP for Europe (2 x 250 g as/ha in cereals).

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: ^{14}C-BAS 500 F

Description:	Pyraclostrobin was applied as undiluted ^{14}C-labelled BAS 500 F (labelled at position 3 of the pyrazole ring) - Label: pyrazole-3-C^{14}
Lot/Batch #:	1073-1008
Purity:	90.7% (radiochemical purity: 99.7%)
CAS#:	175013-18-0
Development code:	BAS 500 F
Spiking levels:	not available

2. Test Commodity:

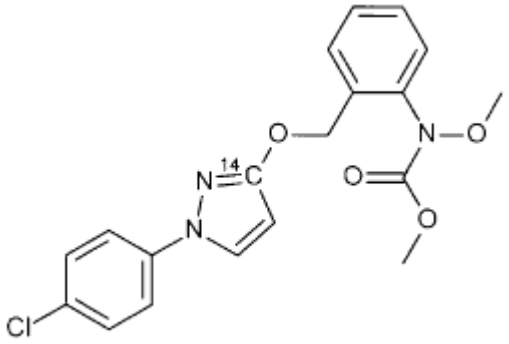
Crop:	radish, wheat, lettuce
Type:	not reported
Variety:	radish: Eiszapfen, wheat: Tassos, lettuce: Hardy
Botanical name:	*Rhaphanus sativus, Triticum L., Lactuca sativa*
Crop parts(s) or processed commodity:	radish: leaf and root wheat: forage lettuce: plant
Sample size:	not applicable

B. STUDY DESIGN

1. Test procedure

The confined indicator rotational crop study was performed with ^{14}C-pyraclostrobin labelled at position 3 of the pyrazole ring.

Figure 6.6.1-1: Structural formula of ^{14}C-BAS 500 F labelled at position 3 of the pyrazole ring



The pure active ingredient was applied to sandy loam soil (USDA scheme) with an application rate of 0.500 kg a.s./ha. After application, the soil was aged for 32 days. After the soil aging period was completed, ploughing was simulated by mixing the treated soil with the help of a concrete mixer. Subsequently the crops radish, wheat and lettuce were sowed or planted. Soil characteristics are given in Table 6.6.1-1.

Table 6.6.1-1: Soil characteristics: soil used for planting

USDA classification	
clay	9.5%
silt	17.4%
sand	73.1%
soil class	sandy loam
DIN classification	
clay	9.5%
silt	21.5%
sand	69.0%
soil class	loamy sand (SL3)
Other soil parameters	
total nitrogen	0.15%
total organic carbon	2.76%
total carbon	2.76%
pH ($CaCl_2$)	7.1
pH (H_2O)	7.9
effective cation exchange capacity	11.5 cmol/kg
max. water holding capacity	25.2 g/100 g dry soil
microbial biomass	35.3 mg C/100 g dry soil
microbial C / organic C	1.3%
bulk density	1344 g/L
dry matter	92.3%

The immature crops were harvested after 42 days, processed and analysed by combustion and radioactivity measurement for the Total Radioactive Residues. In addition, soil samples were taken after ploughing and harvest of the crops.

2. Description of analytical procedures

For the determination of the Extractable Radioactive Residues (**ERR**), the homogenised plant material was extracted three times with methanol and two times with water. After solvent extraction and partition procedures HPLC analyses (Method LC02) were carried out for the concentrated water phases of the methanol extracts with a sufficient level of radioactivity. In context of this HPLC method, a Phenomenex Synergi Polar-RP-column was used (250 x 4.6 mm, particle size 4 µm), operating at a column temperature of 25 °C with a flow rate of 1.0 mL/min. The eluent system consisted of 2 eluents (A: water/acetonitrile/formic acid, 950/50/2.5 & B: water/acetonitrile/formic acid, 50/950/2.5). This system was applied using gradient elution.
The residual radioactive residues after solvent extraction (**RRR**) were characterised by combustion of the dried and homogenised extraction residues.
The Total Radioactive Residues (**TRR**) in *plant* material were obtained by calculating the sum of ERR and RRR (TRR calculated) and additionally by combustion of sample aliquots (TRR Measured). The *soil* sample after aging and ploughing was determined by direct combustion analysis followed by LSC. All calculations throughout the present study were based on the TRR calculated.

II. RESULTS AND DISCUSSION

Total radioactive residues

The Total Radioactive Residues (TRR) of all matrices were very low and ranged from 0.003 mg/kg (radish root) to 0.016 mg/kg (lettuce plant). The TRR determined by combustion analysis showed no major difference to the TRR calculated by summing up the extractable and the residue radioactivity. These results indicate that there was no pronounced translocation of pyraclostrobin or its degradation products from the soil into the plants.

The results of the Total Radioactive Residues (TRR) after ^{14}C-pyraclostrobin treatment in radish, wheat and lettuce are provided in Table 6.6.1-2, the results of the soil samples are shown in Table 6.6.1-3.

Table 6.6.1-2: Total Radioactive Residues in rotational crops after ^{14}C-BAS 500 F treatment

Matrix	Days after sowing / planting DAP	TRR measured[1)] [mg/kg]	TRR calculated[2)] [mg/kg]
Plant back interval: 32 DAT			
Radish leaf	42	0.011	0.010
Radish root	42	0.003	0.003
Wheat forage	42	0.015	0.014
Lettuce plant	42	0.017	0.016

[1)] TRR was determined by direct combustion
[2)] TRR was calculated as the sum of ERR (extraction with methanol and water) + RRR

Due to the very low TRR level in soil samples already after ploughing at 32 DAT, the soil samples collected at 74 DAT after harvest of the mature crops were not further analysed.

Table 6.6.1-3: Total Radioactive Residues in soil samples after ^{14}C-BAS 500 F treatment

Soil samples (Days After Treatment DAT)	Days after sowing DAP	TRR measured[1)] [mg/kg]

Lettuce (74 DAT)	42	n.a.

1) TRR was determined by direct combustion
n.a. not analysed due to the low TRR level already after ploughing at 32 DAT

Extraction behaviour

For all rotational crop matrices the methanol extract and the water extract were summarised as ERR.
The extractabilities with methanol and water are summarised in Table 6.6.1-4. The major portions of the radioactive residues were extracted with methanol (46.9 to 63.3% TRR). The extraction with water released additional 3.9 to 8.5% TRR.

Table 6.6.1-4: Extractability of Radioactive Residues in rotational crops after ^{14}C-BAS 500 F treatment

Matrix	TRR calculated[1)]	Methanol extract		Water extract		ERR[2)]		RRR	
	[mg/kg]	[mg/kg]	[% TRR]	[mg/kg]	[% TRR]	[mg/kg]	[% TRR]	[mg/kg]	[% TRR]
Plant back interval: 32 DAT									
Radish leaf	0.010	0.006	63.3	0.001	8.5	0.007	71.8	0.003	28.2
Radish root	0.003	0.002	46.9	< 0.001	8.0	0.002	55.0	0.002	45.0
Wheat forage	0.014	0.008	59.0	0.001	3.9	0.009	62.9	0.005	37.1
Lettuce plant	0.016	0.008	50.8	0.001	8.0	0.009	58.8	0.006	41.2

1) TRR was calculated as the sum of ERR (extraction with methanol and water) + RRR and set at 100% for all further calculations.
2) Extractable Radioactive Residue (ERR) was calculated as the sum of methanol and water extract.

The extractability of radish leaf with methanol was good and accounted for 63.3% TRR. Subsequent extraction with water released only minor amounts of 8.5% TRR. Thus, the Extractable Radioactive Residue (ERR) from radish leaf was 71.8% TRR. The residue after solvent extraction (RRR) accounted for 0.003 mg/kg and was therefore not further investigated.

The extractability of radish root with methanol accounted for 46.9% TRR. Subsequent extraction with water released only minor amounts of 8.0% TRR. Thus, the Extractable Radioactive Residue (ERR) from radish root was 55.0% TRR. The residue after solvent extraction (RRR) accounted for 0.002 mg/kg. The extracts and the residue after solvent extraction were not further investigated due to low levels of radioactivity.

The extractability of wheat forage with methanol accounted for 59.0% TRR. Subsequent extraction with water released only minor amounts of 3.9% TRR. Thus, the Extractable Radioactive Residue (ERR) from wheat forage was 62.9% TRR. The residue after solvent extraction (RRR) accounted for 0.005 mg/kg and was therefore not further investigated.

The extractability of lettuce plant with methanol accounted for 50.8% TRR. Subsequent extraction with water released only minor amounts of 8.0% TRR. Thus, the Extractable Radioactive Residue (ERR) from lettuce plant was 58.8% TRR. The residue after solvent extraction (RRR) accounted for 0.006 mg/kg and was therefore not further investigated.

Partition behaviour

In order to characterise the radioactive residues in the methanol extract as organo-soluble or water-soluble, liquid / liquid partitions of the methanol extracts from radish leaf, wheat forage and lettuce plant were carried out using iso-hexane as organic solvent. In wheat forage and lettuce plant, higher portions of the radioactive residues were water-soluble, and lower portions were detected in the organic phase. In radish leaf, comparable portions were detected in the organic and in the water phase. Results are summarised in Table 6.6.1-5.

Table 6.6.1-5: Partition characteristics of Radioactive Residues extracted with methanol from rotational crop samples

Matrix	Methanol extract		Isohexane partition				Recovery [1)]
			Organo-soluble		Water-soluble		
	[mg/kg]	[% TRR]	[mg/kg]	[% TRR]	[mg/kg]	[% TRR]	[%]
Radish leaf	0.006	63.3	0.003	29.9	0.003	26.9	89.726
Radish root	0.002	46.9	n.a.				-
Wheat forage	0.008	59.0	0.002	17.3	0.005	32.0	83.576
Lettuce plant	0.008	50.8	0.002	15.2	0.006	38.6	106.087

[1)] Recovery calculated as (Organo-soluble + Water-soluble) [mg/kg] x 100 / Methanol Extract [mg/kg]
n.a. = not applied

Identification and characterization of extractable radioactivity

The concentrated water phases of the methanol extracts of radish leaf, wheat forage and lettuce plant were analysed by HPLC and resulted in a metabolite pattern of one polar peak at a retention time of approximately 4.3 min and three peaks at approximately 20.2 min, 21.7 min and 22.8 min. An assignment of the peaks to a structure was not possible due to the low levels of radioactive residues. All peaks were below the trigger of 0.01 mg/kg. The Residual Radioactive Residues (RRR) were low with values ranging from 0.002 mg/kg to 0.006 mg/kg.
The summaries of characterised residues from radish leaf, wheat forage and lettuce plant are compiled in the tables below.

Radish leaf

The methanol extract of radish leaf was extracted with isohexane, which resulted in a isohexane phase and a water phase. Quantitative analysis of the concentrated water phase using HPLC method LC02 yielded one polar peak at 4.3 min (< 0.001 mg/kg or 4.7% TRR) and three peaks at 20.2 min (0.001 mg/kg or 8.3% TRR), 21.7 min (0.001 mg/kg or 10.5% TRR) and 22.8 min (< 0.001 mg/kg or 3.4% TRR). Furthermore, 0.003 mg/kg or 29.9% TRR were characterised by their solubility in the isohexane phase of the methanol extract and 0.001 mg/kg or 8.5% TRR by their extractability with water. The residue after solvent extraction (RRR) was not further investigated due to low levels of radioactivity (0.003 mg/kg or 28.2% TRR).
In total, 65.3% of the TRR were characterised from the ERR by HPLC or by their extractability. Summarised with the Residual Radioactive Residue, the radioactive residues accounted for 0.010 mg/kg or 93.5% TRR.

Table 6.6.1-6: Summary of identified and characterised Radioactive Residues extracted from radish leaf

Designation	[mg/kg]	[% TRR]
Total Radioactive Residue (TRR)	***0.010***	***100.0***
Characterised from Concentrated Water Phase of Methanol Extract by HPLC		
Peak at 4.3 min	< 0.001	4.7
Peak at 20.2 min	0.001	8.3
Peak at 21.7 min	0.001	10.5
Peak at 22.8 min	< 0.001	3.4
Total Characterised from ERR by HPLC	**0.003**	**26.9**
Isohexane Phase of Methanol Extract	0.003	29.9
Water Extract	0.001	8.5
Total Characterised from ERR	**0.007**	**65.3**
Residual Radioactive Residue (RRR)	0.003	28.2
Sum of RRR and Total Characterised from ERR	**0.010**	**93.5**

Wheat forage

The methanol extract of wheat forage was extracted with isohexane, which resulted in a isohexane phase and a water phase. Quantitative analysis of the concentrated water phase using HPLC method LC02 yielded the polar peak at 4.3 min (0.001 mg/kg or 3.7% TRR) and the two peaks at 20.2 min (0.001 mg/kg or 7.9% TRR) and 21.7 min (0.003 mg/kg or 20.4% TRR). Although the peak at 22.8 min was not integrated in the chromatogram, it was present as a shoulder of peak at 21.7 min. Furthermore, 0.002 mg/kg or 17.3% TRR were characterised by their solubility in the isohexane phase of the methanol extract and 0.001 mg/kg or 3.9% TRR by their extractability with water. The residue after solvent extraction (RRR) was not further investigated due to low levels of radioactivity (0.005 mg/kg or 37.1% TRR).

In total, 53.2% of the TRR were characterised from the ERR by HPLC or by their extractability. Summarised with the Residual Radioactive Residue, the radioactive residues accounted for 0.013 mg/kg or 90.3% TRR.

Table 6.6.1-7: Summary of identified and characterised Radioactive Residues extracted from wheat forage

Designation	[mg/kg]	[% TRR]
Total Radioactive Residue (TRR)	***0.014***	***100.0***
Characterised from Concentrated Water Phase of Methanol Extract by HPLC		
Peak at 4.3 min	0.001	3.7

Residual Radioactive Residue (RRR)	0.005	37.1
Sum of RRR and Total Characterised from ERR	**0.013**	**90.3**

Lettuce plant

The methanol extract of lettuce plant was extracted with isohexane, which resulted in a isohexane phase and a water phase. Quantitative analysis of the concentrated water phase using HPLC method LC02 yielded the polar peak at 4.3 min (0.001 mg/kg or 7.3% TRR) and the three peaks at 20.2 min (0.001 mg/kg or 9.0% TRR), 21.7 min (0.003 mg/kg or 17.4% TRR) and 22.8 min (0.001 mg/kg or 5.0% TRR). Furthermore, 0.002 mg/kg or 15.2% TRR were characterised by their solubility in the isohexane phase of the methanol extract and 0.001 mg/kg or 8.0% TRR by their extractability with water. The residue after solvent extraction (RRR) was not further investigated due to low levels of radioactivity (0.006 mg/kg or 41.2% TRR).
In total, 61.8% of the TRR were characterised from the ERR by HPLC or by their extractability. Summarised with the Residual Radioactive Residue, the radioactive residues accounted for 0.015 mg/kg or 103.0% TRR.

Table 6.6.1-8: Summary of identified and characterised Radioactive Residues extracted from lettuce plant

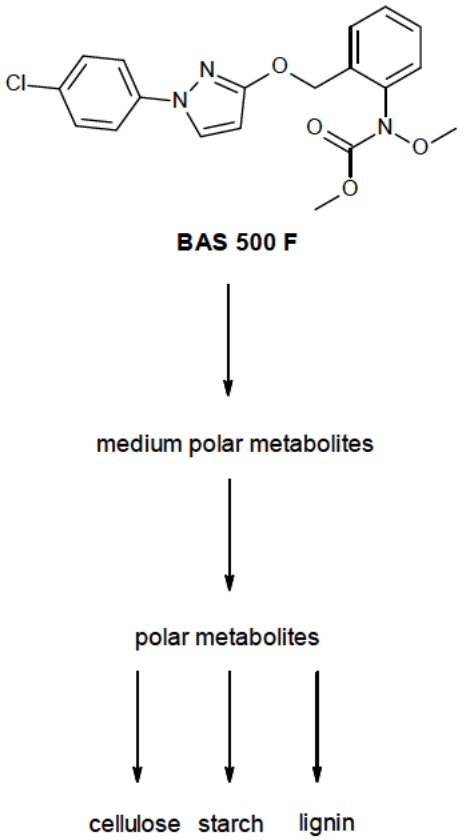
Metabolic pathway

In all matrices analysed by HPLC, the same peaks were detected in the chromatograms. Due to the low levels of radioactivity in the plants, no structure could be assigned to the peaks. Therefore, a metabolic pathway with designated metabolites could not be evaluated.
It can be assumed, that the results from this indicator study with ^{14}C-pyraclostrobin labelled in the pyrazole ring are in good accordance with the results of the confined rotational crop study performed with Pyraclostrobin ^{14}C-labelled in the tolyl and the phenyl ring systems (Veit, P.: Confined Rotational Crop Study with ^{14}C-pyraclostrobin, BASF Doc ID 1999/11829).

Figure 6.6.1-2: Metabolic pathway of BAS 500 F in rotational crops



III. CONCLUSION

In all rotational crop matrices (radish, wheat, lettuce) low levels of radioactive residues were determined. The calculated Total Radioactive Residues (TRR) in radish leaf accounted for 0.010 mg/kg, for radish root 0.003 mg/kg, for wheat forage 0.014 mg/kg and for lettuce plant 0.016 mg/kg. The measured TRR of the top soil layer after aging and ploughing was 0.140 mg/kg.

The extractability of the radioactive residues with methanol and water was good. The major portions of the radioactive residues were extracted with methanol (46.9% to 63.3% TRR). The extractable residues in water were ≤ 8.5% TRR.
After liquid / liquid partitions of the methanol extracts from radish leaf, wheat forage and lettuce plant using isohexane as organic solvent, higher portions of the radioactive residues extracted were water-soluble, and lower portions were found in the organic phase in wheat forage and lettuce plant. In radish leaf, comparable portions were found in the organic and in the water phase.

HPLC analysis of the concentrated water phases of the methanol extracts of radish leaf, wheat forage and lettuce plant resulted in a metabolite pattern of one polar peak at a retention time of approximately 4.3 min and three peaks at approximately 20.2 min, 21.7 min and 22.8 min. An assignment of the peaks to structures was not possible due to the low levels of radioactive residues. All peaks were below the trigger of 0.01 mg/kg. The Residual Radioactive Residues (RRR) were low with values ranging from 0.002 mg/kg to 0.006 mg/kg.

The results indicate that there was no significant translocation of pyraclostrobin and / or its degradation products from the soil.

CA 6.6.2 Magnitude of residues in rotational crops

According to Reg. 283/2013, studies on the magnitude of residues in rotational crops are required under the following circumstances:

If the metabolism studies indicate that residues of the active substance or of relevant metabolites or breakdown products either from plant or soil metabolism may occur (> 0.01 mg/kg), limited field studies and, if necessary, field trials shall be carried out.

Studies shall not be required in the following cases:

- no metabolism studies on rotational crops are to be performed, or
- metabolism studies on rotational crops show that no residues of concern are to be expected in rotational crops

Due to the favorable residue behavior of pyraclostrobin in succeeding crops which has been demonstrated in two studies with different ring labels and under worst case conditions (bare soil application with partly exaggerated rates), no residues are expected. Consequently, no higher tier study is required.

CA 6.7 Proposed residue definitions and maximum residue levels

CA 6.7.1 Proposed residue definitions

The residue definitions currently established in the EU and supported in future are compiled in Table 6.7.1-1. In the subsequent section, detailed justifications for BASF's proposal are provided. The proposal is based on a careful evaluation of all studies being available at the time point of submission. Consequently, it includes considerations for all those crops for which an EU MRL is established. It is not limited to the intended uses in potatoes, cereals and maize.

Table 6.7.1-1: Residue definition - pyraclostrobin

** synonym: 500M85

For deriving appropriate residue definitions for monitoring and risk assessment purposes the principles described in the following document were considered:

- OECD GUIDANCE DOCUMENT ON THE DEFINITION OF RESIDUE (as revised in 2009), SERIES ON TESTING AND ASSESSMENT No. 63 and SERIES ON PESTICIDES No. 31 (ENV/JM/MONO(2009)30)
- EFSA Scientific Opinion on Evaluation of the Toxicological Relevance of Pesticide Metabolites for Dietary Risk Assessment, EFSA Journal 2012;10(07): 2799

The first document covers both aspects whereas the purpose of the PPR Scientific Opinion is limited to the residue definition for risk assessment purposes. The corresponding EU guidance document is in preparation and will be available earliest by end of 2015.

Plant Matrices

For deriving a suitable residue definition for food of plant origin, the following studies were considered:

- Crop metabolism studies
- Confined rotational crop studies
- Hydrolysis studies at exaggerated temperatures simulating processing

For pyraclostrobin, plant metabolism studies have been performed in fruits, root & tuber vegetables, leafy vegetables and cereals (wheat, paddy rice) covering both, foliar and seed treatment applications. During these investigations, samples/matrices were analyzed which serve either as animal feed or human food. Two confined rotational crop studies were additionally conducted; after application of pyraclostrobin to bare soil, representative crops (typically small grain, leafy crops and root vegetables) were investigated at different replant intervals (emergency plant back, fall plant back, annual plant back).

In general, pyraclostrobin follows a common pathway in all crops and independent from the type of application. The following metabolic conversion steps were observed in the plant metabolism and succeeding crop studies:

- Desmethoxylation of the side chain resulting in the metabolite 500M07
- Cleavage between the ring systems resulting in the metabolites 500M04 (followed by conjugation reactions)
- Cleavage between the ring systems resulting in the metabolites 500M24 and 500M72 (tryptophan)
- Hydroxylation of the chlorophenyl pyrazole moiety (followed by conjugation)
- Hydroxylation of the tolyl moiety (followed by conjugation)
- Photolytic rearrangement reaction resulting in the metabolite 500M76.

In almost all samples investigated from metabolism studies, the parent molecule forms by far the predominant residue followed by the metabolite 500M07. All other metabolites are present in significantly lower amounts, but also not consistently in all crops or commodities.

As non- systemic fungicide pyraclostrobin, but also its degradation products formed during soil metabolism (500M01, 500M02) are not taken up by plants. Even at exaggerated rates, the succeeding crop study did not indicate any likelihood for the presence of detectable residues.

To simulate processing, hydrolysis studies were performed at exaggerated temperatures. Radiolabelled test items of pyraclostrobin were incubated under the conditions considered as representative for boiling, baking, brewing, sterilization and pasteurization. Pyraclostrobin was found to be stable under all test conditions applied. At higher temperatures (up to 240°C), which might only occur during one step of oil processing (deodorization step), degradation to the metabolites 500M07 and the subsequent cleavage products 500M04 / 500M49 (anthranilic acid derivative) was observed.

Residue definition for monitoring purposes

According to the OECD Guidance Document, the residue definition for tolerance/MRL enforcement purposes should focus on those analytes which would indicate a possible misuse of the pesticide and which can be easily detected /measured by a broad base of national laboratories (use of a multi-residue method). The analyte(s) to be selected for monitoring purposes should occur in large quantities, and should be common to all commodities in which residues are expected. Ideally, a monitoring method should be based on one single analyte (‘marker or indicator compound’).

In case of pyraclostrobin and its metabolites in food of plant origin, there is only one component which meets all criteria listed in the OECD guidance document. Based on the studies available, the following residue definition is proposed for monitoring purposes in plant commodities (including process fractions thereof):

Pyraclostrobin, parent only

Residue definition for data generation / risk assessment purposes

The derivation of a suitable residue definition for risk assessment purposes is much more complex; according to the OECD guidance document the contribution of each metabolite/ degradates to a potential dietary risk need to be considered.

In general, two factors must be addressed:

- **Potential for exposure** to the metabolite/degradate in the human diet;
- **Relative toxicity** of the metabolite/degradate to the parent.

Metabolites / degradates with higher potential exposures and toxicities are more likely to be included in the dietary assessment. The OECD guidance document provides a first hint how an indicative risk assessment can be performed if metabolites are not readily available as reference substances. For such cases, the document recommends to calculate ratios from the metabolism studies and to apply these ratios in a second step to the residue level being measured during e.g. supervised field trials. The approach is described much more in detail in the EFSA Scientific Opinion 2799 (2012) which also includes the concept of the threshold of toxicological concern (TTC) as screening tool for pesticide metabolites. Main "purpose" of the TTC concept is to check whether there is negligible exposure.

In order to propose a suitable residue definition for risk assessment purposes, the pyraclostrobin metabolites found in plant metabolism studies and during processing were grouped in total into six different groups.

- Group 1: Desmethoxy metabolite 500M07 (synonym: BF 500-3)
- Group 2: Chlorphenyl pyrazole derivatives
- Group 3: Anthranilic acid derivatives 500M24 and 500M49
- Group 4: Hydroxylated metabolites (chlorphenyl pyrazole moiety)
- Group 5: Hydroxylated metabolites (tolyl moiety)
- Group 6: Photo metabolite 500M76

The dietary exposure for each group was assessed separately for identifying the contributions of the plant metabolites to the total dietary risk. Due to obvious reasons no assessment has been performed for the metabolite 500M72 which has been identified as the natural amino acid tryptophan. Due to their absence in succeeding and root crops even at exaggerated rates, the same applies for the aerobic soil metabolites 500M01 and 500M02. The assessments were limited to those target crops from which a contribution to the dietary risk could be expected.

For deriving residue levels to be used in chronic and acute exposure assessments, the following studies were additionally considered:

- Magnitude of residue studies in target crops (supervised field trials)
- Magnitude of residues in processed commodities

In case of group 1 and 2, residue data from supervised field trials are available, whereas for other groups the assessments are based on metabolite / parent ratios. The relevant chronic and acute exposure assessments for plant commodities are summarized more in detail in section 6.9. For groups 1, 4 and 5 the exposure was assessed against the endpoints of the parent molecule as the metabolites were found in significant amounts in the rat metabolism study (see M-CA 5.1). For group 2, several toxicological studies have been performed with the metabolite 500M04. For groups 3 and 6, the assessment is based on acute and chronic Cramer class III endpoints after proving the absence of genotoxicity (see M-CA 5.8). The individual contributions of the metabolites to the dietary risk are summarized in the table below.

Table 6.7.1-2: Contribution of pyraclostrobin plant metabolites to chronic dietary risk

Metabolite group / Metabolites	ADI used [mg/kg bw / day]	ADI utilization [%]	Comment
1 - 500M07	0.03	< 2%	Indicative assessment covering all target crops (worst case)
2 - 500M04 and conjugated	0.52	< 0.1%	
3 - 500M24	0.0015 (TTC)	< 9%	Cereal grain
3 - 500M49	0.0015 (TTC)	0.1%	Oilseeds
3 - 500M51	0.0015 (TTC)	n.a.	Metabolite only found in livestock metabolism studies
4 - Hydroxylated metabolites (chlorphenyl pyrazole moiety)	0.03	0.6%	
5 - Hydroxylated metabolites (tolyl moiety)	0.03	0.6%	
6 - 500M76	0.0015 (TTC)	0.2%	

Table 6.7.1-3: Contribution of pyraclostrobin plant metabolites to acute dietary risk

Metabolite group / Metabolites	ARfD used [mg/kg bw / day]	ARfD utilization [%]	Comment
1 - 500M07	0.03	Max. 30% (celery, onions)	Refined for table grapes, apples and scarole
2 - 500M04 and conjugated	n.a.	n.a.	
3 - 500M24	0.005 (TTC)	Not relevant	Metabolite only found in wheat metabolism study (grain)
3 - 500M49	0.005 (TTC)	0%	
3 - 500M51	0.005 (TTC)	n.a.	Metabolite only found in livestock metabolism studies
4 - Hydroxylated metabolites (chlorphenyl pyrazole moiety)	0.03	8% (melons) 7% (water melons) 5% (table grapes)	Refined for table grapes, apples and scarole
5 - Hydroxylated metabolites (tolyl moiety)	0.03	11% kale 8% (melons) 7% (water melons)	Refined for table grapes, apples and scarole
6 - 500M76	0.005 (TTC)	15% (kale) 9% (globe artichokes) 8% (Chinese cabbage)	Refined for scarole

The data show that the contributions of the metabolites to the dietary risk are small even under unrealistic worst case assumptions. None of the groups should be included in the residue definition for dietary risk assessment. Due to the favorable outcome, no further refinement than indicated above was performed (e.g. by inclusion of processing factors for vegetable crops which are always cooked prior to consumption).

Following an indicative assessment based on an in-depth analysis of all metabolism, residue and processing fraction studies, the residue definition shown below is proposed for risk assessment in plant commodities (including process fractions thereof):

Pyraclostrobin, parent only

Animal matrices

For deriving a suitable residue definition for food of animal origin, the following studies were considered:

- Metabolism study in hens
- Metabolism study in goats (ruminants)
- Metabolism studies in fish (dietary)

For pyraclostrobin, all relevant studies are available.

In general, pyraclostrobin follows a common pathway in different livestock species, which is also comparable to the one observed in rats. As in plant matrices, the following metabolic conversion steps were observed in the relevant studies:

- Desmethoxylation of the side chain resulting in the metabolite 500M07
- Cleavage between the ring systems resulting in the metabolites 500M04, 500M05 and 500M85
- Cleavage between the ring systems resulting in the metabolites 500M49 and 500M51
- Hydroxylation of the chlorophenyl pyrazole moiety (followed by conjugation)
- Hydroxylation of the tolyl moiety (followed by conjugation)

Besides these steps, in fish the metabolite 500M89 was identified in very low amounts; it is formed by desmethylation.

In the majority of samples investigated (poultry fat / eggs, goat milk / meat / fat), the parent molecule forms a predominant part of the residue followed by the metabolite 500M07. In milk, the cleavage products 500M04 / 500M05 are in equal amounts present than parent. Especially in goat liver, but also kidney, relatively high amounts of radioactivity were incorporated into tissues which could be at least partly released by enzymatic techniques. After applying harsh conditions (refluxing with hydrochloric acid), the metabolites 500M04 and 500M85 were detected in the hydrolyzate.
All other metabolites are present in significantly lower amounts, but also not consistently in all livestock commodities.

Residue definition for monitoring purposes

For the residue definition in animal commodities the same criteria apply as for plants. The analyte(s) to be selected for monitoring purposes should occur in large quantities, and should be common to all commodities in which residues are expected. Ideally, the monitoring method should be based on one single analyte (‘marker or indicator compound’).

In case of pyraclostrobin and its metabolites in food of animal origin, there is only one component which meets most of the criteria listed in the OECD guidance document. Based on the studies available where unchanged pyraclostrobin formed a considerable part of the residue in food items being highly consumed (milk for small children, meat / fat for all subpopulation groups), the following residue definition is proposed for monitoring purposes in animal commodities:

Pyraclostrobin, parent only

Residue definition for data generation / risk assessment purposes

As in plants, the derivation of a suitable residue definition for risk assessment purposes is much more complex; according to the OECD guidance document the contribution of each metabolite/ degradates to a potential dietary risk need to be considered.

In order to propose a suitable residue definition for risk assessment purposes, the pyraclostrobin metabolites found in livestock metabolism studies were grouped in total into five different groups. Except group 6 ("photo metabolite"), the grouping followed the same principles as for plants.

- Group 1: Desmethoxy metabolite 500M07 (synonym: BF 500-3)
- Group 2: Chlorphenyl pyrazole derivatives
- Group 3: Anthranilic acid derivatives 500M49 and 500M51
- Group 4: Hydroxylated metabolites (chlorphenyl pyrazole moiety)
- Group 5: Hydroxylated metabolites (tolyl moiety)

The dietary exposure for each group was assessed separately for identifying the contributions of the livestock metabolites to the total dietary risk. For deriving residue levels to be used in chronic and acute exposure assessments, the following studies were additionally considered:

- Magnitude of residue study in cows
- Magnitude of residue study in hens

For deriving the residue levels for risk assessment purposes, the dietary feed burden calculations were fully considered (see M-CA 6.7.2). As the metabolite 500M89 was only found in trace amounts in fish (about 0.01 mg/kg at a 8 x feeding level), no exposure assessment has been carried out.

In case of groups 1 and 2 (plus partly 5), residue data from the livestock feeding studies are available. In the cow feeding study, the samples were analyzed with a "parent method", but also a method including a common moiety approach. The common moiety approach is based on the hydrolytic degradation of pyraclostrobin and its metabolites to 500M04 and 500M85. In poultry, a similar approach was selected; however, it covers a different hydroxylation pattern.

For the other groups the assessments are based on metabolite / parent ratios. The relevant chronic and acute exposure assessments for plant commodities are summarized more in detail in M-CA 6.9. For groups 1, 4 and 5 the exposure was assessed against the endpoints of the parent molecule as the metabolites were found in significant amounts in the rat metabolism study (see M-CA 5.1). For group 2, several toxicological studies have been performed with the metabolite 500M04. For group 3, the assessment is based on acute and chronic Cramer class III endpoints after proving the absence of genotoxicity (see M-CA 5.8). The individual contributions of the metabolites to the dietary risk are summarized in the table below.

Table 6.7.1-4: Contribution of pyraclostrobin livestock metabolites to chronic dietary risk

Metabolite group / Metabolites	ADI used [mg/kg bw / day]	ADI utilization [%]	Comment
1 - 500M07	0.03	< 0.1%	
2 - 500M04 and conjugates	0.52	< 0.1%	
3 - 500M24	0.0015 (TTC)	n.a.	Metabolite only found in wheat metabolism study (grain)
3 - 500M49	0.0015 (TTC)	0%	
3 - 500M51	0.0015 (TTC)	0%	
4 - Hydroxylated metabolites (chlorphenyl pyrazole moiety)	0.03	0.1%	
5 - Hydroxylated metabolites (tolyl moiety)	0.03	< 0.1%	
6 - 500M76	0.0015 (TTC)	n.a.	Metabolite only found in wheat metabolism study (forage)

Table 6.7.1-5: Contribution of pyraclostrobin livestock metabolites to acute dietary risk

Metabolite group / Metabolites	ARfD used [mg/kg bw / day]	ARfD utilization [%]	Comment
1 - 500M07	0.03		
2 - 500M04 and conjugates	n.a.	n.a.	
3 - 500M24	0.005 (TTC)	n.a.	Metabolite only found in wheat metabolism study (grain)
3 - 500M49	0.005 (TTC)	Max. 0.2% (poultry liver)	
3 - 500M51	0.005 (TTC)	Max. 0.2% (bovine kidney)	
4 - Hydroxylated metabolites (chlorphenyl pyrazole moiety)	0.03	< 1% (milk)	
5 - Hydroxylated metabolites (tolyl moiety)	0.03	< 0.5% (milk)	
6 - 500M76	0.005 (TTC)	n.a.	Metabolite only found in wheat metabolism study (forage)

The data demonstrate that the contributions of the individual metabolites to the dietary risk at realistic dose levels are even smaller than for parent.

The proposal below is based on the indicative assessment, but also takes the findings of the cow feeding study into account where residues of 500M04 and 500M85 were found in liver (realistic feed burden), milk and kidney (10 x to 20 x). Accordingly, the following residue definition is proposed for risk assessment in animal commodities:

Pyraclostrobin and its metabolites analysed as the hydroxypyrazoles 500M04 (synonym BF 500-5) and 500M85 (synonym BF 500-8), sum expressed as pyraclostrobin

CA 6.7.2 Proposed maximum residue levels (MRLs) and justification of the acceptability of the levels proposed

The following table shows the current EU MRLs for pyraclostrobin (mg/kg) as of May 7, 2014 (source: DG Sanco website http://ec.europa.eu/sanco_pesticides/public/index.cfm?event =substance.resultat&s=1**)**. * indicates the lower limit of analytical determination and (ft) that a footnote is given at the end of the table.

Footnotes:

Pyraclostrobin (F)
(F) = Fat soluble

0151010 Table grapes
The European Food Safety Authority identified some information on residue trials as unavailable. When re-viewing the MRL, the Commission will take into account the information referred to in the first sentence, if it is submitted by 13 July 2015, or, if that information is not submitted by that date, the lack of it.

0270030 Celery
The European Food Safety Authority identified some information on residue trials as unavailable. When re-viewing the MRL, the Commission will take into account the information referred to in the first sentence, if it is submitted by 13 July 2015, or, if that information is not submitted by that date, the lack of it.

0620000 (ii) Coffee beans
The European Food Safety Authority identified some information on analytical methods as unavailable. When re-viewing the MRL, the Commission will take into account the information referred to in the first sentence, if it is submitted by 13 July 2015, or, if that information is not submitted by that date, the lack of it.

0840040 Horseradish
The applicable maximum residue level for horseradish (Armoracia rusticana) in the spice group (code 0840040) is the one set for horseradish (Armoracia rusticana) in the vegetables category, root and tuber vegetables group (code 0213040) taking into account changes in the levels by processing (drying) according to Art. 20 (1) of Regulation (EC) No 396/2005.

Plant Matrices

For pyraclostrobin MRLs are established in multiple crops. In order to support the renewal of approval for pyraclostrobin, additional residue trials have been performed in the intended uses (potatoes, cereals, maize). In the chapters below, the new data are evaluated using statistical means and compared with the data being included in the most recent EFSA Reasoned Opinions. For the majority of crops, the assessments performed in context of the Reasoned Opinions are covering the new data. In case of cereal feed items and sweet corn, higher residues were detected and considered in the feed burden calculation and the dietary exposure assessment.

Potatoes

In 2003, in total six trials were performed with the formulation BAS 516 00 F. In these trials, an application rate of 20 g as/ha was applied 4 times.

In the growing season 2005, in total ten field trials were performed in Northern Europe (Germany, Belgium, Denmark and Northern France) and Southern Europe (Italy, Spain, Greece and Southern France). The trials were conducted with formulation BAS 536 01 F according to the critical GAP of this formulation (± 25%).

In the growing season 2015, in total four field trials were performed in Southern Europe (Italy, Spain, Greece and Southern France). The trials were conducted with formulation BAS 516 07 F according to the critical GAP of this formulation (± 25%).

For deriving a MRL proposal, the more critical GAP which is applied with BAS 536 01 F was considered.

The following parent compound residues were found in potato tuber samples at a PHI of 7 days (Northern EU) and at a PHI of 3 days (Southern EU):

Northern Europe (n=5): 5x <0.02 mg/kg

Southern Europe (n=5): 5x <0.02 mg/kg

In none of the trials any detectable residue above the limit of quantitation (LOQ) was found. As all residue levels in potato tubers were below the LOQ of 0.02 mg/kg, it is not needed to perform any statistical calculation to derive an MRL.

Based on the findings of the residue trials it is proposed to keep the established EU MRL for potato tubers at the limit of quantitation of the enforcement method which corresponds to 0.02 mg/kg.

Code number 0211000 (potatoes): 0.02 mg/kg (default MRL)

Barley

In the growing seasons 2009 - 2012, in total 28 field trials comprising 36 plots were performed in Northern Europe (Germany, The Netherlands, Denmark, Northern France and The United Kingdom) and Southern Europe (Italy, Spain, Greece and Southern France). The trials were conducted with formulations BAS 500 06 F, BAS 702 01 F and BAS 703 04 F according to the critical GAP of formulation BAS 500 06 F (± 25%).

The following parent compound residues were found in barley grain samples at a PHI of 35 days or later:

Northern Europe (n=18): 0.02, 0.039, 0.043, 0.056, 0.06, 0.065, 0.07 (2x), 0.08, 0.09 (2x), 0.10, 0.11, 0.21, 0.22, 0.25, 0.35, 0.82 mg/kg

Southern Europe (n=18): <0.01 (3x), 0.02 (2x), 0.029, 0.03 (3x), 0.039, 0.06, 0.09, 0.11, 0.13, 0.14, 0.15, 0.27, 0.54 mg/kg

For MRL calculation the current version of the OECD MRL calculator was used. In order to derive the most robust MRL, all trials were considered.

Table 6.7.2-2: MRL calculation for barley grain in the EU for pyraclostrobin based on parent residues (mg/kg)

	Pyraclostrobin [mg/kg]
	North (n=18)
STMR	0.085
HR	0.82
OECD	**0.9**
	South (n=18)
STMR	0.035
HR	0.54
OECD	**0.7**

The data show, that the calculated MRL for pyraclostrobin in barley grain is covered by the current MRL of 1.0 mg/kg. Therefore, BASF proposes to keep the current EU MRL of pyraclostrobin at 1.0 mg/kg for barley grain.

Code number 0500010 (barley): 1.0 mg/kg

Based on the extrapolation rules of the EU guidance document "Guidelines on comparability, extrapolation, group tolerances and data requirements for setting MRLs" (SANCO 7525/VI/95 rev. 9, March 2011), the same MRL should apply for oat grain:

Code number 0500050 (oats): 1.0 mg/kg

Barley straw (feed item)

Despite MRLs are not yet set for animal feed, the residue data summarized in M-CA 6.3 has been used for deriving a *"pseudo MRL"*. The relevant STMR and HR vales can be used for deriving a feed burden and subsequently, a MRL proposal for food of animal origin.

In the growing seasons 2009 - 2012, in total 28 field trials comprising 36 plots were performed in Northern Europe (Germany, The Netherlands, Denmark, Northern France and The United Kingdom) and Southern Europe (Italy, Spain, Greece and Southern France). The trials were conducted with formulations BAS 500 06 F, BAS 702 01 F and BAS 703 04 F according to the critical GAP of formulation BAS 500 06 F (± 25%).

The following parent compound residues were found in barley straw samples at a PHI of 35 days or later:

Northern Europe (n=18): 0.50, 0.93, 1.17, 1.28, 1.4, 1.9, 2.09, 2.1, 2.42, 2.5, 2.61, 2.75, 2.8, 2.9, 3.98, 4.1, 6.3, 8.73 mg/kg

Southern Europe (n=18): <0.01, 0.56, 0.77, 0.79, 0.81, 0.98, 1.04, 1.2, 1.3, 1.94, 2.1, 2.42, 2.87, 3.05, 3.36, 3.53, 3.79, 4.24 mg/kg

For MRL calculation the current version of the OECD MRL calculator was used.

Table 6.7.2-3: MRL calculation for barley straw in the EU for pyraclostrobin based on parent residues (mg/kg)

	Pyraclostrobin [mg/kg]
	North (n=18)
STMR	2.46
HR	8.73
OECD	**15**
	South (n=18)
STMR	1.62
HR	4.24
OECD	**7**

The data show, that the calculated MRL for pyraclostrobin in barley straw is covered by the current *"pseudo MRL"* of 15 mg/kg (see MRL review for pyraclostrobin according to Article 12, EFSA Journal 2011;9(8):2344). Therefore, BASF proposes to keep the current value of pyraclostrobin at 15 mg/kg for barley and oat straw.

The following values were published by EFSA, see EFSA Journal 2011;9(8):2344 (page 37):

Northern EU → STMR = 2.20 mg/kg
HR = 6.0 mg/kg
MRL Proposal = 10 mg/kg

Southern EU → STMR = 3.38 mg/kg
HR = 6.92 mg/kg
MRL Proposal = 15 mg/kg

Sweet corn (extrapolation from maize "cobs without husks")

According to the commodity definition of sweet corn (= cobs without husks) as defined in Regulation (EC) No 396/2005, the relevant residue values from cobs without husks specimens sampled at about BBCH 85 were considered for MRL calculation. Sweet corn is defined as a minor crop (SANCO 7525/VI/95 rev.9) requiring a minimum of 4 trials per residue zone.

In the growing seasons 2012 and 2013, six trials were performed in Northern Europe (Germany, The Netherlands, The United Kingdom, Northern France and Belgium) and four were performed in Southern Europe (Italy, Spain, Greece and Southern France). The following parent compound residues were found in the maize cobs without husks samples collected at about BBCH 85:

Northern Europe (n=6): <0.01 (3x), 0.011, 0.015, 0.039 mg/kg

Southern Europe (n=4): <0.01 (4x) mg/kg

For MRL calculation the current version of the OECD MRL calculator was used.

Table 6.7.2-4: MRL calculation for sweet corn in the EU for pyraclostrobin based on parent residues (mg/kg)

	Pyraclostrobin [mg/kg]
	North (n=6)
STMR	0.011
HR	0.039
OECD	**0.07 ***
	South (n=4)
STMR	0.01 (all residue values <0.01 mg/kg)
HR	0.01 (all residue values <0.01 mg/kg)
OECD	**0.01 (all residue values <0.01 mg/kg)**

* High uncertainty of MRL estimate due to small dataset

The data show, that the calculated MRL for pyraclostrobin in sweet corn after application of formulation BAS 500 06 F is not covered by the current MRL of 0.02 mg/kg (default MRL). Therefore, BASF proposes to establish an EU MRL of pyraclostrobin at 0.07 mg/kg for sweet corn.

Code number 0234000 (sweet corn): 0.07 mg/kg

Maize

In the period from 2008 to 2009, in total 16 residue trials were performed in maize in the EU; 8 trials were located in the Northern Region and 8 in the Southern Region. The formulations BAS 512 04 F (133 g/L pyraclostrobin and 50 g/L epoxiconazole, SE) and BAS 500 06 F (200 g/L of pyraclostrobin, EC) were applied once at a rate of 1.5 L/ha and 1 L/ha, respectively according to GAP ±25%. Maize grain was collected at crop maturity (BBCH 89) corresponding to 49 - 99 DALA.

Additionally, in the growing seasons 2012 and 2013, five trials were performed in Northern Europe (Germany, The Netherlands, The United Kingdom, Northern France and Belgium) and four were performed in Southern Europe (Italy, Spain, Greece and Southern France). In these trials, formulation BAS 500 06 F was applied according to the critical GAP. Maize grain was collected at crop maturity (BBCH 89) corresponding to 34 - 85 DALA.

The trials fulfill the requirements concerning the geographical and the seasonal distribution. The evaluation of the residue data led to the conclusion that there is no significant difference of the residue behavior regarding different seasons, formulations or regions in the North and South EU.

In none of the trials any detectable residue above the limit of quantitation (LOQ) was found.
As all residue levels in maize grain were below the LOQ of 0.01 mg/kg, it is not needed to perform any statistical calculation to derive an MRL.

Based on the findings of the residue trials it is proposed to keep the MRL for maize grain at the limit of quantitation of the enforcement method which corresponds to 0.02 mg/kg. This MRL is also covering potential imports of maize grain from the NAFTA region.

Code number 0500030: 0.02 mg/kg (default MRL)

Maize (feed item)

Despite MRLs are not yet set for animal feed, the residue data summarized in M-CA 6.3 has been used for deriving a *"pseudo MRL"*. The relevant STMR and HR vales can be used for deriving a feed burden and subsequently, a MRL proposal for food of animal origin.

In the period from 2008 to 2009, in total 16 residue trials were performed in maize in the EU; 8 trials were located in the Northern Region and 8 in the Southern Region. The formulations BAS 512 04 F (133 g/L pyraclostrobin and 50 g/L epoxiconazole, SE) and BAS 500 06 F (200 g/L of pyraclostrobin, EC) were applied once at a rate of 1.5 L/ha and 1 L/ha, respectively according to GAP ±25%. Rest of plant without roots were sampled at 7 - 28 DALA at BBCH 71 - 73, at 16 - 42 DALA at BBCH 75 - 79 and at 30 - 70 DALA at BBCH 85.

Additionally, in the growing seasons 2012 and 2013, five trials were performed in Northern Europe (Germany, The Netherlands, The United Kingdom, Northern France and Belgium) and four were performed in Southern Europe (Italy, Spain, Greece and Southern France). In these trials, formulation BAS 500 06 F was applied according to the critical GAP. Rest of plant without roots were sampled at 15 - 36 DALA at BBCH 75 and at 26 - 56 DALA at BBCH 85.

For the calculation, the highest residues of each trial from all sampling stages except of the 0 DALA sample were used. This approach can be considered as worst case assumption covering also drying effects which might occur during ripening of the crop. The following pyraclostrobin parent residues were used for calculation purposes:

Northern Europe (n=15): 0.11, 0.21, 0.22, 0.25 (2x), 0.28, 0.30, 0.33, 0.36, 0.42, 0.43, 0.44, 0.66, 0.71, 0.84 mg/kg

Southern Europe (n=14): 0.15, 0.18, 0.21 (2x), 0.26, 0.27, 0.29, 0.34, 0.50, 0.57, 0.60, 0.74, 0.76, 0.89 mg/kg

For MRL calculation the current OECD calculator was used.

Table 6.7.2-5: MRL calculation for maize - feed items in the EU for pyraclostrobin based on parent residues (mg/kg)

	Pyraclostrobin [mg/kg]
	North (n=15)
STMR	0.33
HR	0.84
OECD	**1.5**
	South (n=14)
STMR	0.315
HR	0.89
OECD	**1.5**

As a conclusion it is proposed to keep the established pseudo MRL for pyraclostrobin of 1.5 mg/kg in maize feed items (silage), see EFSA Journal 2012;10(3):2606. The residue situation is very comparable in the Northern and in the Southern EU.

The following values were published by EFSA, see EFSA Journal 2012;10(3):2606 (page 11 and 12):

Northern EU → STMR = 0.29 mg/kg
HR = 0.84 mg/kg
MRL Proposal = 1.5 mg/kg

Southern EU → STMR = 0.32 mg/kg
HR = 0.89 mg/kg
MRL Proposal = 1.5 mg/kg

Wheat

In the growing seasons 2010 - 2012, in total 24 field trials comprising 28 plots were performed in Northern Europe (Germany, The Netherlands, Denmark, Northern France and The United Kingdom) and Southern Europe (Italy, Spain, Greece and Southern France). The trials were conducted with formulations BAS 500 06 F and BAS 703 04 F according to the critical GAP of formulation BAS 500 06 F (± 25%).

The following parent compound residues were found in wheat grain samples at a PHI of 35 days or later:

Northern Europe (n=14): <0.01 (7x), 0.016, 0.02 (3x), 0.03, 0.039, 0.14 mg/kg

Southern Europe (n=14): <0.01 (7x), 0.01 (2x), 0.011, 0.015, 0.017, 0.02 (2x) mg/kg

For MRL calculation the current version of the OECD MRL calculator was used.

Table 6.7.2-6: MRL calculation for wheat grain in the EU for pyraclostrobin based on parent residues (mg/kg)

	Pyraclostrobin [mg/kg]
	North (n=14)
STMR	0.013
HR	0.14
OECD	**0.2**
	South (n=14)
STMR	0.01
HR	0.02
OECD	**0.03**

The data show, that the calculated MRL for pyraclostrobin in wheat grain is covered by the current MRL of 0.2 mg/kg. Therefore, BASF proposes to keep the current EU MRL of pyraclostrobin at 0.2 mg/kg for wheat grain which covers triticale as well.

Code number 0500090 (wheat): 0.2 mg/kg

Based on the extrapolation rules of the EU guidance document "Guidelines on comparability, extrapolation, group tolerances and data requirements for setting MRLs" (SANCO 7525/VI/95 rev. 9, March 2011), the same MRL should apply for rye grain:

Code number 0500070 (rye): 0.2 mg/kg

Wheat straw (feed item)

Despite MRLs are not yet set for animal feed, the residue data summarized in M-CA 6.3 has been used for deriving a *"pseudo MRL"*. The relevant STMR and HR vales can be used for deriving a feed burden and subsequently, a MRL proposal for food of animal origin.

In the growing seasons 2010 - 2012, in total 24 field trials comprising 28 plots were performed in Northern Europe (Germany, The Netherlands, Denmark, Northern France and The United Kingdom) and Southern Europe (Italy, Spain, Greece and Southern France). The trials were conducted with formulations BAS 500 06 F and BAS 703 04 F according to the critical GAP of formulation BAS 500 06 F (± 25%).

The following parent compound residues were found in wheat straw samples at a PHI of 35 days or later:

Northern Europe (n=14): 0.30, 0.37, 0.41, 0.51, 1.1, 1.3 (2x), 1.74, 1.9, 1.98, 3.01, 5.43, 5.5, 5.76 mg/kg

Southern Europe (n=14): 0.45, 0.46, 0.85, 0.95 (2x), 1.5, 1.55, 1.6, 2.26, 4.08, 4.17, 4.18, 4.40, 6.96 mg/kg

For MRL calculation the current version of the OECD MRL calculator was used.

Table 6.7.2-7: MRL calculation for wheat straw in the EU for pyraclostrobin based on parent residues (mg/kg)

	Pyraclostrobin [mg/kg]
	North (n=14)
STMR	1.52
HR	5.76
OECD	**10**
	South (n=14)
STMR	1.575
HR	6.96
OECD	**10**

The data show, that the calculated MRL for pyraclostrobin in wheat straw is covered by the current *"pseudo MRL"* of 10 mg/kg (see MRL review for pyraclostrobin according to Article 12, EFSA Journal 2011;9(8):2344). Therefore, BASF proposes to keep the current value of pyraclostrobin at 10 mg/kg for wheat and rye straw.

The following values were published by EFSA, see EFSA Journal 2011;9(8):2344 (page 38):

Northern EU → STMR = 1.65 mg/kg
HR = 3.14 mg/kg
Proposal = 5 mg/kg

Southern EU → STMR = 1.85 mg/kg
HR = 5.68 mg/kg
Proposal = 10 mg/kg

Animal matrices

A worst case diet was derived for different livestock species according to the table in Appendix G (Lundehn document 7031/VI/95 rev.4. July 1996). It is assumed that from each group of crops/commodities the item with the highest potential residue contribution on a dry matter basis is chosen. Then, the total diet is composed beginning with the group representing the highest contribution and filling the rest with feed from the other groups in descending order.
The evaluation is based on the following formula:

$$\text{Uptake [mg/kg bw/day]} = \frac{\text{Total intake of dry matter [kg/animal/day]} \times \text{\% of diet} \times \text{Residue in feed item [mg/kg]}}{\text{Dry matter content of feed item [\%]} \times \text{Bodyweight [kg]}}$$

In 2011, the most recent calculation of the overall feed burden has been performed by EFSA in context of the MRL re-evaluation according to EEC 396/2005, § 12. This calculation was used as basis, since it already includes maize grain (based on a NAFTA import tolerance). The contribution of "maize - silage" was additionally considered. For estimating the feed burden, the procedure of EFSA (Profile file) has been applied.

Since then, additional uses of pyraclostrobin containing products with new STMR and HR values were published and accepted by EFSA, e.g. for the use in kale (EFSA Journal 2012;10(3):2606).

The following input values were used for calculation of median and maximum dietary burden:

Table 6.7.2-8: Input values for the revised dietary burden calculation (EU methodology)

Commodity	Median dietary burden		Maximum dietary burden	
	Input value (mg/kg)	Comment	Input value (mg/kg)	Comment
Cabbage [1]	0.02	STMR	0.09	HR

[5] derived in the context of this dossier

The following tables show the calculation of the maximum dietary burden for each relevant livestock species, which are based on the highest and the median residue levels of pyraclostrobin. It should be noted that the doses assume that the diet completely consists of plant material which had been treated with pyraclostrobin. Furthermore, some default processing factors have been included in the calculation. As shown in M-CA 6.5.3, the factor of 8 for bran is extremely conservative. From the trials performed, a PF of 2.7 has been derived.

In addition to the feed burden calculation for those livestock species for which MRLs are already established, the potential feed burden has been also derived for fish (trout, carp). For calculation purposes, the procedure specified in the EU Working Document SANCO/11187/2013 on the nature of pesticide residues in fish (as of 31 January 2013) has been used.

According to the Working Document, fish diet of trout and carp mainly consists of cereals, pulses, oilseeds and processed fractions thereof. Due to the broad use of pyraclostrobin, the contribution of fish meal was not further considered:

The calculation resulted in the following approximate maximum feed burdens:

- Trout: 0.6 mg/kg feed DM
- Carp: 1.3 mg/kg feed DM

Proposed animal MRLs

The doses to be used when estimating the maximum residues in products of animal origin are for

dairy cattle 0.146 mg/kg bw/d
beef cattle 0.296 mg/kg bw/d
chicken 0.041 mg/kg bw/d
pig 0.047 mg/kg bw/d

Cattle (sheep, goat) products

A residue transfer study with pyraclostrobin was conducted in cows. The animals were dosed with 7, 21 and 70 mg/kg feed (dry matter) equal to 140, 420 and 1400 mg/animal and day for a period of 28 days. In the dose group relevant under normal agricultural conditions (7 mg/kg feed), no residues could be detected in milk, meat, fat, kidney and tissues. Low residues of pyraclostrobin metabolites may occur in liver. The revised feed burden calculation presented above indicates that the 1 x dose level is the most appropriate for covering the uses of pyraclostrobin.

In the cow feeding study samples were analysed according to both residue definitions. The analysis according to the residue definition for MRL setting (parent only) resulted in residues below the LOQ of the relevant method (corresponding to 0.01 mg/kg for milk and 0.05 mg/kg for tissues).

Consequently, the current EU MRLs for milk and tissues are re-confirmed.
The analysis of the samples according to the definition of the relevant residue for risk assessment purposes (common moiety method) resulted in residues below 0.1 mg/kg, except for liver where 0.2 mg/kg were found.

Pig products

No separate feeding study with pigs has been performed since common metabolic pathways have been observed in rats and goats and therefore significant differences in the metabolic pathways from pigs as compared to ruminants are very unlikely. The proposals for maximum residue levels for pig products can therefore be derived from the cattle feeding study. The 1 x dose level of the cow feeding study was considered despite the dose level corresponds to 5 x of the pig feed burden. The samples were analysed according to both residue definitions. The residue levels found at the 1 x dose level were all below the LOQ of the monitoring method (0.05 mg/kg). The analytical method following the common moiety concept (corresponding to: definition of the relevant residue for risk assessment) indicates the presence of pyraclostrobin metabolites only in liver at a level of 0.2 mg/kg. All other matrices were below 0.1 mg/kg.

Poultry products

Based on the results of the hen metabolism study and the revised feed burden calculation indicating a very low feed burden with highest contribution of barley, no feeding study in hen would be required. The poultry feeding study which was performed for US submission is provided as supplemental information within this dossier. It confirms the favourable residue behaviour in poultry matrices. The MRLs in poultry tissues and eggs, which are established at the limit of quantitation of the enforcement method (corresponding to 0.05 mg/kg) are re-confirmed.

Fish products

The actual feed burden is compared with the feeding levels and the results of the fish metabolism study in which parent was identified as main residue (see M-CA 6.2). As worst case the feed burden of carp was taken into account. Based on the overdosing factor and the pyraclostrobin levels measured, a preliminary proposal for a future EU MRL for fish can be derived.

Table 6.7.2-28: Expected residue levels of pyraclostrobin in fish matrices

Matrix analyzed	Total radioactive residue [mg/kg]*	Pyraclo strobin [mg/kg]	Feed burden fish metabolism study [mg/kg feed DM]	Feed burden calculated [mg/kg feed DM]	Overdosing factor fish metabolism	Pyraclo strobin calculated [mg/kg]
Fish filet	0.282	0.262	11	1.3	8.5	0.03
Fish skin	0.232	0.21	11	1.3	8.5	0.02
Fish liver	0.556	0.409	11	1.3	8.5	0.05

* highest value from both labels

For further evaluation the following EU MRLs were used:

0.05 mg/kg for all animal matrices (including fish, except milk)
0.01 mg/kg for milk

CA 6.7.3 Proposed maximum residue levels (MRLs) and justification of the acceptability of the levels proposed for imported products (import tolerance)

The MRLs listed in M-CA 6.7.2 include domestic uses, but also values for imported crops. Prior to final approval, the import tolerances have been carefully evaluated by Germany (RMS) and EFSA. Parts of them are resulting from the adoption of CODEX MRLs. In the meantime, pyraclostrobin and its crops have been assessed three times by JMPR.

CA 6.8 Proposed safety intervals

Residue trials have been conducted with applications made at the latest recommended crop growth stage with harvest taking place at the time of crop maturity following good agricultural practice.

Pre-harvest interval
For potatoes the application is intended at growth stages BBCH 41-89 with a pre-harvest interval of 0-3 days. For cereals (wheat, barley, oats, rye and triticale) application is intended at growth stages BBCH 25-69 (corresponding to an approximate minimum period of 35 to 42 days until harvest). For maize incl. sweet corn, latest application is at growth stage BBCH 65. Except for potatoes, the preharvest interval is fixed by the intended use (growth stage at last application ("F")).

Re-entry period for livestock to areas to be grazed
Because pyraclostrobin is not intended to be used in areas to be grazed, no re-entry period for livestock has to be defined.

Re-entry period for man to treated crops
Re-entry assessments are given for the representative uses in the supplemental product dossiers (M-CP 7.2). Re-entry is possible after the spray deposits on the crops have dried given the worker is wearing adequate work clothing.

Withholding period for animal feed stuffs
Treated cereals and maize feed items may be used as fodder for livestock and fish. Pyraclostrobin derived residues in those feed items are assessed in M-CA 6.7 by providing updated calculations of livestock and fish dietary burdens and deriving suitable MRLs for animal products covering the intended uses. There is no additional withholding period needed for animal feeds with regard to pyraclostrobin derived residues.
Due to the favorable residue situation in potatoes with residues consistently below LOQ no withholding period is needed.

Waiting period between application and crop sowing or planting the crop to be protected
No waiting period is necessary since pyraclostrobin is not intended in a pre-emergence use.

Waiting period between application and handling treated produce
This is not relevant here since a post-harvest treatment is not intended for potatoes, cereals and maize incl. sweet corn.

Waiting period between last application and sowing or planting succeeding crops
Due to the favorable residue behavior at all replant intervals investigated, no replant restrictions are needed. Even at exaggerated rates, the residue levels of pyraclostrobin and its metabolites are very low (see M-CA 6.6). No detectable residues above the MRLs can be expected when crops are sown or planted after a previous pyraclostrobin application.

CA 6.9 Estimation of the potential and actual exposure through diet and other sources

Assessments of the potential chronic and acute dietary consumer risk due to exposure to residues of pyraclostrobin were performed using the EFSA model for chronic and acute risk assessment - rev. 2_0 (Model PRIMo). The EFSA model was used since it considers all the different diets in the EU and all consumer groups. In order to check the contribution of fish to the diet, an assessment according to the most recent version of the German model is also included.

The ADI and ARfD for the active substance pyraclostrobin are summarized in the table below. Due to their presence in significant amounts in the rat metabolism study, the same toxicological endpoints are also applying to the metabolites 500M07 (BF 500-3) and the metabolites resulting from simple ring hydroxylation reactions (plants: 500M34, 500M54, 500M56, 500M68, 500M70, 500M71; livestock: 500M08, 500M32, 500M39, 500M45, 500M64, 500M66, 500M67). The use of the same ADI value is further corroborated by investigations performed by the Austrian authority AGES (T. Coja et al., presented e.g. at the 10th International Fresenius Conference held in Mainz in February 2012).

Table 6.9-1: Toxicological endpoints - pyraclostrobin

Endpoint	Value	Study	Safety factor	Reference
Acceptable Daily Intake (ADI)	0.03 mg/kg bw/d	2-year study, rat	100	SANCO/1420/2001-Final (08.09.2004)
Acute Reference Dose (ARfD)	0.03 mg/kg bw/d	developmental toxicity, rabbit (maternal effects)	100	SANCO/1420/2001-Final (08.09.2004)

The ADI and ARfD for the metabolite 500M04 (synonym: BF 500-5) are summarized in the table below.

Table 6.9-2: Toxicological endpoints – 500M04

Endpoint	Value	Study	Safety factor	Reference
Acceptable Daily Intake (ADI)	0.52 mg/kg bw/d	90 day study, rat	200	M-CA 5.8
Acute Reference Dose (ARfD)	none	n.a.	n.a.	M-CA 5.8

The ADI and ARfD for the metabolites 500M24, 500M49, 500M51 and 500M76 are summarized in the table below. For the metabolites, genotoxicity tests have been performed. They are summarized in M-CA 5.8. As none of them showed any genotoxicity potential, TTC values (Cramer class III) can be used for an indicative dietary exposure assessment.

Table 6.9-3: Toxicological endpoints – TTC approach

Endpoint	Value	Study	Safety factor	Reference
Acceptable Daily Intake (ADI)	0.0015 mg/kg bw/d	none	not relevant	TTC
Acute Reference Dose (ARfD)	0.005 mg/kg bw/d	none	not relevant	TTC

For pyraclostrobin, an *in-vitro* comparison study was performed in human, rat, rabbit and dog hepatocytes / microsomes (see M-CA 5.1). Based on the study results, it cannot be excluded that the metabolites 500M02, 500M106 and 500M107 (glucuronic acid conjugate of 500M106) might be also formed in humans under *in-vivo* conditions. These metabolites were identified in rabbit cell cultures, but not detected in significant amounts in rat. For the metabolite 500M106 a 28-day rat study (see M-CA 5.8) was performed which also covers metabolites 500M02 and 500M107.

Table 6.9-4: Toxicological endpoints – 500M02 and 500M106 / 500M107

Endpoint	Value	Study	Safety factor	Reference
Acceptable Daily Intake (ADI)	0.5 mg/kg bw/d	28 day study, rat	600	M-CA 5.8
Acute Reference Dose (ARfD)	none	n.a.	n.a.	M-CA 5.8

Acceptable Daily Intake (ADI) and Dietary Exposure Calculation

Pyraclostrobin

TMDI calculation

A revised chronic exposure assessment was performed, for which all crops and maximum residue levels (either the established MRL value, or if different the proposed MRL) used are summarized in Table 6.9-5. * indicates the lower limit of analytical determination.
The re-evaluation of the existing MRLs according to Reg. 396/2005 Art. 12 is complete. Some MRLs were changed as an outcome of this re-evaluation. As a result of EFSA Journal 2013;11(2):3109 (Reasoned opinion on the modification of the existing MRLs for pyraclostrobin in cucumbers and Jerusalem artichokes) - see also EU regulation 51/2014 - and EFSA Journal 2014;12(5):3685 (Reasoned opinion on the modification of the existing MRL for pyraclostrobin in chicory roots), the MRLs for Jerusalem artichokes and chicory roots were changed.
Beyond that, since the beginning of April 2013 there were further changes of MRLs caused by the adoption of CODEX MRLs into EU law (see Reg. No. 293/2013).
The summary of the calculation using the EFSA model rev 2.0 is presented in Table 6.9-5. For the assessment, an ADI of 0.03 mg/kg bw/day was used. According to the EFSA model the TMDI has been simultaneously calculated for adults, children, toddlers and infants (different age groups), vegetarian and elderly in different EU countries.

With the current EFSA model the chronic risk assessment ranges from 10 to 77% of ADI (see Table 6.9-6). The diet with the highest TMDI is "DE child" with 77% of ADI. For this diet, the highest contributors are oranges with 25.4% of ADI. The diet with the second highest TMDI is “NL child” with 60.1% of ADI, in which also oranges are the major contributor with 20.8% of ADI.

According to the presented TMDI calculation a chronic intake of pyraclostrobin residues is unlikely to present a public health concern.

Table 6.9-6: Pyraclostrobin (BAS 500 F): TMDI calculation based on input values listed in Table 6.9-1

Pyraclostrobin			
Status of the active substance:		Code no.	
LOQ (mg/kg bw):	0.02	proposed LOQ:	
Toxicological end points			
ADI (mg/kg bw/day):	0.03	ARfD (mg/kg bw):	0.03
Source of ADI:	04/30/EC	Source of ARfD:	04/30/EC
Year of evaluation:	2004	Year of evaluation:	2004

Prepare workbook for refined calculations

Undo refined calculations

The risk assessment has been performed on the basis of the MRLs collected from Member States in April 2006. For each pesticide/commodity the highest national MRL was identified (proposed temporary MRL = pTMRL).
The pTMRLs have been submitted to EFSA in September 2006.

Chronic risk assessment

TMDI (range) in % of ADI minimum - maximum	
10	77
No of diets exceeding ADI:	—

Conclusion:
The estimated Theoretical Maximum Daily Intakes (TMDI), based on pTMRLs were below the ADI.
A long-term intake of residues of Pyraclostrobin is unlikely to present a public health concern.

NEDI calculation

In order to check the contribution of fish, a dietary exposure assessment was performed using the German consumption data as published in 2012. Besides the child, the revised spreadsheet contains two additional consumer groups (total population: age group 14 – 80 years, females in child bearing age: 14 – 50 years).

Three assessments are performed; in accordance with the EFSA PRIMo model, the % ADI utilizations are based on mean body weights.

- In the first assessment, the same input values as for PRIMo were entered into the calculation.
- In the second assessment, the contribution of fish (at 0.05 mg/kg) was investigated.
- In the third assessment, the overall assessment was performed.

The NEDI calculation showed the low contribution of fish commodities to the chronic dietary risk for pyraclostrobin. The data clearly demonstrates that the presence of pyraclostrobin in fish does not result in any consumer risk. Compared to all other commodities, the contribution of fish to the chronic exposure is even under worst case assumptions rather small.

Table 6.9-7: NEDI calculations using the German model (NVS2_V_0-9_DE1)

Subpopulation group	% ADI utilization based on current MRLs	% ADI utilization fish commodities	% ADI utilization (total)
German child (VELS)	77	0.1	77.1
General population	36.8	0.1	36.9
Women in child bearing age	39.2	0.1	39.3

Metabolites

Metabolites identified in crop and livestock metabolism studies

The main purpose of the information presented below is to support the establishment of a robust residue definition for risk assessment purposes. Therefore, the data being summarized are going far beyond the scope of this dossier which supports the uses in potatoes, cereals and maize. In the assessment the contributions to the chronic dietary risk of all crops that are currently registered in the EU (including import tolerances) were taken into account.

For facilitating the evaluation of the exposure assessment performed, the relevant exposure data for the metabolites are derived in a separate report.

Report:	CA 6.9/1 Bross M., Mackenroth C., 2014a Pyraclostrobin (BAS 500 F): Refinement of the dietary exposure assessment of Pyraclostrobin metabolites in plant and animal commodities 2014/1001541
Guidelines:	<none>
GLP:	no

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1.	**Test Material:**	BAS 500 F (pyraclostrobin, Reg No. 304428)
	Description:	not relevant
	Lot/Batch #:	not relevant
	Purity:	not relevant
	CAS#:	175013-18-0
	Development code:	not applicable
	Spiking levels:	not relevant

3.	**Test Commodity:**	
	Crop:	not relevant
	Type:	not relevant
	Variety:	not relevant
	Botanical name:	not relevant
	Crop parts(s) or processed commodity:	not relevant
	Sample size:	not relevant

B. STUDY DESIGN AND METHODS

In order to assess the contribution of the metabolites to the chronic dietary risk, the metabolites being present in the plant and livestock metabolism studies were grouped into six groups. The grouping was performed based on sub structural elements.

- Group 1: Desmethoxy metabolite 500M07 (synonym: BF 500-3)
- Group 2: Chlorphenyl pyrazole derivatives
- Group 3: Anthranilic acid derivatives
- Group 4: Hydroxylated metabolites (chlorphenyl pyrazole moiety)
- Group 5: Hydroxylated metabolites (tolyl moiety)
- Group 6: Photo metabolite 500M76

Depending on the availability of exposure data, the input data for the exposure assessment are derived differently for the individual groups.

Desmethoxy metabolite 500M07:
The residue levels of the metabolite 500M07 were quantified in the big majority of the samples generated in the course of the supervised field trials and processing studies. Consequently, the actual values measured were taken into account. In case of food of animal origin, the input values were derived from the metabolism studies.

Chlorophenyl pyrazole derivatives (500M04 and conjugates, 500M85):
The residue levels of the metabolite 500M04 and its glycoside were quantified in selected samples from supervised field trials. For the selection of appropriate samples, the metabolism studies had been re-evaluated before. The metabolite 500M04 and its conjugates were mainly found in the green parts (forage or green matter samplings) of the plants. Consequently, the actual values measured were taken into account. In case of food of animal origin, the input values were derived from the metabolism and the feeding studies. The metabolites 500M04 and 500M85 are covered by the common moiety method used during the analysis of the cow feeding study.

Anthranilic acid derivative 500M24:
The metabolite 500M24 was exclusively identified in grain within the wheat metabolism. The exposure estimate for cereal grains (w/o rice) is based on the calculation of the metabolite / parent ratio from the ^{14}C study.

Anthranilic acid derivative 500M49:
The metabolite 500M49 was detected in the hydrolysis study at exaggerated temperatures (simulating oil deodorization) and in the hen metabolism study. As it was not measured in any residue / feeding study, the potential exposure has been estimated based on the ^{14}C studies.

Anthranilic acid derivative 500M51:
The metabolite 500M51 was exclusively found in the goat metabolism study in kidney. For estimating the amounts being present at a realistic feed burden, the mg/kg values which are expressed in parent equivalents were converted into metabolite levels and adjusted by the overdosing factor.

Hydroxylated metabolites (chlorphenyl pyrazole moiety):
Group 4 type metabolites were found in plant and livestock metabolism studies. As they were not measured in any residue / feeding study, the potential exposure has been estimated based on the ^{14}C studies. For avoiding a considerable overestimation of the exposure, the relevant metabolism studies were carefully re-evaluated. Hydroxylated metabolites were found in the grape metabolism study (fruits) and in green matter samples. The exposure estimate is based on the calculation of the metabolite / parent ratios from the ^{14}C studies. The individual values were finally summed up and compared with the parent ADI.

Hydroxylated metabolites (tolyl moiety):
For group 5 type metabolites the same approach was selected as for group 4.

Photo metabolite 500M76:
The metabolite 500M76 was identified in forage and straw samples within the wheat metabolism. The exposure estimate for leafy crops is based on the calculation of the metabolite / parent ratio.

II. RESULTS AND DISCUSSION

Desmethoxy metabolite 500M07:
With the current EFSA model the chronic risk assessment ranges from 0.3 to 1.7% of ADI (see chapter 5.1.1 of DocID 2014/1001541). The diet with the highest TMDI is "WHO Cluster Diet B" with 1.7% of ADI. For this diet, the highest contributor is wheat with 0.6% of ADI. The diet with the second highest TMDI is “DE child” with 1.7% of ADI, in which pome fruits are the major contributor with 0.8% of ADI.

Chlorophenyl pyrazole derivatives (500M04 and conjugates, 500M85):
With the current EFSA model the chronic risk leads to no values above 0.0% of ADI (see chapter 5.1.2 of DocID 2014/1001541).

Anthranilic acid derivative 500M24:
With the current EFSA model the chronic risk assessment ranges from 0 to 8.9% of ADI (see chapter 5.1.3.1 of DocID 2014/1001541). The diet with the highest TMDI is "IE Adult" with 8.9% of ADI. For this diet, the highest contributor is barley with 8.3% of ADI. The diet with the second highest TMDI is “WHO Cluster Diet E” with 6.3% of ADI, in which also barley is the major contributor with 5.4% of ADI.

Anthranilic acid derivative 500M49:
With the current EFSA model the chronic risk assessment ranges from 0.0 to 0.1% of ADI (see chapter 5.1.3.2 of DocID 2014/1001541). The diet with the highest TMDI is "WHO Cluster Diet E" with 0.1% of ADI. For this diet, the highest contributor is rape seed with 0.1% of ADI. The diet with the second highest TMDI is “WHO Cluster Diet B” with 0.1% of ADI, in which sunflower seed is the major contributor with 0.1% of ADI.

Anthranilic acid derivative 500M51:
The estimation of the metabolite in food of animal origin resulted in median residue levels far below 0.001 mg/kg. Due to negligible exposure, no chronic exposure assessment was performed.

Hydroxylated metabolites (chlorphenyl pyrazole moiety):
With the current EFSA model the chronic risk assessment ranges from 0.1 to 0.6% of ADI (see chapter 5.1.4 of DocID 2014/1001541). The diet with the highest TMDI is "DE child" with 0.6% of ADI. For this diet, the highest contributors are pome fruits with 0.3% of ADI. The diet with the second highest TMDI is “NL child” with 0.5% of ADI, in which also pome fruits are the major contributor with 0.2% of ADI.

Hydroxylated metabolites (tolyl moiety):
With the current EFSA model the chronic risk assessment ranges from 0.1 to 0.6% of ADI (see chapter 5.1.5 of DocID 2014/1001541). The diet with the highest TMDI is "DE child" with 0.6% of ADI. For this diet, the highest contributors are pome fruits with 0.3% of ADI. The diet with the second highest TMDI is “WHO Cluster Diet B” with 0.4% of ADI, in which wine grapes are the major contributor with 0.2% of ADI.

Photo metabolite 500M76:
With the current EFSA model the chronic risk assessment ranges from 0 to 0.2% of ADI (see chapter 5.1.6 of DocID 2014/1001541). The diet with the highest TMDI is "WHO Cluster Diet B" with 0.2% of ADI. For this diet, the highest contributor is lettuce with 0.1% of ADI. The diet with the second highest TMDI is “FR toddler” with 0.2% of ADI, in which leek is the major contributor with 0.1% of ADI.

III. CONCLUSION

Pyraclostrobin follows a common pathway in crops and livestock. In general, the following metabolic key steps were found in all commodities investigated.

- Desmethoxylation of the side chain resulting in the metabolite 500M07
- Cleavage between the ring systems resulting in chlorophenyl pyrazole derivatives
- Cleavage between the ring systems resulting in anthranilic acid derivatives
- Hydroxylation of the chlorophenyl pyrazole moiety (followed by conjugation)
- Hydroxylation of the tolyl moiety (followed by conjugation)
- Photolytic rearrangement reaction resulting in the metabolite 500M76.

For performing indicative assessments, the metabolites were grouped according to sub-structures. In a second step, the exposure was estimated based on all available data (combination of metabolism information and data from residue field trials / feeding studies). Subsequently, chronic dietary exposure assessments were performed for identifying the contributions of the metabolites to the total dietary risk. The exposure estimates applying worst case assumptions (for vegetables: no consideration of processing) did not indicate any dietary concern. The calculation of the % ADI utilizations resulted in values far below 100% and – even more important - clearly below the ones of the parent molecule. No significant contribution to the chronic exposure can be expected from any plant or livestock metabolite.

Metabolites identified in the *in-vitro* comparison study

TMDI calculation

Based on the study results of an *in-vitro* comparison study with cell cultures from different species, it cannot be excluded that humans might be exposed to metabolites 500M02, 500M106 and 500M107 (glucuronic acid conjugate of 500M106) after consumption of food containing pyraclostrobin residues. The "disproportionate" metabolites under consideration are not quantitatively formed from parent. In the *in-vitro* study, further metabolites were found. Metabolites as 500M04, 500M73, 500M108, 500M103, 500M104 and 500M88 are common to all test species and do not require any separate assessment.

For the time being no guidance document exists how to perform a dietary risk assessment for such metabolites. However, as metabolite 500M106 (covering 500M02 and 500M107) showed a considerable lower toxicity in the 28-day rat study compared to parent, no separate dietary risk assessment should be needed. The assessment is covered by the chronic exposure estimate provided for the parent molecule.

The following publication was added as supplemental information to this dossier. The metabolic behaviour of pyraclostrobin and the metabolite BF 500-3 (synonym: 500M07) in plants was investigated over 10 days. It shows the metabolization of the parent molecule, the formation of the metabolite BF 500-3 at intermediate sampling periods and its fast degradation. It supports BASF's proposal not to include the metabolite BF 500-3 into the residue definition for MRL setting / risk assessment purposes.

Report:	CA 6.9/2 Xiangwei Y. et al., 2012a Dissipation of Pyraclostrobin and its metabolite BF-500-3 in maize under field conditions 2012/1366722
Guidelines:	none
GLP:	no

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Pyraclostrobin, BF 500-3

Description:	250 g/L, EC formulation, not further specified
Lot/Batch #:	not applicable
Purity:	Pyraclostrobin: 99.6% BF 500-3: 99.7%
CAS#:	Pyraclostrobin: 175013-18-0 BF 500-3: 512165-96-7
Development code:	not applicable
Spiking levels:	0.01-1.0 mg/kg

2. Test Commodity: Cereals

Crop:	Maize
Type:	not relevant
Variety:	not applicable
Botanical name:	*Zea mays L.*
Crop parts(s) or processed commodity:	maize plant and maize grain
Sample size:	not reported

B. STUDY DESIGN AND METHODS

1. Test procedure

Two experiments were conducted in China (Beijing and Shandong) in the year 2010. In the first experiment each treatment consisted of three replicate plots and a control plot. In order to investigate the dissipation of pyraclostrobin in maize plant, a pyraclostrobin containing formulation (250 g/L EC) was sprayed at a dosage of 0.422 kg a.s./ha in the experiment plots when the maize plant was at 8-10 leaf stage (BBCH 18-19).
The terminal residues of pyraclostrobin in maize grain were investigated in a second experiment. The recommended dosage (0.282 kg a.s./ha) was sprayed 3 times in the first treatment and 4 times in the second treatment. Each treatment consisted one plot. There was a 7 days interval between two applications.
Representative samples were collected at random from each plot at different time intervals. To investigate the dissipation of pyraclostrobin, the maize plant samples were collected 2h, 12h, 1, 3, 5, 7 days after spraying. To determine the terminal residue of pyraclostrobin, both maize grain and maize plant samples were collected at the harvest time (7 and 10 days after the last spraying). All samples were homogenized and stored at -20°C prior to analysis.

2. Description of analytical procedures

The specimens were analyzed for residues of pyraclostrobin and its metabolite BF 500-3. Homogenized samples were extracted with acetonitrile. An aliquot of the extract was centrifuged and clean-up was achieved with C_{18}. The determination of the analytes was performed by HPLC-MS/MS. In context of analysis, a Zorbax XDB C18 column was used. Isocratic elution was performed using an eluent system consisting of methanol and water (90:10, v:v).
The method has a limit of quantification (LOQ) of 0.002 mg/kg for both analytes in maize grain. In maize plant the LOQ was 0.02 mg/kg for pyraclostrobin and 0.01 mg/kg for BF 500-3.
The average recoveries of pyraclostrobin and BF 500-3 were found in the range of 83.6 to 104.9% with relative standard deviations (RSDs) of 2.3 to 10.0%. Further details are given in Table 6.9-8.

Table 6.9-8: Summary of recoveries

Matrix	Fortification Level (mg/kg)	Summary Recoveries							
		n	Mean (%)	SD (+/-)	RSD (%)	n	Mean (%)	SD (+/-)	RSD (%)
		Pyraclostrobin				BF 500-3			
Maize plant	0.01-0.02	5	87.3	n r.	10.0	5	90.4	n.r.	2.5
	0.2	5	95.1	n r.	5.7	5	94.8	n.r.	4.3

	0.1	5	99.2	n r.	3.2	5	97.7	n.r.	6.4

n r. not reported

II. RESULTS AND DISCUSSION

The initial concentrations of total pyraclostrobin (sum of parent pyraclostrobin and its desmethoxy metabolite BF 500-3) in maize plant were 6.43 and 6.54 mg/kg in Shandong and Beijing with half-lives of 1.7 days in both plots. The initial concentrations of parent pyraclostrobin in maize plant were 6.32 and 6.42 mg/kg in Shandong and Beijing with half-lives of 1.7 days and 1.6 days, respectively. Concentrations of both, total pyraclostrobin and parent pyraclostrobin, were reduced more than 90% on day 7 in both Shandong and Beijing. The initial residues of metabolite BF 500-3 in maize plant were 0.012 mg/kg in Shandong and 0.11 mg/kg and Beijing. However, the maximum concentrations emerged at day 1 and day 3 in Beijing and Shandong, respectively.
The terminal residues of pyraclostrobin at harvest time in the maize grain samples were below LOQ and no BF 500-3 residues were detected. The terminal residues of pyraclostrobin and BF 500-3 in maize plant were 0.47-4.91 and 0.063-0.73 mg/kg.

III. CONCLUSION

The results showed, that parent pyraclostrobin dissipated rapidly in maize plant, while the metabolite BF 500-3 (synonym: 500M07) increased first and then decreased continuously.
The terminal residues of pyraclostrobin at harvest time in the maize grain samples were below LOQ and no BF 500-3 residues were detected. The terminal residues of pyraclostrobin and BF 500-3 in maize plant were 0.47-4.91 and 0.063-0.73 mg/kg. These results are indicating that the application of pyraclostrobin at the dosage recommended in China is safe.
The terminal residue results indicated that the residue of pyraclostrobin in maize grain was much lower than the MRL set by USA and Canada. This work will give a reference for the establishment of MRLs in China, and also provide guidance for the safe and reasonable use of pyraclostrobin.

Acute Reference Dose (ARfD) and Dietary Exposure Calculation

Pyraclostrobin

For the assessment, an ARfD of 0.03 mg/kg bw/day was used. The calculation was done with the default variability factor. The following MRLs for the representative crops of the active substance pyraclostrobin were considered as reported in Table 6.9-5:

Potatoes: 0.02 mg/kg
Sweet corn: 0.07 mg/kg
Barley: 1.0 mg/kg
Maize: 0.02 mg/kg
Wheat: 0.2 mg/kg

The evaluation resulted in ARfD utilizations well below 100% for all representative crops, see Table 6.9-9.

Furthermore, potatoes and cereal grains are traded as bulk commodity and are always consumed after processing. Both steps result in a significant decrease of the residue levels. No acute risk can be expected from the consumption of potato and cereal processed fractions.

In context of this dossier, MRLs for fish are proposed for the first time. In order to check the contribution of fish to acute exposure, an indicative assessment has been performed. The proposed MRL of 0.05 mg/kg was entered into the German model as it includes the relevant consumption data. The maximum % ARfD utilizations are comparable for all subpopulation groups (child, total population, women in child bearing age); maximums of about 4.5% are reached for shell fish and freshwater fish, respectively.

Table 6.9-9: NESTI calculation of pyraclostrobin (EFSA model rev. 2), based on established EU-MRLs and default variability factors

Acute risk assessment /children						Acute risk assessment / adults / general population					
The acute risk assessment is based on the ARfD.											
For each commodity the calculation is based on the highest reported MS consumption per kg bw and the corresponding unit weight from the MS with the critical consumption. If no data on the unit weight was available from that MS an average European unit weight was used for the ESTI calculation.											
In the **IESTI 1** calculation, the variability factors were 10, 7 or 5 (according to JMPR manual 2002), for lettuce a variability factor of 5 was used. In the **IESTI 2** calculations, the variability factors of 10 and 7 were replaced by 5. For lettuce the calculation was performed with a variabilty factor of 3.											
Threshold MRL is the calculated residue level which would leads to an exposure equivalent to 100 % of the ARfD.											
No of commodities for which ARfD/ADI is exceeded (IESTI 1)		---	**No of commodities for which ARfD/ADI is exceeded (IESTI 2)**		---	**No of commodities for which ARfD/ADI is exceeded (IESTI 1)**		---	**No of commodities for which ARfD/ADI is exceeded (IESTI 2)**		---

Metabolites

Metabolites identified in crop and livestock metabolism studies

The main purpose of the information presented below is to support the establishment of a robust residue definition for risk assessment purposes. Therefore, the data being summarized are going far beyond the scope of this dossier which supports the uses in potatoes, cereals and maize. The safety of pyraclostrobin parent residues in various crops has been already assessed by Germany / EFSA during the establishment of MRLs. In the re-evaluation according to Regulation 396/2005, Art. 12, the previous assessments have been re-confirmed (Review of the existing maximum residue levels (MRLs) for pyraclostrobin according to Article 12 of Regulation (EC) No 396/2005. EFSA Journal 2011;9(8):2344. [92 pp.]doi:10.2903/j.efsa.2011.2344).

In the assessment performed the contribution of the metabolites to the acute dietary risk of all crops being currently registered in Europe (including import tolerances) was taken into account.

In order to assess the contribution of the metabolites to the acute dietary risk, the metabolites being present in the plant and livestock metabolism studies were grouped into six groups. The grouping was performed based on sub structural elements; in general, they are identical for chronic and for acute assessment.

- Group 1: Desmethoxy metabolite 500M07 (synonym: BF 500-3)
- Group 2: Chlorphenyl pyrazole derivatives
- Group 3: Anthranilic acid derivatives
- Group 4: Hydroxylated metabolites (chlorphenyl pyrazole moiety)
- Group 5: Hydroxylated metabolites (tolyl moiety)
- Group 6: Photo metabolite 500M76

In deviation to the chronic assessment, acute assessments are not required for all groups. They are provided for group 1 and selected metabolites from group 3, 4, 5 and 6. The input values to be used have been derived as described above.

The exposure estimates applying worst case assumptions (for vegetables: no consideration of processing) did not indicate any acute dietary concern. The calculation of the % ARfD utilizations resulted in values far below 100% and – even more important clearly below the % ARfD of the parent molecule. No significant contribution to the acute exposure can be expected from any plant or livestock metabolite.

Desmethoxy metabolite 500M07:
For the assessment, an ARfD of 0.03 mg/kg bw/day was used. The calculation was done with the default variability factors, except of pome fruits and table grapes in the IESTI2 calculation, for which a variability factor of 3 was applied (already accepted by EFSA, see EFSA Journal 2011;9(8):2344).
The evaluation resulted in ARfD utilizations well below 100% for all commodities. Highest ARfD utilization was observed for celery (29.1%), followed by onions (18.1%) and cucumbers (17.5%).

Anthranilic acid derivative 500M49:
For the assessment, an ARfD of 0.005 mg/kg bw/day was used. The calculation was done with the default variability factors. As a result, no ARfD utilization above 0.0% was determined.

Anthranilic acid derivative 500M51:
For the assessment, an ARfD of 0.005 mg/kg bw/day was used. The calculation was done with the default variability factors.
The evaluation resulted in ARfD utilizations well below 100% for all commodities. Highest ARfD utilization was observed for bovine kidney (0.2%), followed by swine kidney (0.1%).

Hydroxylated metabolites (chlorphenyl pyrazole moiety):
For the assessment, an ARfD of 0.03 mg/kg bw/day was used. The calculation was done with the default variability factors, except of pome fruits and table grapes in the IESTI2 calculation, for which a variability factor of 3 was applied (already accepted by EFSA, see EFSA Journal 2011;9(8):2344).
The evaluation resulted in ARfD utilizations well below 100% for all commodities. Highest ARfD utilization (IESTI2) was observed for melons (8.1%), followed by watermelons (6.5%) and table grapes (5.2%).

Hydroxylated metabolites (tolyl moiety):
For the assessment, an ARfD of 0.03 mg/kg bw/day was used. The calculation was done with the default variability factors, except of pome fruits and table grapes in the IESTI2 calculation, for which a variability factor of 3 was applied (already accepted by EFSA, see EFSA Journal 2011;9(8):2344).
The evaluation resulted in ARfD utilizations well below 100% for all commodities. Highest ARfD utilization (IESTI2) was observed for melons (8.1%), followed by kale (7.9%) and watermelons (6.5%).

Photo metabolite 500M76:
For the assessment, an ARfD of 0.005 mg/kg bw/day was used. The calculation was done with the default variability factors.
The evaluation resulted in ARfD utilizations well below 100% for all commodities. Highest ARfD utilization (IESTI2) was observed for kale (10.6%), followed by Chinese cabbage (8.2%) and globe artichokes (6.3%).

Metabolites identified in the *in-vitro* comparison study

Based on the study results from an *in-vitro* comparison study with cell cultures from different species, it cannot be excluded that humans might be exposed to the metabolites 500M02, 500M106 and 500M107 (glucuronic acid conjugate of 500M106) after consumption of food containing pyraclostrobin residues. The "disproportionate" metabolites under consideration are not quantitatively formed from parent. In the *in-vitro* study, further metabolites were found. Metabolites as 500M04, 500M73, 500M108, 500M103, 500M104 and 500M88 are common to all test species and do not require any separate assessment.
For the time being, no guidance document exists how to perform a dietary risk assessment for such metabolites. However, as metabolite 500M106 (covering 500M02 and 500M107) showed a considerable lower acute toxicity compared to parent, no separate dietary risk assessment should be needed. The assessment is covered by the exposure estimates provided for the parent molecule.

CA 6.10 Other studies

No other/special studies are deemed necessary. The studies and information provided in the previous sections are considered adequate and sufficient.

CA 6.10.1 Effect on the residue level in pollen and bee products

Residues in honey are expected when plant protection products have been applied according to Good Agricultural Practice (GAP) in the following cases:

- during the blossom stage of the crop or non-target plants that may be affected by the use of the plant protection product, or
- in cases where the active substance of the plant protection product has systemic properties and can be translocated into pollen and/or nectar and application occurs prior to the flowering stage (before BBCH 59) of the target or non-target plant, or
- via honeydew collected on plant-sucking insects.

The representative uses of this dossier are potatoes, cereals and maize incl. sweet corn. Due to the lack of an appropriate accepted guidance document, but also driven by expected low consumer exposure from pyraclostrobin residues via honey, no study has been performed.

Honey is considered as only relevant matrix in context of dietary exposure and of potential MRL setting. The consumer risk in honey resulting from the uses of pyraclostrobin is considered as negligible due to the following reasons.

- Honey is defined as the natural sweet substance produced by *Apis mellifera* bees from the nectar of plants, from secretions of living parts of plants or excretions of plant-sucking insects on the living parts of plants, which bees collect, transform by combining with specific substances on their own, deposit, dehydrate, store and leave in honeycombs to ripen and mature.
- The draft guidance document for MRL setting in honey (SANCO 11105/2009 rev. 01) includes a decision tree which allows to evaluate by when residues in honey could be expected.
- According to the document, as first step the attractiveness of a crop for bees should be assessed. A given crop is more or less attractive to bees according to availability, quantity, quality of pollen and/or nectar (as well as that of honeydew).
- In Appendix III of the document, a table is provided which gives an indication of the possibility of producing honey from available nectar and/or honeydew in crops.
- Neither nectar nor honeydew are present in potatoes or cereals (including corn) No specific MRL is needed for these cases.
- Pyraclostrobin is a non-systemic and low water soluble fungicide. These properties have been confirmed in metabolism but also in residue studies.
- Furthermore, pollination of cereals (including corn) occurs by wind and not by bees.
- Due to both reasons, it is unlikely that there is any direct transfer of pyraclostrobin residues from maize pollen into honey.

Tier 1 Summaries of the Supervised Field Residue Trials for the Representative Crops

Potatoes

Table of Contents

CA 7 FATE AND BEHAVIOUR IN THE ENVIRONMENT

Pyraclostrobin (BAS 500 F), a fungicide for use in cereals, maize, potatoes, legumes, fruits, vegetables and various other crops, is registered in Europe since many years. It was fully reviewed under Directive 91/414/EEC and included in Annex I by Commission Directive No 2004/30/EC and 2009/25/EC. Inclusion entered into force on 10 March 2004. The approval was transferred to the new Regulation (EC) No 1107/2009 in Commission Implementing Regulation (EU) No 540/2011. Approval extension was granted until 31 January 2017 by Regulation No 823/2012/EU.

All relevant information on the first Annex I review and the endpoints used in environmental risk assessments can be found in the monograph of pyraclostrobin and in the SANCO/1420/2001-Final document (EU Review Report).

For the current registration renewal under Regulation 1107/2009, a data gap analysis according to new guidelines, new guidance documents and new procedures in kinetic evaluations and exposure assessments was performed and new studies or kinetic evaluations were initiated where considered necessary. All new data are provided in this section.

Furthermore, a literature search was performed and scientific publications were evaluated for their endpoint relevance and quality. Although title and abstract of several publications indicated a potential connection to respective environmental fate chapters of this dossier, the detailed evaluation of these publications showed no endpoint of sufficient reliability which could be used for the required risk assessments. Consequently, for environmental fate no summaries of public literature data on pyraclostrobin are provided in this section. Further information on the literature assessment and respective justifications can be found in M-CA 9.

Studies on the route of degradation were usually performed using the tolyl-^{14}C or chlorophenyl-^{14}C labeled pyraclostrobin. For confirmation that no pyrazole-specific metabolite is formed, one new soil metabolism and one new soil photolysis study was performed with pyrazole-^{14}C-labeled active substance.

An overview of metabolites discussed in this section is given below. The table is including the different code numbers that are available for each metabolite. In the following chapters and study summaries synonym metabolite codes are given in brackets where deemed to be helpful.

Substance/ Meatbolite Code	Reference code (Reg.No.)	Synonyms	Structure
Pyraclostrobin BAS 500 F	304428	500M00	BF 500-3	340266	500M07 "des-methoxy"	BF 500-4	358672	500M73 "aniline"	isomer of BF 500-4	not assigned	500M74	isomer of BF 500-4	not assigned	500M75	BF 500-5	298327	500M04 "OH-pyrazole"	BF 500-6	364380	500M01 "azoxy"	 cis-trans isomerization possible (assignment of cis/trans refers to direction of phenyl rings at N=N double bond)
BF 500-7	369315	500M02 "azo"	 cis-trans isomerization possible

Substance/ Meatbolite Code	Reference code (Reg.No.)	Synonyms	Structure
BF 500-11	411847	500M60	BF 500-12	412053	500M59	BF 500-13	412785	500M62	BF 500-14	413038	500M76	500M96	not assigned		500M97	not assigned		500M98/ 500M99	not assigned		
Note: The order of the study summaries shown below is differing compared to the information given in the application submitted for renewal of approval. In case references are summarized that were not contained in the application or in case references listed in the application are not contained in this chapter, comments are made where appropriate.

CA 7.1 Fate and behaviour in soil

CA 7.1.1 Route of degradation in soil

The route of degradation in soil of pyraclostrobin is investigated with three different radio-labels (chlorophenyl-, pyrazole- and tolyl-label).

The degradation of pyraclostrobin in aerobic soil studies is characterized by a rather low mineralization rate (about 5% of applied radioactivity (AR) within 100 days) and a formation of high amounts of bound residues (about 55% AR within 100 days).

First step in degradation is the de-methoxylation of the carbamate group forming metabolite BF 500-3. Further degradation at the carbamate group leads to metabolite BF 500-4. Due to the anilinic structure of this metabolite, it reacts immediately with the organic matrix in soil or with another BF 500-4 molecule forming the dimeric structures BF 500-6 (max. 31% AR) or BF 500-7 (max. 14% AR).

A minor route of degradation can be the cleavage of the pyraclostrobin molecule forming metabolite BF 500-5. In aerobic soil, it never appeared in amounts higher than 2.8% AR, in anaerobic soil, it reached up to 7.7% AR. Some further minor reactions (hydroxylation at the tolyl-ring, de-chlorination of BF 500-6) are also reported, however, those metabolites never exceeded 4% AR.

The metabolites BF 500-3 and BF 500-4 are short-lived intermediates, which are detected in aerobic soil either only in very low amounts < 5% AR (BF 500-3) or not at all (BF 500-4). Only in strong anaerobic soil, where the oxygen demanding degradation reactions are considerably slowed down, these metabolites can be found in higher amounts.

Photolytical degradation leads to the same degradation products as observed during dark incubation. No special photoproduct was detected.

When analyzing the non-extractable residues, the major portion of radioactivity was usually associated with insoluble humins and high-molecular humic acids. A release of pyraclostrobin could never be observed, neither with harsh extraction methods (NaOH) nor by intensive digestion activity of soil-eating animals (earthworms).

Most of the information is derived from studies already peer-reviewed during the previous Annex I inclusion process. Nevertheless, some new studies are described below, which were conducted in order to confirm or complement the knowledge of pyraclostrobin degradation in soil.

CA 7.1.1.1 Aerobic degradation

Although results of the older soil metabolism studies with tolyl-labeled and chlorophenyl-labeled pyraclostrobin did not indicate the formation of a pyrazole-ring specific metabolite, for confirmatory purposes a soil metabolism and a soil photolysis study was performed with pyrazole-labeled active substance. In both cases, no metabolite consisting only of the pyrazole-moiety was detected.

Report:	CA 7.1.1.1/1 Kuhnke G.,Hassink J., 2014a Metabolism of (pyrazole-3-C14) BAS 500 F in soil under aerobic conditions 2013/1337273
Guidelines:	OECD 307, EPA 835.4100
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Note: This study was not correctly listed in the application submitted for renewal of approval. Authors and DocID have changed after submission of the application.

EXECUTIVE SUMMARY

The aerobic soil metabolism of pyrazole-3-^{14}C-labeled pyraclostrobin was investigated in LUFA 5M soil, a sandy loam (USDA). The nominal application rate was 0.67 mg kg^{-1} dry soil (corresponding to 250 g test item ha^{-1}). Soil aliquots of 100 g (dry weight basis) were weighed into test vessels and incubated at 20°C and 53% maximum water holding capacity (pF 2.5) in the dark for 120 days. A closed incubation system with continuous aeration was used with an attached trapping system for the determination of volatile compounds.

Soil samples were taken at 0, 1, 3, 7, 10, 14, 31, 58, 91 and 120 days after treatment (DAT).

The soil samples were extracted three times with acetonitrile and three times with acetonitrile/water (1:1, v:v). The individual extracts were measured for radioactivity by LSC. The combined acetonitrile as well as the combined acetonitrile/water extracts were analyzed by HPLC. The remaining soil after extraction was combusted to determine the amount of non-extractable soil bound residues. The non-extractable residues were further characterized by NaOH and water extraction and subsequent fractionation into fulvic acids, humic acids, and humins. The fulvic acid fraction was furthermore partitioned with ethyl acetate. A full material balance was provided for each sampling interval.

The amount of extractable radioactivity in soil decreased from 99.8% TAR at time 0 to 39.0% TAR at 120 DAT. The amount of test item pyraclostrobin decreased throughout the incubation from 92.0% TAR at day 0 after treatment to 11.2% TAR at the end of the study. The two metabolites BF 500-6 (500M01) and BF 500-7 (500M02) including their isomers were identified by mass spectrometry and by comparison of retention times to reference items in two chromatographic systems. The metabolite BF 500-6 increased to about 16.2% TAR at 91 DAT and still accounted for 11.9% at the end of the study (mean of two replicates). Metabolite BF 500-7 was detected with max. 4.7% TAR at 31 DAT and decreased to 3.6% TAR (mean) at the end of the study. The corresponding isomers of BF 500-6 and BF 500-7 were found only in low amounts of maximum 1.1% TAR.

Non-extractable radioactive residues (NER) were formed in considerable amounts during incubation. They increased from 0.2% TAR on day 0 to a maximum of 52.7% TAR after 120 days. Characterization of the NER at 120 DAT revealed that about half of it was tightly bound to humins, while the rest was distributed in a ratio of about 1:1 between the humic and the fulvic acid fraction. The fulvic acid fraction was further characterized by partitioning with ethyl acetate. Amounts of 9.7% TAR of the fulvic acid fraction were soluble in ethyl acetate, whereas 3.0% TAR remained in the water phase. The ethyl acetate soluble fractions from samples of 120 DAT were investigated by HPLC. The main peak found by HPLC (accounting for 8.4% TAR) was the metabolite BF 500-5 known to occur under alkaline conditions.

$^{14}CO_2$ was formed in low amounts up to 2.2% TAR. No other volatile compounds were detected in significant amounts. The material balance ranged from 93.8 to 110.3% TAR throughout the incubation period of 120 days, resulting in a mean value of 100.6% TAR.

Kinetic analysis and calculation of $DegT_{50}$ and $DegT_{90}$ values for pyraclostrobin and its metabolites BF 500-6 and BF 500-7 was performed following the recommendations of the FOCUS Kinetics workgroup. The analysis was done by non-linear regression methods using the software package KinGUI version 2.2012.320.1629.

A best-fit $DegT_{50}$ value of 22.3 days and $DegT_{90}$ value of 115.2 days were calculated for pyraclostrobin (FOMC). For BF 500-6 and BF 500-7, best-fit $DegT_{50}$ values of 95.9 and 81.5 days and $DegT_{90}$ values of 318.7 and 270.7 days were calculated (SFO), respectively.

Modeling endpoints were derived using SFO kinetics for all compounds. The $DegT_{50}$ of pyraclostrobin equals 26.2 days, the $DegT_{50}$ of BF 500-6 and BF 500-7 equal 68.0 and 59.0 days, respectively.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Internal code:	BAS 500 F
Reg. No.:	304428
CAS-No.:	175013-18-0
Chemical name (IUPAC):	methyl N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3 yl]oxymethyl}phenyl)-(N-methoxy)carbamate
Molar mass:	387.8 g mol^{-1} (unlabeled)
Position of radiolabel:	pyrazol-3-^{14}C
Specific radioactivity of a.s.:	5.5 MBq mg^{-1} (330000 dpm μg^{-1})
Batch No.:	1073-1008
Radiochemical purity:	99.7%

2. Soil

The German soil LUFA 5M from LUFA (Landwirtschaftliche Untersuchungs- und Forschungsanstalt, Speyer, Germany) was used in this study. It was sampled from 0-20 cm depth. The soil was passed through a 2 mm sieve, remoistened to approximately 8-12% soil moisture and stored for no longer than three months at 4°C before use. The soil characteristics are summarized in Table 7.1.1.1-1.

Table 7.1.1.1-1: Characteristics of soil LUFA 5M used for soil metabolism study with ^{14}C-pyraclostrobin

Soil designation	**LUFA 5 M** **13/1651/01** (Germany, Origin: LUFA Speyer)
DIN Particle size distribution [%] Sand 0.063 – 2 mm Silt 0.002 – 0.063 mm Clay < 0.002 mm Textural class	 53.6 33.3 13.1 loamy sand (Sl4)
USDA Particle size distribution [%] Sand 0.050 – 2 mm Silt 0.002 – 0.050 mm Clay < 0.002 mm Textural class	 57.0 29.9 13.1 sandy loam
Organic C [%] Organic matter [%] **	1.98 3.41
pH [H_2O] pH [$CaCl_2$]	7.9 7.4
Cation exchange capacity [$cmol^+ kg^{-1}$]	10.2
Max. water holding capacity [g/100g dry weight]	27.0
Water holding capacity at pF 2.0 [g/100g dry weight] Water holding capacity at pF 2.5 [g/100g dry weight]	0.174 0.147
Microbial biomass (start of study) [mg C/100g dry soil]	27.8 (certificate) 30.1*
Microbial biomass (after 58 days) [mg C/100g dry soil]	19.7*
Microbial biomass (end of study [121 days]) [mg C/100g dry soil]	16.3*

B. STUDY DESIGN

1. Experimental conditions

The test substance was applied at a nominal concentration of 0.67 mg ^{14}C-pyraclostrobin/kg dry soil which corresponds to a field application rate of 250 g a.s. ha^{-1} (calculated on the basis of an equal distribution in the top 2.5 cm soil layer and a soil density of 1.5 g cm^{-3}). Portions of 100 g soil (dry weight basis) were then filled into test vessels.

The mean value of the sum of extractable and non-extractable radioactive residues at day 0 in 100 g dry soil was defined as 100% TAR. The actual application rate was 0.6467 mg kg^{-1} (mean value of two samples immediately extracted after application).

For incubation, all test vessels were connected in line with aeration tubes in the soil metabolism apparatus. During the study, samples were continuously aerated with a slight stream of moistened synthetic air. For removing carbon dioxide, the air was passed through a bottle with NaOH before passing the test vessels. For trapping of volatiles possibly evolving from soil during the incubation, test vessels were connected to three gas washing flasks containing at least 50 mL ethylene glycol, 50 mL 0.5 M H_2SO_4, and 50 mL 0.5 M NaOH. The treated soils were incubated at 53% maximum water holding capacity and 20 ± 2°C in the dark.

To determine the microbial biomass at 0, 58 and 121 days after treatment, an additional soil portion (1500 g dry soil equivalents, 53% maximum water holding capacity) was treated only with 1 mL acetone (without test item). The samples for 58 and 121 DAT were incubated under the same conditions (dark, 20 ± 2°C) as the treated soil.

2. Sampling

Sampling dates were 0, 1, 3, 7, 10, 14, 31, 58, 91 and 120 days after treatment (DAT). On day 0, 58 and 120, two replicate soil samples were worked up.

3. Description of analytical procedures

For the determination of the extractable radioactive residues (ERR), the 100 g (dry weight basis) soil samples were consecutively extracted three times with 100 mL acetonitrile (ACN), and three times with 100 mL ACN/water (1:1; v:v). The ACN-extracts as well as the ACN/water-extracts were pooled and each solution was concentrated (rotary evaporator T≈ 35°C). Then the residues were re-dissolved in a well-defined volume solvent and analyzed by radio HPLC with two different HPLC systems.

The soil residues remaining after extraction were air-dried, homogenized by means of a small mill, and aliquots were combusted in a biological oxidizer. The evolved $^{14}CO_2$ from each combusted aliquot was trapped in Oxysolve C-400 scintillator and measured by LSC to determine the amount of the non-extractable residues (NER).

The non-extractable residues of the 120 DAT samples were further characterized by NaOH extraction. The samples were consecutively extracted with NaOH (three times) and water (twice). Finally, all extracts were pooled and acidified with concentrated hydrochloric acid to pH 1.5 to precipitate the humic acid fraction. After centrifugation, the supernatant (fulvic acids) was separated from the precipitate. The precipitate (humic acid fraction) was dissolved in 50 mL NaOH. The humic acid fraction and the fulvic acid fraction were measured for radioactivity. The remaining soil samples after NaOH and water extraction were dried at room temperature. Afterwards, aliquots were combusted. The released $^{14}CO_2$ was trapped and analyzed by LSC to determine the ^{14}C-residues in the humin fraction.

The fulvic acid fraction was partitioned with ethyl acetate. The organic phase was further analyzed by radio HPLC.

The microbial biomass in the soil samples treated with solvent only was determined at 0, 58 and 121 DAT. The method was based on the determination of oxygen consumption upon addition of glucose. The microbial biomass declined over the incubation phase. However, the results demonstrate that the soil was still viable and microbially active at days 58 and 121 (end) of the study.

4. Calculation of the degradation rate

Kinetic evaluation was performed in order to derive degradation parameters as triggers for additional work (trigger endpoints) as well as modeling endpoints. Kinetic analysis and calculation of $DegT_{50}$ and $DegT_{90}$ values was performed following the recommendations of the FOCUS Kinetics workgroup [*FOCUS (2006) "Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration" Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference Sanco/10058/2005 version 1.0 (November 2011), 436 pp.*].

The software package KinGUI (version 2.2012.320.1629) was used for parameter fitting [*SCHÄFER, D., MIKOLASCH, M., RAINBIRD, P., HARVEY, B. (2007) KinGUI: A new kinetic software tool for evaluations according to FOCUS Degradation Kinetics. In: Del Re, A.A.M. et al. (Eds.): Proceedings of the XIII Symposium on Pesticide Chemistry, Piacenza, 2007, p. 916-923., SCHMITT, W., GAO, Z., MEYER, H. (2011) KinGUII, Version 2.2012.320.1629 Bayer CropScience AG*]. The error tolerance and the number of iterations of the optimization tool were set to 0.00001 and 100, respectively.

For each data set, the kinetic models proposed by the FOCUS Kinetics guidance document were tested in order to identify the best-fit model. The recommended kinetic models, i.e. the single first order kinetics (SFO) and the Gustafson-Holden model (FOMC), are already implemented in KinGUI. The Goodness-of-fit was evaluated by visual assessment, χ^2 minimum error, and type-I-error rate (t-test) [for details see Chapter 6.3 in FOCUS (2006)].

Where available, replicate measurements were considered for the parameter estimation. The initial concentration of the applied test item was set to the material balance recovered at day 0. The χ^2 value for the kinetic model was calculated as recommended by FOCUS, considering the average of replicate measurements. For the individual parameters, the t-test statistics were based on number of individual measurements.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The detailed results on the extractability of radioactive residues are presented in Table 7.1.1.1-2. The mass balance ranged from 93.8 to 110.3% TAR throughout the incubation period of 120 days, resulting in a mean value of 100.6% TAR.

B. EXTRACTABLE AND BOUND RESIDUES

The distribution of radioactivity in the soil is shown in Table 7.1.1.1-2. The total extractable radioactivity from the soils decreased from 99.8% TAR at time 0 to 39.0% TAR after 120 days. The non-extractable residues increased from 0.2% TAR immediately after treatment to 52.7% TAR after 120 days.

Table 7.1.1.1-2: Material balance and distribution of radioactivity after application of ^{14}C-pyraclostrobin to soil [% TAR]

DAT = days after treatment
ACN = acetonitrile
n.a. = not analyzed
* no significant amounts of other volatiles than CO_2 were found

C. VOLATILISATION

Carbon dioxide was the only volatile degradation product reaching 2.2% TAR after 120 days of incubation. In sulfuric acid and ethylene glycol no significant radioactivity could be measured at any time point.

D. TRANSFORMATION OF PARENT COMPOUND

HPLC analysis of the soil extracts revealed degradation of pyraclostrobin in LUFA 5M soil. The extractable amount of pyraclostrobin decreased throughout the incubation period from 92.0% TAR at day 0 to 11.2% TAR at day 120 (Table 7.1.1.1-3).

Two metabolites (BF 500-6 and BF 500-7) were identified by mass spectrometry and by comparison of retention times with those of reference items in two chromatographic systems. The concentrations of pyraclostrobin and the identified metabolites BF 500-6 and BF 500-7 in the organic extracts are given in Table 7.1.1.1-3. Metabolite BF 500-6 increased to about 16.2% TAR at 91 DAT and still accounted for 11.9% TAR at the end of the study (mean of two replicates). Metabolite BF 500-7 was detected with max. 4.7% TAR at 31 DAT and decreased to 3.6% TAR (mean) at the end of the study. Both metabolites can appear in isomeric form (cis-trans isomers). The isomers occurred, if at all, only in very low amounts and never exceeded 1.1% TAR. No other metabolite exceeded 2.1% TAR at any sampling time. No pyrazole-specific metabolite could be identified.

E. CHARACTERIZATION OF NON-EXTRACTABLE RESIDUES (NER)

For the 120 days samples, the non-extractable residues were extracted three times with NaOH (+ two water rinsings). After extraction with NaOH, about half (~26% TAR) of the ^{14}C-residues remained unextractable (humin fraction). The alkali-soluble radioactivity was further fractionated into fulvic and humic acids by precipitation with concentrated HCl. The results are given in Table 7.1.1.1-4 and Table 7.1.1.1-5. The radioactivity was almost evenly distributed between humic and fulvic acid fraction. The humic acid fraction was not further analyzed.

The fulvic acid fraction was partitioned with ethyl acetate. About three quarters of the fulvic acid fraction (9.7% TAR) was soluble in the ethyl acetate phase, whereas one quarter remained in the water phase (see Table 7.1.1.1-6).

HPLC analyses of the ethyl acetate phase of the fulvic acid fraction revealed the presence of one main and three small peaks. The main peak (amounting to 8.4% TAR) is presumably metabolite BF 500-5 known to occur under alkaline conditions. The possible assignment is supported by comparison of retention times in two chromatographic systems.

F. KINETIC MODELING RESULTS

The estimated $DegT_{50}$ and $DegT_{90}$ values for pyraclostrobin as well as its metabolites BF 500-6 and BF 500-7 in soil were calculated according to the recommendation of FOCUS (2006).

$DegT_{50}$/$DegT_{90}$ values obtained are presented in Table 7.1.1.1-7 and Table 7.1.1.1-8.

Table 7.1.1.1-7: Trigger endpoints for pyraclostrobin, BF 500-6 and BF 500-7

Compound	Best-fit model	χ^2 error	$DegT_{50}$ [d]	$DegT_{90}$ [d]
Pyraclostrobin	FOMC	2.20	22.3	115.2

BF 500-7	SFO	10.60	59.0	0.0117	0.112

III. CONCLUSION

Pyrazole-3-^{14}C-pyraclostrobin was degraded rather fast in aerobic soil by formation of non-extractable residues, reaching 52.7% TAR at the end of the study after 120 days. $^{14}CO_2$ was formed in low amounts up to 2.1% TAR. No other volatile compounds were detected in significant amounts.

The two known metabolites BF 500-6 and BF 500-7 were confirmed with maximum concentrations of 17.3% TAR and 5.5% TAR, respectively (sum of both isomers). No pyrazole-specific metabolites could be identified.

A best-fit $DegT_{50}$ value of 22.3 days and $DegT_{90}$ value of 115.2 days were calculated for pyraclostrobin (FOMC). For BF 500-6 and BF 500-7, best-fit $DegT_{50}$ values of 95.9 and 81.5 days and $DegT_{90}$ values of 318.7 and 270.7 days were calculated (SFO), respectively.

Modeling endpoints were derived using SFO kinetics for all compounds. The $DegT_{50}$ of pyraclostrobin equals 26.2 days, the $DegT_{50}$ of BF 500-6 and BF 500-7 equal 68.0 and 59.0 days, respectively.

Normalization of degradation rates
Since for environmental fate modeling $DegT_{50}$ values at reference conditions (temperature of 20°C and soil moisture at field capacity, i.e. pF2) are required, the reported $DegT_{50}$ values for modeling were normalized following the recommendations of *FOCUS (2012):* [*Generic Guidance for Tier 1 FOCUS Ground Water Assessments. Version: 2.1*].

Since the study was performed at 20°C no temperature correction was necessary. The moisture normalization was performed using the moisture dependency equations by Walker as described in Equation 7.1.1.1-1.

Equation 7.1.1.1-1 Calculation of the moisture correction factor according to Walker

$$f_{moist} = \begin{cases} \left(\frac{\theta_{act}}{\theta_{ref}}\right)^{0.7} & if \quad \theta_{act} < \theta_{ref} \\ 1 & if \quad \theta_{act} \geq \theta_{ref} \end{cases}$$

with:			
	f_{moist}	moisture correction factor	[-]
	θ_{ref}	reference soil moisture at field capacity (pF2, 10 kPa)	[g / 100 g dry soil]
	θ_{act}	actual soil moisture during incubation	[g / 100 g dry soil]

The actual soil moisture was taken from the study report and the corresponding reference moisture at pF 2 was derived from FOCUS (2012). The normalized DT_{50} values were calculated by multiplying the DT_{50} values at study conditions by the correction factor f_{moist} as described in Equation 7.1.1.1-2.

Equation 7.1.1.1-2 Calculation of the DT_{50} at reference conditions (20°C, pF2)

$$DegT_{50,ref} = DegT_{50,act} \cdot f_{moist}$$

with:			
	$DegT_{50,ref}$	normalized $DegT_{50}$	[d]
	$DegT_{50,act}$	$DegT_{50}$ at study conditions	[d]
	f_{moist}	moisture correction factor	[-]

A summary of the normalized half-lives of pyraclostrobin and its aerobic soil metabolites BF 500-6 and BF 500-7 is given below:

Table 7.1.1.1-9: Normalization of $DegT_{50}$ values to reference conditions

Compound	Soil	pH ($CaCl_2$)	Kinetic model	θ_{act}	θ_{ref}	f_{moist}	$DegT_{50,act}$	$DegT_{50,ref}$
Pyraclostrobin	LUFA 5M	7.4	SFO	14.3	17.4	0.87	26.2	22.8
BF 500-6							68.0	59.2
BF 500-7							59.0	51.3

θ_{act}	actual soil moisture	[g / 100 g dry soil]
θ_{ref}	reference soil moisture at field capacity (pF 2) according to FOCUS (2012)	[g / 100 g dry soil]
f_{moist}	moisture correction factor	[-]
$DegT_{50,act}$	$DegT_{50}$ at study conditions	[d]
$DegT_{50,ref}$	$DegT_{50}$ at reference conditions	[d]

CA 7.1.1.2 Anaerobic degradation

No new anaerobic soil metabolism study with pyraclostrobin was performed. However, new information was obtained on the isomer structures (500M74, 500M75) of metabolite BF 500-4 (500M73), which were observed during the anaerobic soil metabolism studies with pyraclostrobin (already peer-reviewed during previous Annex I inclusion process). This information is provided in M-CA 7.1.2.1.4 *Anaerobic degradation of metabolites, breakdown and reaction products*.

EXECUTIVE SUMMARY

The soil photolysis of pyraclostrobin (BAS 500 F) was studied in a sandy loam soil (LUFA 5M, Speyer, Germany) for 15 days in a flow through system at 22°C ± 1°C under continuous irradiation and in the dark (control). Pyrazole-^{14}C-labeled pyraclostrobin was used for treatment at an application rate of 1.67 mg kg^{-1}, corresponding to a field application rate of 250 g ha^{-1}.

Soil samples were placed in a SUNTEST apparatus and were continuously exposed to a Xenon arc lamp emitting a light spectrum similar to sunlight (≥ 290 nm), simulating a clear sunny day around noon in Central Europe. The dark controls were stored in an incubator at 22°C ± 1°C.

Duplicate samples were taken at days 0, 2, 5, 8, 12 and 15 after treatment. Dark control samples were analyzed at the same sampling days. Volatiles were trapped in appropriate trapping solutions. Soil samples were extracted three times with acetonitrile (ACN) and three times with acetonitrile/water (1+1; v/v). The combined acetonitrile extracts as well as the combined acetonitrile/water extracts were analyzed by LSC and HPLC. Bound residues were quantified by combustion and subsequent LSC measurement. A full material balance is provided for each sampling interval.

The remaining soils after ACN and ACN/water extraction at 8, 12 and 15 days after treatment (DAT) were extracted three times with NaOH to determine the amount of alkali-soluble components. The dried soil was then combusted to determine the amount of residue in the humin fraction.

In the photolysis test, the total extractable radioactivity did not significantly differ from the dark control. After 15 days, about 7 and 10% of the total applied radioactivity (TAR) were not extractable from the irradiated and dark control samples, respectively. The alkali-soluble radioactivity amounted to 3-4% TAR in the period of 8-15 DAT in the photolysis, representing the fulvic acids and humic acids. The dark control revealed similar values (3-5% TAR).

The pyrazole-labeled pyraclostrobin declined in the photolysis experiment to 82.1% TAR after 15 days under continuous irradiation. A similar degradation was observed in dark control samples with 76.7% TAR pyraclostrobin present in the organic extracts at the end of the study.

Aliquots of all samples were analyzed by radio-HPLC. No degradation product exceeded 3% TAR at any sampling time with the exception of the known soil metabolite BF 500-6 which was confirmed by HPLC-MS/MS. It was detected with up to 3.5% TAR under the influence of light and up to 7.9% TAR in the dark control. A second metabolite identified as BF 500-7 accounted for up to 1.3% TAR in the photolysis experiment and up to 3.0% TAR in the dark control.

Kinetic analysis and calculation of $DegT_{50}$ and $DegT_{90}$ (best-fit and modeling) values for pyraclostrobin in soil was performed following the recommendations of the FOCUS Kinetics workgroup. The analysis was conducted by non-linear regression methods employing the software tool KinGUII. $DegT_{50}$ and $DegT_{90}$ values for pyraclostrobin accounted for 55.2 and 183.3 days in the photolysis experiment and 41.5 and 137.8 days for the dark control, respectively, using SFO kinetics.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Internal code	BAS 500 F
Reg. No.:	304428
CAS-No.:	175013-18-0
Chemical name (IUPAC):	methyl N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxymethyl}phenyl)-(N-methoxy)carbamate
Molar mass:	387.8 g mol^{-1} (unlabeled)
Position of radiolabel:	pyrazol-3-^{14}C
Specific radioactivity of a.s.:	5.5 MBq mg^{-1} (330000 dpm μg^{-1})
Batch No.:	1073-1008
Radiochemical purity:	99.7%

2. Soil

The soil used was classified as a sandy loam and originated from the Landwirtschaftliche Untersuchungs- und Forschungsanstalt (LUFA) Speyer, South Western Germany. The sampling depth was 0-20 cm. The soil was passed through a 2 mm sieve, remoistened to approximately 8-12% soil moisture and then stored at about 4°C in the dark no longer than three months before use. An overview of soil parameters is listed in Table 7.1.1.3-1.

Table 7.1.1.3-1: Characteristics of soil LUFA 5M used for soil photolysis study with ^{14}C-pyraclostrobin

Soil designation	**LUFA 5M** **13/1651/01** Germany (Origin LUFA Speyer)
DIN 4220 Particle size distribution [%] Sand 0.063 – 2 mm Silt 0.002 – 0.063 mm Clay < 0.002 mm Textural class	 53.6 33.3 13.1 loamy sand
USDA Particle size distribution [%] Sand 0.050 – 2 mm Silt 0.002 – 0.050 mm Clay < 0.002 mm Textural class	 57.0 29.9 13.1 sandy loam
Organic C [%]	1.98
pH [H_2O] pH [$CaCl_2$]	7.9 7.4
Cation exchange capacity [$cmol^+ kg^{-1}$]	10.2
Max. water holding capacity [g /100 g dry weight]	27.0
Microbial biomass (start of study) [mg C/100 g dry soil]	27.8

B. STUDY DESIGN

1. Experimental conditions

For each test (photolysis and dark control), ten small steel dishes (88 mm x 44 mm x 10 mm) were filled with soil and arranged in a rectangular stainless steel bowl with a connected thermostat. Soil surfaces were then treated with the radio-labeled test item. The temperature of the dishes used for photolysis was adjusted to 22°C ± 1°C and controlled by an external tempering unit, while the dishes for the dark control were put into an incubator at 22°C ± 1°C. Subsequently, the bowl was closed airtight with a quartz glass covering. A continuous aeration of the whole incubation device was ensured with CO_2-depleted (0.5 M NaOH) and remoistened air applied via an air inlet and an air outlet. The exiting air was flushed through three gas washing flasks containing ethylene glycole, H_2SO_4 (0.5 M), and NaOH (0.5 M) to collect potentially evolving ^{14}C-volatiles.

The incubation bowl for photolysis was placed under a SUNTEST CPS plus (Atlas) equipped with a Xenon lamp emitting light with a sunlight similar spectrum at a light intensity of about 3 mW cm^{-2} (UVA range). This corresponds to a clear summer day in Southern Germany (about 48°N). Wavelengths < 290 nm were filtered off to simulate natural sunlight

To maintain the temperature especially on the quartz glass surface in order to avoid a rapid drying of the soil surface, the air space between lamp and quartz glass within the SUNTEST device was cooled by an external apparatus (Yeti, Seveso). This apparatus was connected to and controlled by the SUNTEST. To maintain the initial water content as constant as possible, dishes were weighed at each incubation day. The evaporated water was replaced.

The amount of test item to be applied on the soil surface was calculated based on a recommended field application rate of 250 g ha^{-1}. If a soil layer of 1 cm and bulk density of 1.5 kg L^{-1} is assumed, the application rate corresponds to about 1.67 mg test item per kg dry soil (and about 50 µg per dish).

2. Sampling

Sampling was performed after an incubation period of 0, 2, 5, 8, 12 and 15 days. At each sampling date, two dishes were taken from the photolysis test system and from the dark control (the day 0 samples were used for both experiments). At each sampling date, the respective volatile trapping solutions were removed.

3. Description of analytical procedures

Each soil sample was consecutively extracted three times with acetonitrile and three times with acetonitrile/water (1:1, v/v). After each extraction step, solid and extract were separated by centrifugation. The three corresponding acetonitrile and three acetonitrile/water extracts were combined, respectively, and analyzed for radioactivity.

After the last acetonitrile/water extraction, the soil residues were air-dried and homogenized by milling. Aliquots of each sample were combusted in a sample oxidizer. Trapped $^{14}CO_2$ was analyzed by LSC.

All extracts were analyzed by radio HPLC to determine the metabolite pattern. Prior to injection, the solvent of the extracts was completely evaporated by a rotary evaporator at 35°C. Then the residues were redissolved in a defined volume of the respective extraction solvent and subjected to HPLC analysis.

Non-extractable residues (NER) were found in amounts of 5-10% TAR at sampling days 8, 12 and 15 in the photolysis experiment as well as in the dark controls. The NER were further characterized by NaOH extraction. Samples were extracted three times with 0.5 M NaOH on a rotary shaker (200 rpm, extraction times: overnight, at least 7 h, overnight) and twice washed with water. Aliquots of the NaOH and the water extracts were analyzed by LSC. NaOH extracts and water extracts were pooled, representing together the fulvic and humic acid fraction. Since the amount of radioactivity did not exceed 5% TAR, no acidic precipitation of the humic acids from the pooled extracts was performed.

The remaining soil samples after NaOH and water extraction were air-dried at room temperature, aliquots were combusted, and the formed $^{14}CO_2$ was trapped and analyzed by LSC to determine the ^{14}C residues in the humin fraction.

4. Calculation of the degradation rate

Kinetic evaluation was performed in order to derive degradation parameters as triggers for additional work (trigger endpoints) as well as modeling endpoints. Kinetic analysis and calculation of $DegT_{50}$ and $DegT_{90}$ values was performed following the recommendations of the FOCUS Kinetics workgroup [*FOCUS (2006)*]. The software package KinGUI (version 2.2012.320.1629) was used for parameter fitting [*Schäfer et al. (2007)*]. The error tolerance and the number of iterations of the optimization tool were set to 0.00001 and 100, respectively.

For each data set, the kinetic models proposed by the FOCUS Kinetics guidance document were tested to identify the best-fit model. The recommended kinetic models, i.e. the single first order kinetics (SFO) and the Gustafson-Holden model (FOMC), are already implemented in KinGUI. The Goodness-of-fit was evaluated by visual assessment, χ^2 minimum error, and type-I-error rate (t-test) [for details see *Chapter 6.3 in FOCUS (2006)*].

Replicate measurements were considered for the parameter estimation. The initial concentration of the applied test item was set to the material balance recovered at day 0. The χ^2 value was calculated for the kinetic model as recommended by FOCUS, considering the average of replicate measurements. For the individual parameters, the t-test statistics were based on number of individual measurements.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

Total recoveries of radioactivity extracted from soil are summarized in Table 7.1.1.3-2 and Table 7.1.1.3-3. The overall mean values for the material balance in the photolysis and in the dark control were in the range of 97.1-102.7% TAR.

B. EXTRACTABLE AND BOUND RESIDUES

The amount of extractable radioactive residues continuously decreased from 100.0% TAR at day 0 to 89.4 (photolysis) and 90.9% TAR (dark control) after 15 days of incubation. The majority of the extractable radioactive residues was always obtained with acetonitrile.

The amount of non-extractable residues increased from 0.0% TAR at day 0 to 7.3% TAR in the irradiated samples after 15 days, compared to 9.8% TAR in the control samples incubated in the dark.

C. VOLATILIZATION

Carbon dioxide was the only volatile degradation product detected during soil photolysis. It was found in amounts of maximum 2.0% TAR after 15 days of irradiation and only in trace amounts (0.1% TAR) after 15 days of dark incubation.

D. TRANSFORMATION OF PARENT COMPOUND

Aliquots of all sample extracts were analyzed by radio HPLC (see Table 7.1.1.3-4 and Table 7.1.1.3-5). After 15 days, the extracted amount of pyraclostrobin decreased to 82.1% TAR in samples of the photolysis experiment and to 76.7% TAR in the dark control samples (mean values of two replicates).

Several degradation products were detected in the extracts, but only the already known soil metabolite BF 500-6 appeared in amounts higher than 5% TAR. It was found up to 3.5% TAR under irradiated conditions and up to 7.9% TAR in the dark control samples. Metabolite BF 500-7 was identified in minor amounts reaching 1.3% TAR in irradiated soil and 3.0% TAR in the dark control soils. All other degradation products never exceeded 2.3% TAR (individual compound). The identity of the two known soil metabolites BF 500-6 and BF 500-7 was confirmed by the second radio HPLC method as well as by HPLC-MS/MS. Metabolite BF 500-3 was not detected in this study by any of the two described HPLC methods.

E. CHARACTERIZATION OF NON-EXTRACTABLE RESIDUES (NER)

Results of the non-extractable residues characterization performed by humic substance fractionation are given in Table 7.1.1.3-6.

The alkali-soluble radioactivity amounted to approximately 4% TAR at day 15 in both experiments (representing the sum of fulvic acids and humic acids). Since the alkali-soluble radioactivity did not exceed 5% TAR, no further separation into humic acids and fulvic acids was performed.

Table 7.1.1.3-6: Characterization of non-extractable residues in soil LUFA 5M after treatment with ^{14}C-pyraclostrobin under irradiated conditions [% TAR]

F. KINETIC MODELING RESULTS

The degradation of pyraclostrobin could be best described by the SFO kinetic fit. The $DegT_{50}$/$DegT_{90}$ values obtained are presented in Table 7.1.1.3-7. As a result, light did not have an effect on the degradation rate of pyraclostrobin in soil.

Table 7.1.1.3-7: Trigger and modeling endpoints for pyraclostrobin

Test system	$DegT_{50}$ [d]	$DegT_{90}$ [d]	Best-fit model	χ^2 error
Photolysis	55.2	183.3	SFO	1.077
Dark control	41.5	137.8	SFO	1.893

III. CONCLUSION

Irradiation in the soil photolysis experiment with pyrazole-^{14}C-labeled pyraclostrobin did not show an influence on the degradation behavior and metabolite formation in soil. Under irradiated conditions, the formation of the known soil metabolites BF 500-6 and BF 500-7 was confirmed, and overall the pyraclostrobin degradation is similar as in the dark. A pyrazole-specific metabolite could not be detected.

Summary: Route of Degradation of pyraclostrobin in Soil

The overall understanding of soil degradation of pyraclostrobin did not change since the evaluation during the previous Annex I inclusion process (according to EU Directive 91/414/EEC).

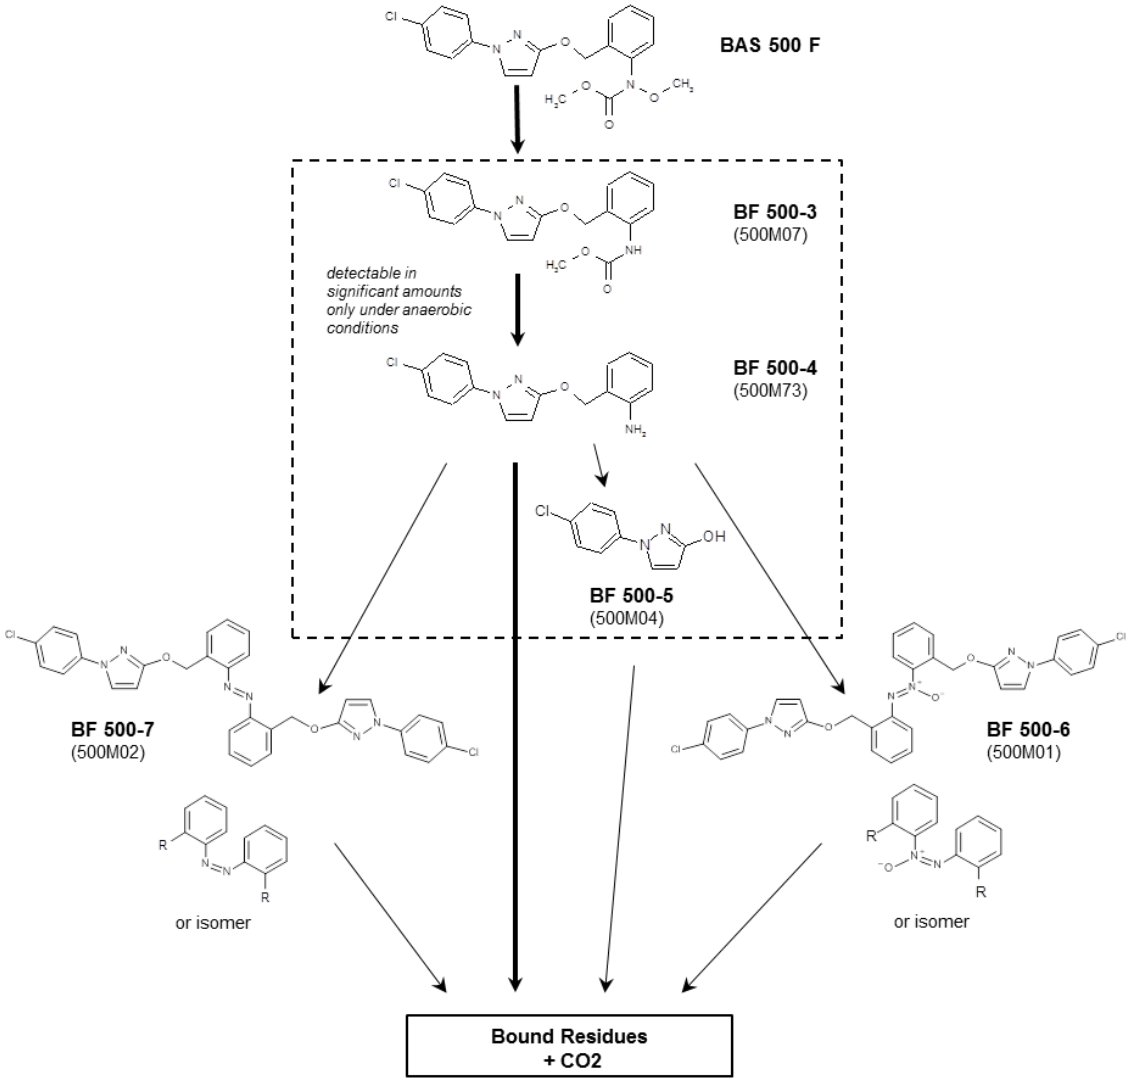
The behavior of pyraclostrobin in soil is characterized by a rather low mineralization rate and the formation of considerable amounts of bound residues.

The first degradation step is the demethoxylation of the carbamate group. The des-methoxy metabolite (BF 500-3) is transformed to the corresponding aniline (BF 500-4). In presence of oxygen, BF 500-4 reacts very fast either with another BF 500-4 molecule (forming metabolites BF 500-6 or BF 500-7) or with the organic matrix in soil leading to high amounts of bound residues. Under natural aerobic conditions, these reactions are very fast so that BF 500-3 or BF 500-4 can be detected, if at all, only in trace amounts. Under anaerobic conditions, the reactions are slowed down and BF 500-3 and BF 500-4 become detectable in soil extracts.

A further (minor) degradation reaction is the cleavage of the ether bond which results in the formation of metabolite BF 500-5. This metabolite further degrades to CO_2 or reacts with humic soil matrix. As with BF 500-3 and BF 500-4, these further degradation reactions are slowed down under anaerobic conditions.

A scheme on the proposed route of degradation is given in Figure 7.1.1.3-1.

Figure 7.1.1.3-1: Proposed route of degradation of pyraclostrobin in soil



CA 7.1.2 Rate of degradation in soil

CA 7.1.2.1 Laboratory studies

CA 7.1.2.1.1 Aerobic degradation of the active substance

In the new soil metabolism study performed with the pyrazole-labeled pyraclostrobin, besides information on the route of degradation also degradation rates were obtained. This study is described in detail in chapter M-CA 7.1.1.1 [*CA 7.1.1.1/1, BASF DocID 2013/1337273*].

Furthermore, a new degradation rate study was performed with pyraclostrobin in various soils, since the old degradation rate study did not provide a full material balance as required by the OECD 307 guideline.

Finally, pyraclostrobin degradation rates were re-calculated from the older, already peer-reviewed studies using their experimental data and analysing the kinetic parameters according to the current FOCUS guidance.

A summary table of all obtained laboratory soil degradation values for pyraclostrobin can be found at the end of this chapter (best-fit and normalized to 20°C, pF 2 and 10°C, pF 2).

Note: This study is already described in detail in chapter M-CA 7.1.1.1 1 [*CA 7.1.1.1/1*]. Therefore, only the executive summary and the result of the kinetic evaluation is repeated here.

EXECUTIVE SUMMARY

The aerobic soil metabolism of pyrazole-3-^{14}C-labeled pyraclostrobin was investigated in LUFA 5M soil, a sandy loam (USDA). The nominal application rate was 0.67 mg kg^{-1} dry soil (corresponding to 250 g test item ha^{-1}). Soil aliquots of 100 g (dry weight basis) were weighed into test vessels and incubated at 20ºC and 53% maximum water holding capacity (pF 2.5) in the dark for 120 days. A closed incubation system with continuous aeration was used with an attached trapping system for the determination of volatile compounds.

Soil samples were taken at 0, 1, 3, 7, 10, 14, 31, 58, 91 and 120 days after treatment (DAT).

The soil samples were extracted three times with acetonitrile and three times with acetonitrile/water (1+1). The individual extracts were measured for radioactivity by LSC. The combined acetonitrile as well as the combined acetonitrile/water extracts were analyzed by HPLC. The remaining soil after extraction was combusted to determine the amount of non-extractable soil bound residues. The non-extractable residues were further characterized by NaOH and water extraction and subsequent fractionation into fulvic acids, humic acids, and humins. The fulvic acid fraction was furthermore partitioned with ethyl acetate. A full material balance was provided for each sampling interval.

The amount of extractable radioactivity in soil decreased from 99.8% TAR at time 0 to 39.0% TAR at 120 DAT. The amount of test item pyraclostrobin decreased throughout the incubation from 92.0% TAR at day 0 after treatment to 11.2% TAR at the end of the study. The two metabolites BF 500-6 (500M01) and BF 500-7 (500M02) including their isomers were identified by mass spectrometry and by comparison of retention times to reference items in two chromatographic systems. Metabolite BF 500-6 increased to about 16.2% TAR at 91 DAT and still accounted for 11.9% at the end of the study (mean of two replicates). Metabolite BF 500-7 was detected with max. 4.7% TAR at 31 DAT and decreased to 3.6% TAR (mean) at the end of the study. The corresponding isomers of BF 500-6 and BF 500-7 were found only in low amounts of maximum 1.1% TAR.

Non-extractable radioactive residues (NER) were formed in considerable amounts during incubation. They increased from 0.2% TAR on day 0 to a maximum of 52.7% TAR after 120 days. Characterization of the NER at 120 DAT revealed that about half of it was tightly bound to humins, while the rest was distributed in a ratio of about 1:1 between the humic and the fulvic acid fraction. The fulvic acid fraction was further characterized by partitioning with ethyl acetate. Amounts of 9.7% TAR of the fulvic acid fraction were soluble in ethyl acetate, whereas 3.0% TAR remained in the water phase. The ethyl acetate soluble fractions from samples of 120 DAT were investigated by HPLC. The main peak found by HPLC (accounting for 8.4% TAR) is metabolite BF 500-5 known to occur under alkaline conditions.

$^{14}CO_2$ was formed in low amounts up to 2.2% TAR. No other volatile compounds were detected in significant amounts. The material balance ranged from 93.8 to 110.3% TAR throughout the incubation period of 120 days, resulting in a mean value of 100.6% TAR.

Kinetic analysis and calculation of $DegT_{50}$ and $DegT_{90}$ values for pyraclostrobin and its metabolites BF 500-6 and BF 500-7 was performed following the recommendations of the FOCUS Kinetics workgroup. The analysis was done by non-linear regression methods using the software package KinGUI version 2.2012.320.1629.

$DegT_{50}$/$DegT_{90}$ values obtained are presented in Table 7.1.2.1.1-1 and Table 7.1.2.1.1-2.

Executive Summary

The objective of the study was to investigate the aerobic soil metabolism of pyraclostrobin in three soils originating from Germany.

The soils were treated with a nominal rate of 0.667 mg tolyl-^{14}C-labeled pyraclostrobin per kg of dry soil which corresponds to a field application rate of 250 g a.s. ha^{-1}. The incubation was carried out in the dark in the laboratory under aerobic conditions at a soil moisture of 40% of the maximum water holding capacity (MWHC) and at a temperature of 20°C. A closed incubation system with continuous aeration (moistened synthetic air) was used with an attached trapping system for the determination of volatile compounds. Samples were taken at 0, 3, 7, 14, 29/30, 59/62, 90 and 120 days after treatment (DAT).

The soil samples were extracted three times with acetonitrile and three times with acetonitrile/water (1:1). The individual extracts were analyzed by LSC. The combined acetonitrile as well as the combined acetonitrile/water extracts were analyzed by HPLC. The amount of non-extractable residues was determined by combustion of the remaining soil after extraction and subsequent LSC measurement.

The mass balance throughout the study ranged from 90.1 to 105.0% of the total applied radioactivity (TAR) for the three soils. The extractable radioactivity decreased from 95.5 - 98.9% TAR at day 0 to 39.0 - 50.9% after 120 days. The non-extractable radioactive residues (NER) increased from 0.6 - 1.0% TAR on day 0 to a maximum of 36.6 – 48.4% TAR after 120 days of incubation. Mineralization to $^{14}CO_2$ reached a total of 6.1 - 7.0% TAR. No other volatile compounds were detected.

The parent compound pyraclostrobin decreased continuously from 92.5 – 94.4% TAR at 0 DAT to 7.2 – 22.0% TAR after 120 days of incubation. Several metabolites were formed in moderate amounts: BF 500-6 (cis and trans isomers), BF 500-7 (cis and trans isomers), BF 500-3, 500M99, 500M97, 500M96 and 500M98. The most prominent metabolite, the trans isomer of BF 500-6, was formed in amounts up to 19.8% TAR. Only one other metabolite, the trans isomer of BF 500-7, reached amounts ≥ 5% TAR in one soil (max. 7.8% TAR).

The kinetic evaluation was re-analyzed in a separate report [*CA 7.1.2.1.1/2, BASF DocID 2014/1093424*], using a newer version of the kinetic software (KinGUI version 2 as compared to v1.1).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

BAS code:	BAS 500 F
Common name:	Pyraclostrobin
Reg.No.:	304428
Chemical name (IUPAC):	methyl N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxymethyl}phenyl)-(N-methoxy) carbamate
Molecular weight:	387.8 g mol^{-1} (unlabeled)
Position of radiolabel:	Tolyl-ring-U-C^{14}
Specific radioactivity:	7.31 MBq mg^{-1}
Batch No.:	566-4040
Radiochemical purity:	98.7%

2. Soils

Three different soils were used for treatment and incubation. The soils were sieved through a 2 mm sieve before use, remoistened to approximately 8 – 12% soil moisture and stored at about 4°C in the dark. The soil characteristics are summarized in Table 7.1.2.1.1-3.

Table 7.1.2.1.1-3: Properties of soils used for investigation of pyraclostrobin degradation rates under aerobic conditions

Soil designation	Li 10 (10/1680/03)	LUFA 5M (10/1651/03)	Speyerer Wald 2 (10/1715/03)

DAT = days after treatment

B. STUDY DESIGN

1. Experimental conditions

The soils were adjusted to about 40% of the maximum water holding capacity and treated at a nominal concentration of 0.667 mg ^{14}C-pyraclostrobin per kg dry soil, which corresponds to a field application rate of 250 g a.s. ha^{-1} (assuming an equal distribution in the top 2.5 cm soil layer and a soil density of 1.5 g cm^{-3}).

For the soil treatment, 2.3 kg of each soil was treated with 1.075 mL of the treatment solution. The treated soils were homogenized and soil portions of 100 g dry soil equivalents were filled into suitable test vessels. The number of vessels was sufficient to allow duplicate sampling at each sampling time and to keep a limited number of reserve vessels.

The vessels were incubated in the dark for 120 days at a temperature of 20°C. Throughout the incubation period, the test vessels were continuously aerated with a slight stream of moistened synthetic air. The outgoing air was led through a series of gas-washing bottles containing trapping solutions for potential volatiles (ethylene glycol, 0.5M H_2SO_4, 0.5M NaOH). The water content of the soils was monitored throughout the incubation period by weighing the sampled vessels.

2. Sampling

Sampling times were 0, 3, 7, 14, 29 (Speyerer Wald 2 soil) / 30 (Li10 and LUFA 5M soil), 59 (Li10 and LUFA 5M soil) / 62 (Speyerer Wald 2 soil), 90 and 120 days after treatment (DAT).

At 0 DAT as well as at 59/62 DAT and 120 DAT two replicate samples were worked up. At the other sampling times only one replicate was worked up, the second one was stored in a freezer.

Suitable amounts of the trapping solutions from the gas washing bottles were subjected to LSC measurement. Measurements were performed in triplicate.

3. Description of the analytical procedures

The soil was extracted three times with 100 mL acetonitrile and three times with 100 mL acetonitrile/water (1:1, v:v) by shaking for about 30 minutes. After each extraction, the suspension was centrifuged and aliquots of each solution were radioassayed.

The three acetonitrile and the three acetonitrile/water extracts, respectively, were combined and the two combined extracts were concentrated to dryness, re-dissolved in the extraction solvent and analyzed by LSC. Aliquots of the combined extracts were analyzed by HPLC to obtain the metabolite pattern.

The extracted soil was dried in a drying oven at 60°C and homogenized. Aliquots were combusted in order to determine the amount of non-extractable radioactive residues (NER). The evolved $^{14}CO_2$ from each combusted aliquot was trapped in an Oxysolve C-400 scintillator and measured by LSC.

4. Calculation of the degradation rate

Kinetic analysis and calculations of best-fit DT_{50} and DT_{90} values was performed in the original study following the recommendations of the FOCUS Kinetics workgroup [*FOCUS (2006)*], using KinGUI version 1.1. An updated kinetic evaluation using a newer version of the kinetic software (KinGUI version 2) was performed separately [*CA 7.1.2.1.1/2, BASF DocID 2014/1093424*].

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The detailed results on the extractability of radioactive residues in the soils are presented in Table 7.1.2.1.1-4 to Table 7.1.2.1.1-6. The material balance ranged from 90.1 to 105.0% TAR for all soils.

B. EXTRACTABLE AND BOUND RESIDUES

The distribution of radioactivity in extractable residues (ERR), non-extractable residues (NER), CO_2 and other volatiles for each soil is shown in Table 7.1.2.1.1-4 to Table 7.1.2.1.1-6. The amount of extractable radioactivity (ERR) decreased from 95.5 - 98.9% TAR (mean of two replicates) at 0 DAT to 39.0 - 50.9% TAR after 120 days of incubation.

The non-extractable radioactive residues increased during the study from 0.6 - 1.0% TAR at 0 DAT to a maximum of 36.6 - 48.4% TAR at the end of the study after 120 days of incubation.

C. VOLATILIZATION

Mineralization to CO_2 reached a total of 6.1 - 7.0% TAR after 120 days. No other volatile compounds were detected.

D. TRANSFORMATION OF PYRACLOSTROBIN

All combined soil extracts were analyzed by radio-HPLC. The results obtained with this system are summarized in Table 7.1.2.1.1-7 to Table 7.1.2.1.1-9.

Since the separation of the parent compound and all metabolites was not successful with one single HPLC system, all extracts were analyzed on two different systems: HPLC method 188-1 (Synergi Polar-RP) and HPLC method 188-2 (Synergi Hydro-RP) with a special long gradient. For a complete picture of the metabolism of the test item, the results of the two HPLC systems were combined: Amounts of pyraclostrobin and BF 500-3 were taken from the analyses with HPLC method 188.1 (Synergi Polar-RP) whereas the amounts of all other metabolites were taken from the analyses with HPLC method 188-2 (Synergi Hydro-RP).

The identity of the peaks of pyraclostrobin, BF 500-6, BF 500-7 and BF 500-3 was determined by co-chromatography with reference compounds and was confirmed by mass spectrometric analysis. The identity of further metabolites was determined by mass spectrometric analysis. The correct assignment of cis and trans metabolites BF 500-6 and BF 500-7 was confirmed by NMR spectroscopic analysis.

The parent compound pyraclostrobin decreased continuously from 92.5 - 94.4% TAR at 0 DAT to 7.2 - 22.0% TAR after 120 days of incubation.

Several metabolites were formed in moderate amounts: BF 500-6 (trans and cis isomers: max. 3.5 and 19.3% TAR, respectively), BF 500-7 (trans and cis isomers: 1.5 and 7.8% TAR, respectively) and BF 500-3 (max. 4.3% TAR). The metabolites 500M99, 500M97, 500M96 and 500M98 were found in amounts below 4% TAR.

The kinetic evaluation was performed in a separate report [*CA 7.1.2.1.1/3, BASF DocID 2014/1093424*], using a newer version of the kinetic software (KinGUI version 2).

III. CONCLUSION

Pyraclostrobin was degraded rather fast in aerobic soil. The fraction of non-extractable residues increased reaching between 36.6 and 48.4% TAR at the end of the study after 120 days. $^{14}CO_2$ was formed in low amounts up to 7% TAR. No other volatile compounds were detected.

Several metabolites were formed in moderate amounts. The most prominent metabolite, the trans isomer of BF 500-6, was formed in amounts up to 19.3% TAR. Only one other metabolite, the trans isomer of BF 500-7, reached amounts ≥ 5% TAR in one soil.

Report: CA 7.1.2.1.1/3
Eickler B., 2014a
Kinetic evaluation of aerobic soil degradation of BAS 500 F - Pyraclostrobin: Determination of trigger and modeling endpoints according to Focus Degradation Kinetics
2014/1093424
Guidelines: FOCUS Kinetics (2006) SANCO/10058/2005 version 1.0 of Nov. 2011
GLP: no

Note: This study, which was erroneously not listed in the application submitted for renewal of approval, is replacing BASF DocID 2010/1197290, which was listed in the application. The reason for submission is provided below.

Executive Summary

The degradation of the fungicide pyraclostrobin (BAS 500 F) in soil has been investigated in four aerobic laboratory soil degradation studies in nine experiments. The purpose of this evaluation was to analyze the degradation kinetics of pyraclostrobin and its metabolites BF 500-3, BF 500-6 and BF 500-7 observed in the studies according to current guidance of the FOCUS workgroup on degradation kinetics.

The appropriate kinetic models to derive trigger and modeling endpoints were identified considering the procedures and kinetic models proposed by the FOCUS kinetics guidance.

The best-fit model to derive trigger endpoints was selected based on a visual and statistical assessment. Modeling endpoints were normalized to reference conditions.

For pyraclostrobin, the kinetic evaluation showed that the SFO model is appropriate to derive trigger endpoints in two soils, while biphasic kinetic models (DFOP or FOMC) were selected as best-fit models in seven soils. The best-fit $DegT_{50}$ values were between 11.2 and 97.9 days, and $DegT_{90}$ values were between 87.7 and >1000 days. Modeling $DegT_{50}$ values range between 24.4 and 97.9 days, whereas normalized modeling endpoints (20°C, pF2) range between 15.6 and 95.4 days.

For metabolites BF 500-6 and BF 500-7 trigger endpoints as well as (normalized) modeling-$DegT_{50}$ values and corresponding formation fractions could be derived for each metabolite in at least two soils. For the transient metabolite BF 500-3, reliable trigger and modeling endpoints could not be derived from any of the soils.

I. MATERIAL AND METHODS

The degradation of pyraclostrobin and its soil metabolites BF 500-3, BF 500-6 and BF 500-7 in eight different soils in nine trials [*old EU Dossier, A II M 7.1.1.2.1/1, Ebert D. - BASF DocID 1998/11201; old EU dossier, A II M 7.1.1.2.1/2, Ebert D. - BASF DocID 1999/10090; old EU dossier, A II M 7.1.1.2.1/3, Ebert D. - BASF DocID 1999/1109; CA 7.1.2.1.1/1, Staudenmaier H., Kuhnke G. - BASF DocID 2011/1102370*] was analyzed taking into account the current guidance of the FOCUS workgroup on degradation kinetics [*FOCUS (2006)*].

Kinetic modeling strategy

Kinetic evaluation was performed in order to derive degradation parameters as triggers for additional work (trigger endpoints) as well as modeling endpoints. The best-fit model was selected based on visual and statistical assessment and the corresponding $DegT_{50}$ and $DegT_{90}$ values are reported as trigger endpoints. Appropriate $DegT_{50}$ values for use in environmental fate models were derived depending on the kinetic model.

For the metabolites of pyraclostrobin, the procedure for deriving modeling and trigger endpoints for metabolites recommended by the FOCUS Kinetics workgroup [*FOCUS (2006)*] was followed. The metabolites were added to the appropriate kinetic model for the parent. In the evaluation of data from the studies [*Ebert D. - BASF DocID 1998/11201; Ebert D. - BASF DocID 1999/10090; Ebert D. - BASF DocID 1999/11091*], the degradation products BF 500-6 and BF 500-7 were considered. Simultaneous formation from the parent was assumed and considered as pathway in the kinetic evaluation. In the evaluation of data from the study [*Staudenmaier H., Kuhnke G. - BASF DocID 2011/1102370*], based on the known degradation pathway of pyraclostrobin, metabolite BF 500-3 was included as transient metabolite. Simultaneous formation of the degradation products BF 500-6 and BF 500-7 from the intermediate BF 500-3 was assumed and considered as pathway for the kinetic evaluation.

Kinetic models included in the evaluations

For each data set, the kinetic models proposed by FOCUS Kinetics [*FOCUS (2006)*] were tested in order to identify the best-fit model, i.e. single first order (SFO) kinetics, the Gustafson-Holden model (FOMC) and the bi-exponential (DFOP) kinetics. The respective model descriptions and corresponding equations for calculating endpoints ($DegT_{50}$, $DegT_{90}$) are shown in the FOCUS Kinetics guidance [*FOCUS (2006), Box 5-1, Box 5.2 and Box 5-4*].

The goodness-of-fit of the kinetic models was assessed by visual inspection and statistical measures, as recommended by the FOCUS Kinetics guidance [*FOCUS (2006)*].

Data handling and software for kinetic evaluation

The initial value at day zero for the parent was set to material balance minus the measured amount of BF 500-3 at DAT 0, as this metabolite was a known impurity in the application solution. The metabolites BF 500-6 and BF 500-7 were considered in the evaluation and initial concentrations were set to zero. In *Staudenmaier H., Kuhnke G.* [*BASF DocID 2011/1102370*], the transient metabolite BF 500-3 was included in the evaluation. Measured values of BF 500-3 were used as initial concentrations. In case metabolite values were not reported and no LOQ or LOD were provided, metabolite values were conservatively set to 0.1% TAR.

The software package KinGUI version 2.2012.320.1629 was used for parameter fitting. The error tolerance and the number of iterations of the optimization tool (IRLS) were set to $1x10^{-6}$ and 100, respectively. Note, that in this software package only SFO kinetic evaluation for the metabolites is considered for determining trigger and modeling endpoints.

Normalization to reference conditions

According to FOCUS *(2006)* the $DegT_{50}$ values obtained from laboratory studies should be normalized for modeling purposes to reference conditions at a temperature of 20°C and soil moisture at pF2 to account for the different soil temperature and moisture conditions during incubation. The laboratory trials were conducted at 20°C, therefore temperature correction was not necessary. The soil moisture was 40% MWHC, and normalization was conducted according to FOCUS *(2006)*. Reference moisture contents for the various soil types were derived from *FOCUS (2011)* [*Generic guidance for Tier 1 FOCUS ground water assessments, version 2.0. FOCUS groundwater scenarios working group*]. For *Staudenmaier H., Kuhnke G.* [*BASF DocID 2011/1102370*] reference water retention characteristics were provided in the study report and included in the normalization.

Experimental data

The kinetic evaluation was conducted for nine trials from four aerobic laboratory soil degradation studies [*Ebert D. - BASF DocID 1998/11201; Ebert D. - BASF DocID 1999/10090; Ebert D. - BASF DocID 1999/11091; Staudenmaier H., Kuhnke G. - BASF DocID 2011/1102370*]. The test substance was applied at a nominal rate of 0.33 and 0.667 mg kg^{-1} soil in all 3 studies of *Ebert D.* and in the study of *Staudenmaier H., Kuhnke G.*, respectively. The soil characteristics of these four studies are summarized in Table 7.1.2.1.1-10 to Table 7.1.2.1.1-13.

II. RESULTS AND DISCUSSION

Pyraclostrobin

The derived trigger endpoints (best-fit) for pyraclostrobin are summarized in Table 7.1.2.1.1-19. The kinetic evaluation showed that the SFO model is appropriate to derive trigger endpoints for additional work in two soils, while biphasic kinetic models (DFOP or FOMC) were selected as best-fit models in seven soils.

Table 7.1.2.1.1-19: Summary of endpoints for use as triggers for additional work of pyraclostrobin

Modeling endpoints for pyraclostrobin were obtained using SFO and FOMC kinetics in six and three soils, respectively. The $DegT_{50}$ values suitable for modeling obtained under different incubation conditions were normalized to a reference moisture of pF2 and a temperature of 20°C. Parameters included in the normalization procedure are shown in Table 7.1.2.1.1-20 while derived modeling endpoints are summarized in Table 7.1.2.1.1-21.

Metabolites of pyraclostrobin

The derived trigger endpoints for BF 500-6 and BF 500-7 are summarized in Table 7.1.2.1.1-22 and Table 7.1.2.1.1-23. The kinetic evaluation showed that the SFO model is appropriate to derive trigger endpoints (best-fit) for additional work in two soils, while for all other soils no reliable endpoints could be derived.

For the transient metabolite BF 500-3, reliable trigger endpoints (SFO kinetics) could not be derived from any of the soils.

For the metabolites, the derived SFO-$DegT_{50}$ values are suitable as modeling endpoints after normalization to reference conditions. The same correction factors f_{temp} and f_{moist} as for the parent (see Table 7.1.2.1.1-20) were used for calculation of normalized $DegT_{50}$ values (Table 7.1.2.1.1-24 and Table 7.1.2.1.1-25).

For the transient metabolite BF 500-3, no adequate fit could be derived using SFO kinetics and therefore no endpoints could be calculated.

III. CONCLUSION

Trigger and modeling endpoints were derived for pyraclostrobin in four laboratory degradation studies with nine trials. Trigger endpoints (best-fit) $DegT_{50}$ values were between 11.2 and 97.9 days, and $DegT_{90}$ values were between 87.7 and >1000 days. Modeling $DegT_{50}$ values range between 24.4 and 97.9 days, whereas normalized modeling endpoints (20°C, pF2) range between 15.6 and 95.4 days.

For metabolites BF 500-6 and BF 500-7 trigger endpoints as well as (normalized) modeling-$DegT_{50}$ values and corresponding formation fractions could be derived for each metabolite in at least two soils. For the transient metabolite BF 500-3, reliable trigger and modeling endpoints could not be derived from any of the soils.

CA 7.1.2.1.2 Aerobic degradation of metabolites, breakdown and reaction products

Degradation rates in three soils could not be reliably obtained for all metabolites from the parent studies. Therefore, separate degradation rate studies were performed using the respective metabolites as test items.

Summary tables on maximum occurrence and degradation rates of metabolites obtained in different parent and metabolite studies are provided at the end of this chapter.

Report: CA 7.1.2.1.2/1
Tornisielo A.,Sacchi R.R., 2011a
Rate of degradation of BF 500-6 on European soils under aerobic conditions
2011/1142307
Guidelines: OECD 307 (2002)
GLP: yes
(certified by Instituto Nacional de Metrologia, Normalizacao e Qualidade Industrial - INMETRO, Rio de Janeiro, Brazil)

Executive Summary

The objective of the present study was to investigate the rate of degradation of BF 500-6 in three soils at a temperature of 20 ± 2°C.

The soils were treated with a nominal rate of 0.267 mg ^{14}C-labeled BF 500-6 per kg of dry soil which corresponds to a field application rate of 100 g a.s. ha^{-1}. The incubation was carried out in the dark in the laboratory under aerobic conditions at a soil moisture of 40% of the maximum water holding capacity. A closed incubation system with continuous aeration (moistened air) was used with an attached trapping system for the determination of volatile compounds. Samples were taken at 0, 3, 7, 14, 31, 60, 91, and 120 days after treatment (DAT).

The soil samples were extracted three times with acetonitrile and twice with acetonitrile/water (1:1) and the extracts were analyzed by LSC and HPLC. The amount of non-extractable residues was determined by combustion and subsequent LSC measurements.

The mass balance throughout the study ranged from 95.5 to 100.9% total applied radioactivity (TAR) for the three soils. The extractable radioactivity decreased from > 99.0% TAR at day 0 to 92.4 - 93.9% after 120 days. The majority of radioactivity in the extracts was always unchanged test item. At the end of incubation, BF 500-6 was detected in amounts of 86.6 - 90.6% TAR.

Seven minor unknown metabolites (UK) were detected showing maximum values of 1.6% (UK 2 and UK 6) and 2.3% (UK 5) TAR. Formation of CO_2 was observed in the three soils reaching 0.2 - 0.4% TAR after 120 days. No other volatile compounds were detected. Non-extractable residues were formed in amounts with a maximum of 4.1 to 4.9% TAR at the end of the study.

Degradation times of BF 500-6 were calculated with the computer program KinGUI 1.1 applying first order kinetics (SFO). DegT_{50} values were between 753 and 921 days.

I. MATERIAL AND METHODS

A. MATERIALS

BAS code:	BF 500-6
Synonym:	500M01
Reg.No.:	364380
Chemical name (IUPAC):	N,N'-bis-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl] oxymethyl} phenyl) diazene N-oxide
Molecular weight:	611.486 g mol^{-1} (unlabeled)
Position of radiolabel:	Tolyl-ring-U-C^{14}
Batch No.:	658-2004
Specific radioactivity:	8.42 MBq mg^{-1}
Radiochemical purity:	96.9% (according to certificate) 100.0% (determined by radio-HPLC prior to soil treatment in this study)

2. Soils

Three different soils were used for treatment and incubation. The soils were sieved through a 2 mm sieve before use. The soil characteristics are summarized in Table 7.1.2.1.2-1.

Table 7.1.2.1.2-1: Properties of soils used to investigate degradation rate of ^{14}C-BF 500-6

*data obtained before starting the study
DAT = days after treatment

The soils were transported from Germany to Brazil in a temperature range of 4 - 20°C and were stored in a refrigerator at 4 ± 2°C before use.

B. STUDY DESIGN

1. Experimental conditions

The soils were adjusted to about 40% MWHC and treated at a nominal concentration of 0.267 mg ^{14}C-BF 500-6 per kg dry soil, which corresponds to a field application rate of 100 g a.s. ha^{-1} (assuming an equal distribution in the top 2.5 cm soil layer and a soil density of 1.5 g cm^{-3}).

For the soil treatment, one kg of each soil was treated with 5 mL of the treatment solution. The treated soils were homogenized and soil portions of 50 g dry soil equivalents were filled into suitable test vessels. The number of vessels was sufficient to allow duplicate sampling at each sampling time and to keep a limited number of reserve vessels.

The vessels were incubated in the dark for 120 days at a temperature of 20 ± 2°C. Throughout the incubation period, the test vessels were continuously aerated with a slight stream of moistened and CO_2-free air. The outgoing air was led through a series of gas-washing bottles containing trapping solutions for potential volatiles (ethylene glycol, 0.5M H_2SO_4, 0.5M NaOH). The water content of the soils was monitored throughout the incubation period by weighing representative vessels at each sampling time.

For determination of the microbial biomass during (60 days) and at the end of incubation (120 days), additional soil samples without test item were incubated under the same conditions.

2. Sampling

Sampling times were 0 (no sampling of volatiles), 3, 7, 14, 31, 60, 91 and 120 days after treatment (DAT).

At 0 DAT as well as at 60 DAT and 120 DAT two replicate samples were worked up. At the other sampling times only one replicate was worked up, the second one was stored in a freezer.

3. Description of the analytical procedures

The soil was extracted consecutively three times with 100 mL acetonitrile and two times with 100 mL water/acetonitrile (1:1) by shaking for about 30 minutes. After each extraction, the suspension was centrifuged and two aliquots of the supernatant were measured by LSC.

After the last extraction, the soil was rinsed with 100 mL acetone. The acetone was also checked for radioactivity but no HPLC analysis was performed since the amounts of radioactive residues never exceeded 0.8% of the total applied radioactivity (TAR).

All the extracts were combined and concentrated to a small volume. Prior to HPLC analysis, the concentrated extracts were centrifuged. Then the supernatant was radio-assayed and analyzed by HPLC to obtain the metabolite pattern.

The extracted soil was dried at room temperature. Then, the soil was homogenized with a laboratory mill and at least aliquots combusted in order to determine the amount of non-extractable radioactive residues (NER, bound residues).

All liquid samples were measured for radioactivity by LSC. The radioactivity in the extracted and dried soil samples was determined by combustion of at least three aliquot parts. Combustion products were absorbed in the Oxysolve C-400 scintillation cocktail.

4. Kinetic modeling

The kinetic analysis was carried out following the recommendations of the FOCUS work group on degradation kinetics [*FOCUS (2006)*] in order to derive degradation kinetics and trigger endpoints. The analysis was conducted by non-linear regression methods using the software tool KinGUI 1.1.

For each data set, the kinetic models proposed by the FOCUS Kinetic guidance document were tested in order to identify the best-fit model. The recommended kinetic models, i.e. the single first order kinetics (SFO), the Gustafson-Holden model (FOMC) and the bi-exponential kinetic model (DFOP) are already implemented in KinGUI.

The goodness-of-fit of the kinetic models was assessed by visual inspection and statistical measures recommended by the FOCUS guidance. The goodness-of-fit used for the identification of the best-fit kinetic model is the χ^2 minimum error level. The kinetic endpoints (DT_{50} and DT_{90} values) are reported for the kinetic models, which were selected based on statistical and visual assessment. The reliability of individual parameters was judged by means of a single-sided t-test. When available, replicate measurements were used for the parameter estimation.

In all soils, the measured value at DAT 0 was set to the material balance. At later sampling time points (3, 7, 14. 31, 60, 91 and 120 DAT), the measured values were set to the amount of extractable residues.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The detailed results on the extractability of radioactive residues in the soils are presented in Table 7.1.2.1.2-2 to Table 7.1.2.1.2-4. The material balance ranged from 95.5 to 100.9% TAR for all soils.

B. EXTRACTABLE AND BOUND RESIDUES

The distribution of radioactivity in extractable residues (ERR), non-extractable residues (NER), CO_2 and other volatiles for each soil is shown in Table 7.1.2.1.2-2 to Table 7.1.2.1.2-4. The amount of extractable radioactivity (ERR) moderately decreased from more than 99% TAR at 0 DAT to 92.4 - 93.9% TAR after 120 days of incubation.

Non-extractable radioactive residues (NER) reached maximum values of 4.1 to 4.9% TAR at the end of the study after 120 days of incubation.

C. VOLATILIZATION

Formation of CO_2 was negligible in all three soils reaching in total only 0.2 to 0.4% TAR after 120 days. No other volatile compounds were detected.

D. TRANSFORMATION OF BF 500-6

All combined soil extracts were analyzed by radio-HPLC. The results obtained with this system are summarized in Table 7.1.2.1.2-5.

The concentration of BF 500-6 decreased slowly in the three soils from 95.0% TAR at 0 DAT to approximately 86.6 - 90.6% TAR after 120 days of incubation. The identification of BF-500-6 was achieved by chromatographic comparison with the retention time of the ^{14}C-test item.

During the course of the study, seven minor unknown metabolites (UK) were visible in the chromatograms showing maximum values of 1.6% TAR (UK 2 and UK 6) and 2.3% TAR (UK 5).

Calculation of the degradation rates

All visual fits were good and the residuals were evenly distributed. The χ^2 errors were below 2 for all models. As no obvious biphasic degradation pattern was observed in any of the soils, SFO was selected as best fit model in all cases.

It was shown that the observed degradation of BF 500-6 in the different experiments could be well described by single first order (SFO) kinetics. In Table 7.1.2.1.2-6, the $DegT_{50}/DegT_{90}$ values of the selected kinetic models are presented.

Table 7.1.2.1.2-6: Best-fit kinetic $DegT_{50}$ and $DegT_{90}$ values of metabolite BF 500-6

Soil	$DegT_{50}$ [d]	$DegT_{90}$ [d]	Kinetic model	χ^2 error
Li 10	855	>1000	SFO	1.18
LUFA 5M	921	>1000	SFO	1.04
Speyerer Wald 2	753	>1000	SFO	1.40

III. CONCLUSION

BF 500-6 degraded in three different soils with $DegT_{50}$ values between 753 and 921 days under aerobic conditions at 20 ± 2°C and a soil moisture of 40% of the maximum water holding capacity. Seven minor unknown metabolites appeared during the course of the study. However, none of them exceeded 2.3% of the total applied radioactivity (TAR). After 120 days of incubation, the mineralization rate reached 0.2 to 0.4% TAR and the non-extractable residues amounted to 4.1 - 4.9% TAR.

Normalization of degradation rates
Normalization to reference conditions (20°C, pF2) was performed as described for the parent (see paragraph after CA 7.1.1.1/1). A summary is provided below:

Table 7.1.2.1.2-7: Normalization of BF 500-6 $DegT_{50}$ values to reference conditions

Executive Summary

The objective of the present study was to investigate the rate of degradation of BF 500-7 in three soils at a temperature of 20 ± 2°C.

The soils were treated with a nominal rate of 0.267 mg ^{14}C-labeled BF 500-7 per kg of dry soil which corresponds to a field application rate of 100 g a.s. ha^{-1}. The incubation was carried out in the dark in the laboratory under aerobic conditions at a soil moisture of 40% of the maximum water holding capacity. A closed incubation system with continuous aeration (moistened air) was used with an attached trapping system for the determination of volatile compounds. Samples were taken at 0, 3, 7, 14, 29, 62, 87 and 121 days after treatment (DAT).

The soil samples were extracted three times with acetonitrile and twice with acetonitrile/water (1:1) and the extracts were analyzed by means of LSC and HPLC. The amount of non-extractable residues was determined by combustion and subsequent LSC measurements.

The mass balance throughout the study ranged from 94.3 to 101.5% of the total applied radioactivity (TAR) for the three soils. The extractable radioactivity decreased from > 97.0% TAR at day 0 to 89.4 – 94.1% after 121 days. The majority of radioactivity in the extracts was always unchanged test item. At the end of incubation, BF 500-7 was detected in amounts of 84.4 - 90.8% TAR.

Three metabolites were detected showing maximum values of about 2.6 - 3.2% TAR. Formation of CO_2 was observed in the three soils reaching 0.3 to 0.4% TAR after 121 days. No other volatile compounds were detected. Non-extractable residues were formed in amounts with a maximum of 6.3 to 7.4%TAR at the end of the study.

Degradation times of BF 500-7 were calculated with the computer program KinGUI 1.1 applying first order kinetics (SFO). DegT_{50} values were between 727 and >1000 days.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

BAS code:	BF 500-7
Synonym:	500M02
Reg.No.:	369315
Chemical name (IUPAC):	N,N'-bis-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxymethyl} phenyl) diazene
Molecular weight:	595.4884 g mol^{-1} (unlabeled)
Position of radiolabel:	Tolyl-ring-U-C^{14}
Specific radioactivity:	8.90 MBq mg^{-1}
Batch No.:	933-2025
Radiochemical purity:	98.8% (according to certificate) 100.0% (determined by radio-HPLC prior to soil treatment in this study)

2. Soils

Three different soils were used for treatment and incubation. The soils were sieved through a 2 mm sieve before use. The soil characteristics are summarized in Table 7.1.2.1.2-8.

Table 7.1.2.1.2-8: Properties of soils used to investigate degradation rate of ^{14}C-BF 500-7

Soil designation	Li10 (10/1680/03)	LUFA 5M (10/1651/03)	Speyerer Wald 2 (10/1715/03)

Microbial biomass at 121 DAT [mg C/100g dry soil]	14.0	24.0	60.0

* data obtained before starting the study
DAT = days after treatment

The soils were transported from Germany to Brazil in a temperature range of 4 - 20°C and before use were stored in a refrigerator at 4 ± 2°C.

B. STUDY DESIGN

1. Experimental conditions

The soils were adjusted to about 40% max. water holding capacity and treated at a nominal concentration of 0.267 mg ^{14}C-BF 500-7 per kg dry soil, which corresponds to a field application rate of 100 g a.s. ha^{-1} (assuming an equal distribution in the top 2.5 cm soil layer and a soil density of 1.5 g cm^{-3}).

For the soil treatment, one kg of each soil was treated with 5 mL of the treatment solution. The treated soils were homogenized and soil portions of 50 g dry soil equivalents were filled into suitable test vessels. The number of vessels was sufficient to allow duplicate sampling at each sampling time and to keep a limited number of reserve vessels.

The vessels were incubated in the dark for 121 days at a temperature of 20°C ± 2°C. Throughout the incubation period, the test vessels were continuously aerated with a slight stream of moistened and CO_2-free air. The outgoing air was led through a series of gas-washing bottles containing trapping solutions for potential volatiles (ethylene glycol, 0.5M H_2SO_4, 0.5M NaOH). The water content of the soils was monitored throughout the incubation period by weighing representative vessels at each sampling time.

For determination of the microbial biomass during (62 days) and at the end of incubation (121 days), additional soil samples without test item were incubated under the same conditions.

2. Sampling

Sampling times were 0 (no sampling of volatiles), 3, 7, 14, 29, 62, 87 and 121 days after treatment (DAT).

At 0 DAT as well as at 62 DAT and 121 DAT two replicate samples were worked up. At the other sampling times only one replicate was worked up, the second one was stored in a freezer.

3. Description of the analytical procedures

The soil was extracted consecutively three times with 100 mL acetonitrile and two times with 100 mL acetonitrile/water (1:1) by shaking for about 30 minutes. After each extraction, the suspension was centrifuged and two aliquots of the supernatant were measured by LSC.

After the last extraction, the soil was rinsed with 100 mL acetone. The acetone was also checked for radioactivity but no HPLC analysis was performed since the amounts of radioactive residues never exceeded 1.1% of the total applied radioactivity (TAR).

All the extracts were combined and concentrated to a small volume. Prior to HPLC analysis, the concentrated extracts were centrifuged. After centrifugation, the supernatant was radio-assayed and analyzed by HPLC to obtain the metabolite pattern.

The extracted soil was dried at room temperature. Then, the soil was homogenized with a laboratory mill and aliquots combusted in order to determine the amount of non-extractable radioactive residues (NER, bound residues).

All liquid samples were measured for radioactivity by LSC. The radioactivity in the extracted and dried soil samples was determined by combustion of at least three aliquots. Combustion products were absorbed in the Oxysolve C-400 scintillation cocktail.

4. Calculation of the degradation rate of BF 500-7

The kinetic analysis was carried out following the recommendations of the FOCUS work group on degradation kinetics [*FOCUS (2006)*] in order to derive degradation kinetics and trigger endpoints. The analysis was conducted by non-linear regression methods using the software tool KinGUI 1.1.

For each data set, the kinetic models proposed by the FOCUS Kinetic guidance document were tested in order to identify the best-fit model. The recommended kinetic models, i.e. the single first order kinetics (SFO), the Gustafson-Holden model (FOMC) and the bi-exponential kinetic model (DFOP) are already implemented in KinGUI.

The goodness-of-fit of the kinetic models was assessed by visual inspection and statistical measures recommended by the FOCUS guidance. The goodness-of-fit used for the identification of the best-fit kinetic model is the χ^2 minimum error level. The kinetic endpoints (DT_{50} and DT_{90} values) are reported for the kinetic models, which are selected based on statistical and visual assessment. The reliability of individual parameters was judged by means of a single-sided t-test. When available, replicate measurements were used for the parameter estimation.

In all soils, the measured value at DAT 0 was set to the material balance. At later sampling time points (3, 7, 14. 29, 62, 87 and 121 DAT), the measured values were set to the amount of extractable residues.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The detailed results on the extractability of radioactive residues in the soils are presented in Table 7.1.2.1.2-9 to Table 7.1.2.1.2-11. The material balance ranged from 94.3 to 101.5% TAR for all soils.

B. EXTRACTABLE AND BOUND RESIDUES

The distribution of radioactivity in extractable residues (ERR), non-extractable residues (NER), CO_2 and other volatiles for each soil is shown in Table 7.1.2.1.2-9 to Table 7.1.2.1.2-11. The amount of extractable radioactivity (ERR) decreased from more than 97% TAR at 0 DAT to 89.4 - 92.9% TAR after 121 days of incubation.

Non-extractable radioactive residues (NER) reached maximum values of 6.3 to 7.4%TAR at the end of the study after 121 days of incubation.

C. VOLATILIZATION

Formation of CO_2 was negligible in all three soils reaching in total only 0.3% TAR after 121 days. No other volatile compounds were detected.

D. TRANSFORMATION OF BF 500-7

All combined soil extracts were analyzed by radio-HPLC. The results obtained with this system are summarized in Table 7.1.2.1.2-12.

The concentration of BF 500-7 decreased slowly in the three soils from more than 94.0% TAR at 0 DAT to approximately 84.4-90.8% TAR after 121 days of incubation. The identification of BF 500-7 was achieved by chromatographic comparison with the retention time of the ^{14}C-test item.

During the course of the study, three minor unknown metabolites (UK) were visible in the chromatograms showing maximum values of 1.4% TAR (UK 1 and UK 3) and 3.2% TAR (UK 2).

t_R = retention time [min]

Calculation of the degradation rates

All visual fits were good and the residuals were evenly distributed. The χ^2 errors were below 2 for all models. As no obvious biphasic degradation pattern was observed in any of the soils, SFO was selected as best fit model in all cases.

It was shown that the observed degradation of BF 500-7 in the different experiments could be well described by single first order (SFO) kinetics. In Table 7.1.2.1.2-13, the $DegT_{50}$/$DegT_{90}$ values of the selected kinetic models are presented.

Table 7.1.2.1.2-13: Best-fit kinetic $DegT_{50}$ and $DegT_{90}$ values of metabolite BF 500-7

Soil	$DegT_{50}$ [d]	$DegT_{90}$ [d]	Kinetic model	χ^2 error
Li 10	727	>1000	SFO	2.08
LUFA 5M	>1000	>1000	SFO	1.49
Speyerer Wald 2	745	>1000	SFO	1.43

III. CONCLUSION

BF 500-7 degraded in three different soils with $DegT_{50}$ values between 727 and >1000 days under aerobic conditions at 20 ± 2°C and a soil moisture of 40% of the maximum water holding capacity. Three minor unknown metabolites appeared during the course of the study. However, none of them exceeded 3.2% of the total applied radioactivity (TAR). After 121 days of incubation, the mineralization rate had reached 0.3% TAR and the non-extractable residues amounted to 6.3 – 7.4% TAR.

Normalization of degradation rates

Normalization to reference conditions (20°C, pF2) was performed as described for the parent (see paragraph after *CA 7.1.1.1/1*). A summary is provided below:

Table 7.1.2.1.2-14: Normalization of BF 500-7 $DegT_{50}$ values to reference conditions

Report:	CA 7.1.2.1.2/3 Ebert D.,Dalkmann P., 2014a Rate of degradation of BF 500-4 (Reg. No. 358672) in soil under aerobic conditions 2013/1294779
Guidelines:	OECD 307, EPA 835.4100
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The degradation rate of BF 500-4 (500M73, Reg. No. 358672), anaerobic soil metabolite of pyraclostrobin, was investigated under aerobic conditions in three German agricultural soils.

The soils were treated with radiolabelled test item BF 500-4 at a nominal rate of 0.27 mg per kg dry soil, which corresponds to a field application rate of 100 g a.s. ha^{-1} calculated on the basis of an equal distribution in the top 2.5 cm soil layer and a soil density of 1.5 g cm^{-3}. This application rate is not related to any expected occurrence of this compound in soil, but was chosen for practical reasons to enable reliable quantification. Detectable concentrations of BF 500-4 in aerobic soil are generally not to be expected.

Soil aliquots of 100 g (dry weight basis) were weighed into test vessels and incubated in the dark under aerobic conditions with a soil moisture of 45% of the maximum water holding capacity and a temperature of 20°C ± 2°C.

Samples were taken after 0 and 2 hours and after 1, 3, 7, 14 and 28 days of incubation. All soil samples were worked up in duplicate. The soil samples were extracted three times with acetonitrile and once with acetonitrile/water (50/50, v/v). The individual extracts were analyzed by liquid scintillation counting (LSC). The extracts were then concentrated and analyzed by HPLC. The remaining soil after extraction was combusted to determine the amount of non-extractable soil bound residues. Additionally, the amount of formed volatiles was determined. A full material balance was provided for each sampling interval.

The amount of extractable radioactivity decreased continuously in the aerated soils from 89.4 to 93.1% TAR on hour 0 to 16.3 to 24.0% TAR after 28 days of incubation. The amount of non-extractable radioactive residues increased during the study from 2.1 to 3.3% TAR to 63.0 to 67.3% TAR after 28 days of incubation, representing the major route of degradation of BF 500-4. Mineralization to $^{14}CO_2$ reached between 5.1 and 6.3% TAR at the end of incubation. The material balance ranged from 85.9 to 98.1% TAR for all soils and sampling times.

The test item BF 500-4 degraded quickly already during the first day. From a level of 79.0 to 83.5% TAR at hour 0, the level dropped to 35.3 to 51.7% TAR after 1 day and decreased further to 1.2 to 3.0% TAR after 28 days.

The known pyraclostrobin metabolites BF 500-6 and BF 500-7 were detected in all three soils, reaching a maximum of 8.0% TAR (BF 500-6) and 2.2% TAR (BF 500-7) in soil LUFA 5M. Numerous unknown metabolites were formed over time, however, the majority of them in amounts < 2% TAR. Three unknown metabolites eluting at approximately 16, 33, and 40 min reached maximum amounts of 9.9, 8.6, and 5.8% TAR, respectively. Since BF 500-4 is itself a metabolite being detectable only under strict anaerobic soil conditions [old *EU Dossier, A II M 7.1.1.2.1/5, Kellner O. - BASF DocID 1999/10079*; old *EU Dossier, A II M 7.1.1.2.1/6, Kellner O. - BASF DocID 1999/11103*], these degradation products are considered to be not environmentally relevant. All other degradation products never exceeded 5% TAR.

Kinetic analysis and calculation of DT_{50} and DT_{90} values was performed following the recommendations of the FOCUS Kinetics workgroup. The analysis was conducted by non-linear regression methods employing the software tool KinGUII. Best-fit DT_{50} values ranged from 0.3 to 1.8 days (DT_{90}: 3.9 – 13.5 days) and modeling- DT_{50} values were between 2.2 and 6.1 days.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

BAS code:	^{14}C-BF 500-4
Synonym:	500M73
Reg. No.:	358672
Chemical name (IUPAC):	2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxymethyl}phenylamine
Molar mass:	299.76 g mol^{-1} (unlabeled)
Position of radiolabel:	Tolyl-U-C^{14}
Specific radioactivity of a.s.:	8.49 MBq mg^{-1}
Batch No.:	1072-1004
Radiochemical purity:	≥ 96.0%

2. Soils

Three agricultural soils were used for treatment and incubation. The soils were sieved through a 2 mm sieve before use. The soil characteristics are summarized in Table 7.1.2.1.2-15.

Table 7.1.2.1.2-15: Properties of soils used to investigate the degradation rate of ^{14}C-BF 500-4

Soil designation	LUFA 5M (14/1651/01)	Li10 (14/1680/01)	LUFA 2.2 (14/736/01)

B. STUDY DESIGN

1. Experimental conditions

Before treatment, soil moisture was adjusted to about 45% of the maximum water holding capacity. Each test vessel contained 100 g soil portions (dry weight equivalents) and was treated with ^{14}C-labeled BF 500-4 at a nominal concentration of 0.27 mg kg^{-1} dry soil, which corresponds to a field application rate of 100 g a.s. ha^{-1}. This application rate is not related to any expected occurrence of this compound in soil, but was chosen for practical reasons to enable reliable quantification. Detectable concentrations of BF 500-4 in aerobic soil are generally not to be expected.

The test vessels were incubated in the dark for up to 28 days at a temperature of 20 ± 2°C. Throughout the incubation period, the test vessels were continuously aerated with a slight stream of moistened synthetic air. The outgoing air was led through a series of gas-washing bottles containing trapping solutions for potential volatiles (0.5 M NaOH, ethylene glycol, 0.5 M H_2SO_4). H_2SO_4 traps were omitted after day three, since no radioactivity evolving from BF 500-4 was expected in this solution. The water content of the soils was monitored and re-adjusted if necessary throughout the incubation period by weighing the sampled vessels.

Since BF 500-4 showed instability in the soil extracts, treatment and incubation for the 1 d sampling had to be repeated for all soils. Also a 0 hour sampling (one replicate per soil) was repeated, because BF 500-4 amounted to < 80% TAR in some of the extracts. This treatment was done using non-treated spare vessels still kept in the incubator.

2. Sampling

Duplicate samples were taken at 0 and 2 hours and 1, 3, 7, 14 and 28 days after treatment (DAT). Except for 0 and 2 hours, the volatile trapping solutions were sampled and replaced by new flasks with fresh solutions.

3. Description of the analytical procedures

Several pre-tests were performed to optimize the extraction procedure. On the basis of the results in these pre-tests, an extraction procedure consisting of three steps of acetonitrile and one step of acetonitrile/water (50/50, v/v) was selected as extraction procedure for the main part of the study, since this procedure resulted in a high extraction yield of 92.9% TAR.

Therefore, the soil was consecutively extracted three times on a laboratory shaker for about 20 min, first with about 150 mL ACN, followed by twofold extraction with about 100 mL ACN and finally with about 100 mL of ACN/H_2O (50/50, v/v).

After each extraction step, the suspension was centrifuged, the supernatant was filtered and aliquots of each solution were radio-assayed. Since BF 500-4 showed some instability in soil extracts, the first ACN extract of the 0 – 24 h samples, which contained the majority of radioactivity, was immediately prepared for HPLC analysis. It was concentrated by rotary evaporation (temp. ≤ 40°C), redissolved in ACN and subjected to HPLC. The second and third ACN extract, which contained much less radioactivity, were combined, concentrated and analyzed by HPLC. For the 3 - 28 day samples, showing already a significantly reduced extractability, all three ACN extracts were combined, concentrated and analyzed by HPLC. Also the ACN/H_2O extracts were concentrated and subjected to HPLC analysis.

The procedural recoveries after concentration were checked by LSC. The recoveries were always ≥ 90% for the first ACN extract, and ≥ 79% for the pooled ACN extracts. The recovery for the ACN/H_2O extracts after concentration and redissolving was partially below 50%, however, this is considered negligible since the total amount of radioactivity never exceeded 3.4% in this fraction.

The extracted soil was dried at room temperature, homogenized in an analytical mill and aliquots were combusted to determine the amount of non-extractable radioactive residues (NER). Combustion products were trapped in an Oxysolve C-400 scintillator and measured by LSC.

The solutions from the volatile traps (0.5 M NaOH, ethylene glycol and 0.5 M H_2SO_4) were subjected to LSC measurement.

4. Calculation of the degradation rate of BF 500-4

The kinetic analysis was carried out following the recommendations of the FOCUS work group on degradation kinetics [*FOCUS (2006)*] in order to derive trigger and modeling endpoints. The software package KinGUII (version 2.2012.320.1629) was used for parameter fitting.

For each data set, the kinetic models proposed by the FOCUS Kinetic guidance document were tested in order to identify the best-fit model, i.e. single first order kinetics (SFO), the Gustafson-Holden model (FOMC) and bi-exponential kinetics (DFOP).

The goodness-of-fit of the kinetic models was assessed by visual inspection and statistical measures recommended by the FOCUS guidance. The goodness-of-fit used for the identification of the best-fit kinetic model is the χ^2 minimum error level. The reliability of individual parameters was judged by means of a single-sided t-test.

The initial concentration of the applied substance was set to the material balance recovered at day 0.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The detailed results on the extractability of radioactive residues in the soils are presented in Table 7.1.2.1.2-16 to Table 7.1.2.1.2-18. The material balance throughout the incubation period ranged from 85.9 to 95.2% TAR for soil LUFA 5M, from 88.3 to 94.3% TAR for soil Li10 and from 89.1 to 98.1% TAR for soil LUFA 2.2. The average material balance for all soil samples was 91.6% TAR for soil Li10, 91.2% TAR for soil LUFA 5M and 93.9% TAR for soil LUFA 2.2.

B. EXTRACTABLE AND BOUND RESIDUES

The distribution of radioactivity in extractable residues, non-extractable residues (NER), CO_2 and other volatiles for each soil is shown in Table 7.1.2.1.2-16 to Table 7.1.2.1.2-18. Considering all three soils, the amount of extractable radioactivity decreased quickly already during the first day. From a level of 89.4 to 93.1% TAR at hour 0, it decreased to 58.7 to 63.6% TAR after 1 day and then decreased continuously further to 16.3 to 24.0% TAR after 28 days of incubation.

The amount of NER increased during the study from 2.1 - 3.3% TAR at hour 0 to 63.0 - 67.3% TAR after 28 days of incubation.

C. VOLATILIZATION

The formation of volatiles was exclusively related to the mineralization to $^{14}CO_2$, reaching a total of 5.1 to 6.3% TAR after 28 days of incubation. In ethylene glycol traps as well as in H_2SO_4 traps no radioactive residues were found.

D. TRANSFORMATION OF BF 500-4

All soil extracts were analyzed by radio-HPLC. The summarized results are presented in Table 7.1.2.1.2-19 to Table 7.1.2.1.2-21.

Considering all three soils, the concentration of the test item BF 500-4 decreased quickly already during the first day. From a level of 79.0 to 83.5% TAR at hour 0, it decreased to 35.3 to 51.7% TAR after 1 day and then decreased continuously further to 1.2 to 3.0% TAR after 28 days of incubation.

The known metabolites BF 500-6 as well as BF 500-7 were detected in all three soils, reaching maximum values of 8.0% TAR (BF 500-6) and 2.2% TAR (BF 500-7), respectively, in soil LUFA 5M.

Numerous unknown metabolites were formed over time, however, most of them in amounts < 2% TAR. Three unknown metabolites eluting at approximately 16, 33, and 40 min reached maximum amounts of 9.9, 8.6, and 5.8% TAR, respectively. The peaks with retention times 33 and 40 min were already present at low amounts in the application solution. None of the peaks were persistent and since all these compounds represent secondary metabolites, which can appear in the environment only if BF 500-4 is formed out of the active ingredient pyraclostrobin under anaerobic conditions, it is very unlikely that they will ever reach environmentally significant amounts.

Calculation of the degradation rates

The soil residues for LUFA 5M, Li10, and LUFA 2.2 could be best described by the DFOP kinetic fit approach. The calculated best-fit DT_{50}/DT_{90} values and the selected kinetic models are presented in Table 7.1.2.1.2-22, while modeling endpoints are summarized in Table 7.1.2.1.2-23.

Table 7.1.2.1.2-22: Best-fit kinetic DT_{50} and DT_{90} values of metabolite BF 500-4

Soil	DT_{50} [d]	DT_{90} [d]	Kinetic model	χ^2 error
LUFA 5M	0.3	3.9	DFOP	6.8
Li10	0.2	13.5	DFOP	7.6
LUFA 2.2	1.8	13.0	DFOP	3.9

Table 7.1.2.1.2-23: Modeling endpoints for BF 500-4

Soil	Kinetic model	χ^2 error	Modeling $DegT_{50}$ [d]
Soil Lufa 5M	FOMC	13.8	2.2*
Soil Li 10	DFOP	7.6	6.1**
Soil Lufa 2.2	SFO	14.7	2.8

* calculated as $DegT_{90}$ FOMC / 3.32 according to FOCUS (2006)
** calculated as $\ln(2)/k_2$ according to FOCUS (2006)

III. CONCLUSION

BF 500-4, metabolite of pyraclostrobin, degraded fast in aerobic soil. After 28 days of incubation, only 1.2 - 3% TAR remained as unchanged test item in soil. The degradation was dominated by the formation of non-extractable residues. $^{14}CO_2$ was formed in low amounts (5.1 - 6.3% TAR, tolyl-^{14}C-label). No other volatile residues were detected. BF 500-4 is not persistent in soil and degrades with half-lives of 0.2 - 1.8 days. The DT_{90} values were calculated with 3.0 - 13.5 days.

Numerous metabolites were formed, most of them in amounts <2% TAR. Three unknown metabolites reached maximum amounts of 9.9, 8.6, and 5.8% TAR, respectively. Since the test item BF 500-4 occurred only under strict anaerobic soil conditions in detectable amounts, it can be concluded that these metabolites will not reach significant amounts under realistic agricultural conditions.

Normalization of degradation rates

Normalization to reference conditions (20°C, pF2) was performed as described for the parent (see paragraph after CA 7.1.1.1/1). A summary is provided below:

Table 7.1.2.1.2-24: Normalization of BF 500-4 $DegT_{50}$ values to reference conditions

Compound	Soil	pH ($CaCl_2$)	Kinetic Model	θ_{act}	θ_{ref}	f_{moist}	$DegT_{50,act}$	$DegT_{50,ref}$
BF 500-4	LUFA 5M	7.2	FOMC [1]	13.7	21.1	0.74	2.2	1.6
	Li 10	6.1	DFOP [2]	11.5	10.1	1	6.1	6.1

Rate of degradation of BF 500-5 (Reg.No. 298327) in soil under aerobic conditions
2013/1294780
Guidelines: OECD 307 (2002), EPA 835.4100
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The objective of the present study was to investigate the rate of degradation of BF 500-5, a metabolite of pyraclostrobin, in three soils under aerobic conditions.

The soils were treated with ^{14}C-labeled BF 500-5 at a nominal rate of 0.27 mg kg^{-1} dry soil which corresponds to a field application rate of 100 g a.s. ha^{-1} assuming equal distribution in the top 2.5 cm of soil layer and a soil bulk density of 1.5 g cm^{-3}. The incubation was carried out under aerobic conditions in the dark at 20 ± 2°C and a soil moisture of 40% of the maximum water holding capacity. A closed incubation system with continuous aeration was used with an attached trapping system for the determination of volatile compounds. Duplicate samples were taken at 0, 2 and 5 hours and after 1, 2, 4, 7, 14, 29 and 56 days after treatment (DAT).

The soil samples were extracted four times with acetonitrile/water (80:20, v/v) and the individual extracts were analyzed by Liquid Scintillation Counting (LSC). Combined extracts were concentrated and analyzed by HPLC. The amount of non-extractable residues was determined by combustion and subsequent LSC measurements.

The mass balance throughout the study ranged from 86.9 - 108.7% total applied radioactivity (TAR) for the three soils. The amount of extractable radioactivity (ERR) decreased quickly from 94.4 - 97.3% TAR on hour 0 to 25.7 - 32.6% TAR 1 DAT and decreased further to 8.4 - 11.8% TAR after 56 days of incubation.

One unknown metabolite was present in the soil extracts with up to 17.6% TAR. The maxima were reached after 5 hours and decreased thereafter. Since this compound can be regarded as secondary metabolite, which can appear in the environment only if BF 500-5 is formed out of pyraclostrobin under anaerobic conditions, it is very unlikely that it will ever reach environmentally significant amounts and it was not investigated further. All other peaks in the chromatograms never exceeded 1.3% TAR at any sampling time.

Formation of CO_2 was negligible in all three soils reaching in total only 2.0% TAR after 56 days. In ethylene glycol up to 0.2% TAR were detected, while no radioactive residues were found in the H_2SO_4 traps. The non-extractable residues increased during the study from 2.7 - 5.6% TAR at hour 0 to 83.1 - 88.2% TAR after 56 days of incubation.

The kinetic analysis and calculation of dissipation times of BF 500-5 were performed according to the FOCUS kinetic workgroup using the software tool KinGUI (version 2). The DT_{50} values ranged from 0.09 to 0.24 days.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

BAS code:	BF 500-5
Synonym:	500M04
Reg.No.:	298327
Chemical name (IUPAC):	1-(4-chlorophenyl)-1H-pyrazol-3-ol
Molecular weight:	194.6 g mol^{-1} (unlabeled)
Position of radiolabel:	Phenyl-ring-U-C^{14}
Specific radioactivity of a.s.:	8.99 MBq mg^{-1}
Batch No.:	724-2102
Radiochemical purity:	99.8% (according to certificate) > 98.0% (determined in the application solution by radio-HPLC prior to soil treatment in this study)

2. Soils

Three different soils were used for treatment and incubation. The soils were sieved through a 2 mm sieve before use, remoistened to approximately 8 – 12% of the respective soil moisture and stored in the dark at about 4°C. The soil characteristics are summarized in Table 7.1.2.1.2-25.

Table 7.1.2.1.2-25: Properties of soils used to investigate degradation rate of ^{14}C-BF 500-5

B. STUDY DESIGN

1. Experimental conditions

The soil moisture was adjusted to about 40% of the maximum water holding capacity (MWHC) and treated with ^{14}C-labeled BF 500-5 at a nominal concentration of 0.27 mg kg^{-1} dry soil, which corresponds to a field application rate of 100 g a.s. ha^{-1}.

For soil treatment, approximately 2.0 kg of each soil (dry weight) was treated with 2.0 mL of the treatment solution. The treated soils were homogenized and soil portions of 100 g dry soil equivalents were filled into 20 test vessels. The number of vessels was sufficient to allow duplicate sampling at each sampling time and to keep a limited number of reserve vessels.

During the soil incubation, a rapid degradation of BF 500-5 was observed. Therefore, single test vessels (6 vessels per soil type) were prepared and applied separately with test item for the three soil types in order to investigate very early time points. For these applications, aliquots of the soil (100 g dry weight) were spiked with 0.1 mL of the application solution and homogenized by shaking.

The test vessels were incubated in the dark for up to 56 days at a temperature of 20°C. Throughout the incubation period, the test vessels were continuously aerated with a slight stream of moistened synthetic air. The outgoing air was led through a series of gas-washing bottles containing trapping solutions for potential volatiles (0.5M NaOH, ethylene glycol, 0.5M H_2SO_4). The water content of the soils was monitored and re-adjusted if necessary throughout the incubation period by weighing the sampled vessels.

For the short incubation series, the test vessels were incubated in the dark at 20°C for up to 5 hours. No volatile traps were used for the short time incubation.

For determination of the microbial biomass at the end of the incubation period (55 days), additional soil samples were treated with the application solution and incubated under the same conditions. However, no trapping system for volatiles was used.

2. Sampling

Duplicate samples were taken at 0, 2 and 5 hours and 1, 2, 4, 7, 14, 29 and 56 days after treatment (DAT).

3. Description of the analytical procedures

The extractability of the test item from soil was investigated for one soil using different solvent systems: threefold extraction with acetonitrile, acetonitrile/water (80:20, v/v) or methanol, respectively. The best performing solvent mixture was acetonitrile/water (80:20, v/v) which resulted in a total extractable amount of 94.4% TAR. For the solvent mixture acetonitrile/water (80:20, v/v) it was additionally tested how many extraction steps were needed for an exhaustive extraction. Four extractions were shown to be sufficient for an exhaustive extraction.

The soil samples were extracted consecutively four times with about 100 mL acetonitrile/water (80:20, v/v) by shaking for about 20 minutes. Two replicates of soil LUFA 5M from the short time series were extracted five times with acetonitrile/water (80:20, v/v) shortly after the application (0 hours after treatment). An additional 0.5% TAR was extracted by the 5th step confirming that four extraction steps are sufficient to extract the majority of radioactivity from the soil.

After each extraction step, the suspension was centrifuged, the supernatant was filtered and aliquots of each solution were radio-assayed. The extracts were combined, concentrated to a small volume and analyzed by LSC. After an additional concentration step, aliquots of the combined extracts were analyzed by HPLC to obtain the metabolite pattern.

The extracted soil was dried at room temperature, homogenized in an analytical mill and aliquots were combusted to determine the amount of non-extractable radioactive residues (NER). Combustion products were trapped in an Oxysolve C-400 scintillator and measured by LSC.

4. Calculation of the degradation rate of BF 500-5

The kinetic analysis was carried out following the recommendations of the FOCUS work group on degradation kinetics [*FOCUS (2006)*] in order to derive trigger and modeling endpoints. The software package KinGUI (version 2.2012.320.1629) was used for parameter fitting.

For each data set, the kinetic models proposed by the FOCUS Kinetic guidance document were tested in order to identify the best-fit model, i.e. single first order kinetics (SFO), the Gustafson-Holden model (FOMC) and bi-exponential kinetics (DFOP).

The goodness-of-fit of the kinetic models was assessed by visual inspection and statistical measures recommended by the FOCUS guidance. The goodness-of-fit used for the identification of the best-fit kinetic model is the χ^2 minimum error level. The kinetic endpoints (DT_{50} and DT_{90} values) are reported for the kinetic models, which are selected based on statistical and visual assessment. The reliability of individual parameters was judged by means of a single-sided t-test.

The initial concentration of the applied substance was set to the material balance recovered at day 0 minus the percentage of ‘Unknown 1’ as the latter was an impurity in the application solution.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The detailed results on the extractability of radioactive residues in the soils are presented in Table 7.1.2.1.2-26 to Table 7.1.2.1.2-28. The average material balance ranged from 86.9 to 108.7% TAR for all soils.

B. EXTRACTABLE AND BOUND RESIDUES

The distribution of radioactivity in extractable residues (ERR), non-extractable residues (NER), CO_2 and other volatiles for each soil is shown in Table 7.1.2.1.2-26 to Table 7.1.2.1.2-28. The amount of extractable radioactivity (ERR) decreased quickly from 94.4 - 97.3% TAR at hour 0 to 25.7 - 32.6% TAR after 1 DAT and decreased further to 8.4 to 11.8% TAR after 56 days of incubation.

The amount of NER increased during the study from 2.7 - 5.6% TAR at hour 0 to 83.1 - 88.2% TAR after 56 days of incubation.

Table 7.1.2.1.2-26: Distribution of radioactivity and material balance after application of ^{14}C-BF 500-5 to soil Li 10 [%TAR]

TAR = total applied radioactivity
ERR = extractable radioactive residues
NER = non-extractable radioactive residues
ACN = acetonitrile
n.d. = not determined

C. VOLATILIZATION

Formation of CO_2 was negligible in all three soils reaching in total only 2.0% TAR after 56 days. In ethylene glycol up to 0.2% TAR were detected, while no radioactive residues were found in the H_2SO_4 traps.

D. TRANSFORMATION OF BF 500-5

All combined soil extracts were analyzed by radio-HPLC. The results obtained with this system are summarized in Table 7.1.2.1.2-29 to Table 7.1.2.1.2-31.

The concentration of BF 500-5 decreased very quickly during the first day from 89.1 - 94.8% TAR at hour 0 to 15.0 - 19.7% TAR at 1 DAT, and then continuously to 0.6 - 1.4% TAR after 56 days of incubation.

One unknown metabolite was present in the soil extracts with up to 17.6% TAR. A peak with similar retention time was already present in the application solution. The maxima were reached after 5 hours and decreased thereafter. Since this compound can be regarded as secondary metabolite, which can appear in the environment only if BF 500-5 is formed out of pyraclostrobin under anaerobic conditions, it is very unlikely that it will ever reach environmentally significant amounts and it was not further investigated. All other peaks in the chromatograms never exceeded 1.3% TAR at any sampling time.

Calculation of the degradation rates

The residue data of soils Li 10 and LUFA 2.2 could be best described by the FOMC kinetic model, while the residue data of soil LUFA 5M was best described by the DFOP kinetic model which further improved the statistical and visual fit for the measured data. The calculated $DegT_{50}$/$DegT_{90}$ values and the selected kinetic models are presented in Table 7.1.2.1.2-32 (best-fit) and Table 7.1.2.1.2-33 (modeling).

Table 7.1.2.1.2-32: Best-fit kinetic DT_{50} and DT_{90} values of metabolite BF 500-5

Soil	DT_{50} [d]	DT_{90} [d]	Kinetic model	χ^2 error
Li 10	0.20	2.63	FOMC	3.74
LUFA 5M	0.09	2.95	DFOP	4.79
LUFA 2.2	0.24	1.77	FOMC	5.01

Table 7.1.2.1.2-33: Modeling endpoints ($DegT_{50}$) for metabolite BF 500-5

Soil	Kinetic model	χ^2 error	Modeling $DegT_{50}$ [d]*
Li 10	FOMC	3.74	0.79
LUFA 5M	FOMC	10.61	0.63
LUFA 2.2	FOMC	5.01	0.53

* calculated as $DegT_{90}$ FOMC / 3.32 according to FOCUS (2006)

III. CONCLUSION

BF 500-5, a metabolite of pyraclostrobin, degraded rather fast in three different soils with DT_{50} values of <1 day. After 56 days of incubation, the mineralization rate had reached 0.7 - 2.2% TAR and the non-extractable residues amounted to 83.1 – 88.2% TAR.

Normalization of degradation rates

Normalization to reference conditions (20°C, pF2) was performed as described for the parent (see paragraph after CA 7.1.1.1/1). A summary is provided below:

Table 7.1.2.1.2-34: Normalization of BF 500-5 $DegT_{50}$ values to reference conditions

Compound	Soil	pH ($CaCl_2$)	Kinetic Model	θ_{act}	θ_{ref}	f_{moist}	$DegT_{50,act}$	$DegT_{50,ref}$
BF 500-5	Li 10	6.3	FOMC[1]	9.9	11.0	0.93	0.8	0.7
	LUFA 5M	7.4	FOMC[1]	10.8	17.4	0.72	0.6	0.5

CA 7.1.2.1.3 Anaerobic degradation of the active substance

No new experimental data were generated.

Although the available studies were done according to the previous guideline on anaerobic soil metabolism (without an aerobic pre-incubation phase), the results are still considered valid, since aerobic and anaerobic degradation follow the same metabolic pathway (see route of degradation, Figure 7.1.1.3-1).

Since the kinetic evaluations provided in the old reports are outdated, new kinetic evaluations for pyraclostrobin and metabolites were performed according to current FOCUS guidelines.

Report:	CA 7.1.2.1.3/1 Pape L., 2014a Kinetic evaluation of anaerobic soil degradation studies for BAS 500 F - Pyraclostrobin according to FOCUS 2014/1000701
Guidelines:	FOCUS Kinetics (2006) SANCO/10058/2005 version 1.0 of Nov. 2011
GLP:	no

Note: This study was not correctly listed in the application submitted for renewal of approval. Author and annex point has changed after submission of the application.

Executive Summary

The degradation of pyraclostrobin (BAS 500 F) in soil has been investigated in two anaerobic laboratory soil degradation studies. The purpose of this evaluation was to analyze the degradation kinetics of pyraclostrobin and its metabolites BF 500-3, BF 500-4, BF 500-5, 500M74 and 500M75 according to the current guidance of the FOCUS workgroup on degradation kinetics.

The appropriate kinetic models were selected based on visual and statistical assessment. The kinetic evaluation of the data showed that the DFOP model is the best-fit model for pyraclostrobin, while SFO can be used to derive modeling endpoints. The best-fit $DegT_{50}$ values were 1.5 and 2.3 days, and $DegT_{90}$ values were 6.5 and 8.4 days. The modeling $DegT_{50}$ values equal 2.0 and 2.4 days.

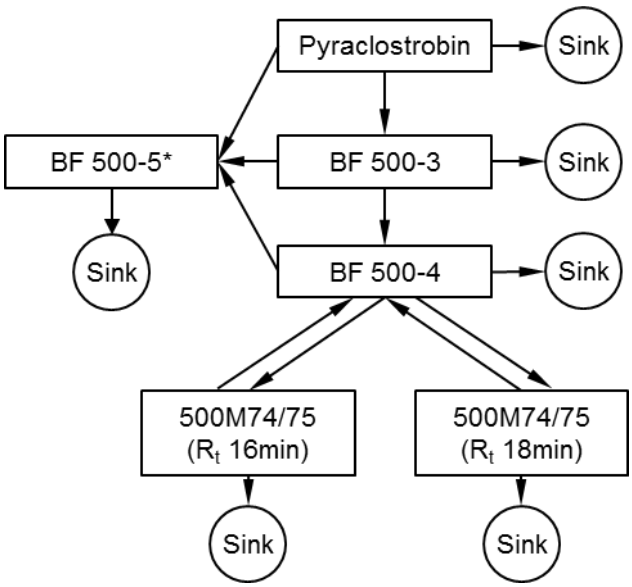
I. MATERIAL AND METHODS

The degradation of pyraclostrobin in soil under anaerobic laboratory conditions from two studies was analyzed taking into account the current guidance of the FOCUS workgroup on degradation kinetics [*FOCUS (2006)*].

Kinetic modeling strategy

Kinetic evaluation was performed in order to derive i) degradation parameters as triggers for additional work (trigger endpoints) and ii) degradation parameters for environmental fate models (modeling endpoints). The best-fit model was selected based on visual and statistical assessment and the corresponding $DegT_{50}$ and $DegT_{90}$ values are reported as trigger endpoints. Appropriate $DegT_{50}$ values for use in environmental fate models were derived depending on the kinetic model.

For the metabolites of pyraclostrobin, the procedure for deriving modeling and trigger endpoints for metabolites recommended by the FOCUS Kinetics workgroup [*FOCUS (2006)*] was followed. The metabolites were added stepwise to the appropriate kinetic model for the parent. The conceptual degradation pathway considered is given in Figure 7.1.2.1.3-1. The metabolite BF 500-5 could be formed from different precursors (i.e. pyraclostrobin, BF 500-3 and BF 500-4). Therefore, all three formation routes were considered in the conceptual degradation pathway. The metabolites 500M74 and 500M75 are formed as isomers from BF 500-4 with possible reverse reactions. This was considered by including the reverse reaction routes in the conceptual degradation pathway. The pathway was stepwise adapted based on the results of the kinetic evaluation.



* BF 500-5 was only detected in 1999/11103

Figure 7.1.2.1.3-1: Setup of possible degradation pathways used for the kinetic evaluation

Kinetic models included in the evaluations

For the pyraclostrobin data set, the kinetic models proposed by FOCUS Kinetics [*FOCUS (2006)*] were tested in order to identify the best-fit model, i.e. single first order (SFO) kinetics, the Gustafson-Holden model (FOMC) and the bi-exponential (DFOP) kinetics. For the assessment of the formation and degradation parameters of the metabolites, the SFO model was used.

The goodness-of-fit of the kinetic models was assessed by visual inspection and statistical measures, as recommended by the FOCUS Kinetics guidance [*FOCUS (2006)*].

Data handling and software for kinetic evaluation

Degradation products which occurred at an amount of >5% TAR were included in the calculation. Degradation products which were detected at levels far below 5% TAR were not considered.

The initial concentrations of the metabolites BF 500-3 [old *EU Dossier, A II M 7.1.1.2.1/5, Kellner O. - BASF DocID 1999/10079*; old *EU Dossier, A II M 7.1.1.2.1/6, Kellner O. - BASF DocID 1999/11103*] and BF 500-4 [*Kellner O. - BASF DocID 1999/11103*] were found to be larger than zero. As both compounds occurred as impurities in the radiochemical purity analysis the initial concentration of the metabolites was set to the measured value. Accordingly, for the parent the initial concentration was set to difference between the material balance and the measured values of the metabolites. For all other metabolites the initial concentrations were set to zero.

According to *FOCUS (2006)* the first non-detect was set to ½ LOD and later sampling points were omitted. For the metabolites the last non-detect before the first reported value greater than zero was set to ½ LOD and earlier sampling points were omitted. In *Kellner O.* [*BASF DocID 1999/11103*] the LOD was not reported. Therefore, the lowest reported value for the HPLC analysis which was different from zero, i.e. 0.001 mg kg^{-1}, was assumed to represent the LOD. Hence, ½ LOD was assumed to be 0.0005 mg kg^{-1}, which corresponds to 0.15% TAR. In *Kellner O.* [*BASF DocID 1999/10079*] the reported LOD is 0.001 mg kg^{-1}. Hence, ½ LOD is 0.0005 mg kg^{-1}, which corresponds to 0.17% TAR.

The software package KinGUI version 2.2012.320.1629 was used for parameter fitting. The error tolerance and the number of iterations of the optimization tool (IRLS) were set to $1x10^{-6}$ and 100, respectively.

Experimental data

The kinetic evaluation was based on the findings of two laboratory anaerobic soil degradation studies with German standard soils. The soil characteristics are summarized in Table 7.1.2.1.3-1.

Table 7.1.2.1.3-1: Soil characteristics

Study (BASF DocID)	**1999/11103**	**1999/10079**
Soil designation	**BASF 98/060/01**	**BASF 97/060/02**
Origin	Bruch West, Germany	Bruch West, Germany
Textural class (USDA)	Loamy sand	Loamy sand
Particle size distribution [%] sand 0.050 – 2 mm silt 0.002 – 0.050 mm clay < 0.002 mm	 79 16 5	 73 17 10
Organic C [%]	1.4	1.5
Microbial biomass [mg C 100 g^{-1} dry soil]	40.3	38.3
CEC [meq 100 g^{-1}]	13	12.1
pH ($CaCl_2$) [-]	7.2	7.5
MWC [g H_2O 100 g^{-1} dry soil]	44	40
Soil moisture at field capacity (0.33 bar) [g H_2O 100 g^{-1} dry soil]	16.1	16.3

CEC = cation exchange capacity
MWC = maximum water holding capacity

The test soils were treated with chlorophenyl-^{14}C-pyraclostrobin [*Kellner O. - BASF DocID 1999/11103*] or tolyl-^{14}C-pyraclostrobin [*Kellner O. - BASF DocID 1999/10079*] at a nominal application rate of 0.33 mg kg^{-1} dry soil (corresponding to 250 g a.s. ha^{-1}) and incubated anaerobically at 20°C in the dark for 120 days. Soil samples were taken at 0, 3, 7, 14, 28, 63, 88 and 120 days after treatment (DAT) [*BASF DocID 1999/11103*] or 0, 7, 14, 28, 62, 90 and 120 DAT [*BASF DocID 1999/10079*].

The measured data as well as resulting datasets submitted to kinetic analysis are given in Table 7.1.2.1.3-2 to Table 7.1.2.1.3-5.

II. RESULTS AND DISCUSSION

Kinetic evaluation of BASF DocID 1999/11103 - derivation of trigger endpoints

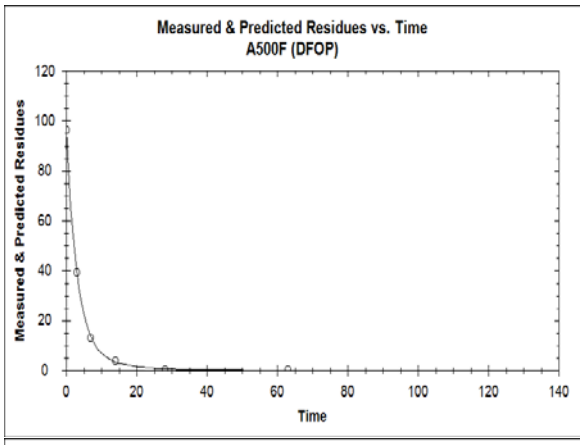
Metabolites were included stepwise into the best-fit model for the parent.

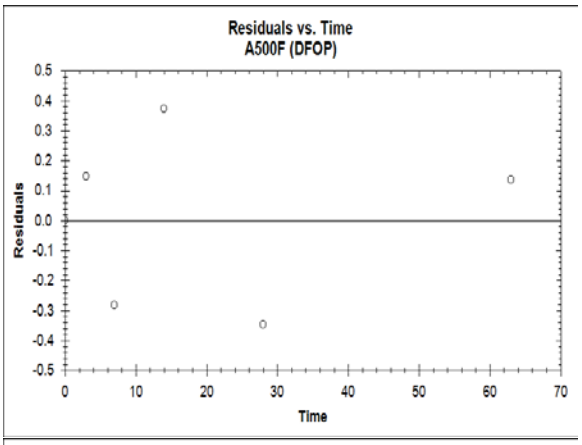
Table 7.1.2.1.3-6: Statistical and visual assessment of different kinetic models for pyraclostrobin and its metabolites (BASF DocID 1999/11103)

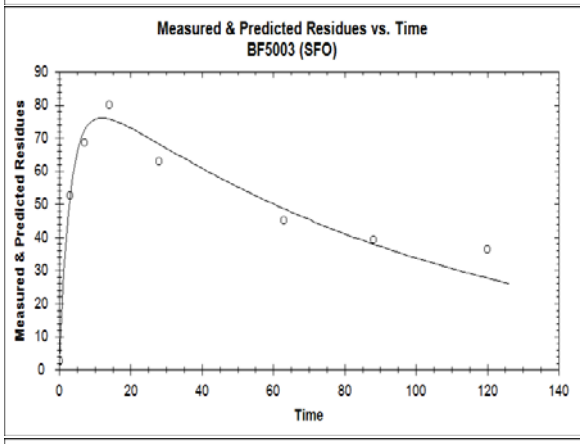
Step in FOCUS flowchart	Kinetic model	χ^2 error	p (t-test)	Visual assessment	$DegT_{50}$ [d]	$DegT_{90}$ [d]
(1) & (2) Run parent only SFO & FOMC	SFO	2.8	k: <0.01	good	2.4	7.9
	FOMC	1.3	β: <0.05	excellent	2.3	8.5
(3) Run DFOP (parent only)	DFOP	1.0	k1: <0.01 k2: not sig. g: <0.01	excellent	2.3	8.4
⇨ Overall, the DFOP model results in the best fit. ⇨ **Conclusion**: Use DFOP for derivation of trigger endpoints; use SFO for derivation of modeling endpoints.						
(4) Run parent DFOP and BF 500-3 SFO	Parent DFOP	1.0	k1: <0.01 k2: <0.01 g: <0.01	excellent	2.3	8.4
	BF 500-3 SFO	6.5	k: <0.01	good	78.5	260.8
⇨ DFOP fit for parent is visually acceptable, χ^2 error is low, k1, k2 are significantly different from zero. SFO fit for BF 500-3 is visually acceptable, χ^2 error is low, k is significantly different from zero. ⇨ Include BF 500-4.						
(5) Run parent DFOP and BF 500-3 and BF 500-4 SFO	Parent DFOP	2.5	k1: not sig. k2: <0.01 g: <0.05	good	2.2	8.4
	BF 500-3 SFO	7.1	k: <0.01	good	68.4	227.3
	BF 500-4 SFO	14.5	k: <0.01	moderate	7.6	25.2
⇨ DFOP fit for parent is visually acceptable, χ^2 error is low, k1 is not significantly different from zero and changed from 0.3348 in run (4) to 8.5551. The resulting $DegT_{50}$ and $DegT_{90}$ values are similar to run (4). ⇨ Repeat run with fixed parameters from run (4) for the parent.						
(6) Run parent DFOP (fixed M0, k1, k2, g) and BF 500-3 and BF 500-4 SFO	Parent DFOP	0.7	k1: fixed k2: fixed g: fixed	excellent	2.3	8.4
	BF 500-3 SFO	7.4	k: <0.01	good	67.8	225.1
	BF 500-4 SFO	14.7	k: <0.01	moderate	7.5	25.0
⇨ SFO fit for BF 500-3 is visually acceptable, χ^2 error is low, k is significantly different from zero. SFO fit for BF 500-4 is visually acceptable, χ^2 error is acceptable, k is significantly different from zero. ⇨ Include BF 500-5 as degradate from parent, BF 500-3 and BF 500-4.						
(7) Run parent DFOP (fixed M0, k1, k2, g) and BF 500-3, BF 500-4 and BF 500-5 SFO	Parent DFOP	0.7	k1: fixed k2: fixed g: fixed	excellent	2.3	8.4
	BF 500-3 SFO	7.4	k: <0.01	good	67.6	224.5
	BF 500-4 SFO	14.6	k: <0.01	moderate	7.5	24.8
	BF 500-5 SFO	12.0	k: <0.05	good	42.6	141.5
⇨ SFO fit for BF 500-3, BF 500-4 and BF 500-5 are visually acceptable, χ^2 errors are below 15%, k values are significantly different from zero. The formation fractions of BF 500-5 from parent and BF 500-3 are below 0.01 and not significantly different from zero. ⇨ Repeat run with BF 500-5 only formed from BF 500-4						

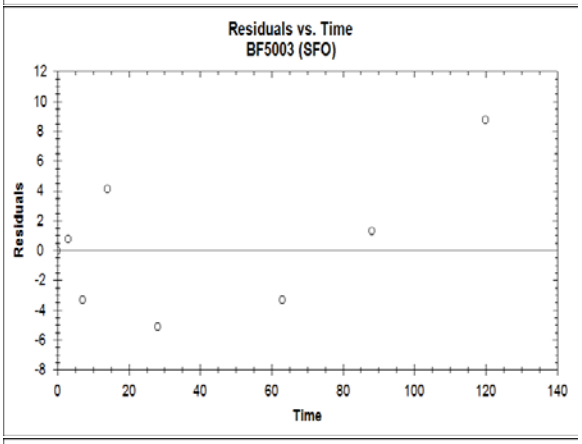
Step in FOCUS flowchart	Kinetic model	χ^2 error	p (t-test)	Visual assessment	$DegT_{50}$ [d]	$DegT_{90}$ [d]
(8) Run parent DFOP (fixed M0, k1, k2, g) and BF 500-3, BF 500-4 and BF 500-5 SFO	Parent DFOP	0.7	k1: fixed k2: fixed g: fixed	excellent	2.3	8.4
	BF 500-3 SFO	7.4	k: <0.01	good	67.7	225.0
	BF 500-4 SFO	14.7	k: <0.01	moderate	7.4	24.7
	BF 500-5 SFO	11.9	k: <0.01	good	34.0	113.0
⇨ SFO fit for BF 500-3, BF 500-4 and BF 500-5 are visually acceptable, χ^2 errors are below 15%, k values are significantly different from zero. The formation fraction of BF 500-5 from BF 500-4 is significantly different from zero. ⇨ Include 500M74/75 (R_t 16min) and 500M74/75 (R_t 18min) as degradates of BF 500-4 with possible reverse reaction.						
(9) Run parent DFOP (fixed M0, k1, k2, g) and BF 500-3, BF 500-4, BF 500-5, 500M74/75 (R_t 16min) and 500M74/75 (R_t 18min) SFO	Parent DFOP	0.7	k1: fixed k2: fixed g: fixed	excellent	2.3	8.4
	BF 500-3 SFO	7.0	k: <0.01	good	69.9	232.1
	BF 500-4 SFO	17.9	k: not sig.	moderate	7.7	25.7
	BF 500-5 SFO	11.9	k: <0.01	good	32.1	106.5
	500M74/75 (R_t 16min)	5.0	k: <0.05	good	64.3	213.7
	500M74/75 (R_t 18min)	6.4	k: <0.01	good	23.4	77.7
⇨ All fits are visually acceptable, for BF 500-3, BF 500-5, 500M74/75 (R_t 16min) and 500M74/75 (R_t 18min) χ2 errors are below 15% and k values are significantly different from zero. For BF 500-4, χ2 error is above 15% and k is not significantly different from zero. The formation fractions for the reverse reactions from 500M74/75 (R_t 16min) and 500M74/75 (R_t 18min) to BF 500-4 are very low and not significantly different from zero. ⇨ Repeat run without reverse reaction of 500M74/75 (R_t 16min) and 500M74/75 (R_t 18min) to BF 500-4.						
(10) Run parent DFOP (fixed M0, k1, k2, g) and BF 500-3, BF 500-4, BF 500-5, 500M74/75 (R_t 16min) and 500M74/75 (R_t 18min) SFO	Parent DFOP	0.7	k1: fixed k2: fixed g: fixed	excellent	2.3	8.4
	BF 500-3 SFO	7.0	k: <0.01	good	70.1	232.9
	BF 500-4 SFO	15.5	k: <0.01	moderate	7.8	25.9
	BF 500-5 SFO	11.9	k: <0.01	good	32.2	107.1
	500M74/75 (R_t 16min)	5.0	k: <0.01	good	64.6	214.7
	500M74/75 (R_t 18min)	6.4	k: <0.01	good	23.5	78.0
⇨ SFO fits for BF 500-3, BF 500-5, 500M74/75 (R_t 16min) and 500M74/75 (R_t 18min) are visually acceptable, χ2 errors are below 15%, k values are significantly different from zero. SFO fit for BF 500-4, is visually acceptable, χ2 error is slightly above 15%, k is significantly different from zero. ⇨ **Conclusion**: The pathway is reliable. The results are adequate to be used as trigger endpoints.						

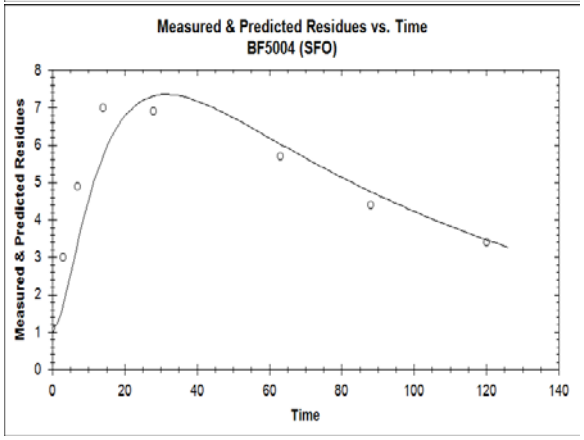
The fits of the final run are presented in Figure 7.1.2.1.3-2: .

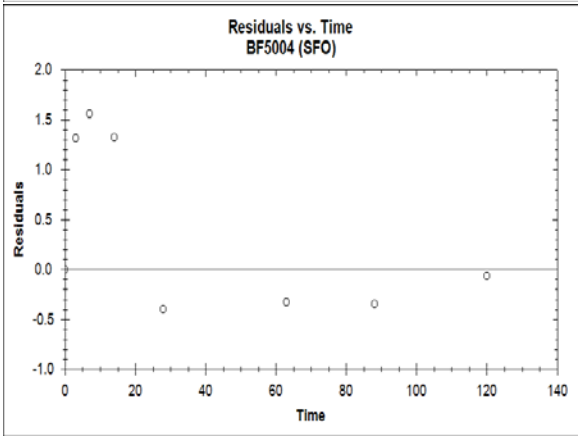












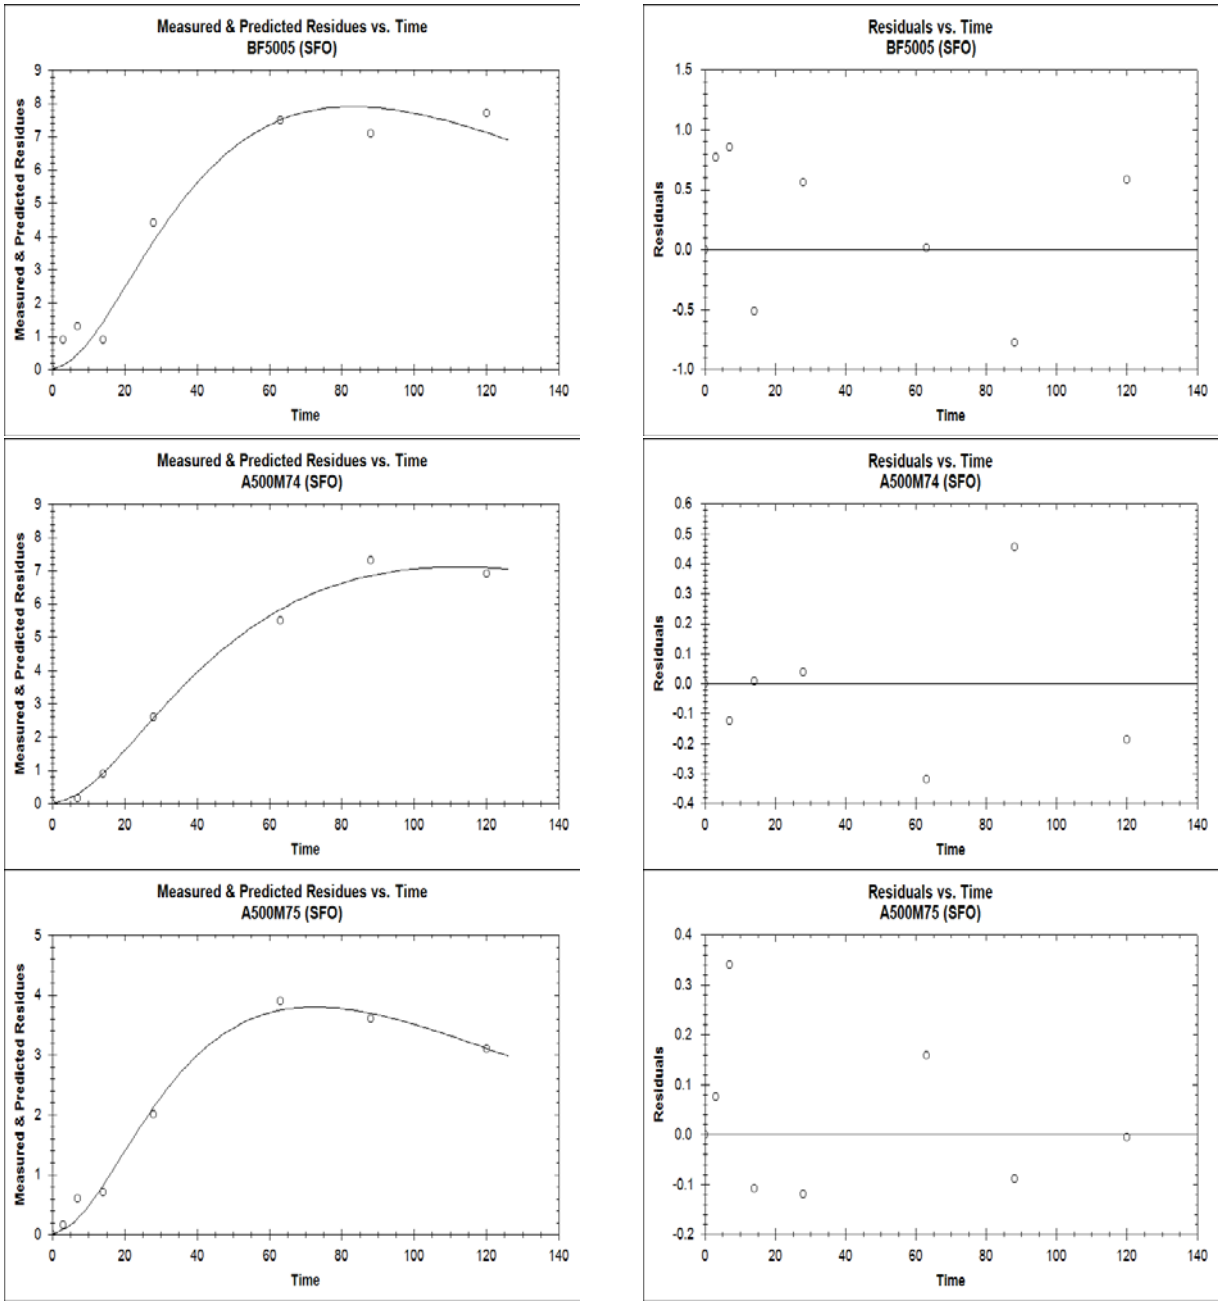


Figure 7.1.2.1.3-2: Final Kingui fit for pyraclostrobin, BF 500-3, BF 500-4, BF 500-5, 500M74 and 500M75, DFOP kinetics for the parent, fixed parameters for parent, adapted pathway (BASF DocID 1999/11103)

The adapted degradation pathway is given in Figure 7.1.2.1.3-3 and the complete parameter estimation for derivation of trigger endpoints of pyraclostrobin and its metabolites BF 500-3, BF 500-4, BF 500-5, 500M74/75 (R_t 16min) and 500M74/75 (R_t 18min) are presented in Table 7.1.2.1.3-7.

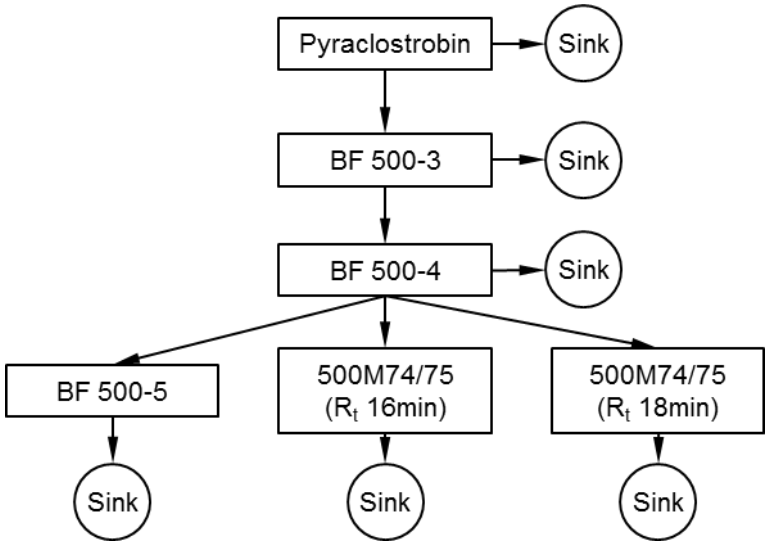

Figure 7.1.2.1.3-3: Degradation pathway of pyraclostrobin derived from the kinetic evaluation of BASF DocID 1999/11103

Table 7.1.2.1.3-7: Parameters for pyraclostrobin and its metabolites for derivation of trigger endpoints (BASF DocID 1999/11103)

Parameter	Pyraclostrobin [a)]	BF 500-3	BF 500-4	BF 500-5	500M74/75 (R_t 16min) [b)]	500M74/75 (R_t 18min) [b)]

k-rate [d^{-1}]	k1: 0.3348 k2: 0.1077 g: 0.8856	0.0099	0.0888	0.0215	0.0107	0.0295
$DegT_{50}$ [d]	2.3	70.1	7.8	32.2	64.6	23.5
$DegT_{90}$ [d]	8.4	232.9	25.9	107.1	214.7	78.0

a) The values from Step (4) are reported (see Table 7.1.2.1.3-6) as degradation parameters were fixed during the assessment of the pathway fit.

b) Metabolites could not be unambiguously assigned to HPLC peaks with retention times of 16 and 18 min.

Kinetic evaluation of BASF DocID 1999/11103 - derivation of modeling endpoints

The same degradation pathway derived from the derivation of trigger endpoints was considered. All metabolites were included simultaneously into the SFO model for the parent.

The complete parameter estimation for derivation of modeling endpoints of pyraclostrobin and its metabolites BF 500-3, BF 500-4, BF 500-5, 500M74/75 (R_t 16min) and 500M74/75 (R_t 18min) is given in Table 7.1.2.1.3-8.

Table 7.1.2.1.3-8: Parameters for pyraclostrobin and its metabolites for derivation of modeling endpoints (BASF DocID 1999/11103)

Parameter	Pyraclostrobin	BF 500-3	BF 500-4	BF 500-5	500M74/75 (R_t 16min) [a]	500M74/75 (R_t 18min) [a]

[a] Metabolites could not be unambiguously assigned to HPLC peaks with retention times of 16 and 18 min.

[b] from BF 500-3

[c] from BF 500-4

[d] No reliable formation fraction could be determined.

Kinetic evaluation of BASF DocID 1999/10079 - derivation of trigger endpoints

Metabolites were included stepwise into the best-fit model for the parent. The conceptual degradation pathway was adapted according to the results of the kinetic evaluation of BASF DocID 1999/11103, i.e. the possible reverse reaction of the metabolites 500M74/75 (R_t 16min) and 500M74/75 (R_t 18min) to BF 500-4 was not considered.

Table 7.1.2.1.3-9: Statistical and visual assessment of different kinetic models for pyraclostrobin and its metabolites (BASF DocID 1999/10079)

Step in FOCUS flowchart	Kinetic model	χ^2 error	p (t-test)	Visual assessment	$DegT_{50}$ [d]	$DegT_{90}$ [d]
(1) & (2) Run parent only SFO & FOMC	SFO	5.2	k: <0.01	good	2.1	6.9
	FOMC	0.7	β: <0.05	excellent	1.1	6.4
(3) Run DFOP (parent only)	DFOP	0.2	k1: <0.05 k2: <0.05 g: <0.01	excellent	1.5	6.5
⇨ Overall, the DFOP model results in the best fit ⇨ **Conclusion**: Use DFOP for derivation of trigger endpoints; use SFO for derivation of modeling endpoints.						
(4) Run parent DFOP and BF 500-3 SFO	Parent DFOP	0.2	k1: <0.01 k2: <0.01 g: <0.01	excellent	1.5	6.5
	BF 500-3 SFO	8.8	k: <0.01	good	58.9	195.6
⇨ DFOP fit for parent is visually acceptable, χ^2 error is low, k1, k2 are significantly different from zero. SFO fit for BF 500-3 is visually acceptable, χ^2 error is low, k is significantly different from zero. ⇨ Include BF 500-4.						
(5) Run parent DFOP and BF 500-3 and BF 500-4 SFO	Parent DFOP	0.2	k1: <0.01 k2: <0.01 g: <0.01	excellent	1.5	6.5
	BF 500-3 SFO	8.8	k: <0.01	good	58.4	193.9
	BF 500-4 SFO	33.1	k: <0.05	poor	19.2	63.7
⇨ The fits for the parent and BF 500-3 are visually acceptable, χ^2 errors are low, k values are significantly different from zero. SFO fit for BF 500-4 is poor, χ^2 error is above 15% but k is significantly different from zero. ⇨ Include 500M74/75 (R_t 16min) and 500M74/75 (R_t 18min).						
(6) Run parent DFOP and BF 500-3, BF 500-4, 500M74/75 (R_t 16min) and 500M74/75 (R_t 18min) SFO	Parent DFOP	0.2	k1: <0.01 k2: <0.01 g: <0.01	excellent	1.5	6.5
	BF 500-3 SFO	8.9	k: <0.01	good	56.9	189.0
	BF 500-4 SFO	39.4	k: <0.01	poor	11.3	37.7
	500M74/75 (R_t 16min)	14.3	k: <0.01	moderate	36.6	121.5
	500M74/75 (R_t 18min)	11.1	k: <0.01	good	15.4	51.0
⇨ The fits for the parent, BF 500-3, 500M74/75 (R_t 16min) and 500M74/75 (R_t 18min) are visually acceptable, χ^2 errors are below 15%, k values are significantly different from zero. The fit for BF 500-4 is visually poor, χ^2 error is above 15% but k is significantly different from zero. As the fit provides a conservative estimate for k it is considered to be acceptable for derivation of trigger endpoints. ⇨ **Conclusion**: The pathway is reliable. The results are adequate to be used as trigger endpoints.						

The fits of the final run are presented in Figure 7.1.2.1.3-4.

III. CONCLUSION

Trigger and modeling endpoints were derived for pyraclostrobin and its metabolites in two anaerobic laboratory degradation studies. The kinetic evaluation of the data showed that the DFOP model is the best-fit model for pyraclostrobin, while SFO can be used to derive modeling endpoints. For the metabolites the SFO model was appropriate to derive trigger and modeling endpoints.

The derived trigger endpoints for pyraclostrobin and its metabolites are summarized in Table 7.1.2.1.3-12, and modeling endpoints are summarized in Table 7.1.2.1.3-13.

CA 7.1.2.1.4 Anaerobic degradation of metabolites, breakdown and reaction products

Pyraclostrobin converted under anaerobic conditions within few days to the des-methoxy metabolite BF 500-3, which is further transformed to BF 500-4 (and its isomers). Binding to the organic matrix in soil results then in the formation of non-extractable residues which reached 37 - 61% TAR after 120 days. Low amounts of the cleavage product BF 500-5 could also be detected.

New kinetic evaluations of the already peer-reviewed anaerobic soil metabolism studies were performed according to current FOCUS guidelines. The new best-fit $DegT_{50}$ values of the anaerobic metabolites are listed together with the parent data in Table 7.1.2.1.3-10.

During data gap analysis for the renewal of approval, it became clear that the isomer structures 500M74 and 500M75 of BF 500-4 (500M73) were never unambiguously assigned to the two peaks at 16 and 18 min in the chromatograms of the anaerobic soil metabolism studies with pyraclostrobin and that the structures originally proposed are rather unlikely from a chemical point of view. Therefore, further investigations of the isomerization behaviour of BF 500-4 were performed. The experiments were included in the BF 500-4 aerobic soil degradation report. The soil degradation rate results of BF 500-4 are already described under *CA7.1.2.1.2/3*. The results of the isomer investigations are described below.

Report:	CA 7.1.2.1.4/1 Ebert D.,Dalkmann P., 2014a Rate of degradation of BF 500-4 (Reg. No. 358672) in soil under aerobic conditions 2013/1294779
Guidelines:	OECD 307, EPA 835.4100
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Note: This study was erroneously not listed in the application submitted for renewal of approval. The reason for submission is described below.

Executive summary

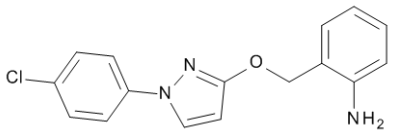
In order to get more information on the isomer structures of BF 500-4, 50 µg of ^{14}C-labeled test item was incubated in 20 mL of various aqueous and organic solvent solutions, respectively, and the isomer formation was followed over a period of 27 days by HPLC analysis. In addition, the interconversion of isomers was checked by fractionation of an isomeric peak and re-injection into HPLC.

For NMR analysis, larger amounts of isomers were produced by incubating non-labeled BF 500-4 in acetonitrile/H_2O mixture (20:80, v:v). The isomers were then fractionated by preparative HPLC and the fractions analysed by NMR for structure elucidation.

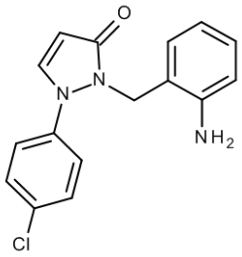
The results showed that the isomerization of BF 500-4 to 500M74 and 500M75 takes place preferably in pure water and buffer pH 9, as well as in acetonitrile water mixtures up to a maximum acetonitrile content of 50%. In acetonitrile/water 80:20 (v:v) and pure acetonitrile, the parent compound BF 500-4 was rather stable and the isomerization negligible.

When fractionating one isomer and reinjecting into HPLC, the other two isomers were formed again, proving that the isomers are interconvertible.

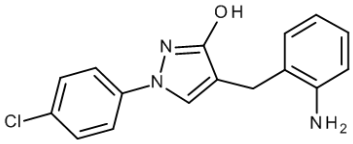
By NMR analysis, structures could be assigned to the two observed isomer peaks (500M74 and 500M75). The structure of BF 500-4 (500M73) was confirmed.



BF 500-4 (500M73)
m/z 299



500M74
m/z 299



500M75
m/z 299

The overall environmental significance of these isomers is considered rather low, since BF 500-4 occurs in detectable amounts only under strong anaerobic conditions in nitrogen-flushed, water-logged soil.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

^{14}C-labelled material

BAS code:	^{14}C-BF 500-4
Synonym:	500M73
Reg. No.:	358672
Chemical name (IUPAC):	2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxymethyl}phenylamine
Molar mass:	299.76 g mol^{-1} (unlabeled)
Position of radiolabel:	Tolyl-U-C^{14}
Specific radioactivity of a.s.:	8.49 MBq mg^{-1}
Batch No.:	1072-1004
Radiochemical purity:	≥ 96.0%

non-labelled material

Batch No.:	01586-68
Purity:	99.8%

2. Test Design

Isomerization in different aqueous media / solvents

In order to investigate in which test medium the isomerization takes preferably place, a volume of 20 mL of each test solution (see Table 7.1.2.1.4-1) was treated with ~50 µg ^{14}C-BF 500-4 (200 µL of application solution in acetone). After application, a sample of 250 µL was taken from each test vessel. The amount of dissolved radioactivity was checked by LSC and subaliquots were analysed by HPLC.

Table 7.1.2.1.4-1: Test solutions used to investigate isomerization of BF 500-4

Test medium	test volume [mL]	measured amount ^{14}C-equivalents in 250 µL [µg]	actual dissolved amount of ^{14}C-equivalents in 20 mL [µg]
dest. H_2O, acidified to pH 1 with 100 µL HCOOH	20	1.290	51.6
dest. H_2O	20	1.072	42.9
buffer pH 9 *	20	0.930	37.2
ACN/H_2O 20:80 (v:v)	20	0.831	33.2
ACN/H_2O 50:50 (v:v)	20	1.294	51.8
ACN/H_2O 80:20 (v:v)	20	1.298	51.9
pure ACN	20	1.265	50.6

* Fa. Merck, Darmstadt, Germany (Order #109889)

As expected, the solubility in aqueous media proved to be significantly lower than in solution with a high acetonitrile content. The seemingly good solubility observed in dest. H_2O pH1 was attributed to the fact that BF 500-4 hydrolyzed almost immediately and formed polar substances.

The glass test vessels (20 mL vials) were closed with a screw cap and placed on a magnetic stirrer in a 20 ± 2°C incubator. After 7, 14 and 27 days, 250 µL aliquots were taken from each test solution and subjected to HPLC analysis. The isomer formation (peaks at ~21 and ~24 min) could be observed in pure dest. H_2O, buffer pH9, and ACN/H_2O 20:80 (v:v).

Interconversion of BF 500-4 isomers

During HPLC analysis of the 14 day sample of the dest. H_2O solution, the 24 min peak (representing an isomer of metabolite BF 500-4), was fractionated by hand (about 1 mL) and immediately re-injected into HPLC without further workup.

Sample preparation for MS and NMR analysis of BF 500-4 isomers

Parallel to the ^{14}C-test solutions, 25 mL of test solutions, in which formation of larger amounts of isomers was expected (see Table 7.1.2.1.4-2), were treated with non-labeled BF 500-4 in order to produce larger substance amounts for NMR analysis.

First, 20 mL of the test solution was filled in a 25 mL volumetric flask, then non-labeled BF 500-4 was carefully weighed into the flask until the solubility was (visibly) reached. Then the flask was filled to the calibration mark, closed with a glass stopper and placed on magnetic stirrers in a 20°C incubator.

Table 7.1.2.1.4-2: Test solutions used for production of isomers for NMR analysis

Test medium	test volume [mL]	added amounts of non-labeled BF 500-4 [mg]
buffer pH 9	25	32.8
ACN/H_2O 20:80 (v:v)	25	34.5
ACN/H_2O 50:50 (v:v)	25	164.1
ACN/H_2O 80:20 (v:v)	25	521.4

At day 0 as well as after 12 and 19 days, a 250 µL sample of each solution was taken and subjected to HPLC.

After 20/21 days, 10 x 2 mL aliquots from the ACN/H_2O 20:80 (v:v) solution were fractionated via preparative HPLC. The fractions 7 - 9.5 min, 16.5 - 19.5 min, and 27.5 - 29.5 min contained the compounds of interest, each with the mass 299 (500M74, 500M75 and BF 500-4 (500M73)). The fractions were separately collected in round bottom flasks. The water from the elution solvent was immediately evaporated by rotary evaporation. After 4 fractionation cycles, the dry residues were dissolved in 1 mL acetonitrile, respectively, and 200 µL subsampled for MS analysis. Then the fractionation was continued for another 6 fractionation cycles.

The collected fractions were dried by rotary evaporation and transferred in 1 mL volumetric flasks. The acetonitrile was evaporated under a stream of nitrogen and two times redissolved with few amounts of deuterated acetonitrile (to remove residual non-deuterated solvent). Finally, the flasks were made to volume with deuterated acetonitrile. These samples were subjected to NMR analysis.

II. RESULTS & DISCUSSION

Isomerization in different test solutions

The results of the isomerization experiment in various solutions are shown in Table 7.1.2.1.4-3. The isomerization of BF 500-4 can be observed in all aqueous media except in water pH 1, where the substance immediately hydrolysed to polar substances.

uk = unknown tRet = retention time [min] * sum of several peaks; each single peak < 5% area in chromatogram

The isomerization seemed to be clearly dependent on the water content in the solution. The higher the water content, the higher the percentage of isomers visible in the chromatogram. In pure ACN and ACN/H_2O 80:20 (v:v), BF 500-4 was rather stable. However, it has to be pointed out that the total amount of isomers formed is dependent on the solubility of BF 500-4 in the respective solution.

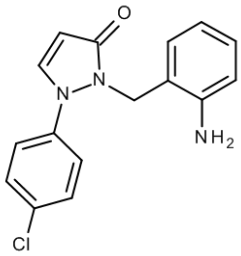
Interconversion of isomers

The reinjection of the fractionated BF 500-4 isomer (peak 24 min) showed that the isomers are easily interconvertible. Immediately, the fractionated peak transformed back into BF 500-4. Also small amounts of the isomer peak 21 min became visible.

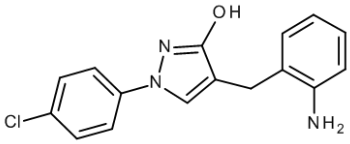
MS and NMR analysis

This interconversion was also observed during sample preparation for MS and NMR analysis. The immediate evaporation of water from the mobile phase of the preparative HPLC was still not fast enough to prevent conversion into another isomeric form within a fractionated sample. HPLC-MS/MS as well as NMR revealed that a second isomer was always present .

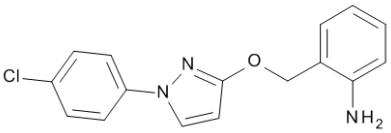
Nevertheless, the following isomeric structures could be concluded from NMR analysis:



500M74
m/z 299
ret. time 21 min



500M75
m/z 299
ret. time 24 min



BF 500-4 (500M73)
m/z 299
ret. time 34 min

Since it can be assumed that the sequence of peak elution from reversed phase columns will be kept, especially when using the same H_2O/acetonitrile HPLC solvent system, it can be concluded that the 21 min isomer peak from the 20:80 ACN/H_2O solution corresponds to the 16 min isomer peak in the ACN/H_2O extract of the anaerobic soil metabolism, and the 24 min isomer peak from the 20:80 ACN/H_2O solution corresponds to the 18 min isomer peak in the ACN/H_2O extract of the anaerobic soil metabolism.

Thus, the compound codes and structures of the BF 500-4 isomers found during pyraclostrobin anaerobic soil metabolism could finally be determined.

III. CONCLUSION

As a results of these investigations, the compound codes and isomeric structures of BF 500-4 are clearly assigned. The environmental significance of these isomers is however considered low since BF 500-4 itself is a very short lived intermediate within the pyraclostrobin degradation route in soil. It could only be formed when pyraclstrobin is sprayed into an anoxic water compartment. And only then the isomerization could take place. This scenario is very unlikely to occur under realistic agricultural field conditions. Furthermore, the isomers proved to be interconvertible and can thus be considered as one metabolite entity.

Summary of the maximum metabolite percentages reached during anaerobic soil metabolism of pyraclostrobin

Executive Summary

The dissipation behavior of pyraclostrobin in soil has been investigated in two field dissipation studies [*BASF DocID 1999/11301; BASF DocID 1999/11292*]. The purpose of the evaluation was to analyze the dissipation behavior of pyraclostrobin in six soils under different climatic conditions and to derive non-normalized trigger and normalized modeling endpoints according to the current guidance of the FOCUS workgroup on degradation kinetics and the EFSA guidance on estimating $DegT_{50}$ values in soil for modeling purposes.

The field trials were situated in different regions of Europe (Germany, Spain and Sweden), considering a range of different soils and climatic conditions. The two field dissipation trials conducted in Spain are potentially sufficient for the calculation of dissipation rates, but both are not representative with respect to EU climate conditions (following CTB criteria), and the estimated half-lives are not sufficient for modeling purposes. Hence, data from the Spanish trials were excluded from the evaluation for derivation of modeling endpoints. However, best-fit endpoints were estimated as field trials can be assumed to represent worst-case conditions.

Kinetic evaluation of pyraclostrobin dissipation observed in the six field trials was performed in order to derive field dissipation parameters that are adequate to be used as trigger endpoints. The non-normalized field half-lives ($DisT_{50}$) for pyraclostrobin ranged from 5.2 to 55.8 days. The corresponding $DisT_{90}$ values ranged from 80.3 to 347.8 days.

Kinetic evaluation of pyraclostrobin dissipation observed in the four field trials from Germany and Sweden was performed to derive appropriate field half-lives for environmental fate modeling. Prior to kinetic evaluation, the studies were normalized to reference conditions (pF2, 20°C) by time-step normalization and kinetic evaluation was performed on the normalized dataset. Normalized (pF2, 20°C) field half-lives ($DegT_{50}$) for pyraclostrobin ranged from 15.5 to 32.2 days.

I. MATERIAL AND METHODS

The kinetic evaluation was conducted for six field trials with pyraclostrobin from the data of two field dissipation studies [*Kellner O., Zangmeister W. – BASF DocID 1999/11301; Kellner O., Zangmeister W. – BASF DocID 1999/11292*]. The trials were situated in different regions of Europe (Germany, Spain, Sweden) considering a range of different soils and climatic conditions. Pyraclostrobin was applied as EC formulation BAS 500 01 F to bare soil. The nominal application rate was 250 g a.s. ha^{-1} at all trial sites. Soil samples were collected at several post-application intervals to a depth of 50 cm and analyzed for pyraclostrobin.

Characteristics of the soils from the trial sites were determined from soil samples taken before application to a depth of 25 cm. Soil characteristics are summarized in Table 7.1.2.2.1-1.

Table 7.1.2.2.1-1: Characteristics of the field dissipation studies

Normalization procedure

Evaluation of the suitability of field dissipation data for normalization was performed according to the evaluation criteria for normalization compiled by the Dutch regulatory authority (CTB criteria).

For the four field dissipation trials conducted in Germany and Sweden, all criteria were fulfilled. The Spanish field trials did not fulfil the crucial evaluation criteria 5 on representative climate for European conditions. The locations were potentially sufficient for the performance of dissipation trials, but had a long period without a noteworthy degradation. This phenomenon, which is not characteristic for pyraclostrobin, can be attributed to the late application dates (7th May for Manzanilla, 26th May for Alcala del Rio), that were followed by a long dry period that reduced microbial activity and thus microbial degradation in soil. Such climatic conditions are not typical for use of fungicides such as pyraclostrobin. Hence, these trials are not representative and the estimated half-lives would not be sufficient for modeling purposes. As climate conditions were not representative for the EU, data from the Spanish trials were excluded from the evaluation for derivation of modeling endpoints. However, the evaluation was conducted for best-fit endpoints, as the trial sites are assumed to represent worst-case conditions.

Temperature correction factors (f_{temp}) were determined to account for differences between actual daily temperatures as calculated by FOCUS-PEARL 3.3.3 and a reference temperature of 20°C using the Q_{10} approach as described in the report of the FOCUS soil modeling working group [*FOCUS (1997): Soil persistence models and EU registration. The final report of the work of the Soil Modeling Work group of FOCUS (Forum for the Co-ordination of pesticide fate models and their Use)*]. The Q_{10} response function was applied for temperatures above 0°C. For field temperatures below 0°C, it was assumed that no degradation occurs (Equation 7.1.2.2-1 a). For the evaluation, the EFSA opinion on the default Q_{10} value [*EFSA (2007): Scientific Opinion of the Panel on Plant Protection Products and their Residues on a request from EFSA related to the default Q10 value used to describe the temperature effect on transformation rates of pesticides in soil. The EFSA Journal (2007) 622, 1-32*] was followed and a Q_{10} value of 2.58 was included in the assessment.

Moisture correction factors (f_{moist}) were determined to account for differences between actual daily soil moisture as calculated by FOCUS-PEARL 3.3.3 and the reference soil moisture (θ_{ref}) (Equation 7.1.2.2-1 b).

Equation 7.1.2.2-1: Calculation of normalized day length based on combination of soil moisture and soil temperature correction factors

a)

$$f_{temp} = \begin{cases} Q_{10}^{\frac{Tact-Tref}{10}} & \text{for } T_{act} > 0°C \\ 0 & \text{for } T_{act} \leq 0°C \end{cases}$$

b)

$$f_{moist} = \begin{cases} \left(\frac{\theta_{act}}{\theta_{ref}}\right)^{B} & \text{for } \theta_{ref} > \theta_{act} \\ 1 & \text{for } \theta_{ref} \leq \theta_{act} \end{cases}$$

with:

D_{norm} =	normalized day length (temperature and moisture)	
f_{temp} =	temperature correction factor	[-]
f_{moist} =	moisture correction factor	[-]
D =	1 d	[days]
T_{act} =	actual soil temperature	[C°]
T_{ref} =	reference temperature (20°C)	[C°]
Q_{10} =	factor of increase of degradation rate with an increase in temperature of 10°C (Q_{10} = 2.58)	[-]
θ_{act} =	actual soil moisture (vol. water content)	[m^3 m^{-3}]
θ_{ref} =	reference soil moisture at pF2	[m^3 m^{-3}]
B =	exponent of the moisture response function, B = 0.7	[-]

The trial data were normalized by time-step correction (varying the 'day length' virtually by applying the correction factors to the time given in days). The corrected day lengths for the time-step normalization are shown in Table 7.1.2.2.1-3.

Table 7.1.2.2.1-3: Corrected time from the time-step normalization and concentration of pyraclostrobin in soil of the field trials after modification of LOQ data for kinetic modeling following FOCUS

[a] days after treatment
[b] corrected time (days after treatment) for time-step normalization

To derive appropriate field half-lives for environmental fate modeling, the recommendations provided in the EFSA guidance to obtain DT_{50} values in soil [*EFSA (2010): Guidance for evaluating laboratory and field dissipation studies to obtain $DegT_{50}$ values of plant protection products in soil. EFSA Journal 2010;8(12):1936, 67 pp.*] were considered, i.e. splitting of field dissipation trials into two parts, i.e. before and after 10 mm of rain has fallen since application.

The day when 10 mm of rainfall were reached in the field studies is given in Table 7.1.2.2.1-4 for the original sampling days and normalized days after treatment, respectively.

Table 7.1.2.2.1-4: Day at which 10 mm of rainfall was reached

Kinetic modeling

The software package KinGUI version 2.2012.320.1629 was used for parameter fitting [*BASF DocID 2007/1062781*]. The error tolerance and the number of iterations of the optimization tool (IRLS) were set to the default values of 1×10^{-6} and 100, respectively.

Datasets were prepared for kinetic evaluation as follows:

- Values below the quantification or detection limit were treated as recommended by the FOCUS workgroup [*see FOCUS (2006), chapter 6.1.4 and chapter 8.3.1*]. As the LOD has not been reported, samples below LOQ (= 15 g ha^{-1}) were set to 0.5 x LOQ. Furthermore, all samples after the first non-detect (< LOQ) were omitted as no positive detections were made later. For the kinetic fits, the measured concentrations were scaled to %-values in order to minimize the effect of scale in the fitting procedure.
- For each sampling point, the residues of the single core segments given in mg kg^{-1} were transformed to residues given in g ha^{-1} considering the thickness of the respective segment and the default soil density of 1.5 g cm^{-3}.

Kinetic models included in the evaluations

The kinetic models which can be employed for these evaluations were described by the FOCUS workgroup on degradation kinetics [*FOCUS (2006)*]:

- Single-First-Order (SFO); Box 5-1 in *FOCUS (2006)*
- Gustafson and Holden (FOMC); Box 5-2 in *FOCUS (2006)*
- Double first-order in parallel (DFOP); Box 5-4 in *FOCUS (2006)*
- Hockey-stick (HS); Box 5-3 in *FOCUS (2006)*

According to the EFSA guidance [*EFSA (2010)*], the kinetic models named above with exception of the FOMC model are proposed for the calculation of the DT_{50} for normalized decline curves.

The appropriateness of a distinct kinetic model to describe soil degradation can be tested according to the following criteria recommended by FOCUS [*FOCUS (2006), chapter 6.3.1*]:

- Visual assessment of goodness-of-fit
- Statistical evaluation of the goodness-of-fit by estimation of the error percentage at which the χ^2 test is passed [*Equation 6-2 in FOCUS (2006)*]
- Estimation of the reliability of parameter estimation using the t-test to evaluate whether estimated degradation parameters differ significantly from zero [*Equation 6-3 in FOCUS (2006)*]

A kinetic model is considered appropriate if the residuals are randomly distributed around zero, the χ^2 error value is <15% and the estimated degradation parameters differ from zero as outlined by *FOCUS (2006)*.

II. RESULTS AND DISCUSSION

A summary of the adequate $DisT_{50}$ and $DisT_{90}$ values to be used as trigger endpoints is given in Table 7.1.2.2.1-5. The visual fits are acceptable for all trials, moreover the χ^2 error is mostly < 15% and within range of acceptance for laboratory standards.

Table 7.1.2.2.1-5: Summary of best-fit endpoints of pyraclostrobin

Field trial	Soil type (DIN)	Best-fit kinetic model	$DisT_{50}$ [d]	$DisT_{90}$ [d]
D05/02/97, Germany	Loamy sand	SFO	33.3	110.5
D08/01/97, Germany	Loamy silt	FOMC	18.4	130.4
DU2/02/97, Germany	Loamy sand	SFO	24.2	80.3
ALO/01/98, Spain	Sandy loam / loamy sand	DFOP	5.2	86.9
ALO/02/98, Spain	Sandy loam	DFOP	14.2	347.8
HUS/02/98, Sweden	Loamy sand	SFO	55.8	185.3

The rate constants (*k*) and field half-lives ($DegT_{50}$) adequate to be used in environmental fate modeling are summarized in Table 7.1.2.2.1-6. The visual fits are acceptable for all trials; moreover the χ^2 error is < 15%.

Table 7.1.2.2.1-6: Summary of endpoints for use in modeling of pyraclostrobin

III. CONCLUSION

Kinetic evaluation of six field trials with pyraclostrobin was conducted in order to derive trigger and modeling endpoints according to the current guidance of the FOCUS workgroup on degradation kinetics and the EFSA guidance on estimating $DegT_{50}$ values in soil for modeling purposes. The field trials were situated in different regions of Europe (Germany, Spain and Sweden), considering a range of different soils and climatic conditions. The two field dissipation trials conducted in Spain were found to be not representative and were excluded from the evaluation for derivation of modeling endpoints. However, best-fit endpoints were estimated as field trials can be assumed to represent worst-case conditions.

Kinetic evaluation of pyraclostrobin dissipation observed in the six field trials was performed in order to derive field dissipation parameters that are adequate to be used as trigger endpoints. The non-normalized field half-lives (DT_{50}) for pyraclostrobin ranged from 5.2 to 55.8 days. The corresponding DT_{90} values ranged from 80.3 to 347.8 days.

Kinetic evaluation of pyraclostrobin dissipation observed in the four field trials from Germany and Sweden was performed to derive appropriate field half-lives for environmental fate modeling. Normalized (pF2, 20°C) field half-lives (DT_{50}) for pyraclostrobin ranged from 15.5 to 32.2 days.

A **new field dissipation study** with pyraclostrobin was initiated in order to cover the requirements of the EPA/NAFTA guidelines (implemented in the new data requirements for EU registration) and in order to provide additional degradation rates in the soil matrix for modeling following the new EFSA guidance [*EFSA (2010)*], i.e. excluding soil surface processes.

Report:	CA 7.1.2.2.1/2 Bayer H.,Marwitz A., 2014a Field soil dissipation study of BAS 500 F (Pyraclostrobin) in the formulation BAS 500 14 F on bare soil at four different sites in Europe, 2011-2012 2013/1348661
Guidelines:	NAFTA Guidance Document for Conducting Terrestrial Field Dissipation Studies Regulatory Directive DIR2006-01 (March 2006), EPA 835.6100, SETAC Procedures for assessing the environmental fate and ecotoxicity for pesticides (March 1995), EFSA Guidance to obtain DegT50 values in soil (2010), SANCO/825/00 rev. 8.1 (16 November 2010), SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Note: This study was not correctly listed in the application submitted for renewal of approval. Authors have changed after submission of the application.

Executive Summary

The dissipation of pyraclostrobin (BAS 500 F) and its metabolites BF 500-6 (500M01), BF 500-7 (500M02) and BF 500-3 (500M07) under field conditions was investigated at four sites in Europe representative of Northern, Central and Southern EU conditions (Denmark, Germany, Italy and France). All sites represent typical regions of agricultural practice representative for the use of pyraclostrobin. The trial sites consisted of an untreated and a treated plot, the latter being subdivided into three subplots that were assigned for replicates.

The product BAS 500 14 F, formulated as an emulsifiable concentrate (EC), was applied to bare soil in a single application at a nominal rate of 250 g a.s. ha^{-1} using a target water volume of 300 L ha^{-1}. Applications were conducted in May 2011 using a calibrated boom sprayer. The actual application rates for each trial (determined by quantifying the amount of spray discharged) ranged from 245 to 256 g a.s. ha^{-1}, with an average of 252 g a.s. ha^{-1}. Results from spray broth analysis for the individual trial sites revealed mean concentrations between 106 and 114% of the nominal value with an average of 110% across all sites. Dose verification conducted via application monitors yielded mean recovery values for the individual trial sites ranging from 101 to 117% of the target rate and an average recovery of 109% across all sites.

Immediately after application of the test item, the plots were covered with a layer of sand of approximately 6 mm depth to protect the applied product from surface processes like photolysis or volatilization, and to exclude any potential impact on the degradation of the test item caused by any of these processes. The application of sand was conducted until complete coverage of the soil surface was achieved. The layer of sand was controlled up to at least 27 days after application and was renewed when needed. It remained intact until at least 27 days. Within this time period, the individual fields received a cumulative precipitation (rain and irrigation) of 49 mm (Denmark), 71 mm (Germany), 48 mm (Italy) and 50 mm (Southern France), respectively.

No tillage or fertilization was performed during the course of the study and no crops were grown throughout any of the trials. The plots were kept free of vegetation via the application of herbicides. Rainfall was supplemented with irrigation at sites in Denmark (91 mm), Germany (129 mm), Italy (439 mm) and Southern France (319 mm).

Soil samples were taken up to 540 days after application and down to a maximum soil depth of 50 cm. Soil cores were cut into 10 cm sections. Soil segments of the same depth and subplot from a defined sampling event were pooled and homogenized and a representative sub-sample of each depth was taken for residue analysis. All soil specimens were stored at about -18°C within a maximum of 8 hours 30 minutes after sampling and remained frozen until analysis.

In order to demonstrate stability of the residues in soil during storage and any shipments, shipment verification specimens were prepared at selected sampling occasions by fortifying untreated soil from the field sites with known amounts of pyraclostrobin. These specimens were stored and shipped under the same conditions as the actual residue specimens. Analysis of the shipping verification specimens on pyraclostrobin yielded an average recovery value of 103% across all sites confirming residue stability of pyraclostrobin during all storage and shipment procedures.

Soil specimens and shipping verification samples were analyzed for pyraclostrobin and its metabolites BF 500-6, BF 500-7 and BF 500-3 according to BASF method L0166/01. Application monitors (Petri dish specimens) were analyzed for pyraclostrobin according to BASF method L0161/01. The analytical methods involved extraction of the soil with acetonitrile and acetonitrile/water (80/20, v/v) or with acetonitrile/water (80/20, v/v) only. The final determination of the analytes was performed by LC-MS/MS with a limit of quantification (LOQ) of 0.001 mg kg^{-1} for each analyte. The limit of detection (LOD) was set at 0.0002 mg kg^{-1} (20% of LOQ).

Residue concentrations of the individual analytes in the untreated control samples were below the LOQ, proving that there were no interferences of the untreated soil material with the analytical procedures used. Procedural recovery experiments performed with untreated field soils spiked with the four analytes at concentration levels of 0.001, 0.01 and 0.1 mg kg^{-1} yielded mean recovery rates between 97.0 and 104.2% for the individual analytes, confirming the validity of the analytical method used in this study.

Residue values of pyraclostrobin and metabolites BF 500-6, BF 500-7 and BF 500-3 in mg kg^{-1} dry soil were converted to residue rates in g ha^{-1} taking into account the actual dry soil density of the individual field samples. Afterwardsb they were summed up for all depths between 0 and 50 cm that has been analyzed. Residue values were not corrected for procedural recoveries except for results obtained from Petri dish analysis.

Pyraclostrobin degraded under field conditions in soil at all four European field sites. The total amount of pyraclostrobin residues detected in the soil profiles decreased from an average of 196 g ha^{-1} at day 0 to an average of 17 g ha^{-1} after 1.5 years.

Pyraclostrobin residues were almost exclusively found in the top 0-10 cm soil layer, with only small amounts of the compound sporadically detected in the 10-20 cm layer. No residues above the LOQ were detected below 20 cm in any sample. It can be concluded that pyraclostrobin does not show any significant tendency to move into deeper soil layers, indicating low potential for pyraclostrobin residues to leach to groundwater.

Metabolites BF 500-6, BF 500-7, and BF 500-3 were detected at all sites reaching maximum amounts of 43 g ha^{-1}, 29 g ha^{-1}, and 2.4 g ha^{-1}, respectively. They were exclusively found in the top 0-20 cm soil layer, except for one single detection of BF 500-6 at the LOQ in the 30-40 cm layer at the site in Denmark. Apart from that, no residues of the 3 metabolites above the LOQ were observed in deeper soil layers in any sample at any site.

No calculation of dissipation times is provided in the summarized report. A detailed kinetic evaluation of the degradation behavior of pyraclostrobin and its metabolites in the four European field soils is provided in separate modeling reports.

I. MATERIAL AND METHODS

1. Test Material

Test item (formulation):	BAS 500 14 F
Active substance (a.s.):	Pyraclostrobin (BAS 500 F, Reg.No. 304428)
Type of formulation:	EC
Batch No.:	0003191314
Content of a.s.:	239.3 g L^{-1} (nominal 250.0 g L^{-1})
Expiration date:	June 30, 2011

2. Test sites

The dissipation of pyraclostrobin under field conditions was investigated at four sites in Europe representative of Northern, Central, and Southern EU conditions. Trials were performed in Denmark (L110057), Germany (L110058), Italy (L110059), and Southern France (L110060). The homogeneity of the upper soil layer was verified prior to the start of the trials. The site characteristics are presented in Table 7.1.2.2.1-7. Soil parameters were determined from untreated soil samples taken from the fields following segmentation according to the soil horizons. Soil taxonomy was determined on the basis of regional soil maps.

The selected fields represented typical regions of agricultural practice with soils representative for growing crops including cereals, and had been under cultivation for many years. The sites were flat without any significant slope. Before commencement of the first sampling, the soil at each trial site was prepared as for sowing and was rolled if considered necessary, but then was left fallow.

No product containing the active substance of the test item had been used on the test plots in the last three years.

3. Experimental treatments

The trial area at each site was divided into two plots, one untreated control plot (size: 30 - 108 m^2) and one treated plot (size: 306 - 648 m^2). The treated plot consisted of three equal sized subplots A, B, and C that were assigned for replicates.

The product formulated as an emulsifiable concentrate (EC), was broadcast applied to bare soil in a single application at a nominal rate of 250 g a.s. ha^{-1} using a target water volume of 300 L ha^{-1}. Applications were conducted in May 2011 using a calibrated boom sprayer. Treated plots were three-fold replicated with a subplot size ranging from 108 to 216 m^2. For each treated replicate, a separate spray mixture was prepared and the test item was applied to each subplot individually. Each spray mixture was visually checked for homogeneity, and small aliquots of the spray mixture were taken before and after application of each subplot for later analysis.

The actual application rates (determined by quantifying the amount of spray discharged) ranged from 245 to 256 g a.s. ha^{-1} averaged over the three replicates of each treated plot. In addition, the dose was verified by means of sampling Petri dishes filled with standard soil (approximately 50 g per dish, sieved to 2 mm). The Petri dishes with an inner diameter of 10.8 cm were placed on the treated plot (ten in each subplot) before application. On completion of the application, the petri dishes were closed with a lid, sealed with adhesive tape, chilled on blue ice or dry ice and placed in freezer storage within 3.5 hours. Further details of application are presented in Table 7.1.2.2.1-8.

Immediately after application of the test item and before subsequent soil sampling, the control plot and the treated replicates were covered with a thin layer of sand to protect the applied product from surface processes like photolysis or volatilization, and to exclude any potential impact on the degradation of the test item caused by any of these processes. The application of sand was conducted manually or using a sand spreader until complete coverage of the soil surface was achieved. Fine or medium grained sand was used. The thickness of the sand layer necessary for complete coverage of the soil was approximately 6 mm (range: 4-10 mm) averaged across the sites. The layer of sand was controlled up to at least 27 days after application and was renewed when needed. It remained intact until at least 27 days. Within this time period of 27 days, the individual fields received a cumulative precipitation (rain and irrigation) of 49 mm (Denmark), 71 mm (Germany), 48 mm (Italy), and 50 mm (Southern France), respectively.

No tillage or fertilization was performed during the course of the study from first to last sampling and no crops were grown throughout any of the trials. The plots were kept free of vegetation via the application of metribuzin, 2,4-D, MCPA, and/or glyphosate.

Rainfall was supplemented with irrigation at sites in Denmark (91 mm), Germany (129 mm), Italy (439 mm) and Southern France (319 mm).

Actual weather data are based on records of appropriate weather stations located on-site. Monthly summary results on temperature, precipitation and irrigation are presented in Table 7.1.2.2.1-9.

Weather data refer to time period from start of trial (day of application) until end of trial (day of last sampling)

Historical (long-term) weather data on precipitation and average air temperature from at least 10 years were taken from official weather stations located nearby (8-34 km distance to trial site). The historical and actual data each averaged over the complete duration of the individual trials are presented in Table 7.1.2.2.1-10.

The actual air temperature recorded at the four field sites during the study period was slightly higher than the historic values. Whereas the sites in Northern Europe (Denmark and Germany) received more rain during the study period compared to the historic values, rainfall was less than the historic values in Southern Europe (Italy and Southern France). Due to additional irrigation, the Southern sites as well received a total water input sufficient to allow the cultivation of crops like cereals.

Table 7.1.2.2.1-10: Summary of historical and actual weather data at field trial sites averaged over entire trial duration (1.5 years)

4. Sampling

Replicate soil specimens (8 per treated subplot and 10 or 15 per control plot) were taken at intervals up to 540 days and down to a maximum soil depth of 50 cm. At day 0, immediately after application, the treated plots were sampled down to 10 cm only. The detailed sampling intervals are presented in Table 7.1.2.2.1-11.

Table 7.1.2.2.1-11: Summary of sampling intervals at each field trial site

Trial	Country	Sampling intervals [days after treatment]
L110057	Denmark	0, 6, 13, 28, 58, 85, 119, 148, 175, 230, 300, 363, 448, 539

L110060	France (South)	-1, 0, 7, 14, 30, 63, 93, 127, 155, 174, 245, 308, 364, 449, 534

CTRL = Control; TRT = Treated

Untreated specimens were collected from the control plot on three occasions, between 3 days before the application and the day of application down to a depth of 50 cm, and after about one and 1.5 years to a depth of 10 cm. The specimens were taken randomly from one third of the untreated plot each time. The 15 cores collected at the first sampling interval were taken using a common soil probe equipped with a plastic liner of 4.5 to 5.0 cm diameter except for 30-50 cm samples taken at the site in Italy that were sampled using liners with 2.5 cm diameter. The cores were sectioned into 10 cm segments and pooled by depth. The 10 cores taken after about one year and 1.5 years were collected with a metal tube of minimum 7.5 and maximum 9.8 cm diameter.

Treated soil specimens were taken randomly (from eight points of each of the three treated subplots A – C) and were pooled according to subplot and depth. All soil specimens from 0-10 cm depth being collected from the treated plots, were taken separately using a metal tube of minimum 7.5 to maximum 9.8 cm diameter, which was pressed into the ground, and collecting the soil with a spoon or similar device. Soil specimens deeper than 10 cm were collected through the center of the excavation hole contained by the metal tube, using a common soil corer fitted with a plastic liner of diameter 4.5 to 5.0 cm, except for 30-50 cm samples taken at the site in Italy, which were sampled using liners with 2.5 cm diameter. Sampling of the 10-50 cm cores was conducted in one run or in two consecutive steps. All soil cores collected with the soil probe were sectioned into 10 cm segments and pooled by depth.

In addition to the main sampling described above, a second complete sampling (double sampling) was carried out for back-up purposes. The double samples were directly put into the freezers at the field test sites and were sectioned into 10 cm segments prior to processing.

All soil specimens intended for residue analysis were stored at about -18°C within a maximum of 8 hours and 30 minutes after sampling and remained frozen through storage, shipping and processing until final analysis. Sample processing was conducted in frozen state in a mill together with dry ice.

Shipment verification specimens were prepared to demonstrate stability of the residues in soil during storage and through any shipping processes. The samples were prepared at three occasions by fortification of soil with 0.15 mg/kg pyraclostrobin and were subsequently handled in the same manner as the actual residue samples.

5. Analytical procedure

Field soil specimens and shipping verification samples were analyzed for pyraclostrobin and metabolites BF 500-6, BF 500-7, and BF 500-3 according to the validated BASF method L0166/01 [*CA 4.1.2/1, BASF DocID 2013/1184817*]. The analytical method involved extraction of the soil with acetonitrile and acetonitrile/water (80/20, v/v) and final determination of the analytes by LC-MS/MS. In case of BF 500-7, the sum of E- and Z-isomers was used for calibration and calculation of residues (peak areas of E- and Z-isomer summarized). The limit of quantification (LOQ) was 0.001 mg kg^{-1} for each individual analyte. The limit of detection (LOD) was set at 0.0002 mg kg^{-1} (20% of LOQ). Analysis of field soil specimens originating from the treated plots was conducted down to 50 cm and was performed until a maximum of 540 days after treatment (DAT).

Petri dish specimens were analyzed for pyraclostrobin according to the validated BASF method L0161/01 [*CA 4.1.2/2, BASF DocID 2010/1075848*]. The analytical method involved extraction of the soil with acetonitrile/water (80/20, v/v) and final determination of the analyte by LC-MS/MS. The LOQ for pyraclostrobin was 0.001 mg kg^{-1}.

Spray broth specimens were analyzed for pyraclostrobin according to validated BASF analytical method L0184/01 (previously named APL0500/03) [*CA 4.1.2/3, BASF DocID 2008/1042150*]. Analysis was performed by diluting aliquots of the application solutions with acetonitrile/water, acidification with formic acid and subsequent HPLC-MS analysis. The LOQ was 1 µg L^{-1} for pyraclostrobin.

Generally, for soil samples, a second mass transition was monitored for each analyte.

The validity of the analytical methods for soil samples was proven within the present study by analysis of untreated control and fortified samples within each analytical sample set.

6. Storage stability experiments

Storage stability of pyraclostrobin and its metabolites BF 500-6, BF 500-7, and BF 500-3 in frozen soil was investigated in a separate study [*CA 7.1.2.2.1/5, Tilting N. et al., BASF DocID 2014/1000723*] with soils originating from the individual trial sites of the present terrestrial field dissipation study.

7. Calculation of dissipation times

No calculation of dissipation times is provided in the study report. A detailed kinetic evaluation of the degradation behavior of pyraclostrobin and its metabolites in the four European field soils is presented in two separate modeling reports [*CA 7.1.2.2.1/3, Pape L., BASF DocID 2014/1105763 and CA 7.1.2.2.1/4, Pape L., BASF DocID 2014/1105764*].

II. RESULTS AND DISCUSSION

1. Spray broth concentration and application verification

Spray broth homogeneity was confirmed by visual check for all trials. In addition, spray mixtures sampled before and after application of each subplot were analyzed for pyraclostrobin. Analyzed concentrations averaged across the individual trial sites were in the range of 0.887 to 0.949 g L^{-1} corresponding to 106-114% of the target concentration of 0.833 g L^{-1}. The analytical results were not corrected for procedural recoveries and confirm the integrity of the test item used in the trials.

Application verification was conducted by means of Petri dishes filled with standard soil. Untreated and fortified specimens of this soil were analyzed with the applied Petri dishes from the field. Fortification levels of pyraclostrobin were at 0.5 and 5.0 mg kg^{-1}. Mean recoveries for each analyzed set of samples ranged from 103.2 to 110.5% with an overall mean recovery of 106.5 ± 3.9% (mean ± RSD, n = 14). Residues in blank specimens were not detectable above the LOQ of 0.001 mg/kg.

Residue levels of pyraclostrobin achieved on extraction and analysis of the application monitors (Petri dishes filled with soil) were corrected for the mean recovery of the respective analytical set and converted into residue rates (in g ha^{-1}) taking into account the area of the Petri dishes (91.6 cm^2) used. The obtained application rates for the individual trials ranged from 253 to 293 g ha^{-1} representing 101-117% of the target rate (see Table 7.1.2.2.1-8 for individual figures). The applied amount determined by the application monitors in these trials is slightly above the nominal value of 250 g ha^{-1}, which is in agreement with the results obtained from the spray broth samples.

2. Residues in field soil samples

Untreated soil specimens (control samples) of the respective soil depths from each trial were analyzed for residues of pyraclostrobin, BF 500-6, BF 500-7, and BF 500-3. No residues above the LOQ of any analyte were detected in any of the untreated control samples proving that there were no interferences of the untreated soil material with the analytical procedures used. Procedural recovery experiments performed with untreated field soil specimens spiked with the four analytes at concentration levels of 0.001, 0.01, and 0.1 mg kg^{-1} yielded mean recovery rates for the individual analytes between 97.0 and 104.2%, confirming the validity of the analytical method used in this study. Detailed results are summarized in Table 7.1.2.2.1-12.

Table 7.1.2.2.1-12: Method procedural recoveries

Analyte	Trial	n	Mean recovery ± RSD* [%]
Pyraclostrobin	L110057	50	101.9 ± 7.5
	L110058	43	101.1 ± 6.9
	L110059	63	101.0 ± 6.3
	L110060	46	99.1 ± 6.0

	L110058	43	104.2 ± 8.8
	L110059	62	102.6 ± 7.7
	L110060	44	101.7 ± 9.2
BF 500-3	L110057	46	101.3 ± 8.3
	L110058	43	101.5 ± 7.7
	L110059	61	100.5 ± 6.9
	L110060	44	97.0 ± 8.6

* mean values are across all soil depths and fortification levels; RSD = relative standard deviation [%]

These data prove that the analytical method applied was suitable to accurately determine residues of pyraclostrobin and its metabolites in soil down to a concentration of 0.001 mg kg^{-1} for each analyte.

Field soil specimens from the treated plots were analyzed down to a depth of 50 cm and up to a sampling event of 540 days after treatment (DAT). For confirmatory purposes, selected samples were measured twice. If samples were analyzed in duplicate, the individual numbers were averaged to produce a mean for the respective soil sample. When one of the values was below the LOQ, it was averaged as half of LOQ. For all trials, the 0 DAT double samples of the 0-10 cm soil layer were analyzed as well, in order to account for the importance of the day 0 value, and the final data were obtained by averaging the values of the respective main and double samples. Additionally, selected double samples from other sampling occasions were analysed replacing individual main samples that had been contaminated during processing.

All residue values presented are related to the dry weight of the soil and were not corrected for procedural recoveries. Residue levels of the four analytes in mg kg^{-1} dry soil were converted to residue rates in g ha^{-1} taking into account the actual dry soil density of the field samples, which was calculated based on the dry weight and the volume of the sampled soil specimens. The obtained residue rates in g ha^{-1} were summed up for all depths between 0 and 50 cm analyzed. Results are presented in Table 7.1.2.2.1-13 to Table 7.1.2.2.1-16.

* calculations are based on actual dry soil density for individual soil layers
Residue values < 1 µg kg^{-1} (<LOQ) were reported and treated as zero.
DAT = days after treatment

Pyraclostrobin degraded at all four European field sites. The total amount of pyraclostrobin residues detected in the soil profiles decreased from an average of 196 g ha^{-1} at day 0 to an average of 17 g ha^{-1} after 1.5 years.

Pyraclostrobin was almost exclusively found in the top 0-10 cm soil layer, with only small amounts of the compound sporadically detected in the 10-20 cm layer (≤ 0.004 mg kg^{-1}). No residues above the LOQ were detected below 20 cm in any sample. It can be concluded that pyraclostrobin does not show any significant tendency to move into deeper soil layers indicating low potential for pyraclostrobin residues to leach to groundwater.

Metabolite BF 500-6 was found in significant amounts at all sites. It was detected earliest from 7 DAT onwards reaching maximum values (mean of 3 replicates) of 43 g ha^{-1} (Denmark), 37 g ha^{-1} (Germany), 5.7 g ha^{-1} (Italy), and 42 g ha^{-1} (Southern France). Thereafter, residues declined to values between 3.0 and 33 g ha^{-1} by the end of the study. The maximum occurrence of BF 500-6 corrected for the molar mass in the field trials was observed at the site in Denmark accounting for 28% of the maximum amount of pyraclostrobin measured in this trial.

Metabolite BF 500-7 was also found in significant amounts at all sites. It was detected earliest from 7 DAT reaching maximum values (mean of 3 replicates) of 29 g ha^{-1} (Denmark), 22 g ha^{-1} (Germany), 2.2 g ha^{-1} (Italy), and 18 g ha^{-1} (Southern France). Thereafter, residues declined to values between 0.8 and 20 g ha^{-1} by the end of the study. The maximum occurrence of BF 500-7 corrected for the molar mass in the field trials was observed at the site in Denmark accounting for 19% of the maximum amount of pyraclostrobin measured in this trial.

Metabolite BF 500-3 was detected only in trace amounts at or close to the LOQ. It was found earliest from 6 DAT, but never reached values above 2.4 g ha^{-1} (mean of 3 replicates). At sites in Germany and Southern France, BF 500-3 was only detected sporadically. The maximum occurrence of BF 500-3 corrected for the molar mass in the field trials was 1% of the maximum amount of pyraclostrobin at trials in Denmark, Germany, and Italy.

Metabolites BF 500-6, BF 500-7, and BF 500-3 were exclusively found in the top 0-20 cm soil layer, except for one single detection of BF 500-6 at the LOQ in the 30-40 cm layer at the site in Denmark. Apart from that, no residues of the three metabolites above the LOQ were observed in deeper soil layers in any sample at any site.

3. Shipment verification specimens

Shipping verification specimens spiked with pyraclostrobin were analyzed to check stability of the residues in soil during storage at the test site and through any shipping processes. Concentrations of pyraclostrobin were not corrected for procedural recoveries.

The analytical results demonstrated no losses from the shipping verification samples. The average recovery of pyraclostrobin from the soil samples spiked at the field test sites was 103% across all trials. The results prove that pyraclostrobin residues were stable in all soils under the shipping and storage conditions used.

4. Time of storage

The predominant part of the samples was analyzed within 2 years (720 days). Very few individual samples typically foreseen for re-analysis were stored for a longer time period prior to analysis. From sampling till analysis, the maximum storage period for any soil sample from the present study was 763, 569, 763 and 748 days for trials L110057, L110058, L110059, and L110060, respectively.

III. CONCLUSION

Pyraclostrobin properly degraded under field conditions in soil at all four European field sites. The total amount of pyraclostrobin residues detected in the soil profiles decreased from an average of 196 g ha^{-1} at day 0 to an average of 17 g ha^{-1} after 1.5 years.

Pyraclostrobin residues were almost exclusively found in the top 0-10 cm soil layer, with only small amounts of the compound sporadically detected in the 10-20 cm layer. No residues above the LOQ were detected below 20 cm in any sample. It can be concluded that pyraclostrobin does not show any significant tendency to move into deeper soil layers, indicating low potential for pyraclostrobin residues to leach to groundwater.

Metabolites BF 500-6, BF 500-7, and BF 500-3 were detected at all sites reaching maximum amounts of 43 g ha^{-1}, 29 g ha^{-1}, and 2.4 g ha^{-1}, respectively. They were exclusively found in the top 0-20 cm soil layer, except for one single detection of BF 500-6 at the LOQ in the 30-40 cm layer at the site in Denmark. Apart from that, no residues of the 3 metabolites above the LOQ were observed in deeper soil layers in any sample at any site.

Report: CA 7.1.2.2.1/3
Pape L., 2014a
Kinetic evaluation of a field dissipation study with BAS 500 F – pyraclostrobin conducted in 2011 and 2012: Determination of best-fit endpoints according to FOCUS
2014/1105763
Guidelines: none
GLP: no

Note: This study was not listed in the application submitted for renewal of approval. The reason for submission is described below.

Executive Summary

Kinetic evaluation of the field dissipation of pyraclostrobin (BAS 500 F) was conducted on the data from a field dissipation study, in which four field trials with pyraclostrobin were included. The purpose of this evaluation was to analyze the degradation kinetics of pyraclostrobin and its metabolites BF 500-3, BF 500-6 and BF 500-7 observed in the four soils according to the current guidance of the FOCUS workgroup on degradation kinetics in order to derive reliable best-fit $DegT_{50}$ and $DegT_{90}$ values.

The field trials were situated in different regions of Europe (Denmark, Germany, Italy and Southern France), considering a range of different soils and climatic conditions [*BASF DocID 2013/1348661*].

For each trial, the best-fit model was selected based on a visual and statistical assessment. Kinetic evaluation showed that the dissipation behavior of pyraclostrobin and its metabolites BF 500-6 and BF 500-7 was best described using single first-order (SFO) kinetics for three trials (Denmark, Germany and Southern France). For the metabolite BF 500-3 no reliable endpoints could be derived from these trials. For the trial in Italy, kinetic evaluation showed that the dissipation behavior of pyraclostrobin was best described using double first-order in parallel (DFOP) kinetics, while for the metabolites BF 500-3, BF 500-6 and BF 500-7 no reliable endpoints could be derived. The best-fit field half-lives ($DegT_{50}$) for pyraclostrobin ranged from 27.5 to 161.0 days, for metabolite BF 500-6 from 553.1 to 944.1 days and for metabolite BF 500-7 from 412.8 to >1000 days. The corresponding $DegT_{90}$ values ranged from 91.3 to >1000 days and were >1000 days for pyraclostrobin and for metabolites BF 500-6 and BF 500-7, respectively.

As degradation caused by surface processes like photolysis or volatilization was excluded by covering all plots with a sand layer the reported best-fit endpoints represent a conservative estimate of the dissipation behavior of pyraclostrobin and its metabolites in soil. Therefore, the derived best-fit endpoints should not be used as triggers for additional work (trigger endpoints).

I. MATERIAL AND METHODS

The kinetic evaluation was conducted for four field trials with pyraclostrobin from the data of one field dissipation study, which can be found in *CA 7.1.2.2.1/2* [*Bayer, H., Marwitz, A. – BASF DocID 2013/1348661*]. The trials were situated in different regions of Europe (Denmark, Germany, Italy and Southern France) considering a range of different soils and climatic conditions. Detailed soil characteristics in each trial are reported in the cited study. Applications were made to bare soil in May 2011 using a calibrated boom sprayer. Immediately after application and before subsequent soil sampling all plots were covered with a thin layer of sand to protect the applied product from surface processes like photolysis or volatilization, and to exclude any potential impact on the degradation of the test item caused by any of these processes. Soil samples were taken at 14 sampling dates up to 540 days after application and down to a soil depth of up to 50 cm from three individual subplots.

Pyraclostrobin residues were almost exclusively found in the top 0-10 cm soil layer, with only small amounts of the compound sporadically detected in the 10-20 cm layer (≤ 0.004 mg/kg). No residues above the LOQ were detected below 20 cm in any sample.
Metabolites BF 500-6, BF 500-7 and BF 500-3 were detected at all sites. They were exclusively found in the top 0-20 cm soil layer, except for 1 single detection of BF 500-6 at the LOQ in the 30-40 cm layer at the site in Denmark. Apart from that, no residues of the 3 metabolites above the LOQ were observed in deeper soil layers in any sample at any site.
The samples were extracted with acetonitrile and acetonitrile/water (80/20, v/v) and extracts were analyzed for pyraclostrobin and its metabolites BF 500-3, BF 500-6 and BF 500-7 by means of LC-MS/MS. The limit of quantification (LOQ) was 0.001 mg kg^{-1}. The limit of detection (LOD) was set at 0.0002 mg kg^{-1} (20% of LOQ).

Kinetic modeling

The software package KinGUI version 2.2012.320.1629 was used for parameter fitting [*Schäfer et al. (2007)*]. The error tolerance and the number of iterations of the optimization tool (IRLS) were set to the default values of 1×10^{-6} and 100, respectively.

Datasets were prepared for kinetic evaluation as follows:

- Values below LOQ (0.001 mg kg^{-1}) or LOD (0.0002 mg kg^{-1}) were treated as recommended by the FOCUS workgroup [*FOCUS (2006), chapter 6.1.4*]. According to FOCUS, values between LOQ and LOD were set to:
  $0.5 \times (LOQ + LOD) = 0.0006$ mg kg^{-1}
  and values below LOD were set to:
  $0.5 \times LOD = 0.0001$ mg kg^{-1}.
- For each sampling point, the concentration of a compound in the single soil layer given in mg kg^{-1} was transformed to its residue given in g ha^{-1} considering the height of the respective layer and the respective undisturbed soil bulk density for each sample as given in the study report. The total residues in the sampled subplot were calculated as the sum of residues of the single soil layers.
- For the metabolites, the residues in g ha^{-1} were transformed into parent equivalents in g a.s. ha^{-1}. The metabolites BF 500-6 and BF 500-7 are formed by a dimeric reaction, i.e. one metabolite molecule is formed out of two parent molecules. Hence, the molar mass of the parent had to be considered twice.

The measured data as well as resulting datasets submitted to kinetic analysis are provided in the original evaluation report.

Kinetic models included in the evaluations

For each data set, the kinetic models proposed by FOCUS Kinetics [*FOCUS (2006)*] were tested. The recommended kinetic models, i.e. single-first order (SFO), double first-order in parallel (DFOP) and first-order multi-compartment (FOMC), were applied to the pyraclostrobin data. The respective model descriptions and corresponding equations for calculating endpoints ($DegT_{50}$, $DegT_{90}$) are shown in the FOCUS Kinetics guidance [*FOCUS (2006), Box 5-1, Box 5-4 and Box 5-2*].

The goodness-of-fit of the kinetic models was assessed by visual inspection and statistical measures, as recommended by the FOCUS Kinetics guidance [*FOCUS (2006)*]. A kinetic model is considered appropriate if the residuals are randomly distributed around zero, the χ^2 error value is ideally <15% and the estimated degradation parameters differ significantly from zero.

The metabolites were subsequently added to the selected model for the parent considering the SFO kinetic model. Based on the known degradation pathway of pyraclostrobin, the metabolite BF 500-3 was included as transient metabolite where appropriate which is further transformed to BF 500-6 and BF 500-7. Simultaneous formation of the degradation products was assumed for the kinetic evaluation.

II. RESULTS AND DISCUSSION

Kinetic evaluation showed that the dissipation behavior of pyraclostrobin and its metabolites BF 500-6 and BF 500-7 was best described using SFO kinetics for three trials (Denmark, Germany and Southern France). For the metabolite BF 500-3 no reliable endpoints could be derived. For one trial (Italy) kinetic evaluation showed that the dissipation behavior of pyraclostrobin was best described using DFOP kinetics. For the metabolites BF 500-3, BF 500-6 and BF 500-7 no reliable endpoints could be derived. A summary of the adequate $DegT_{50}$ and $DegT_{90}$ values is given in Table 7.1.2.2.1-17 to Table 7.1.2.2.1-19.

III. CONCLUSION

Kinetic evaluation of four field trials with pyraclostrobin was conducted in order to derive reliable best-fit $DegT_{50}$ and $DegT_{90}$ values according to the current guidance of the FOCUS workgroup on degradation kinetics.

The best-fit field half-lives ($DegT_{50}$) for pyraclostrobin ranged from 27.5 to 161.0 days, for metabolite BF 500-6 from 553.1 to 944.1 days and for metabolite BF 500-7 from 412.8 to >1000 days. The corresponding $DegT_{90}$ values for pyraclostrobin ranged from 91.3 to >1000 days. For metabolites BF 500-6 and BF 500-7 the corresponding $DegT_{90}$ values were >1000 days.

Surface processes had been excluded by covering the soil with sand in the field study. Therefore, the derived best-fit endpoints should not be used as trigger endpoints.

Pape L., 2014b
Kinetic evaluation of a field dissipation study with BAS 500 F – pyraclostrobin conducted in 2011 and 2012: Determination of modeling endpoints according to FOCUS
2014/1105764
Guidelines: none
GLP: no

Note: This study was not listed in the application submitted for renewal of approval. The reason for submission is described below.

Executive Summary

The dissipation behavior of the pyraclostrobin (BAS 500 F) in soil has been investigated in a field dissipation study including four field trials located in Denmark, Germany, Italy and Southern France. The purpose of this evaluation was to analyze the degradation kinetics of pyraclostrobin and its metabolites BF 500-3, BF 500-6 and BF 500-7 observed in the four soils according to the current guidance of the FOCUS workgroup on degradation kinetics in order to derive reliable normalized modeling endpoints.

The field trials were situated in different regions of Europe (Denmark, Germany, Italy and Southern France), considering a range of different soils and climatic conditions [*BASF DocID 2013/1348661*].

As the study design was tailored to exclude surface processes, kinetic evaluation was performed according to FOCUS kinetics as recommended by *EFSA (2010)*.

Prior to kinetic evaluation, sampling intervals of the field studies were normalized to reference conditions (20°C, pF2) by time-step normalization. The kinetic evaluation was performed on the normalized dataset. Modeling endpoints were derived based on a visual and statistical assessment. Kinetic evaluation of the time-step normalized dataset (20°C, pF2) resulted in normalized field half-lives (SFO-DegT_{50}) for pyraclostrobin between 15.0 and 181.2 days, for BF 500-6 between 163.5 and 361.4 days and for BF 500-7 between 183.7 and 460.1 days. For the metabolite BF 500-3 no reliable endpoints could be derived.

I. MATERIAL AND METHODS

The kinetic evaluation was conducted for four field trials with pyraclostrobin from the data of one field dissipation study, which can be found in *CA 7.1.2.2.1/2* [*Bayer, H., Marwitz, A. – BASF DocID 2013/1348661*].

The data set has already been evaluated for best-fit endpoints; a summary of the material and methods including data handling and kinetic models considered can be found in *CA 7.1.2.2.1/3* [*Pape, L. – BASF DocID 2014/1105763*].

Surface processes had been excluded by covering the soil with sand in the field study. Therefore, kinetic evaluation was performed according to FOCUS kinetics as recommended by EFSA [*EFSA (2010)*].

In order to derive modeling endpoints, kinetic evaluation was performed on the time-step normalized data set.

Normalization procedure

Evaluation of the suitability of field dissipation data for normalization was performed according to the evaluation criteria for normalization compiled by the Dutch regulatory authority (CTGB criteria).

Temperature correction factors (f_{temp}) were determined to account for differences between actual daily soil temperatures as calculated by FOCUS-PEARL 4.4.4 and a reference temperature of 20°C using the Q_{10} approach as described in the report of the FOCUS soil modeling working group [*FOCUS (2012)*]. The Q_{10} response function was applied for temperatures above 0°C and below field temperatures of 0°C it was assumed that no degradation occurs (Equation 7.1.2.2-2 c). For the evaluation, the EFSA opinion on the default Q_{10} value [*EFSA (2007)*] was followed and a Q_{10} value of 2.58 was included in the assessment.

Moisture correction factors (f_{moist}) were determined to account for differences between actual daily soil moisture as calculated by FOCUS-PEARL 4.4.4 and the reference soil moisture at field capacity (pF 2) (Equation 7.1.2.2-2 d).

The normalized day lengths were derived according to Equation 7.1.2.2-2 a. For DAT 0, no normalization was considered and application was assumed to occur at the time point zero. Normalized sampling days (DAT_{norm}) after application were calculated by cumulatively summing up normalized day lengths according to Equation 7.1.2.2-2 b.

Equation 7.1.2.2-2: Calculation of normalized day length based on combination of soil moisture and soil temperature correction factors

a) $$D_{norm} = D * f_{temp} * f_{moisture}$$

b) $$t_i = \sum_{t=1}^{i-1} D_{norm}$$

with:

t_i =	Time from application till sampling at day i	[d]
D_{norm} =	Normalized day length (20°C, pF2)	[d]
i =	Time span between application and sampling	[d]

c) $$f_{temp} = \begin{cases} Q_{10}^{\frac{Tact-Tref}{10}} & \text{for } T_{act} > 0°C \\ 0 & \text{for } T_{act} \leq 0°C \end{cases}$$

d) $$f_{moist} = \begin{cases} (\frac{\theta_{act}}{\theta_{ref}})^B & \text{for } \theta_{ref} > \theta_{act} \\ 1 & \text{for } \theta_{ref} \leq \theta_{act} \end{cases}$$

with:

D_{norm} =	normalized day length (temperature and moisture)	
D =	actual day length (1 d)	[days]
f_{temp} =	temperature correction factor	[-]
f_{moist} =	moisture correction factor	[-]
T_{act} =	actual soil temperature (°C)	[C°]
T_{ref} =	reference temperature (20°C)	[C°]
Q_{10}=	factor of increase of degradation rate with an increase in temperature of 10°C (Q_{10} = 2.58 [EFSA 2007])	[-]
θ_{act} =	actual soil moisture (vol. water content)	[m^3 m^{-3}]
θ_{ref} =	reference soil moisture at pF2	[m^3 m^{-3}]
B =	exponent of the moisture response function, B = 0.7	[-]

Table 7.1.2.2.1-20 shows the field sampling dates for the trial locations and the normalized (20°C, pF2) day lengths based on soil moisture and soil temperature data as simulated by FOCUS-PEARL 4.4.4.

II. RESULTS AND DISCUSSION

The dissipation behavior of pyraclostrobin and its metabolites BF 500-6 and BF 500-7 was best described using SFO kinetics for all trials. For the metabolites BF 500-6 and BF 500-7 no reliable endpoints could be derived for one trial (Italy). For the metabolite BF 500-3 no reliable endpoints could be derived for any trial. A summary of the adequate $DegT_{50}$ and $DegT_{90}$ values, as well as of the formation fractions for the metabolites, is given in Table 7.1.2.2.1-21 to Table 7.1.2.2.1-23.

Report: CA 7.1.2.2.1/5
Tilting N. et al., 2014a
Stability of residues of BAS 500 F (Pyraclostrobin, Reg.No 304428) and its metabolites 500M01 (Reg.No. 364380), 500M02 (Reg.No. 369315), and 500M07 (Reg.No. 340266) in various soils under frozen conditions
2014/1000723
Guidelines: OECD 506 (Oct. 2007)
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The storage stability of pyraclostrobin (BAS 500 F) and its metabolites BF 500-6 (500M01), BF 500-7 (500M02), and BF 500-3 (500M07) in four soils was investigated under frozen conditions (approx. -18°C) over a period of two years. The soils were derived from four field dissipation trials of a parallel field study [*BASF DocID 2013/1348661*]. Trials were conducted in Denmark, Germany, Italy and France.

The soil samples were fortified at a concentration level of 0.01 mg kg^{-1} (fortified samples). Each soil aliquot was only spiked with a single test item (two replicates per soil type and analyzed time point). Soil samples without test item were used for control measurements and stored as treated samples (one sample per soil type and time point). At different intervals (approximately 0, 30, 60, 120, 240, 365, 540 and 720 days) soil samples were analyzed using BASF method L0166/01. The limit of quantitation of the method is 0.001 mg kg^{-1}. Procedural recoveries analyzed within each analytical series proved the validity of the analytical method and were used for recovery correction of stored samples.

Results from the present study showed that the field soil samples from the trials in Denmark, Germany, Italy and France, containing pyraclostrobin and its metabolites BF 500-6, BF 500-7 and BF 500-3, can be stored under frozen conditions (approx. -18°C) without any significant loss of analytes over a period of two years.

B. STUDY DESIGN

1. Experimental Conditions

Four soils from a related field soil dissipation study [*CA 7.1.2.2.1/2, Bayer H., Marwitz A. – BASF DocID 2013/1348661*] were used in the storage stability study for pyraclostrobin and its metabolites. The analytes were dosed at 0.01 mg kg^{-1} to soil samples (5 g) and then stored frozen for 0, 30 (± 2), 60 (± 2), 120 (± 5), 240 (± 7), 365 (± 7), 540 (± 14) and 720 (± 14) days. All samples were stored in a freezer throughout the entire period of the experiment at ≤-18°C. Plastic tubes (50 mL) were used as storage containers.

2. Description of analytical procedures

Determination of pyraclostrobin and its metabolites BF 500-6, BF 500-7 and BF 500-3

For determination of pyraclostrobin and its metabolites BF 500-6, BF 500-7 and BF 500-3, soil samples were extracted with acetonitrile. Soils were separated from the liquid phase by centrifugation. The supernatants were taken to dryness while the solid remainder was re-extracted with acetonitrile : water (80/20, v/v). After centrifugation, the liquid phase was separated and used to dissolve the dried residue from the first extraction. Afterwards, samples were analyzed by LC-MS/MS. The method achieved a limit of quantitation (LOQ) of 0.001 mg kg^{-1} and a limit of detection (LOD) of 0.05 pg (concentration on the LC column) for the individual compounds in soil.

LC-MS/MS measurements were performed as soon as possible after sample extraction and extract clean-up. If the sample extracts had to be stored prior to final measurement due to instrument shortage, they were kept refrigerated.

The validation of the method is described in *CA 4.1.2/1* [*Tilting N., Sopeña-Vazquez F. - BASF DocID* 2013/*1184817*].

The method was concurrently validated with analyses of stored soil samples within the summarized study, processing dose level fortifications (0.01 mg kg^{-1}), which resulted in overall average recoveries of 98 to 106% (RSD ≤ 10%).

II. RESULTS AND DISCUSSION

Frozen-storage stability of pyraclostrobin and its metabolites BF 500-6, BF 500-7 and BF 500-3 in four soils over approximately 0, 30, 60, 120, 240, 365, 540 and 720 days of storage was investigated. Soil extracts and freshly prepared standard dilutions were examined by LC-MS/MS. The results for pyraclostrobin and its metabolites BF 500-6, BF 500-7 and BF 500-3 at 0.01 mg kg^{-1} in soil samples stored frozen for up to 720 days prior to extraction are given in Table 7.1.2.2.1-26.

Overall results revealed that concentrations of BAS 500 F and its three metabolites BF 500-6, BF 500-7, and BF 500-3 remained stable in the treated soil samples from all trials when stored at -18°C over the tested period of 720 days.

According to the respective guidelines, the degradation of all analytes was not significant (≤ 30%) within the storage period of two years.

III. CONCLUSION

The results obtained from the storage stability study demonstrated that pyraclostrobin and its metabolites BF 500-6, BF 500-7 and BF 500-3 are stable in soil when stored frozen for up to 720 days, if, as a stability criterion, a threshold value of at least 85% recovery of the initial rate is applied.

CA 7.1.2.2.2 Soil accumulation studies

No experimental data available. Since all best-fit pyraclostrobin DT_{90} values from the field soil dissipation study used for derivation of trigger endpoints are < 1 year (Table 7.1.2.2.1-5), accumulation data are not needed for the active substance. The soil accumulation risk of metabolites BF 500-6 and BF 500-7 is addressed via PECsoil calculations.

CA 7.1.3 Adsorption and desorption in soil

CA 7.1.3.1 Adsorption and desorption

CA 7.1.3.1.1 Adsorption and desorption of the active substance

No new studies on adsorption/desorption behavior of the active substance pyraclostrobin were performed. The study as peer-reviewed during the previous Annex I listing process is considered to be still valid. The adsorption values as listed in the EU Review Report (SANCO/1420/2001) are shown in Table 7.1.3.1.1-1.

Table 7.1.3.1.1-1: Adsorption of pyraclostrobin on different soils (SANCO/1420/2001)

CA 7.1.3.1.2 Adsorption and desorption of metabolites, breakdown and reaction products

The adsorption/desorption behavior of the pyraclostrobin metabolites BF 500-3, BF 500-6 and BF 500-7 was already evaluated during the previous Annex I listing process.

The study performed with **BF 500-3** is considered to be still valid, and the adsorption values as given in the Monograph 12945/ECCO/BBA/01 are presented in Table 7.1.3.1.2-1.

Table 7.1.3.1.2-1: Adsorption of BF 500-3 on different soils as listed in the Monograph 12945/ECCO/ BBA/01

Soil	Soil type	OC [%]	pH [-]	K_f [-]	1/n	K_{foc} [mL g^{-1}]
Li 35 b	Loamy sand	1.1	6.5	74.3	0.802	6750
LUFA 2.2	Sand / loamy sand	2.5	5.8	268	0.942	10700
Bruch West	Sandy loam	1.5	7.5	63.5	0.688	4240
USA 538-30-5	Loamy sand	0.4	5.8	47.3	0.942	11800
USA 538-31-2	Loam	0.5	5.2	60.1	0.773	12000
CAN-95012	Sandy clay loam	3.4	7.5	354	0.831	10400
Arithmetic mean				**144.5**		**9315**

Metabolites **BF 500-6 and BF 500-7** showed very high adsorption values in the already peer-reviewed studies. Due to the very low water solubilities of both compounds and thus difficult analytics, the recoveries reported in those old studies were quite low and do not meet the requirements of guideline OECD 106. Although both compounds can be considered immobile in soil, new studies were initiated to confirm the high adsorption values under the provision of an acceptable material balance.

The old adsorption values for **BF 500-6** as given in the Monograph 12945/ECCO/BBA/01 are presented in Table 7.1.3.1.2-2, followed by the study summary of the new adsorption study performed with non-labeled BF 500-6.

Due to the very low water solubility, the compound could be tested only at one concentration.

Table 7.1.3.1.2-2: Adsorption of BF 500-6 on different soils as listed in the Monograph 12945/ECCO/BBA/01

Soil	Soil type	OC [%]	pH [-]	K_d [-]	K_{oc} [mL g^{-1}]

GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In laboratory experiments the adsorption behavior of the pyraclostrobin metabolite BF 500-6 was investigated on five European soils. The five tested soils covered a range of pH ($CaCl_2$) from 5.6 to 7.4, a range of organic carbon content from 0.60 to 1.85%, and four different USDA textural classes: one sand, two sandy loams, one silt loam and one sandy clay loam. Due to the low water solubility of BF 500-6, adsorption was only tested for one concentration level. Hence, no adsorption or desorption isotherm was determined. The application solution was prepared in 0.01 M $CaCl_2$ solution with a nominal concentration of 1 ng mL^{-1} of the test item. The ratio of soil versus test solution was 1 : 20, and the measurements were performed at the adsorption equilibrium time of one hour.

Sorption of BF 500-6 to soil proceeded fast, expressed by solution concentrations < LOD after one hour of shaking. Calculated mean distribution coefficients (K_d) differed only slightly between all soils ranging from 1732 mL g^{-1} (LUFA 2.3) to 1985 mL g^{-1} (Nierswalde). As almost the entire applied dose of BAS 500-6 was sorbed to the soil phase, distribution coefficients normalized to the fraction of organic carbon in the soils (K_{OC}) increased from the soil exhibiting the highest (Nierswalde; K_{OC}: 107301 mL g^{-1}) to the soil exhibiting the lowest organic carbon content (LUFA 2.1; K_{OC}: 311704 mL g^{-1}).

I. MATERIAL AND METHODS

B. STUDY DESIGN

1. Experimental conditions

Preliminary tests: adsorption kinetics and soil/solution ratio

A preliminary experiment was run with two soils to determine the time needed to establish equilibrium conditions. The experiments were run with a soil / solution ratio of 1/20, using the soils LUFA 2.1 and La Gironda. The test was performed in 50 mL glass centrifuge vials containing 2 g soil and 40 mL application solution (1 ng mL^{-1} BF 500-6 in 0.01 M aqueous $CaCl_2$). The vials were protected from light and shaken for 0, 2, 4, 6 and 24 hours (225 rpm). The soil / solution suspension was then centrifuged and the mass of the test vessel including contents was determined before and after decanting the supernatant. An aliquot of the supernatant was sampled and the concentration of test item in the $CaCl_2$ solution was determined by LC-MS/MS.

Results of this first trial revealed that the adsorption equilibrium was reached fast (< 1 h). Therefore, a second trial was performed applying shorter incubation times (5, 15, 30, 60 and 90 minutes).

To find the optimal soil / solution ratio for the adsorption tests, another experiment was run with LUFA 2.1 and La Gironda soil. Three different soil / solution ratios were tested: 1/10, 1/20, and 1/40 applying an application solution with a concentration of 1 ng mL^{-1}. Samples were incubated for five minutes by mechanical shaking.

The adsorption experiments were carried out in duplicate at room temperature (22 ± 2°C). Due to the low solubility of the test item, the soils were not pre-equilibrated with $CaCl_2$ solution, but the $CaCl_2$ solution containing the dissolved test item was added in one step.

Stability and adsorption of the test substance

Due to the low solubility of the test item, no adsorption or desorption isotherms could be determined in this study. Hence, the stability test, which is typically performed during the pre-tests, corresponds to the adsorption test.

The test was performed as described for the equilibrium time test, additionally analyzing the soil by extraction with 25 mL of acetonitrile and then with 25 mL of acetonitrile / water (80/20; v/v), followed by quantification using LC-MS/MS.

2. Description of analytical procedures

The method for determining metabolite BF 500-6 in $CaCl_2$ solution was newly developed and validated within this study (method L0211/01). For determination of BF 500-6 in soil, the technical procedure of method L0166/1 was used as basis, adapted to the expected concentration range, and then also validated in two soils within this study.

Principle of the methods:

To analyze BF 500-6 in $CaCl_2$ solution, 5 mL of 0.01 M $CaCl_2$ solution was extracted into cyclohexane by mechanical shaking for 30 min at 225 rpm. A 2.5 mL aliquot of the sample was evaporated to dryness using an N-Evap at 40°C. Subsequently, the sample was reconstituted in 1 mL of acetonitrile/water (80/20; v/v) and analyzed by LC-MS/MS. The method has a limit of quantification (LOQ) of 0.02 µg L^{-1} and a limit of detection (LOD) of 0.004 µg L^{-1}.

For soil analysis, a 2 g soil aliquot was extracted with 25 mL acetonitrile on a mechanical shaker (30 min at 225 rpm). After extraction, the tube was centrifuged at 3000 rpm (5 min, 20°C). The liquid phase was separated and taken to dryness. The solid remainder was re-extracted with 25 mL acetonitrile / water 80/20 (v/v). After centrifugation, the liquid phase was separated and used to dissolve the dried residue from the first extraction. For HPLC-MS/MS measurement the extract was further diluted.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

Analytical methods L0211/01 ($CaCl_2$ solution) and L0166/01 (soil) were validated within this study. Both methods revealed good average recoveries (91.5 – 116.9%) and relative standard deviations (< 7%) for the dose levels of 0.02 and 0.2 µg L^{-1} for $CaCl_2$ solution as well as 2 and 20 µg kg^{-1} for soil, respectively.

In the adsorption test, the average recovery values ($CaCl_2$ solution plus soil extract) ranged from 102.5 to 118.1%.

B. FINDINGS

Based on the results obtained, methods L0211/01 and L0166/01 are considered valid for the determination of BF 500-6 in $CaCl_2$ solution and in soil with a validated LOQ of 0.02 µg L^{-1} and 0.002 mg kg^{-1}, respectively.

Results of the adsorption equilibrium test carried out with BF 500-6 indicated that the adsorption equilibrium was reached after five minutes.

Results of control samples, where the test item was applied to $CaCl_2$ solution incubated without soil, revealed that BF 500-6 was sorbed to the wall of the test vessels, as only about 59% of the applied BF 500-6 could still be detected in solution after 1 hour. However, it is assumed that in experiments with soil, the presence of soil will generally reduce such adsorption.

No matrix interferences were detected.

After one hour of shaking, solution concentrations (C_{ads-aq}) were < LOQ for all soils. Hence, almost the entire applied amount of BF 500-6 was accounted to the fraction sorbed to the soil phase. Calculated mean distribution coefficients (K_d) differed only slightly between all soils ranging from 1732 mL g^{-1} (LUFA 2.3) to 1985 mL g^{-1} (Nierswalde). Distribution coefficients normalized to the fraction of organic carbon in the soils (K_{OC}) increased from the soil exhibiting the highest (Nierswalde; K_{OC}: 107301 mL g^{-1}) to the soil exhibiting the lowest organic carbon content (LUFA 2.1; K_{OC}: 311704 mL g^{-1}). Calculated K_d as well as K_{OC} values are presented in Table 7.1.3.1.2-4.

Table 7.1.3.1.2-4: Measured equilibrium concentrations and calculated distribution coefficients K_d and K_{OC} of BF 500-6

Soil	Soil Type (USDA)	Org. C [%]	pH ($CaCl_2$)	Measured concentration			Adsorption	
				C_0 [µg L^{-1}]	C_{ads-aq} (eq) [µg mL^{-1}]	C_{ads-s} (eq) [µg g^{-1}]	K_d [mL g^{-1}]	K_{OC} [mL g^{-1}]

La Gironda	Sandy clay loam	1.22	7.4	0.93	0.00001	0.01885	1885	154525

III. CONCLUSION

The adsorption behavior of the test item BF 500-6, metabolite of pyraclostrobin, was determined on five European soils. The soils covered a range of pH from 5.6 to 7.4 and a range of organic carbon content from 0.60 to 1.85%. The soils were classified by USDA scheme into four different textural classes: one sand, two sandy loams, one silt loam, and one sandy clay loam.

The test item BF 500-6 was fast and nearly completely adsorbed to the soil phase. This was expressed by high distribution coefficients with K_d values of 1732 – 1985 mL g^{-1} as well as high K_{OC} values of 107301 – 311704 mL g^{-1}.

B. STUDY DESIGN

1. Experimental conditions

Preliminary tests: adsorption kinetics and soil/solution ratio

A preliminary experiment was run with two soils to determine the time needed to establish equilibrium conditions. The experiments were run with a soil / solution ratio of 1/20, using the soils LUFA 2.1 and La Gironda. The test was performed in 50 mL glass centrifuge vials, containing 2 g soil and 40 mL application solution (2.5 ng mL^{-1} BF 500-7 in 0.01 M aqueous $CaCl_2$). The vials were protected from light and shaken on a mechanical shaker for 0, 5, 15, 30, 60, 90 min, 2, 4, 6 and 24 hours (225 rpm). The soil / solution suspension was then centrifuged and the mass of the test vessel including contents was determined before and after decanting of the supernatant. An aliquot of the supernatant was sampled and the concentration of test item in the $CaCl_2$ solution was determined by LC-MS/MS.

To find the optimal soil / solution ratio for the adsorption tests, another experiment was run with LUFA 2.1 and La Gironda soil. Three different soil / solution ratios were tested: 1/10, 1/20, and 1/40 applying an application solution with a concentration of 2.5 ng mL^{-1}. Samples were incubated for five minutes by mechanical shaking.

The adsorption experiments were carried out in duplicate at room temperature (22 ± 2°C). Due to the low solubility of the test item, the soils were not pre-equilibrated with $CaCl_2$ solution, but the $CaCl_2$ solution containing the dissolved test item was added in one step.

Stability and adsorption of the test substance

Due to the low solubility of the test item (BF 500-7), no adsorption or desorption isotherms could be determined in this study. Hence, the stability test, which is typically performed during the pre-tests, corresponds to the adsorption test.

The test was performed as described for the equilibrium time test, additionally analyzing the soil by extraction with 25 mL of acetonitrile and then with 25 mL of acetonitrile / water (80/20; v/v), followed by quantification using LC-MS/MS.

2. Description of analytical procedures

The method for determining metabolite BF 500-7 in $CaCl_2$ solution was newly developed and validated within this study (method L0221/01). For determination of BF 500-7 in soil, the technical procedure of method L0166/1 was used as basis, adapted to the expected concentration range, and then also validated in two soils within this study.

Principle of the methods:

To analyze BF 500-7 in $CaCl_2$ solution, 5 mL of 0.01 M $CaCl_2$ solution were extracted into cyclohexane by mechanical shaking for 30 min at 225 rpm. A 2.5 mL aliquot of the sample was evaporated to dryness using an N-Evap at 40°C. Subsequently, the sample was reconstituted in 1 mL of acetonitrile / water (80/20; v/v) and analyzed by LC-MS/MS.

For soil analysis, a 2 g soil aliquot was extracted with 25 mL acetonitrile on a mechanical shaker (30 min at 225 rpm). After extraction, the tube was centrifuged at 3000 rpm (5 min, 20°C). The liquid phase was separated and taken to dryness. The solid remainder was re-extracted with 25 mL acetonitrile / water 80/20 (v/v). After centrifugation, the liquid phase was separated and used to dissolve the dried residue from the first extraction. For HPLC-MS/MS measurement the extract was further diluted.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

Analytical methods L0221/01 ($CaCl_2$ solution) and L0166/01 (soil) were validated within this study. Both methods revealed average recoveries of 83.1 – 117.9% and relative standard deviations < 12% for the dose levels of 0.02 and 0.2 µg L^{-1} for $CaCl_2$ solution as well as 5 and 50 µg kg^{-1} for soil, respectively.

In the adsorption test, the average recovery values ($CaCl_2$ solution plus soil extract) ranged from 100.4 to 112.4%.

B. FINDINGS

Based on the results obtained, methods L0221/01 and L0166/01 are considered valid for the determination of BF 500-7 in $CaCl_2$ solution and in soil with a validated LOQ of 0.02 µg L^{-1} and 0.005 mg kg^{-1}, respectively.

Results of the adsorption equilibrium test carried out with BF 500-7 indicated that the adsorption equilibrium was reached after five minutes (0.083 h).

Results of control samples, where the test item was applied to $CaCl_2$ solution incubated without soil, revealed that BF 500-7 was sorbed to the wall of the test vessels, as only about 56% of the applied BF 500-7 could still be detected in solution after 1 hour. However, it is assumed that in experiments with soil, the presence of soil will generally reduce such adsorption.

No matrix interferences were detected.

After one hour of shaking, solution concentrations ($C_{ads\text{-}aq}$) were < LOQ for all soils. Hence, almost the entire applied amount of BF 500-7 was accounted to the fraction sorbed to the soil phase. Calculated mean distribution coefficients (K_d; mean) differed only slightly between all soils ranging from 4732 mL g^{-1} (LUFA 2.3) to 5025 mL g^{-1} (La Gironda). Distribution coefficients normalized to the fraction of organic carbon in the soils (K_{OC}) increased from the soil exhibiting a large (Nierswalde; K_{OC}: 242564 mL g^{-1}) to the soil exhibiting a low organic carbon content (LUFA 2.1; K_{OC}: 801927 mL g^{-1}). Calculated K_d as well as K_{OC} values are presented in Table 7.1.3.1.2-8.

Table 7.1.3.1.2-8: Measured equilibrium concentrations and calculated distribution coefficients K_d and K_{OC} of BF 500-7

Soil	Soil Type (USDA)	Org. C [%]	pH ($CaCl_2$)	Measured concentration			Adsorption	
				C_0 [µg L^{-1}]	$C_{ads\text{-}aq}$ (eq) [µg mL^{-1}]	$C_{ads\text{-}s}$ (eq) [µg g^{-1}]	K_d [mL g^{-1}]	K_{OC} [mL g^{-1}]
LUFA 2.1	Sand	0.60	5.6	2.13	0.00001	0.04812	4812	801927

III. CONCLUSION

The adsorption behavior of test item BF 500-7, a metabolite of pyraclostrobin, was determined on five European soils. The soils covered a range of pH from 5.6 to 7.4 and of organic carbon content from 0.60 to 2.01%. The soils were classified by USDA scheme into four different textural classes: one sand, two sandy loams, one silt loam, and one sandy clay loam.

The test item BF 500-7 was fast and nearly completely adsorbed to the soil phase. This was expressed by high values of the distribution coefficients with K_d values of 4732 – 5025 mL g^{-1} as well as high K_{OC} values of 242564 – 801927 mL g^{-1}.

Overview adsorption values of metabolite BF 500-7

Due to the new data requirements under EU Regulation 1107/2009, two additional metabolites appearing in amounts > 5% TAR in soil (although only under anaerobic conditions) are considered for leaching assessment. Therefore, adsorption/desorption studies with the anaerobic soil metabolites **BF 500-4** and **BF 500-5** were performed.

(certified by Department of Health of the Government of the United Kingdom, United Kingdom)

Executive Summary

In laboratory experiments the adsorption behavior of the pyraclostrobin metabolite BF 500-4 was investigated on five European soils. The soils covered a range of pH from 5.6 to 7.4 and of organic carbon content from 0.60 to 1.85%. The soils were classified by USDA scheme into four different textural classes: one sand, two sandy loams, one silt loam, and one sandy clay loam.

Due to the observed instability and high adsorption rate of the test item and the limitation of solubility concentrations, no isotherms could be obtained and the main phase of the study was conducted at a single target concentration of 0.125 µg mL^{-1}. In addition, no desorption experiments were conducted as the test item was not sufficiently stable in the $CaCl_2$/soil test system.

The application solution was prepared in 0.01 M $CaCl_2$ solution with a nominal concentration of 0.125 µg mL^{-1} of the test item. The ratio of soil versus test solution was 1 : 25, and the measurements were performed at the adsorption equilibrium time of two hours.

Distribution coefficients K_d ranged from 64 mL g^{-1} (soil LUFA 2.1) to 291 mL g^{-1} in soil Nierswalde. Distribution coefficients normalized to the organic carbon content K_{OC} varied between 6871 mL g^{-1} (Bruch West) and 15748 mL g^{-1} (Nierswalde).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

BAS code: BF 500-4
Synonym: 500M73
Reg. No. 358672
Chemical name (IUPAC): 2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxymethyl}phenylamine
Molar mass: 299.8 g mol^{-1} (unlabeled)
Position of radiolabel: Tolyl-ring-U-^{14}C
Specific radioactivity of a.i.: 8.49 MBq mg^{-1}
Batch No.: 1072-1004
Radiochemical purity: 98.0%

2. Soils

The study was conducted with five different soils originating from Europe. The physico-chemical properties of the soils are provided in Table 7.1.3.1.2-10.

Table 7.1.3.1.2-10: Characterization of soils used to determine the adsorption behavior of pyraclostrobin metabolite BF 500-4

Soil designation Origin	Bruch West Germany	Nierswalde Germany	LUFA 2.1 Germany	LUFA 2.3 Germany	La Gironda Spain
Textural class (DIN 4220)	Loamy sand	Clay silt	Sand	Loamy sand	Sandy clay loam
Soil texture [%], (ISO 11277)					
Sand	61.1	15.1	89.5	66.9	48.0
Silt	27.6	76.2	8.2	24.8	24.3
Clay	11.3	8.8	2.3	8.3	27.7

B. STUDY DESIGN

1. Experimental conditions

Preliminary tests: adsorption kinetics and soil/solution ratio

The adsorption of the test item to glass, polypropylene, and Teflon vessel surfaces was investigated at a nominal concentration of 0.125 µg mL^{-1} in vessels with no soil present after an agitation period of 24 hours. Measurements of total radioactivity remaining in the aqueous solution were determined and demonstrated that there was significant adsorption to both glass and polypropylene test vessels (mean recoveries of 33 and 18%, respectively), but reduced adsorption to Teflon vessels (mean recovery of 78%). Therefore, Teflon vessels were used throughout further experiments.

The solution to soil ratio to be used for the main experiment was investigated using LUFA 2.1 (lowest pH) and La Gironda soil (highest pH) at a nominal/target test item solution concentration of 0.125 µg mL^{-1}. Adsorption experiments were conducted with duplicate vessels prepared at solution/soil ratios of 1:1, 5:1, and 25:1. The vessels were mixed continuously on a roller mixer at 20±2°C for approximately 24 hours in darkness. The solutions were then separated by centrifugation at 2000 rpm (1162 G) for 60 minutes and the solution radioactivity concentrations were measured by liquid scintillation counting (LSC). The percentage of applied radioactivity adsorbed to soil was calculated from these measurements by subtraction (indirect method). Due to the observed strong adsorption of the test item, the highest solution to soil ratio of 25:1 was chosen for the main experiment.

The equilibration time experiments were performed at a solution to soil ratio of 25:1 and at the proposed test substance concentration of 0.125 µg mL^{-1} using LUFA 2.1 and La Gironda soils. After intervals of 2, 4, 8 and 12 hours single tubes for the soil were removed and centrifuged at 3200 rpm (2977 G) for 15 minutes. The direct method was applied, in which both the aqueous and soil phases were quantified. The soil phase was quantified following solvent extraction and the extracts were analyzed by LSC; the soil residue was quantified by combustion in a sample oxidizer. The aqueous and pooled soil extracts were analyzed by radio-HPLC to identify the proportion of test item present.

It was noted that after 12 hours agitation up to 6 components were present in the aqueous phase indicating potential degradation of the test item within the system. In order to minimize degradation, the agitation time for the main experiment was reduced to 2 hours. A peak at ca. 3.2 min retention time by HPLC analysis, which was formed even within the short agitation time of 2 hours, was further investigated by LC-MS/MS.

Determination of distribution constants

For the adsorption experiment, a solution to soil ratio of 25:1 and equilibration time of 2 hours was chosen for all soils. Due to the observed instability and high adsorption rate of the test item and the limitation of solubility, concentrations below the half water solubility of 0.125 µg mL^{-1} were not possible due to detection sensitivity and thus no isotherms could be obtained. Therefore, the main phase of the study was conducted at a single target concentration of 0.125 µg mL^{-1}. In addition, no desorption experiments were conducted as the test item was not sufficiently stable in the $CaCl_2$/soil test system. Hence, no desorption isotherms were established.

Portions (1.2 g) of air dried soils were weighed into 50 mL Teflon centrifuge tubes, in triplicate. The soils were pre-conditioned with 30 mL of 0.01 M $CaCl_2$ solution overnight prior to the application. Then, the $CaCl_2$ solution in the test vessels was spiked with 30 µL of the [^{14}C]-BF 500-4 application solution forming an achieved test substance concentration of 0.124 µg mL^{-1} determined by comparison of dose check solutions produced with the theoretical dose calculation.

Following application, the vessels were agitated on a roller mixer at 20 ± 2°C in darkness for 2 hours. At the end of the equilibration period, each sample tube was centrifuged at 3200 rpm (2977 G) for 15 minutes to separate the soil and solution. The supernatant solution was carefully decanted into pre-weighed 50 mL Teflon tubes and the weight recorded.

2. Description of analytical procedures

The direct method was applied where both the aqueous and soil phases consisting of three solvent extractions were analyzed by LSC followed by soil residue combustions. The aqueous and extraction phases (pooled) were then further analyzed by radio-HPLC to identify the proportion of test item present within the system and subsequent distribution coefficient calculations adjusted accordingly. From this data the distribution coefficient K_d and organic carbon content adjusted K_{oc} values were generated for the test item for each soil.

After removal of the $CaCl_2$ phase, the soil samples were extracted to determine the adsorbed amount of [^{14}C]-BF 500-4 on the soil. The soil samples were extracted with 6 mL of acetonitrile by shaking on an orbital shaker for at least 15 minutes, followed by centrifugation at 3200 rpm (2977 G) for 15 minutes. The supernatant was carefully decanted into pre-weighed 20 mL glass vials and the weight was recorded. The concentration of the radioactivity in the extracts was determined in duplicate by LSC. The extraction procedure was repeated two more times and the corresponding extracts of each soil sample were then pooled and analyzed by radio-HPLC.

In order to obtain a material balance, 0.2 g aliquots of the remaining soil were air dried and combusted in a sample oxidizer and samples set for LSC. Aqueous solutions that were not analyzed immediately by HPLC were stored at -80°C until required. Soil extracts and aqueous solutions after HPLC analysis and residues were kept in a freezer at <-15°C.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The aqueous and pooled extract phases were analyzed using radio-HPLC analysis. The total mass balance of applied radioactivity of the aqueous phase, soil extracts, and soil combustion was between 83.6 - 99.6% for all soils.

B. FINDINGS

As the amount of test item in the aqueous solution of the sample containing no soil was less than 90%, the direct method of analyzing both the aqueous and soil phases (by extraction) and combustion of the residues was used throughout all further experiments.

LC-MS/MS analysis of the peak present at ca. 3.2 min retention time present after the short agitation time of 2 hours was performed. The absence of a peak in the three summary MRM (Multiple Reaction Monitoring) chromatograms corresponding to the peak observed at ca. 2.4 min in the [^{14}C] radiochromatogram (ca. 3.2 min in the profiling system) confirms that this peak has no relation to the test item BF 500-4.

After an adsorption time of 2 hours, between 70.6 and 84.3% were sorbed to the soils. The data were adjusted for the proportion of radioactivity recovery of test item in both the aqueous phase and soil extracts following analysis by HPLC.

Calculated distribution coefficients K_d ranged from 64 mL g^{-1} (soil LUFA 2.1) to 291 mL g^{-1} in soil Nierswalde. Distribution coefficients normalized to the organic carbon content K_{OC} varied between 6871 mL g^{-1} (Bruch West) and 15748 mL g^{-1} (Nierswalde). Calculated K_d as well as K_{OC} values are presented in Table 7.1.3.1.2-11.

Table 7.1.3.1.2-11: Calculated distribution coefficients K_d and K_{OC} of BF 500-4

Soil	Soil Type (USDA)	Organic C [%]	pH ($CaCl_2$)	Adsorption (2 h)	
				K_d [mL g^{-1}]	K_{OC} [mL g^{-1}]
Bruch West	Sandy Loam	1.63	7.3	112	6871
Nierswalde	Silt Loam	1.85	5.7	291	15748
LUFA 2.1	Sand	0.60	5.6	64	10667
LUFA 2.3	Sandy Loam	0.99	6.7	74	7475
La Gironda	Sandy Clay Loam	1.22	7.4	102	8333
Arithmetic mean				**129**	**9819**

III. CONCLUSION

The adsorption behavior of test item BF 500-4, metabolite of pyraclostrobin, was determined on five soils. The soils covered a range of pH from 5.6 to 7.4 and of organic carbon content from 0.60 to 1.85%. The soils were classified by USDA scheme into four different textural classes: one sand, two sandy loams, one silt loam, and one sandy clay loam.

The adsorption of BF 500-4 on five soils was high. Calculated distribution coefficients K_d values were lowest in soil LUFA 2.1 (64 mL g^{-1}) and highest in soil Nierswalde (291 g mL^{-1}). Distribution coefficients normalized to the organic carbon content K_{OC} varied between 6871 mL g^{-1} (Bruch West) and 15748 mL g^{-1} (Nierswalde).

Report:	CA 7.1.3.1.2/4 Tuffnail W., 2014a Adsorption/desorption of BF 500-5 (Reg.No. 298327) on soil 2014/1000722
Guidelines:	OECD 106 (2000)
GLP:	yes (certified by Department of Health of the Government of the United Kingdom, United Kingdom)

Executive Summary

In laboratory experiments the adsorption behavior of the pyraclostrobin metabolite BF 500-5 was investigated on five European soils. The soils covered a range of pH from 5.6 to 7.4 and of organic carbon content from 0.60 to 1.85%. The soils were classified by USDA scheme into four different textural classes: one sand, two sandy loams, one silt loam, and one sandy clay loam.

For the determination of the adsorption isotherm, the soils were treated at five concentrations; 0.001, 0.01, 0.025, 0.05 and 0.1 µg mL^{-1} in the adsorption solution. No desorption phases were required as the apparent instability of the test compound determined that the direct method of analyzing soil extracts was employed. The ratio of soil versus test solution was 1 : 25, and the measurements were performed at the adsorption equilibrium time of four hours.

The mass balance recoveries of total applied radioactivity for each soil type were in the range 80.1 – 96.5%. Recoveries related to percent radioactivity of test item were 68.5 - 88.5%.

Calculated K_f values ranged from 5 mL g^{-1} in soil LUFA 2.1 to 15 mL g^{-1} in soil Nierswalde. Carbon normalized adsorption coefficients $K_{f,oc}$ varied between 400 (Bruch West) and 831 mL g^{-1} (La Gironda). Freundlich exponents 1/n ranged from 0.7985 (LUFA 2.3) to 0.8798 (Bruch West).

B. STUDY DESIGN

1. Experimental conditions

Preliminary tests: adsorption kinetics and soil/solution ratio

The adsorption of the test substance to glass and polypropylene vessel surfaces was investigated at the highest concentration in vessels (0.1 µg mL^{-1}) with no soil present.

The solution to soil ratio to be used for the main experiment was investigated using LUFA 2.1 (lowest pH) and La Gironda (highest pH) at the highest test substance solution concentration (0.1 µg mL^{-1}). Adsorption experiments were conducted with duplicate vessels prepared at solution/soil ratios of 1:1, 5:1 and 25:1. The vessels were mixed continuously on a roller mixer, at approximately 20°C for approximately 24 hours in darkness. The solutions were then separated by centrifugation at 8500 rpm (7027 G) for 15 minutes and the solution radioactivity concentration measured by liquid scintillation counting (LSC). The percentage of applied test compound adsorbed to soil was calculated from these measurements with a target percentage adsorbed to the soil above 20% and preferably <80%. A solution to soil ratio of 25:1 was chosen for the main experiment.

Adsorption experiments to determine the time needed to establish equilibrium conditions were set up using the solution/soil ratio determined above, with LUFA 2.1 and La Gironda soils and a test substance concentration of 0.1 µg mL^{-1}. After intervals of 2, 4, 8 and 24 hours single tubes for the soil were removed for separation by centrifuging and LSC as described above. The direct method was employed where both the aqueous phase and soil extracts were analyzed by HPLC for test item at the highest concentration. Results indicated that an equilibrium time of 4 hours agitation was required for all the soil types to give a high degree of determinable test item at or near equilibrium.

Determination of Freundlich adsorption isotherms

Since BF 500-5 could not be regarded as stable only adsorption but no desorption isotherms were established.

Portions of air dried soils (ca. 1.2 g) were weighed into 50 mL polypropylene centrifuge tubes. The soils were conditioned for use by mixing with 0.01 M calcium chloride overnight prior to the application. Application solutions of the test substance, prepared in acetonitrile, were applied by spiking to the test vessels. The achieved test substance concentrations of BF 500-5 were 0.001, 0.01, 0.025, 0.05 and 0.1 µg mL^{-1}. The test was conducted in duplicate at each test substance concentration, except for the highest concentration which was performed in triplicate. Single blank tubes at each concentration excluding soil were also treated to confirm that the test material did not adsorb to the test vessels.

Following application, the vessels were mixed at approximately 20°C, in a controlled temperature room in darkness, for the equilibration time of 4 hours.

2. Description of analytical procedures

At the end of the equilibration period, each sample tube was centrifuged (3200 rpm (2977 G) for 30 minutes) to separate the soil and solution. As much as reasonably possible of the supernatant solution was removed into pre-weighed 50 mL centrifuge tubes and the weight was recorded with the concentration of radioactivity in the solution determined in duplicate by LSC for all samples and radio-HPLC at the highest concentration only.

Following adsorption in the main study, all soil samples for each soil type were taken for extraction. The soil residues were extracted with 5 mL of acetonitrile by shaking for 10 minutes, followed by centrifugation at 8500 rpm (7027 G) for 15 minutes. As much as reasonably possible the extract solution was removed into pre-weighed 50 mL centrifuge tubes and the weight recorded with the concentration of radioactivity in the solution determined in duplicate by LSC. The procedure repeated two more times and selected samples at the highest concentration were analyzed by radio-HPLC.

Extracts of soil, adsorption solution, soil extracts and soil residues following extraction were stored at <-15°C.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The mass balances of the test item in the adsorption and extraction phases were between 68.52 - 88.48%. These recovery values are from both phases (preliminary and adsorption phase) and were adjusted for test item using the HPLC analysis from selected samples from the highest concentration. All soils after combustion gave a total mass balance of applied radioactivity of between 80.05 – 96.46%. It is suggested that the low recoveries may be due to compound becoming bound to the vessel surface, although this was not apparent when tested in tier 1.

B. FINDINGS

Following treatment at rates ranging from 0.1 to 0.001 µg mL^{-1} and an adsorption time of 4 hours, the Freundlich adsorption coefficients were calculated from the corresponding $CaCl_2$-solution and soil concentration data. The data were adjusted for recovery of test item in both the aqueous phase and soil extracts.

Adsorption coefficients K_f ranged from 5 (LUFA 2.1) to 15 mL g^{-1} (Nierswalde), while the coefficients adjusted for the organic carbon content ($K_{f,oc}$) was highest in soil La Gironda (831 mL g^{-1}) and lowest in soil Bruch West (400 mL g^{-1}). Freundlich exponents 1/n ranged from 0.7985 (LUFA 2.3) to 0.8798 (Bruch West). Results are summarized in Table 7.1.3.1.2-13.

Table 7.1.3.1.2-13: Calculated adsorption coefficients K_f, carbon normalized adsorption coefficients $K_{f,oc}$ and Freundlich exponents 1/n of BF 500-5

Soil	Soil Type (USDA)	Organic C [%]	pH ($CaCl_2$)	Adsorption (4 h)		
				K_f [mL g^{-1}]	1/n [-]	$K_{f,oc}$ [mL g^{-1}]
Bruch West	Sandy Loam	1.63	7.3	7	0.8798	400
Nierswalde	Silt Loam	1.85	5.7	15	0.8311	830
LUFA 2.1	Sand	0.60	5.6	5	0.8578	785
LUFA 2.3	Sandy Loam	0.99	6.7	7	0.7985	678
La Gironda	Sandy Clay Loam	1.22	7.4	10	0.8774	831
Arithmetic mean				**8.8**	**0.85**	**705**

III. CONCLUSION

The adsorption behavior of test item BF 500-5 (500M04), metabolite of pyraclostrobin, was determined on five soils. The soils covered a range of pH from 5.6 to 7.4 and of organic carbon content from 0.60 to 1.85%. The soils were classified by USDA scheme into four different textural classes: one sand, two sandy loams, one silt loam, and one sandy clay loam.

Calculated K_f values ranged from 5 mL g^{-1} in soil LUFA 2.1 to 15 mL g^{-1} in soil Nierswalde. Carbon normalized adsorption coefficients $K_{f,oc}$ varied between 400 (Bruch West) and 831 mL g^{-1} (La Gironda).

CA 7.1.3.2 Aged sorption

No experimental data are available. Due to the high soil adsorption values of all pyraclostrobin metabolites, no aged sorption experiments are considered necessary.

CA 7.1.4 Mobility in soil

CA 7.1.4.1 Column leaching studies

CA 7.1.4.1.1 Column leaching of the active substance

No new experimental data are available. The soil mobility of pyraclostrobin and its metabolites was evaluated during the previous Annex I inclusion process based on non-aged and aged column leaching studies. No residues were found in any of the leachates.

CA 7.1.4.1.2 Column leaching of metabolites, breakdown and reaction products

Please see justification in M-CA 7.1.4.1.1 above.

CA 7.1.4.2 Lysimeter studies

The leaching risk of pyraclostrobin and its metabolites is addressed by PEC_{gw} calculations using results from degradation rate and adsorption/desorption studies. Neither the active substance nor its metabolites reveal any risk for groundwater contamination. Lysimeter studies are therefore considered to be not necessary.

CA 7.1.4.3 Field leaching studies

Neither the active substance nor its metabolites reveal any risk for groundwater contamination. Field leaching studies are therefore considered to be not necessary.

CA 7.2 Fate and behaviour in water and sediment

CA 7.2.1 Route and rate of degradation in aquatic systems (chemical and photochemical degradation)

CA 7.2.1.1 Hydrolytic degradation

Hydrolysis of BAS 500 F (Report Amendment)
2011/1201705
Guidelines: EEC 94/37, EPA 161-1
GLP: yes
(certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

No new experimental data were produced, however, a typing error occurred in the text of the original study in the results part of the 50°C experiment (page 20, chapter 4.2.1.1, tolyl label, first paragraph, third sentence) leading to a wrong designation of one of the identified peaks (BF 500-5 instead of BF 500-3). The text was corrected in the report amendment. The overall results as presented in the tables were unaffected.

Pyraclostrobin was stable at pH 4, 5, and 7. Only at pH 9 a slow hydrolysis was observed with formation of known derivatives (BF 500-6, BF 500-7 and BF 500-5).

CA 7.2.1.2 Direct photochemical degradation

The already peer-reviewed data are considered to be still valid. Therefore, no new experimental data are provided. Pyraclostrobin degraded under irradiated conditions with half-lives << 1 d.

CA 7.2.1.3 Indirect photochemical degradation

Since pyraclostrobin degraded very fast during the direct aqueous photolysis study and in the irradiated water/sediment studies, an indirect aqueous photolysis study is considered to be not necessary.

CA 7.2.2 Route and rate of biological degradation in aquatic systems

CA 7.2.2.1 "Ready biodegradability"

The already peer-reviewed data are considered to be still valid. Therefore, no new experimental data are provided. According to the previous EU evaluation pyraclostrobin has to be considered as "*not readily biodegradable*".

CA 7.2.2.2 Aerobic mineralisation in surface water

Report:	CA 7.2.2.2/1 Ebert D.,Possienke M., 2013a ^{14}C-BAS 500 F (Pyraclostrobin): Aerobic mineralisation in surface water 2013/1002741
Guidelines:	OECD 309 (April 2004)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The degradation of pyraclostrobin under aerobic aquatic conditions was investigated over a period of up to 63 days at 20°C in the dark. The study was performed according to OECD guideline 309 (Aerobic mineralization in surface water – Simulation biodegradation test). Two test variants, pelagic test and suspended solid test, were investigated in parallel. Both test variants were performed with two different pyraclostrobin concentrations (10 µg L^{-1} and 50 µg L^{-1}). Two differently ^{14}C-labeled test items were applied (chlorophenyl-label and tolyl-label). The chlorophenyl-labelled test item contained the metabolite BF 500-3 as impurity.

The test vessels were attached to a flow-through system for continuous aeration and incubated at a temperature of approximately 20 ± 2°C in the dark. Samples for the experiment were taken at 0, 3, 7, 14, 30, 44 and 63 days after treatment. Water and sediment of the suspended solid test were worked up separately. Water samples and sediment extracts were analyzed by liquid scintillation counting (LSC) and radio-HPLC. The amount of non-extractable residues was determined by combustion and LSC analysis. Volatiles were trapped in appropriate trapping solutions and also analyzed by LSC.

The obtained results showed that pyraclostrobin was degraded very slowly in a pure water environment as provided in the pelagic test. More than 78 – 97% TAR were still detectable as unchanged parent in the water phase 63 days after treatment under dark conditions. The results were overall very comparable to the sterile test vessels. The degradation of pyraclostrobin under the pelagic test conditions was thus characterized by slow hydrolysis and formation of low amounts of cleavage products, of which BF 500-5 occurred at 5.6 - 10.9% TAR. All other peaks never exceeded 2.1% TAR.

In the suspended solid test, pyraclostrobin dissipated at a fast rate from the water phase (< 45% TAR after 3 days) and adsorbed to the solid particles floating in the water. Despite the overall low amount of suspended solids, pyraclostrobin behaved as known from soil and sediment studies and converted quickly from extractable residues into non-extractable residues due to binding to the organic matrix.

In the water phase of the suspended solid test, the hydrolysis product BF 500-5 was detected in maximum amounts of 7.7% TAR with the chlorophenyl-label. One peak in the tolyl-label treated test vessels (low concentration) reached 5.8% TAR after 44 days (but only max. 2% TAR in the high concentration test). It declined again to 2.1% TAR after 63 days. Due to the low substance amounts, identification was not possible. All other peaks never exceeded 3.8% TAR.

In the sediment extracts of the suspended solid test, besides BF 500-3 which was present in the treatment solution of the chlorophenyl-labelled test item, also the known soil and sediment metabolites BF 500-6 (≤ 2.3% TAR) and BF 500-7 (≤ 2.6% TAR) were formed. Other components did not exceed 0.5% TAR at any sampling time.

Overall, the degradation of pyraclostrobin was characterized by a low mineralization rate in both test variants irrespective of test concentration or label position. The amount of $^{14}CO_2$ never exceeded 5% TAR within 63 days.

Kinetic analysis and calculations of DT_{50} and DT_{90} values for the pelagic and the suspended solid test were performed following the recommendations of the FOCUS Kinetics workgroup [FOCUS, 2006] to derive aquatic persistence and modeling endpoints. The analysis was done by a non-linear regression method (Iteratively Reweighted Least Squares) using the software package KinGUI version 2.

The $DegT_{50}$ values in the pelagic test ranged from 410 to 458 days for pyraclostrobin and from 11 to 29 days for BF 500-3. In the suspended solid test, the $DegT_{50}$ for pyraclostrobin for the whole system ranged from 26 to 28 days, while the $DisT_{50}$ for the water compartment was calculated to range from 7 to 10 days and for the suspended sediment from 44 to 47 days. The $DisT_{50}$ for BF 500-5 was 103 days when calculated with the high test concentration. For the low test concentration no adequate fit was achieved.

In general, pyraclostrobin hydrolyses only slowly under the pelagic test conditions, but adsorbs quickly to suspended solids, when available, and is then further degraded by formation of bound residues.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material	Pyraclostrobin (BAS 500 F)
Chemical name:	methyl N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3yl]oxymethyl} phenyl)-(N-methoxy)carbamate
Molecular formula:	$C_{19}H_{18}ClN_3O_4$
Molar mass:	387.82 g mol^{-1} (unlabeled)

Label 1 (chlorophenyl label)

Label:	chlorophenyl-U-^{14}C
Batch No.:	579-6103
Specific activity of a.s.:	6.57 MBq mg^{-1}
Radiochemical purity:	98.3%
Chemical purity:	97.6%

Label 2 (tolyl label)

Label:	tolyl-U-^{14}C
Batch No.:	566-4201
Specific activity of a.s.:	7.32 MBq mg^{-1}
Radiochemical purity:	99.4%
Chemical purity:	97.8%

2. Test system

Water and small amounts of sediment were collected from Berghäuser Altrhein, a pond-like side arm of the river Rhine south of Speyer (Rhineland-Palatinate, Germany).

The sediment was passed through a 2 mm sieve, and the water was filtered through an 0.2 mm sieve. Sieving and transfer of water and sediment into the test vessels was done at the same day after collection of the water/sediment systems. The physico-chemical properties of the system are summarized in Table 7.2.2.2-1.

Table 7.2.2.2-1: Characterization of the water/sediment system

B. STUDY DESIGN

1. Experimental conditions

A total of 72 flasks was prepared: 36 flasks for the pelagic test, 28 flasks for the suspended solid test, 6 flasks as system control with benzoic acid and 2 flasks as untreated control samples for the pelagic test.

The flasks were filled with about 450 mL water. For the suspended solid test, about 0.9 g wet sediment was added to the respective test vessels. Taking into account that the wet sediment still contained a high percentage of water (water content of 64.37% determined in a random sample), the overall suspended sediment concentration was finally about 0.9 - 1 g L^{-1}. Four test vessels (for the pelagic test) were sterilized in an autoclave.

Appropriate amounts (20 µL) of the respective application solutions were pipetted to the water surface to achieve a nominal application rate of 50 µg L^{-1} or 10 µg $L^{-1,}$ respectively.

The systems were incubated at 20 ± 2°C in a metabolism apparatus (incubator) with a gas flow system. The test vessels were placed on multiplate magnetic stirrers. For the pelagic test, the upper 1-2 cm water layer was slightly agitated to keep the oxygen saturation on sufficient high level, while for the suspended solid test the water was completely agitated to keep the sediment particles in suspension. However, the arrangement of the high number of test vessels in the incubator prevented optimal cooling, and the running magnetic stirrers also emitted low heat, so that a slightly increased temperature of 24°C was measured in the water of the vessels on the third day after treatment. Therefore, the incubator temperature was stepwise adjusted within the next days to decrease the temperature about 2-3°C to the desired range.

Each test vessel was connected to a volatile trapping system of two gas washing bottles containing different trapping solutions (ethylene glycol, NaOH) for the ^{14}C-volatiles to be expected. Sterilized test vessels were not connected to the air flow system to prevent contamination by airborne germs.

2. Sampling

Samples were taken at 0, 3, 7, 14, 30, 44 and 63 days after treatment (DAT). The sterile vessels (only pelagic test) were sampled after 28 and 63 days.

For sampling, the respective flasks were removed from the incubator. The following physico-chemical parameters were determined: oxygen content, pH and redox potential of the water and temperature.

3. Description of analytical procedures

Water
The radioactivity in the water samples was measured by Liquid Scintillation Counting (LSC). Aliquots of the water samples were analyzed by High Performance Liquid Chromatography (HPLC).

Sediment (only suspended solid test)
The sediment was extracted 3 times with acetonitrile (ACN; 9-10 mL) by shaking for 15 minutes. Due to the high water content of the sediment after separation from the water phase, the first extraction is referred to as ACN/H_2O extraction. The extracts were collected separately and analyzed for radioactivity by LSC. Subsequently, the extracts were combined and measured again for radioactivity by LSC to ensure that no material losses due to adsorption at glass walls occurred. Both extracts were finally subjected to HPLC analysis without further clean-up or concentration.

The extracted sediment residue was dried under nitrogen flow. The amount of sediment was just sufficient for one combustion sample to determine the non-extractable residues. Nevertheless, it enabled to establish a material balance for each test vessel.

Volatiles
Radioactivity in the trapping solutions was determined by LSC. In order to confirm mineralization to CO_2, selected NaOH traps from the suspended solid test (59/63 day samples) were further investigated by addition of 1 mL concentrated HCl and expelling CO_2 by sonication and purging with nitrogen. Then the samples were measured again by LSC. No significant amounts of radioactivity could be detected anymore (<0.2% TAR), confirming that the radioactivity found in the NaOH traps consisted originally of $^{14}CO_2$.

Benzoic acid (system control)
The volatile traps of the ^{14}C-benzoic acid treated test vessels were sampled at 0, 3, 8, 15, 29, 43 and 64 days after treatment, whereas water samples were taken after 15, 29 and 64 days. The parameters temperature, O_2 content, pH and redox potential of the water were measured on the days of water sampling. Since one test vessel showed no mineralization at all, it was defined as an outlier and excluded from further evaluation.

4. Calculation of the degradation/dissipation rates

The kinetic analysis was carried out following the recommendations of the FOCUS work group on degradation kinetics [*FOCUS (2006): "Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration" Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference Sanco/10058/2005 version 2.0*] in order to derive modeling endpoints. The analysis was done by non-linear regression methods (Iteratively Reweighted Least Squares) using the KinGUI software version 2.

The evaluation of the results of the pelagic test system for high and low test concentrations showed that degradation in the water phase was best described by SFO kinetics. Degradation of the metabolite BF 500-3 could also be sufficiently described with SFO kinetics. For the metabolite BF 500-5, no adequate fit could be achieved.

The evaluation of the results of the suspended sediment test system at P-I level showed that degradation in the total system and dissipation from the sediment phase could be described by SFO kinetics, while dissipation from the water phase could be adequately described by bi-phasic models (FOMC and DFOP). Kinetic evaluation at P-II level was not reliable and was not pursued further.

The evaluation of the results of the metabolites at M-I level provided adequate dissipation parameters for BF 500-5 in the high test concentration with the chlorophenyl label. For the low test concentration, no adequate fit could be achieved.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The distribution of radioactivity in the different compartments of the water/sediment system treated with ^{14}C-pyraclostrobin is presented in Table 7.2.2.2-2 and Table 7.2.2.2-3.

The actual applied amounts of test item per test vessel were 23.54 µg (high concentration, chlorophenyl label), 22.98 µg (high concentration, tolyl label), 4.81 µg (low concentration, chlorophenyl label) and 4.64 µg (low concentration, tolyl label). In general, no significant differences were found in pyraclostrobin behavior between the high and low test concentration. Therefore, results mentioned in the text are described always for both concentrations.

Pelagic test

The material balance for the pelagic test ranged from 92.0 - 98.2% of the total applied radioactivity (TAR). In the sterile vessels, the material balance ranged from 96.3 - 99.7% TAR.

The amount of radioactivity in the water was found to be very stable. At the end of the study (63 DAT) it ranged from 91.5 to 97.0% TAR. For all pelagic test samples and sampling time points, the radioactivity in the volatile traps never exceeded 0.7% TAR indicating a low rate of mineralization in this test variant.

Suspended solid test

For the suspended solid test the material balance ranged from 84.4 - 99.4% TAR. The values for the sampling time point directly after application (0 DAT) were taken from the pelagic test samples since similar conditions at the experiment start were assumed for both test variants.

The radioactivity dissolved freely in the water phase declined relatively fast for the suspended solid test. After 3 days, only 34.4 - 44.5% of the applied radioactivity was still detectable in the water phase and it declined further to 8.7 - 12.2% TAR at the end of incubation. Since pyraclostrobin quickly adsorbed to the sediment, the radioactivity in the sediment increased to maximum amounts of 73.0 – 80.2% TAR at the end of incubation.

Whereas at early samplings, most of the radioactivity was still extractable from the sediment (49.4 to 55.0% TAR after 3 days), the extractability declined significantly to 19.1 - 30.6% TAR after 63 days. Further degradation processes took place in or on the sediment particles, since the non-extractable residues increased constantly, reaching 47.3 - 57.5% TAR at the end of incubation.

Comparable to the pelagic test, the mineralization rate was rather low. In the NaOH traps, the $^{14}CO_2$ formation accumulated to 2.8 - 4.6% TAR over the test period. Other volatiles never exceeded 0.3% TAR at any sampling time.

Table 7.2.2.2-2: Material balance and distribution of radioactivity after application of ^{14}C-pyraclostrobin to pelagic test and incubation under dark conditions [%TAR]

B. TRANSFORMATION OF PARENT COMPOUND

Characterization and identification of residues in water and sediment extracts

The summary of radio-HPLC analysis of the water samples and sediment extracts is presented in Table 7.2.2.2-4 to Table 7.2.2.2-6.

Water
In the **pelagic test**, pyraclostrobin degraded only slowly. After 63 days, between 78.3 and 97.0% TAR could still be recovered as unchanged parent for the different concentrations and radiolabels. The sterile controls showed in principle the same results as the viable test vessels. The occurrence of hydrolysis product BF 500-5 (max. 5.6 - 10.9% TAR) and the low formation of other metabolites (BF 500-3 was present already in the application solution of the chlorophenyl-labelled test item) indicated that only negligible microbial degradation took place.

In the **suspended solid test**, the behavior of pyraclostrobin was very different. It was quickly eliminated from the water phase by binding to the suspended solids. Already after 3 days, only 30 - 45% TAR of parent was dissolved in the water and the amount declined further to 1.5 - 6.1% TAR at the end of incubation. BF 500-3 (applied as impurity in the chlorophenyl-label treated vessels) also quickly disappeared from the water, which can be explained by fast adsorption to the suspended sediment due to the low water solubility and high K_{oc} values of this compound.

The formation of the hydrolysis product BF 500-5 was observed in the chlorophenyl-label treated test vessels, whereas several minor unknown degradation products were formed in the tolyl-label treated vessels. One of them reached 5.8% TAR after 44 days in the low concentration test and declined again to 2.1% TAR after 63 days. In the high concentration test it reached only 2% TAR. Identification of this peak was not possible due to the low total substance amount. All other peaks never exceeded 3.8% TAR.

Sediment (only suspended solid test)
Due to the fast adsorption, the highest amount of unchanged pyraclostrobin was detected in sediment extracts already after three days (47.2 - 55.0% TAR). During further incubation, it started to degrade to 17.1 - 27.5% TAR after 63 days. Again, the results were independent of test concentration or label-position. As in the water phase, metabolite BF 500-3 could be detected in the sediment extracts of the chlorophenyl-label treated test vessels. The HPLC retention time of two further peaks matched with the reference items BF 500-6 and BF 500-7. However, they never exceeded 2.3% TAR. All other peaks were found only sporadically in trace amounts ($\leq$ 0.5% TAR).

Control samples
The control vessels treated with ^{14}C-benzoic acid (pelagic test) showed that the system Berghäuser Altrhein was microbially active. After 64 days, 77.9 - 83.0% TAR were evolved as $^{14}CO_2$.

Regarding the sterilized incubations, there was in principle no difference in pyraclostrobin concentration compared to the viable vessels. This shows that the major route of degradation of pyraclostrobin under the applied test conditions consisted of slow hydrolysis. Microbial degradation played only a minor role.

Degradation rates

A summary of the DT_{50} and DT_{90} values of pyraclostrobin and its metabolite BF 500-3 for the pelagic test are given in Table 7.2.2.2-7. A summary of the DT_{50} and the DT_{90} values of pyraclostrobin for total system as well as for water and sediment separately determined for the suspended solid test is presented in Table 7.2.2.2-8. DT_{50} and DT_{90} values of the metabolite BF 500-5 for the suspended solid test are shown in Table 7.2.2.2-9.

Table 7.2.2.2-7: Summary of the kinetic evaluation of pyraclostrobin and its metabolite BF 500-3 for the pelagic test

Low test concentration	-	No adequate fit could be achieved		

III. CONCLUSION

The results showed that pyraclostrobin was degraded very slowly in a pure water environment as provided in the pelagic test. The major route of degradation under those conditions represented hydrolysis to cleavage products (BF 500-5 detected at max. 5.6 - 10.9% TAR with the chlorophenyl-label, and trace amounts of several unknown peaks). However, it adsorbed and degraded very fast as soon as dissolved particles were available as shown in the suspended solid test. Even with low amounts of suspended sediment particles, it was quickly converted from extractable residues into non-extractable residues and thus tightly bound to the organic matrix.

The formation of volatiles in both test variants was generally low (<5% TAR at any time point), irrespective of test concentration or label position.

The $DegT_{50}$ values in the pelagic test were calculated to range from 410 to 458 days for pyraclostrobin and from 11 to 29 days for BF 500-3.

In the suspended solid test, the $DegT_{50}$ for pyraclostrobin ranged for the whole system between 26 and 28 days, while the $DisT_{50}$ for the water compartment was calculated to range from 7 to 10 days and for the suspended sediment from 44 to 47 days. The $DisT_{50}$ for BF 500-5 was 103 days when calculated with the high test concentration. For the low test concentration no adequate fit was achieved.

CA 7.2.2.3 Water/sediment studies

The already peer-reviewed data are considered to be still valid. Therefore, no new experimental data are provided, however, the kinetic evaluation of the old dark water/sediment study was updated according to the newest guidelines and guidance documents.

Report: CA 7.2.2.3/1
Wiedemann G., 2013a
Kinetic evaluation of BAS 500 F - Pyraclostrobin in water/sediment systems under aerobic conditions
2012/1165029

Guidelines: FOCUS (2006): Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration Sanco/10058/2005 version 2.0 434 pp.

GLP: no

Executive Summary

The aim of the study was to evaluate the dissipation and degradation kinetics of pyraclostrobin in two aerobic water/sediment systems with two different labels [*BASF DocID 1999/11241*] and to derive persistence and modeling endpoints according to the recommendations of FOCUS kinetics.

In the laboratory study the degradation of pyraclostrobin was investigated over a period of 100 days in two water/sediment systems called System A and B (a pond and a pond-like side arm of a river located in Southern Germany). Two radio-labels of the active substance were used in the study and were considered independently as replicates in the kinetic evaluation. The experimental data were evaluated using single first order (SFO), first-order multi-compartment (FOMC), double first-order in parallel (DFOP) and hockey stick (HS) kinetic models at the evaluation levels P-I and P-II.

The evaluation at the P-I level resulted in reliable persistence and modeling half-lives for System A for all compartments. The persistence and modeling $DegT_{50}$ for the whole system ranged from 23.3 to 26.8 days. Regarding System B the $DisT_{50}$ in the water compartment could reliably be estimated, however, the dissipation in sediment could not be characterized. Therefore, no endpoints could be derived for the whole system $DegT_{50}$ and the $DisT_{50}$ in sediment for System B. The P-II level did not yield any reliable fits.

I. MATERIAL AND METHODS

The kinetic evaluation of pyraclostrobin was conducted for an aerobic water/sediment study in the dark with two natural aerobic aquatic systems [*old EU Dossier, A II M 7.2.1.3.2/1, Staudenmaier H. - BASF DocID 1999/11241*]. One of them represented a pond (area of "Kastenbergheide" west of Schifferstadt, Germany) and the other a pond-like side arm of a river ("Berghäuser Althrein" south of Speyer, Germany). Kinetic evaluation was performed in order to derive persistence and modeling endpoints according to the recommendation of the FOCUS workgroup on degradation kinetics [*FOCUS (2006)*].

Two radio-labels of the active substance, referred to as chlorophenyl- and tolyl-label, respectively, were used in each system of the study. The test vessels were treated with 83 µg a.s. L^{-1} to represent the recommended field application rate of 250 g a.s. ha^{-1}. The test system was incubated for up to 100 days at 20°C in the dark.

Kinetic modeling

The appropriate kinetic model was identified considering the procedures and kinetic models proposed by the FOCUS workgroup on degradation kinetics [*FOCUS (2006)*]. The best-fit model was selected based on visual and statistical assessment, and corresponding DT_{50} and DT_{90} values are reported as *persistence endpoints*. Appropriate DT_{50} values for use in environmental fate models were derived depending on the kinetic model and are reported as *modeling endpoints*.

Kinetic models included in the assessment

The kinetic models employed for this evaluation were described by the FOCUS workgroup on degradation kinetics [*FOCUS (2006)*]. The analysis at P-I level (one-compartment approach) was done for degradation in the whole system as well as the respective dissipations from the water and sediment phases of the test system. At the P-II level (two-compartment approach) the kinetic analysis considered the degradation in water and sediment taking into account the partitioning between the two phases.

As the purpose of the study was to derive modeling and persistence endpoints, all four kinetic models proposed by FOCUS were used during the evaluation (SFO, FOMC, DFOP and HS). Details on the models are given in the FOCUS Kinetics guidance [*FOCUS (2006)*].

The appropriateness of a distinct kinetic model to describe degradation can be tested with the following checks recommended by *FOCUS (2006)*:

- Visual assessment of goodness-of-fit
- Estimation of the error percentage at which the χ^2 test is passed [*Equation 6-2 in FOCUS (2006)*]
- t-test to evaluate whether estimated degradation parameters differ from zero.

A kinetic model is considered appropriate if the residuals are randomly distributed, the χ^2 - error value is < 15% and the estimated degradation parameters differ from zero as outlined by *FOCUS (2006)*.

Data handling

Degradation kinetics were evaluated for the parent substance pyraclostrobin. Degradation in the whole system and dissipation from the water compartment (P-I level) were evaluated starting on the day of treatment (i.e. 0 days after treatment, DAT 0). The dissipation from the sediment phase (P-I level) was evaluated starting from the point of maximum occurrence. For the P-II level, the initial concentration of the sediment compartment was assumed to be zero. The FOCUS kinetics guidance recommends using the material balance at DAT 0 as the initial value in water for the parent substance. Thus, the total measured occurrence of the radioactive label in water and sediment (parent + metabolites + unknowns) was used as the initial value for the parent.

All measurements were used for the analysis; outlier tests were not performed since the visual evaluation did not reveal any deviating or inappropriate measurements. Concentrations in all analyzed samples were above the limit of quantification.

Software for kinetic evaluation

The software package KinGUII (version 2.2011) was used for parameter fitting [*Schäfer, D., Mikolasch, M., Rainbird, P., Harvey, B. (2007) KinGUII: A new kinetic software tool for evaluations according to FOCUS Degradation Kinetics. In: Del Re, A.A.M. et al. (Eds.): Proceedings of the XIII Symposium on Pesticide Chemistry, Piacenza, 2007, p. 916-923. - BASF DocID 2007/1062781*].

Experimental data

The kinetic evaluation was based on the findings from a dark water/sediment study [*Staudenmaier H. - BASF DocID 1999/11241*]. The experimental data of the parent substance used as model input values for the kinetic evaluations are given in Table 7.2.2.3-1 and Table 7.2.2.3-2.

Sediment values before the maximum occurrence were not used, when fitting only degradation in sediment at the P I-level.

II. RESULTS AND DISCUSSION

For modeling endpoints, the initial fit was performed using SFO kinetics. If the fit was not satisfactory, FOMC, DFOP and HS kinetics were tested. For persistence endpoints, SFO and FOMC kinetics were tested in a first step; if SFO was not acceptable or worse than FOMC, DFOP and HS kinetics were tried in addition. Graphical presentations of the tested kinetic models and the results of the χ^2 - test and all other statistical endpoints used in the decision-making process are given in the original study report.

Level P-I

The evaluation of persistence and modeling endpoints of both test systems for both labels at P-I level showed that dissipation in the water phase could be well described by bi-phasic kinetics (FOMC: System A, chlorophenyl label; DFOP: System A, tolyl label, and System B, both labels), while dissipation from sediment and degradation in the whole system were best described by SFO kinetics (System A, both labels). For system B, none of the models was acceptable for dissipation from sediment and degradation in the whole system.

An overview of the estimated persistence and modeling endpoints for pyraclostrobin from both water/sediment systems is given in Table 7.2.2.3-3 and Table 7.2.2.3-4.

Table 7.2.2.3-3: Persistence endpoints at P-I level

System, Label	Water		Sediment		Whole system	
	DT_{50}/DT_{90} [d]	Kinetic model	DT_{50}/DT_{90} [d]	Kinetic model	DT_{50}/DT_{90} [d]	Kinetic model
System A, chlorophenyl-label	2.13 / 28.8	FOMC	25.7 / 85.5	SFO	23.3 / 77.4	SFO
System A, tolyl-label	2.30 / 17.5	DFOP	29.8 / 98.9	SFO	26.8 / 89.1	SFO
System B, chlorophenyl-label	0.636 / 6.19	DFOP	-*	-	-*	-
System B, tolyl-label	0.443 / 6.28	DFOP	-*	-	-*	-

* The data could not reliably be described by the models and should therefore not be considered for the assessment. Note, that in the study report a default of 1000 days was reported, which, however, is not in line with FOCUS and should therefore be corrected.

Table 7.2.2.3-4: Modeling endpoints at P-I level

System, Label	Water		Sediment		Whole system	
	DT_{50} [d]	Kinetic model	DT_{50} [d]	Kinetic model	$DegT_{50}$ [d]	Kinetic model
System A, chlorophenyl-label	8.67*	FOMC	25.7	SFO	23.3	SFO
System A, tolyl-label	5.27*	DFOP	29.8	SFO	26.8	SFO
System B, chlorophenyl-label	1.86*	DFOP	-**	-	-**	-
System B, tolyl-label	1.89*	DFOP	-**	-	-**	-

* Back-calculated from DT_{90} ($DT_{50} = DT_{90} / 3.32$) as required by FOCUS kinetics.

** The data could not reliably be described by the models and should therefore not be considered for the assessment. Note, that in the study report a default of 1000 days was reported, which, however, is not in line with FOCUS and should therefore be corrected.

Level P-II

Degradation of pyraclostrobin in water and sediment as well as partitioning between both phases was analyzed according to the P-II level kinetic concept (two-compartment approach) of the FOCUS guidance document. A compartment model was used and SFO kinetics were considered for the transfer and degradation rates.

P-II level analysis was performed for both systems and both labels, however, the results showed a poor fit to the measured data. For system A the fits were visually good for water and sediment, but statistically poor. While for system B (chlorophenyl label) the fits were visually good and statistically poor for water, it was the contrary for sediment. The fit in water and sediment did not reflect sufficiently the substance behavior in the system, probably because the degradation in sediment seemed to stop soon after the beginning of the study. Repeating the optimization with different starting values did not change the estimated values. The visual fit for water and sediment was moderate for system B (tolyl label), but statistically poor.

The F_{sed} test was performed for both systems and labels, but failed in all cases.

No reliable fits for the level P-II could be obtained.

III. CONCLUSION

The dissipation and degradation of pyraclostrobin in water/sediment systems under dark conditions was evaluated according to the recommendations of the FOCUS workgroup on degradation kinetics [*FOCUS (2006)*] to determine persistence and modeling endpoints.

The experimental data on pyraclostrobin in both test systems (Systems A and B) and for both labels (chlorophenyl- and tolyl-labels) were evaluated at Level P-I and Level P-II. For system B no reliable endpoints could be derived for the sediment compartment and for the whole system, for both labels. As a consequence a "default" value was assumed, which, however, is not correct following the FOCUS kinetics guidance. According to FOCUS kinetics a case-by-case decision should be made if reliable endpoints cannot be derived with the recommended standard procedures. Moreover, for System B a $DegT_{90}$ in the whole system of approximately 30 days can be estimated visually, which is considerably shorter than the endpoint calculated for System A. Hence, the results of the kinetic evaluation of System A represent the worst-case of the two w/s systems investigated. Consequently, only the results of the kinetic evaluation of System A are to be considered as worst-case for further usage.

Reliable $DegT_{50}$ values for the whole system were derived for System A for both labels which range from 23.3 to 26.8 days. The analysis at the P-II level did not result in reliable fits.

CA 7.2.2.4 Irradiated water/sediment study

Since pyraclostrobin proved to be very susceptible for photolytic breakdown, information on the degradation in an irradiated water/sediment system was already provided in the old EU dossier submitted for the previous Annex I listing process. A new kinetic evaluation of this study was performed and summarized in *CA 7.2.2.4/1*.

Since no complete material balance was measured at that time during the study, a new water/sediment study under irradiated conditions was performed with an updated study design (including collection of volatiles). This study is summarized in *CA 7.2.2.4/2*.

An overview of metabolite occurrences in the different water/sediment studies (dark and irradiated) and of degradation rates are given in Table 7.2.2.4-30 and Table 7.2.2.4-31, respectively, at the end of this chapter.

Kinetic evaluation of BAS 500 F in water/sediment systems under aerobic conditions
2012/1021122
Guidelines: FOCUS Kinetics Report SANCO/10058/2005 ver. 2.0
GLP: no

Executive Summary

The aim of the study was to evaluate the dissipation and degradation kinetics of pyraclostrobin in aerobic water/sediment systems under irradiated conditions [*BASF DocID 1999/11791*] and to derive modeling endpoints to be used in FOCUS surface water modeling. The fate and behavior of pyraclostrobin was investigated over a period of up to 62 days in one natural water/sediment system (Kellmetschweiher pond, Germany). Two radio-labels of the active substance were used in the study and were treated as replicates for the kinetic evaluation. The experimental data were evaluated using single first order (SFO) kinetic models at levels P-I, P-II and M-I. In addition to the parent compound, the metabolites BF 500-3, BF 500-11, BF 500-13 and BF 500-14 were considered.

The best-fit $DegT_{50}$ was 7.2 days in the total system (Level P-I), and the best-fit $DegT_{50}$ were 7.5 and 6.5 days in the water and sediment phase, respectively (Level P-II).

For the metabolites BF 500-11 and BF 500-14, the best-fit total system $DisT_{50}$ values were 22.6 and 17.3 days, respectively. For the metabolite BF 500-3, a system $DisT_{50}$ of 92.5 days could be determined. For the metabolite BF 500-13, no reliable dissipation and degradation rates could be determined. Consequently, a conservative default value of 1000 days should be used for risk assessment.

I. MATERIAL AND METHODS

The kinetic evaluation was based on the results of an irradiated aerobic water/sediment study [*old EU Dossier, A II M 7.2.1.3.2/2, Ebert, D. - BASF DocID 1999/11791*] where the degradation of pyraclostrobin was investigated over a period of 62 days in one water/sediment system (Kellmetschweiher, a pond close to Schifferstadt, Germany). The kinetic analysis was carried out following the recommendations of the FOCUS work group on degradation kinetics [*FOCUS (2006)*] in order to derive modeling aquatic degradation endpoints.

Two radio-labels of the active substance, referred to as chlorophenyl- and tolyl-label, respectively, were used in the study. The test vessels were treated with 250 µg L^{-1} representing an application rate of 500 g a.s. ha^{-1}. The test system was incubated for up to 62 days under a temperature and light regime simulating the climate of central Europe for the period mid-May to mid-July. The two radio-labels were tested separately and were therefore considered in the kinetic evaluation as replicates for each sampling time.

Kinetic modeling

Kinetic evaluations were performed for pyraclostrobin and four of its metabolites considering the different levels proposed by the FOCUS Kinetics Guidance [*FOCUS (2006)*]. For the parent substance, the analysis at P-I level (one compartment approach) was done for degradation in the whole system as well as the respective dissipations from the water and sediment phases of the test system. At the P-II level (two-compartment approach), the kinetic analysis considered the degradation in water and sediment taking into account the partitioning between the two phases.

For the metabolites, dissipation calculations were performed at level M-I, although the considered radio-labels and system compartments differed for each metabolite.

As the purpose of the study was to derive modeling endpoints, only the single first order (SFO) kinetic model was considered as long as acceptable results were obtained in line with the FOCUS Kinetics Guidance [*FOCUS (2006)*].

Evaluation at level P-I was carried out using the KinGUII software version 2.2, while the models at level P-II were implemented in ModelMaker [*Anonymous (1997): Model Maker User Manual, Version 3. Cherwell Scientific Publishing Limited*] by means of a compartment model.

Level M-I kinetic analysis was performed for dissipation and degradation of the metabolites BF 500-3, BF 500-11, BF 500-13 and BF 500-14 was carried out using the KinGUII software version 2.2. The metabolite kinetics were described with the SFO kinetic model.

The dissipation kinetics were evaluated for the metabolites BF 500-11 and BF 500-14 in the water compartment, for BF 500-3 in the sediment compartment, and for all three metabolites in the total system.

Degradation kinetics for the water/sediment system were evaluated for the metabolites BF 500-3, BF 500-11, and BF 500-14. The metabolite BF 500-13 could not be evaluated in either compartment.

The appropriateness of a distinct kinetic model to describe degradation can be tested with the following checks recommended by *FOCUS (2006)*:

- Visual assessment of goodness-of-fit
- Estimation of the error percentage at which the χ^2 test is passed [*Equation 6-2 in FOCUS (2006)*]
- t-test to evaluate whether estimated degradation parameters differ from zero.

A kinetic model is considered appropriate if the residuals are randomly distributed, the χ^2 - error value is < 15% and the estimated degradation parameters differ from zero as outlined by *FOCUS (2006)*.

Data handling

Where possible, replicate measurements (chlorophenyl- and tolyl-label) for each time point were used in the parameter estimation for the parent compound. While the sampling times can be equal for synchronous replicates in KinGUII, for technical reasons they were entered in ModelMaker with a small time offset (0.0001 days). The impact of this time offset on the calculated kinetics is however negligible.

Degradation in the whole system and dissipation from the water compartment of the parent compound (P-I level) were evaluated starting at DAT 0. The dissipation of the parent from the sediment phase (P-I level) was evaluated starting from the point of maximum occurrence.

For the P-II level, the initial concentration of the sediment compartment was assumed to be zero as recommended by the FOCUS Kinetics Guidance [*FOCUS (2006)*]. However in the degradation study the first measurement for the sediment was taken after 1 day, so a complete material balance for DAT 0 was not available. Instead the total measured occurrence of the radioactive labels in water (parent + metabolites + unknowns) was used as the initial value for the parent. It can be assumed that this will be lower than the actual mass balance at DAT 0, which means that using these values in the parameter estimation will result in conservative values for the degradation rates.

At M-I level, the dissipation calculations were conducted from the point of maximum occurrence of the considered metabolite, with the time of maximum occurrence set as the initial time (t=0) in the evaluation and the subsequent observation times corrected accordingly. For the degradation, the recovered amount of the parent substance at DAT 0 was set equal to the total measured occurrence of the radioactive labels in water (parent + metabolites + unknowns) and the initial concentration of the metabolites was fixed to zero.

Software for kinetic evaluation

The analysis was done by non-linear regression methods (Marquardt algorithm, ordinary least squares optimization) using the KinGUII (version 2.2011 [*Schäfer, D. et al. - BASF DocID 2007/1062781*]) and ModelMaker (version 3.0.4 [*Anonymous (1997): Model Maker User Manual, Version 3. Cherwell Scientific Publishing Limited*]) software packages.

Experimental data

The kinetic evaluation was based on the findings of *Ebert D.* [*BASF DocID 1999/11791*]. The experimental data of the parent substance used as model input values for the kinetic evaluations are given in Table 7.2.2.4-1.

II. RESULTS AND DISCUSSION

As the purpose of the study was to derive modeling endpoints, only the single first order (SFO) kinetic model was considered. Graphical presentations of the tested kinetic models and the results of the χ^2 - test and all other statistical endpoints used in the decision-making process are given in the original study report.

Level P-I

The dissipation in the water and sediment compartments and the total system degradation could be well described by the SFO kinetic model (Table 7.2.2.4-2) without apparent significant systematic deviations in the residual errors. The fitted parameter values with their associated statistical attributes are given in Table 7.2.2.4-3. An overview of the estimated modeling endpoints for pyraclostrobin at Level P-I is given in Table 7.2.2.4-4.

Table 7.2.2.4-2: Evaluation of SFO kinetic models for pyraclostrobin at P-I level

	Number of measurements used for fitting	χ^2 error	Visual fit
BAS 500 F Whole system	16	4.568	Excellent

BAS 500 F Water	4.47	-
BAS 500 F Sediment	5.93	-

Level P-II

Degradation of pyraclostrobin in water and sediment as well as partitioning between both phases was analyzed according to the P-II level kinetic concept (two-compartment approach) of the FOCUS guidance document [*FOCUS (2006)*]. A compartment model was used and SFO kinetics were considered for the transfer and degradation rates.

Good visual fits were obtained with SFO kinetics for both the water and sediment compartments. The standard errors were low for all of the estimated parameters and the t-test was passed in all cases (Table 7.2.2.4-5).

Table 7.2.2.4-5: Evaluation of SFO kinetic model for pyraclostrobin at P-II level with fitted parameter values

	χ^2 error	Visual fit	Parameter	Estimated value	Std error	type I error rate
BAS 500 F – Water	3.0	Good	M(0)	87.71	1.13	<0.001
			k_{water}	9.24E-02	1.64E-02	<0.001
			$r_{W\rightarrow S}$	0.143	1.45E-02	<0.001
BAS 500 F – Sediment	12.0	Good	M(0)	Fixed to 0		
			k_{sed}	1.07E-01	4.22E-02	0.011
			$r_{S\rightarrow W}$	0.227	4.68E-02	<0.001

The F_{sed} test was additionally performed and passed, showing that the estimated parameter values for the transfer rates are plausible (Table 7.2.2.4-6). As the K_{oc} value for pyraclostrobin with the Kellmetschweiher sediment was not determined in the study, the average value from two soils with comparable OC content and particle size distributions determined in an adsorption/desorption study for pyraclostrobin [*old EU Dossier, A II M 7.1.2/1, Ziegler, G. – BASF DocID 1998/10650*] was used. As a further plausibility check for the P-II evaluation, the total system degradation half-life ($DegT_{50}$) was estimated from the total calculated degradation for the two compartments. This crosscheck yielded a $DegT_{50}$ of 7.25 – 7.5 days, which is consistent with the value of 7.22 days for total system degradation obtained in the P-I evaluation.

Table 7.2.2.4-6: F_{sed} test for pyraclostrobin for transfer rates fitted at P-II level

The results obtained for the SFO kinetic model at Level P-II can be considered acceptable and the estimated degradation rates can be used as modeling endpoints. The $DegT_{50}$ values are given in Table 7.2.2.4-7.

Table 7.2.2.4-7: Modeling endpoints for pyraclostrobin at P-II level

	$DegT_{50}$ [days]
Water	7.50
Sediment	6.48

Level M-I

Five metabolites were found in the water/sediment systems: BF 500-3, BF 500-11, BF 500-12, BF 500-13 and BF 500-14. Metabolite BF 500-12, however, was not evaluated because the total occurrence in water and sediment was below 5% TAR. Both dissipation and degradation of the metabolites were studied at the M-I level according to the FOCUS guidance. The metabolite BF 500-13 could not be evaluated on the basis of the experimental data.

Dissipation

The dissipation kinetics were evaluated for the metabolites BF 500-11 and BF 500-14 in the water compartment and for BF 500-3 in the sediment compartment, and for all three metabolites in the whole system. The dissipation in the water and sediment compartments for the metabolites could be adequately described by the SFO kinetic model without apparent significant systematic deviations in the residual errors and with the t-test passed in all cases (Table 7.2.2.4-8; Table 7.2.2.4-9). The resulting modeling endpoints are given in Table 7.2.2.4-10.

Table 7.2.2.4-8: Evaluation of SFO kinetic models for metabolite dissipation at M-I level

	Number of measurements used for fitting	χ^2 error	Visual fit
BF 500-3 Sediment	6	1.74	Good
BF 500-3 Whole System	6	1.56	Good
BF 500-11 Water	4	7.62	Medium
BF 500-11 Whole System	3	6.41	Good
BF 500-14 Water	10	5.16	Good
BF 500-14 Whole System	8	5.30	Good

Table 7.2.2.4-9: Fitted parameter values and statistical assessment for metabolite dissipation at M-I level

	Parameter	Estimated value	Std error	type I error rate

	k	4.01E-02	4.22E-03	<0.001

Table 7.2.2.4-10: Modeling endpoints for metabolite dissipation evaluated at M-I level

	DT_{50} [days]
BF 500-3 Sediment	78.55
BF 500-3 Whole System	92.54
BF 500-11 Water	25.22
BF 500-11 Whole System	22.62
BF 500-14 Water	15.88
BF 500-14 Whole System	17.29

Degradation

Evaluations of the degradation kinetics of BF 500-3, BF 500-11 and BF 500-14 were carried out for the water-sediment system. In contrast to the dissipation kinetics, in which only the metabolites are considered from the point of maximum occurrence, in the evaluation of the degradation kinetics both parent and metabolite are considered using all data points from DAT = 0 onwards.

The formation and degradation of BF 500-3 in this evaluation could not be adequately reproduced by the SFO model, as the model generally overestimated the concentrations in the early stages of the simulation, but underestimated maximum occurrence concentrations. There was no justification to remove any points as experimental outliers. For the metabolite BF 500-3 the degradation rate could not be adequately determined.

For the remaining two metabolites the formation and degradation in the water-sediment system could be adequately described by the SFO kinetic model, with the t-test passed in all cases. The resulting modeling endpoints are given in Table 7.2.2.4-11.

Table 7.2.2.4-11: Modeling endpoints for metabolite system degradation evaluated at M-I level

	$DegT_{50}$ [days]
BF 500-11	22.90
BF 500-14	8.21

III. CONCLUSION

Kinetic evaluations of an irradiated water/sediment study were carried out according to the FOCUS kinetics recommendations [*FOCUS (2006)*] to determine modeling endpoints for pyraclostrobin. The experimental data were evaluated using single first order (SFO) kinetic models at levels P-I, P-II and M-I. In addition to the parent compound, the metabolites BF 500-3, BF 500-11 and BF 500-14 were considered.

At the M-I level dissipation kinetics were evaluated for the metabolites BF 500-11 and BF 500-14 in the water compartment and for BF 500-3 in the sediment compartment. Degradation kinetics in the complete system were evaluated for all three metabolites. The metabolite BF 500-13 could not be evaluated on the basis of the experimental data.

The endpoints for FOCUS surface water modeling according to the selection scheme given in the FOCUS Kinetics Guidance are given in Table 7.2.2.4-12 to Table 7.2.2.4-16.

(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The degradation of ^{14}C-pyraclostrobin in aerobic water/sediment systems was investigated under irradiated conditions. Test vessels were treated separately with chlorophenyl-^{14}C- and tolyl-^{14}C-labeled pyraclostrobin with a concentration corresponding to a field application rate of about 500 g a.s. ha^{-1} when assuming overspray over a 1 m deep water body.

The test vessels were connected to an aeration system and placed in a climatic chamber (phytotron) providing a uniform day/night cycle with 13 hours light (constant light intensity of about 28 kilolux) and 11 hours dark. The temperature in the test vessels was kept in a range of about 21 - 25°C during daylight and 18 - 20°C during night.

Samples were taken at 0, 0.25, 1, 3, 7, 10, 14, 21, 29, 35, and 42 days after treatment (DAT). Water samples and sediment extracts were analyzed by radio-HPLC. The amount of non-extractable residues was determined by combustion and liquid scintillation counting (LSC). Volatiles were trapped in appropriate trapping solutions and also analyzed by LSC. Metabolite identification was done by co-chromatography with reference substances and by HPLC-MS/MS analysis.

Pyraclostrobin dissipated quickly from the water phase reaching ≤ 35% TAR already after 1 day and < 0.5% TAR at the end of incubation.

Numerous medium polar and polar metabolites were formed in water, of which BF 500-11 (max. 5.4% TAR), and BF 500-14 (max. 2.5% TAR) were included in the kinetic analysis. All identified metabolites decreased again during the course of the study or even disappeared completely during the last sampling intervals. Several unknown products were detected in the water during the incubation time; however, none of them ever exceeded 3.8% TAR and all appeared to be of transient nature.

In the sediment, pyraclostrobin quickly reached its maximum amounts after three days (54 - 63% TAR) and declined moderately fast to 15 - 18% TAR at the end of incubation by incorporation into the humic substance matrix.

Only low amounts of metabolites were extractable from the sediment. The des-methoxy- metabolite (BF 500-3) was formed in maximum amounts of 4 - 6% TAR and declined again towards the end of incubation to 1 - 3% TAR. The two dimeric structures BF 500-6 (500M01) and BF 500-7 (500M02) never exceeded 3.7 and 2.3% TAR, respectively.

The non-extractable residues reached amounts of 63 - 66% TAR at the end of incubation, with the majority of radioactivity associated with the humic acids (max. 17 - 18% TAR) and only a small portion associated with the fulvic acids (max. 5 - 7% TAR).

Mineralization was detectable but overall very low (max. 3 - 4% TAR). No other volatiles were observed.

In the dark control vessels, pyraclostrobin also disappeared quickly from the water phase, however, the degradation in the sediment (formation of bound residues) was slower compared to the irradiated incubation.

Kinetic analysis was performed following the recommendations of the FOCUS Kinetics workgroup. Pyraclostrobin degraded rather fast in the total water/sediment system with a DT_{50} of 13.5 days under irradiated conditions. It quickly dissipated from the water phase with a DT_{50} of < 0.5 days. In sediment, further degradation led to incorporation into the organic matrix (humic substances) with a DT_{50} of about 20 days. The metabolites degraded with the following half-lives: 29.1 days (BF 500-3, whole system), 9.0 days (BF 500-11, water) and 6.7 days (BF 500-14, sediment).

Overall, the results of this study showed that pyraclostrobin degraded relatively fast under irradiated as well as under dark conditions. Under sunlight-similar conditions, several photolytical breakdown products appeared in the water phase, which contributed to a faster degradation rate also in the sediment compared to dark conditions.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material Pyraclostrobin (BAS 500 F)
Chemical name: methyl N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]-oxymethyl} phenyl)-(N-methoxy)carbamate
Molecular formula: $C_{19}H_{18}ClN_3O_4$
Molecular mass: 387.8212 g mol^{-1} (non-labeled)

Label 1
Label: [chlorophenyl-U-^{14}C]-pyraclostrobin
Batch No.: 579-4006
Specific activity: 7.68 MBq mg^{-1}
Radiochemical purity: 99.6%

Label 2
Label: [tolyl-U-^{14}C]-pyraclostrobin
Batch No.: 566-4040
Specific activity: 7.31 MBq mg^{-1}
Radiochemical purity: 98.7%

2. Test system

A natural water and sediment system was sampled: “Berghäuser Altrhein”, a pond-like side arm of the river Rhine, south of Speyer surrounded by a forest.

The sediment was passed through a 2 mm sieve, and the water was filtered through a 0.2 mm sieve. Sieving of sediment and filling of sediment and water into the test vessels was done at the day of collecting the water/sediment system. The physico-chemical properties of the systems are summarized in Table 7.2.2.4-17.

Table 7.2.2.4-17: Characterization of the water/ sediment system

B. STUDY DESIGN

1. Experimental conditions

A total of 45 flasks were prepared: 15 flasks for incubation under irradiated conditions and 5 flasks for the dark control for each label. In addition, 3 flasks were prepared for system characterization at the end of the incubation and 2 flasks for continuous temperature recording.

The flasks were filled with about 130 g of wet sediment and 290 mL of water. This corresponded to a sediment layer of about 2 cm and a water layer of about 6 cm. After being filled with sediment and water, the flasks were allowed to equilibrate for 21 days under dark conditions.

Appropriate amounts (20 µL) of the respective application solutions were pipetted to the water surface to achieve a nominal amount of about 15 µg test item per test vessel. This corresponds to a field application rate of about 500 g active substance/ha assuming overspray over a 1 m deep water body. The amount of test item per test vessel is calculated for a 300 mL water volume.

The test vessels were capped air-tight and the upper 1-2 cm water layer was slightly agitated to keep the oxygen saturation on a sufficient high level. Either one or two of the treated test vessels were connected to a volatile trapping system of two gas washing flasks containing different trapping solutions for potential ^{14}C-volatiles (ethylene glycol, 0.5 M NaOH).

Equilibration and subsequent incubation was carried out in a climatic chamber (phytotron) with temperature and light control. The test vessels were connected to a system providing a constant stream of air to be able to establish a full ^{14}C-material balance.

Incubation was conducted simulating a uniform day/night cycle with 13 hours irradiation and 11 hours dark (light intensity: 28 kilolux) in a phytotron chamber with the light being very similar to natural sunlight. The air temperature in the phytotron was kept in the range between 16 and 17.5°C, the temperature in the test vessels was kept in a range of about 21 - 25°C during daylight and 18 - 20°C during night.

The equilibration was monitored by measuring redox potential of water and sediment, temperature, O_2 content and pH of randomly selected flasks at intervals of a few days. After treatment, the same parameters were measured in each sample before workup during the irradiation phase. Dark control samples were also processed.

2. Sampling

Samples for the irradiated experiment were taken at 0, 0.25, 1, 3, 7, 10, 14, 21, 29, 35, and 42 days after treatment (DAT). Since two radio-labels were tested separately, they can be considered as replicates for the degradation results of the test item. Dark control samples were worked up after 14, 29 and 42 days.

For sampling, the parameters temperature, O_2 content, pH and redox potential of the water and the redox potential of the sediment were measured. Then water and sediment were separated by careful decantation. The volatile traps were disconnected from the air stream and stored at room temperature until measurement.

3. Analytical procedures

Water
The radioactivity in the water samples was measured by LSC (3 x 1 or 2 mL aliquots). Aliquots of the water samples were analyzed by HPLC without further workup.

Sediment
The wet sediment (total amount) was extracted once with 80 mL acetonitrile, which is considered overall as an acetonitrile/water extraction due to the water left in the sediment. This extraction was followed by one extraction with 100 mL acetonitrile/water (1:1, v:v) and two extractions with 100 mL pure acetonitrile. Each extraction step was performed on a rotary shaker at 250 rpm for 15 minutes. The phases were separated by centrifugation and analyzed for radioactivity by LSC.

The four corresponding acetonitrile and acetonitrile/water extracts were combined, dried and re-dissolved in acetonitrile. After centrifugation two aliquots of the supernatants were checked for radioactivity to ensure that all radioactivity was recovered after rotary evaporation and centrifugation. The concentrated extracts were finally subjected to HPLC analysis.

The extracted sediment residue was dried at room temperature under a stream of nitrogen and homogenized in a laboratory mill. The amount of non-extractable radioactive residues (NER) in the extracted sediment was determined by combustion of 4 aliquots in an oxidizer. The total amount of radioactivity in the sediment was determined by calculating the sum of extractable and non-extractable residues.

Characterisation of bound residues

The non-extractable radioactivity in sediment was further characterized by separation into fulvic acids, humic acids and humins. For each sampling time of 10, 29, and 42 days, one tolyl-label and one chlorophenyl-label treated sediment sample was selected, respectively. For each sample, the dried sediment (25 g) was extracted three times with 0.5 M NaOH. The radioactivity in the extracts of each extraction step was determined by LSC.

The corresponding extracts of a sample were then combined and acidified with conc. HCl to pH 1-2 to precipitate the acid-insoluble humic acids. For the precipitation phase, the samples were kept in a refrigerator. After centrifugation, the radioactivity in the supernatant (fulvic acids) was determined by LSC.

The precipitate (humic acids) was redissolved in 0.5 M NaOH and the solution measured for radioactivity. The remaining non-extractable radioactivity in the sediment (humins) was determined by combustion.

Since the majority of radioactivity was associated with the high molecular humic acids and humins and the amounts of radioactivity in the fulvic acid fractions were less than 7% TAR, no attempts were made to further characterize the ^{14}C-compounds.

Radioactivity in the volatile trapping solutions was determined by LSC. Although the radioactivity in the volatile traps was very low, two NaOH trapping solutions, one for each radio-label of the 0 - 14 days sampling period, containing 0.7 and 1.7% of the applied radioactivity were treated with conc. HCI, ultrasonicated, additionally flushed with nitrogen gas and then measured again for radioactivity. All radioactivity was purged out of the NaOH by this procedure leading to the conclusion that it consisted originally of $^{14}CO_2$.

4. Kinetic modeling

The kinetic analysis was carried out following the recommendations of the FOCUS work group on degradation kinetics [*FOCUS (2006)*] in order to derive persistence and modeling aquatic degradation endpoints. The analysis was done by non-linear regression methods (Marquardt algorithm, ordinary least squares optimization) using the KinGUII (version 2.2011) and ModelMaker (version 3.0.4) software packages.

Kinetic evaluations were performed for pyraclostrobin and three of its metabolites (BF 500-3, BF 500-11, BF 500-14) considering the different levels proposed by the FOCUS kinetics guidance. For the parent substance, the analysis at P-I level (one-compartment approach implemented in KinGUII) was done for degradation in the whole system as well as the respective dissipations from the water and sediment phases of the test system. At the P-II level (two-compartment approach implemented in ModelMaker), the kinetic analysis considered the degradation in water and sediment taking into account the partitioning between the two phases.

For the metabolites (Level M-I), both dissipation and degradation calculations were performed using KinGUII, although the considered radio-labels and system compartments differed for each metabolite (see section on data handling).

The goodness-of-fit of the model was assessed by visual assessment as well as by means of statistical measures as recommended by the FOCUS work group on degradation kinetics. Visual assessment of the model fit, considering the concentration time curve as well as the residual plots, is the principal indicator for the appropriateness of a kinetic model. In addition, the decision on the best kinetic model is supported by χ^2 statistics, and the kinetic model with smaller error levels to pass the χ^2 test is usually preferred. The χ^2 statistics was calculated using mean of replicate measurements when available.

Data handling

For each time point, replicate measurements (chlorophenyl- and tolyl-label) for each time point were used in the parameter estimation for the parent compound.

Degradation in the whole system and dissipation from the water phase of the parent compound (P-I level) were evaluated starting at DAT 0. The dissipation of the parent from the sediment phase (P-I level) was done starting at the day of maximum occurrence. In these cases, the zero time (T_0) was corrected to the time of maximum observed and all later times were adjusted accordingly as days after maximum concentrations (DAMC).

At the P-II level, the initial concentration of the sediment compartment was assumed to be 0. Furthermore, at the P-I and P-II levels of the analysis the measured initial concentrations of the parent substance in the whole system or in the water was set to the material balance at DAT 0, as recommended by the FOCUS Kinetics guidance.

At the M-I level, the dissipation calculations were conducted from the point of maximum occurrence of the considered metabolite, with T_0 corrected accordingly. For the degradation, the recovered amount of the parent substance at DAT 0 was set equal to the material balance of the whole system and the initial concentration of the metabolites was fixed to zero.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The distribution of radioactivity in the different compartments of the water/sediment system treated with ^{14}C-labels of pyraclostrobin is presented in Table 7.2.2.4-18 and Table 7.2.2.4-19.

The material balances in the test vessels ranged between 93.6 and 98.6% of the total applied radioactivity (TAR) for the chlorophenyl-label and between 94.0 and 98.2% TAR for the tolyl-label.

The radioactivity in the water of the irradiated test vessels quickly declined with both labels to 38 - 39% TAR after one day to about 4% at the end of incubation after 42 days. The reduction of radioactivity in the water phases of the dark controls was in principle comparable, reaching 3 - 5% TAR at the end of incubation.

Corresponding to the decline of radioactivity in the water phase, the total radioactivity in the sediment quickly increased within the first 14 days to 82 and 85% TAR in the irradiated vessels, and 91 and 80% TAR in the dark controls for chlorophenyl and tolyl-label, respectively. At the end of the incubation the total amount of radioactivity increased even further to 88 - 89% TAR in the irradiated vessels and 90 - 93% TAR in the dark controls.

At the earlier sampling times, the major part of radioactivity in sediment was always extractable, but under irradiated conditions, the non-extractable part increased with time up to 63 - 66% TAR after 42 days. In the dark controls, the non-extractable radioactivity also increased, but reached only 50 - 51% TAR at the end of the incubation.

Volatiles

Overall, the degradation of pyraclostrobin in water/sediment systems was characterized by a very low mineralization rate. The amount of $^{14}CO_2$ never exceeded 5% TAR within 100 days. No other volatiles were detected.

B. TRANSFORMATION OF PARENT COMPOUND

Characterization and identification of residues in water and sediment extracts

An overview of active ingredient and metabolites for the water samples and sediment extracts is presented in Table 7.2.2.4-20 to Table 7.2.2.4-22.

A proposed route of degradation of pyraclostrobin in water/sediment systems is given in Figure 7.2.2.4-1.

Pyraclostrobin dissipated quickly from the water phase reaching ≤ 35% TAR already after 1 day and < 0.5% TAR at the end of incubation after 42 days.

Water

Numerous medium polar and polar metabolites were formed of which BF 500-5 (max. 0.9% TAR), BF 500-11 (max. 5.4% TAR), BF 500-12 (max. 1.4% TAR), BF 500-13 (max. 0.9% TAR) and BF 500-14 (max. 2.5% TAR) could be identified by co-chromatography with reference compounds. BF 500-11, BF 500-13 and BF 500-14 were confirmed by HPLC/MS-MS analysis. All of those identified metabolites decreased again or disappeared completely during the last sampling intervals.

The des-methoxy-metabolite of pyraclostrobin (BF 500-3) could also be sporadically detected, which is explainable since the degradation route of pyraclostrobin is supposed to start with the des-methoxylation at the carbamate group. However, the appearance of this compound with 2.5% TAR in the 0 day sample of the tolyl-label treated vessel may also be attributed to the fact that it was already present as impurity in the treatment solution.

Several unknown products were detected in the water during the incubation time, however, none of them ever exceeded 3.8% TAR, and all appeared to be of transient nature.

As expected, the photolysis breakdown products like BF 500-14, BF 500-13, and BF 500-12 were not detected in the dark controls. One peak (approximately 51.4 min) detected in the dark control waters of the chlorophenyl-label test vessels matched the retention time of BF 500-5 (considering the delay between UV and ^{14}C-detector); however, no HPLC/MS-MS confirmation could be performed due to the overall low radioactivity and so the structure has to be considered as not confirmed. It is however very unlikely that a typical photoproduct like BF 500-5 appears under dark conditions.

Sediment
Because of the fast precipitation, pyraclostrobin reached its maximum amounts of 63 and 54% TAR, for chlorophenyl-label and tolyl-label, respectively, at three days after treatment. Afterwards it declined moderately fast by incorporation into the organic sediment matrix, amounting to 18 and 15% TAR at the end of incubation.

Metabolites in the sediment extract were detected only at low amounts among which BF 500-3, BF 500-6 and BF 500-7 could be identified by co-chromatography with reference compounds and HPLC/MS-MS analysis.

The des-methoxy-metabolite (BF 500-3) was formed at maximum amounts of 4 - 6% TAR and declined again towards the end of incubation to 1 - 3%. The two dimeric structures BF 500-6 (500M01) and BF 500-7 (500M02) never exceeded 3.7 and 2.3% TAR, respectively.

The extractable amount of pyraclostrobin in the sediment at the end of incubation was higher in the dark control samples than under irradiated conditions. In the time interval 14 to 42 days, the active substance decreased under dark conditions from 59 to 32% TAR with the chlorophenyl-label and from 49 to 29% TAR with the tolyl-label. The metabolite BF 500-3 was detected only in low amounts of <3%, whereas BF 500-6 and BF 500-7 reached up to 7% and 4% TAR, respectively.

Non-extractable residues
The non-extractable (bound) residues reached high amounts of 63 and 66% TAR during the incubation and were therefore further characterized by NaOH-extraction and separation into fulvic acids, humic acids and non-extractable humins (Table 7.2.2.4-24).

For all investigated samples, less than half of the radioactivity associated with the organic matrix in the sediment could be released by NaOH extraction. After separation of fulvic and humic acids, the majority of radioactivity stayed in the humic acids (max. 17 - 18% TAR) and only a small portion was measured in the fulvic acids (max. 5 - 7% TAR).

Since under irradiated conditions, the formation of non-extractable residues was faster than under dark conditions, it can be concluded that the photolytical breakdown in the water phase also contributed to the overall faster degradation of pyraclostrobin in the sediment, or rather on the sediment surface. The similar distribution of the two radiolabels between the humic substance fractions showed that the two ring moieties were both readily incorporated into the humic substances in the sediment.

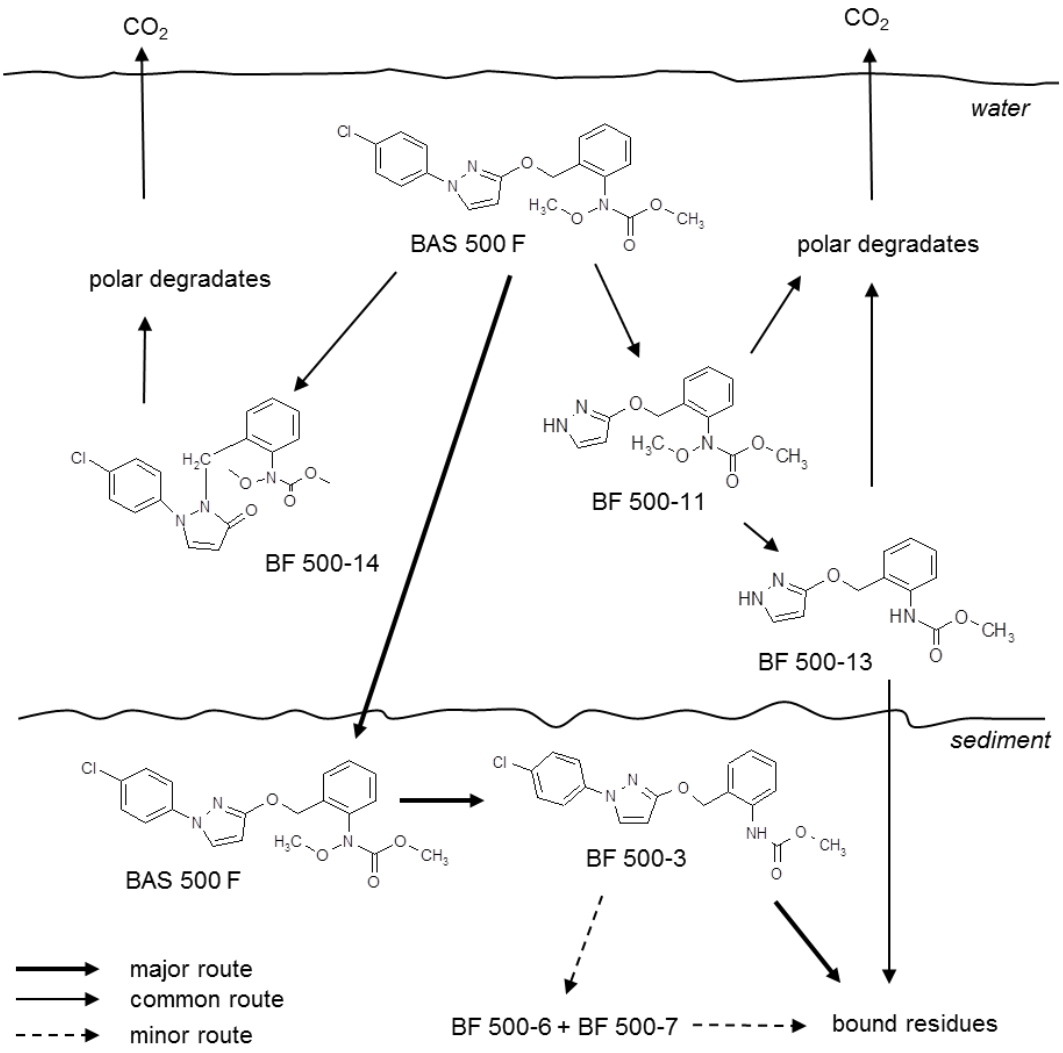
Figure 7.2.2.4-1: Proposed route of degradation of pyraclostrobin in water/sediment systems



Dissipation and degradation rates

The dissipation and degradation rates in water, sediment and the whole system could be calculated for the active substance pyraclostrobin and its metabolites BF 500-3 (sediment), BF 500-11 and BF 500-14 (both water).

The kinetics of the dissipation and degradation of BF 500-3 were established for the whole system, but using only the results of the chlorophenyl-label. The measurements for the tolyl-label in water showed a peculiarly high initial concentration of the metabolite at time zero, which was quite unusual for a metabolite forming in sediment and was not observed for the chlorophenyl-label. This fact skewed the description of the formation kinetic, and the apparition of the maximum occurrence concentration only very late toward the end of the experiment left too few measurement points to conduct the dissipation analysis. For these reasons, the measurements from the tolyl-label were discarded in the calculations of the dissipation and the degradation of BF 500-3. Furthermore, the dissipation of BF 500-3 was calculated for the whole system. While it was mainly found in sediment, the small quantities in the water phase were also considered as a worst-case perspective.

The metabolite BF 500-11 was only studied in water for both dissipation and degradation as it only appeared in this compartment. Additionally, no replicate was available as this metabolite formation implies the elimination of the molecular segment carrying the chlorophenyl-label, thus only the tolyl-label could be used to quantify it. Likewise, the metabolite BF 500-14 was studied from the tolyl-label in the water compartment as it was not observed in sediment.

The best-fit (persistence) and modelling values for pyraclostrobin after a P-I analysis are listed in Table 7.2.2.4-25. No reliable degradation rates with a P-II analysis could be determined.
Persistence and modelling endpoints for the metabolites of pyraclostrobin are provided in Table 7.2.2.4-26 (dissipation) and Table 7.2.2.4-27 (degradation). No degradation rate for metabolite BF 500-3 could reliably be determined.

III. CONCLUSION

Overall, it can be concluded that pyraclostrobin degrades rather fast in the total water/sediment system with a best-fit $DegT_{50}$ of 13.5 days under irradiated conditions. It quickly dissipates from the water phase with a DT_{50} of < 0.5 days. In sediment, further degradation leads to incorporation into the organic matrix (humic substances) with a DT_{50} of about 20 days.

Summary of degradation and dissipation endpoints for pyraclostrobin in different water/sediment systems

(t), (c) - tolyl or chlorophenyl-labeled test item used
n.a. not applicable
n.c. not calculated
[1] No reliable endpoints derived in kinetic evaluation.
[2] Endpoints at P-I level are reported as modeling endpoints and no biphasic kinetic models were tested in the study. However, as the SFO model provides excellent fits (excellent visual fit, very low χ^2 error and type I error rate), the endpoints are appropriate for use as trigger endpoints.
[3] Outdoor temperatures and light conditions were simulated in a climatic chamber.
[4] DT_{90} not reported; calculated from SFO DT_{50} as $DT_{90} = DT_{50} \times 3.32$
[5] The P-II level provides degradation endpoints for water and sediment compartment, in contrast to P-I where dissipation endpoints are estimated for water and sediment.

CA 7.2.3 Degradation in the saturated zone

Due to its low leaching potential, pyraclostrobin is not expected to reach deeper soil layers or saturated zones. Therefore, investigations on the degradation in the saturated zone are considered to be not necessary.

CA 7.3 Fate and behaviour in air

Pyraclostrobin is characterized by a low vapor pressure (2.6 x 10^{-8} Pa at 20°C) and a low volatilization from soil and plant surfaces (< 3% in 24h). Furthermore, in the air it is rapidly degraded by photochemical processes.

CA 7.3.1 Route and rate of degradation in air

No new experimental data are available, but a new calculation of the photochemical oxidative degradation in air (Atkinson) according to the newest model is provided below.

Report: CA 7.3.1/1
Hassink J., 2013a
Photochemical oxidative degradation of BAS 500 F (QSAR estimates)
2013/1350648
Guidelines: EC 1107/2009 of the European Parliament
GLP: no (not applicable)

Executive Summary

The degradation rates for reactions of pyraclostrobin with OH-radicals and ozone in the atmosphere were calculated using the AOPWIN program based on ATKINSON's increment method. Based on the resulting degradation rate of k_{OH} = 206.3747 x 10^{-12} cm^3 $molecule^{-1}$ s^{-1}, the atmospheric degradation half-life of the substance via this reaction route was estimated to be $t_{1/2}$ = 0.05 d (12 h day). Although O_3 is likely to react with pyraclostrobin, the degradation rate resulting from ozone attack could not be estimated.

Due to the rapid degradation in air, it can be concluded that there is no risk of long-range transport of pyraclostrobin.

I. MATERIAL AND METHODS

The degradation rate resulting from attack of OH-radicals was calculated with the AOPWIN Program (Atmospheric Oxidation Program for Microsoft Windows 3.1, Version 1.88, Syracuse Research Corp. 1997) based on ATKINSON's increment method [*Atkinson, R. (1987) A Structure-Activity Relationship for the Estimation of Rate Constants for the Gas-Phase Reactions of OH Radicals with Organic Compounds, Int.J.Chem.Kin. 19, 799*]. The degradation rate resulting from attack of ozone was calculated according to an OECD method [*Anonymous (1992): The rate of photochemical transformation of gaseous organic compounds in air under tropospheric conditions. OECD Environment Monographs No. 61, OECD, Paris*].

The degradation rate of pyraclostrobin with OH-radicals was estimated based on the structural formula. The SMILE notation used for pyraclostrobin in AOPWIN was:

COC(=O)N(c1ccccc1COc2nn(cc2)c3ccc(cc3)CL)OC

II. RESULTS AND DISCUSSION

Assuming a pseudo-first order reaction, the degradation half-life was calculated by taking into account the diurnally and seasonally averaged concentration of hydroxyl-radicals in the troposphere. The total rate constant was estimated to be k_{OH} = 206.3747 x 10^{-12} cm^3 $molecule^{-1}$ s^{-1}.

Considering a weighted global average tropospheric hydroxyl-radical concentration of 1.5 x 10^6 mol cm^{-3}, the half-life for the degradation of pyraclostrobin by OH-radicals was calculated according to Equation 7.3.1-1.

Equation 7.3.1-1 Estimation of the atmospheric degradation half-life ($t_{1/2}$) of pyraclostrobin

$$t_{1/2} = \ln 2 / (206.3747\ 10^{-12} \times 1.5\ 10^{6})\ s$$
$$= 0.622\ h$$
$$= \underline{0.05\ d\ (12\ h\ day)}$$

Although pyraclostrobin contains reactive sites for an ozone attack, a reasonable approximation by AOPWIN was not possible. Therefore, although O_3 is likely to react with pyraclostrobin, no degradation estimation could be given.

III. CONCLUSION

Based on the results of the atmospheric degradation half-life of pyraclostrobin ($t_{1/2}$ = 0.05 d), it can be concluded that the substance will be rapidly degraded by photochemical processes in the troposphere. Hence, due to the rapid degradation in air, it can be concluded that there is no risk of long-range transport of pyraclostrobin.

CA 7.3.2 Transport via air

Pyraclostrobin has a very low volatilization potential and is degraded very fast by photochemical processes. Consequently, there is no risk of long-range transport of pyraclostrobin.

CA 7.3.3 Local and global effects

No effects are expected since transport via air is very unlikely (for details see above).

CA 7.4 Definition of the residue

CA 7.4.1 Definition of the residue for risk assessment

According to the results presented in M-CA 7.1 – 7.3 the following compounds have to be considered for the environmental risk assessment:

Soil:
Pyraclostrobin and its aerobic soil metabolites BF 500-6, BF 500-7

Both metabolites were tested in chronic earthworm and collembola studies due to their potential persistence in soil. Based on the results it can be concluded that the risk of metabolites for soil organisms is negligible.

Groundwater:
Pyraclostrobin, its aerobic soil metabolites BF 500-6, BF 500-7, and its anaerobic soil metabolites BF 500-3, BF 500-4 and BF 500-5

Based on the high adsorption and/or the fast degradation rates in soil, neither the parent molecule nor one of its metabolites poses any risk of leaching to groundwater. The predicted annual leachate concentrations of pyraclostrobin and all soil metabolites were below 0.001 µg L^{-1}.

Surface Water:
Pyraclostrobin and its metabolites BF 500-5, BF 500-11, BF 500-13, BF 500-14

The aquatic toxicity of all metabolites was tested and was found to be three orders of magnitude lower for the most sensitive species than parent. Sufficient margins of safety were reached after FOCUS surface water step 1-2 calculations and it is concluded that the risk of metabolites for aquatic organisms is negligible.

Sediment:
Pyraclostrobin and its metabolites BF 500-3, BF 500-6 and BF 500-7

The sediment toxicity of the metabolites was tested in chronic *Chironomus* studies. Sufficient margins of safety were reached already after FOCUS surface water step 1-2 calculations (worst case) and it is concluded that the risk of metabolites for sediment organisms is very low.

Air:
Pyraclostrobin

No volatile metabolite was detected.

CA 7.4.2 Definition of the residue for monitoring

According to the results of the risk assessment the following compounds should be considered for environmental monitoring:

Soil: Pyraclostrobin (parent only)

Ground Water: Pyraclostrobin (parent only)

Surface Water: Pyraclostrobin (parent only)

Sediment: Pyraclostrobin (parent only)

Air: Pyraclostrobin (parent only)

CA 7.5 Monitoring data

According to the knowledge of the applicant, there are currently no published environmental monitoring data available for pyraclostrobin or its metabolites, which would provide knowledge on the environmental behaviour not covered by this dossier.

During literature search a few publications were found dealing with environmental monitoring of various pesticides in surface water, groundwater and/or sediment outside EU (e.g. US, Australia, Costa Rica) mentioning also pyraclostrobin. The results showed that pyraclostrobin could be detected in local areas characterized by intensive fungicide use during the spraying season, however, frequency of detection as well as measured concentrations were usually very low.

One publication described an air monitoring in France (near Straßbourg) in April/May 2007. Pyraclostrobin was included as an analyte, however, it was not detected.

Table of Contents

CA 8 ECOTOXICOLOGICAL STUDIES ON THE ACTIVE SUBSTANCE

Pyraclostrobin (BAS 500 F), a fungicide for use in cereals, maize, potatoes, legumes, fruits, vegetables and various other crops, is registered in Europe since many years. It was fully reviewed under Directive 91/414/EEC and included in Annex I by Commission Directive No 2004/30/EC and 2009/25/EC. Inclusion entered into force on 10 March 2004. The approval was transferred to the new Regulation (EC) No 1107/2009 in Commission Implementing Regulation (EU) No 540/2011. Approval extension was granted until 31 January 2017 by Regulation No 823/2012/EU.

All relevant information on the first Annex I review and the endpoints used in ecotoxicological risk assessments can be found in the monograph of pyraclostrobin and in the SANCO/1420/2001-Final document (EU Review Report).

For the current registration renewal under Regulation 1107/2009, a data gap analysis according to new guidelines and new guidance documents was performed and new studies or evaluations were initiated where considered necessary. All new data are provided in this section or in the respective sections of the dossiers for the two new representative formulations.

Furthermore, a literature search was performed and scientific publications were evaluated for their endpoint relevance and quality. Summaries of relevant and reliable public literature data on pyraclostrobin are provided in this section (or in the respective sections of the dossiers for the two new representative formulations) as appropriate. Further information on the literature assessment and respective justifications can be found in M-CA 9.

An overview of metabolites relevant for the environment is given in M-CA 7. The table is including the different code numbers that are available for each metabolite. In the following chapters and study summaries synonym metabolite codes are given in brackets where deemed to be helpful.

CA 8.1 Effects on birds and other terrestrial vertebrates

Data from new studies conducted with the active substance pyraclostrobin or the representative formulation BAS 500 06 F and relevant for the risk assessment of birds and mammals are summarized below. An overview on the reports and documents is given in Table 8.1-1.

Besides the here summarized substance-specific study reports and documents, further information (either generic or formulation-specific studies and information) used in the risk assessment for birds and mammals will be given in M-CP 10.1.1 and M-CP 10.1.2.

Table 8.1-1: Overview of study reports and documents whose summaries are given in M-CA 8.1.1 and 8.1.2

CA 8.1.1 Effect on birds

CA 8.1.1.1 Acute oral toxicity to birds

Report: CA 8.1.1.1/1
[redacted] 2014a
BAS 500 F (Pyraclostrobin) - Acute Toxicity in the canary (Serinus canaria) after single oral administration (LD50)
2013/1400375
Guidelines: EPA 850.2100, EPA 850.2000, EPA 712-C-025
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

An avian acute oral toxicity test with the active substance pyraclostrobin (BAS 500 F) was conducted. The objective of the study was to evaluate the acute toxicity of the substance in Canaries (*Serinus canaria*) and to determine the oral LD_{50} in the Canary after a single oral administration of the test substance and a 14-day post observation period.

The test substance was administered via a single oral dose of 0 (control), 210, 340, 551, 893 and 1446 mg a.s./kg body weight to groups of 28 weeks old Canaries. Ten birds (5 males and 5 females) were used in each test substance group. The doses were administered undiluted in two gelatin capsules directly into the crop. Birds that have been fasted for about 3 to 5 hours were administered the test substance. Birds of all groups received food and water *ad libitum* throughout the test. The test was terminated after 14 days.

All groups were observed for mortality, signs of clinical toxicity, impact on food consumption and body weight for 14 consecutive days post dosing. Gross-pathological examinations were conducted on all birds sacrificed at the termination of the test.

No mortality occurred throughout the duration of the study in the control and in the 210, 893 and 1446 mg a.s./kg b.w. dose groups. There was one mortality each in males of the dose groups of 340 and 551 mg a.s./kg b.w who were considered not to be treatment related as there was no mortality in the higher dose groups. No regurgitation was observed during the first hour after dosing in any of the dose groups. Thus all birds received the full dose. No substance-related impairment of food uptake in comparison to the control was observed in any of the dose groups. No statistically significant (Dunnett test) substance-related reduction of the body weights in the male and female birds was observed on day 7 and at day 14 (sacrifice) in any of the dose groups compared to the control. The body weight development of the females was not statistically different from the control in any of the dose groups. In males the body weight development on some occasions was higher than in the control group, however, without any dose-response pattern. It was not considered to be treatment-related. All birds were examined macroscopically (post-mortem) after study termination. No abnormalities caused by the test substance were observed in birds that died and sacrificed birds.

In an acute oral toxicity test with the canary (*Serinus canaria*), the LD_{50} of pyraclostrobin was found to be >1446 mg a.s./kg b.w. The NOEL was ≥ 1446 mg a.s./kg b.w.

I. MATERIAL AND METHODS

Test item:	BAS 500 F (Reg. No. 304428), batch no. COD 001236, purity: 99.02% (tolerance ± 1.0%).
Test species:	Canary (*Serinus canaria*), visually indistinguishable from wild birds; adults, age: approx. 28 weeks old (before beginning of first egg-laying period); supplier: Zoowelt, Bechtheim, Germany.
Test design:	Birds were administered single doses of 210, 340, 551, 893 and 1446 mg a.s./kg body weight of the test substance pyraclostrobin (BAS 500 F) undiluted in two gelatin capsules directly into the crop; 5 males and 5 females per dose group were used. The birds were observed for regurgitation for 1 - 3 hours after dosing. An observation period of 14 days followed, during which mortalities and signs of toxicity were recorded, four times on day of dosing and daily thereafter; assessment of body weight was carried out on the day before dosing and on days 7 and 14 after dosing; mean food consumption (g/bird/day) was calculated from the daily food consumption per cage separately for male and female birds after dosing. Gross-pathological post-mortem examinations of all birds at study termination on day 14 after dosing.
Endpoints:	Mortality, clinical signs, feed consumption, body weight (b.w.), and gross-pathological examinations were conducted on all birds sacrificed at the termination of the test. Calculation of LD_{50} and NOEL.
Test concentrations:	0 (Control), 210, 340, 551 and 893 mg a.s./kg body weight (nominal).
Test conditions:	Birds fasted for about 3 h to 5 h before administration of the test substance; temperature: 19.1°C (minimum) and 21.1°C (maximum); values within the limits of 21°C ± 2°C; relative humidity: 36.8% and 76.8%; values not within limits of 45% - 70%, time below limit 11 days and 7 hours. The deviations had no relevant influence on the study results, since the limits were exceeded only to a small extent and no adverse effects were observed in the control group; photoperiod: 8 hours light : 16 hours dark, light intensity: lux 20 - 38 lux.
Analytics:	The test substance concentrations were analyzed using HPLC.
Statistics:	Descriptive statistics. No statistical calculation of the LD_{50} was performed since no substance related mortality was observed in the tested dose. Dunnett test was used for body weight data and Fisher's exact test for pair-wise comparison of mortality data.

II. RESULTS AND DISCUSSION

Analytical measurements: No analytical determinations of the test substance in the carrier were necessary since the test substance was applied without carrier.

Biological results: No mortality occurred throughout the duration of the study in the control and in the 210, 893 and 1446 mg a.s./kg b.w. dose groups. There was one mortality each in males of the dose groups of 340 and 551 mg a.s./kg b.w who were considered not to be treatment related as there was no mortality in the higher dose groups. No regurgitation was observed during the first hour after dosing in any of the dose groups. Thus all birds received the full dose. No substance-related impairment of food uptake in comparison to the control was observed in any of the dose groups. No statistically significant (Dunnett test) substance-related reduction of the body weights in the male and female birds was observed on day 7 and at day 14 (sacrifice) in any of the dose groups compared to the control. The body weight development of the females was not statistically different from the control in any of the dose groups. In males the body weight development on some occasions was higher than in the control group, however, without any dose-response pattern. It was not considered to be treatment-related. All birds were examined macroscopically (post-mortem) after study termination. No abnormalities caused by the test substance were observed in birds that died and sacrificed birds. The relevant data and endpoints are summarized in the table below.

Table 8.1.1.1-1: Acute toxicity of pyraclostrobin (BAS 500 F) to the canary (*Serinus canaria*)

	Dose rate [mg a.s./kg b.w.]					
	0 (control)	**210**	**340**	**551**	**893**	**1446**
Number of birds per dose group	10	10	10	10	10	10
Number of dead birds	0	0	1[1)]	1[1)]	0	0
Dead birds percentage [%]	0	0	10	10	0	0

Endpoints	**Dose [mg a.s./kg b.w.]**
Highest dose causing no substance-related mortality	1446
LD_{50} (14 d)	>1446
NOEL	≥ 1446

b.w. = body weight

1) One male bird of group 2 died five days after dosing and one male bird of group 3 died one day after dosing. According to the test guideline 10% mortality is acceptable for the control group. Because the mortality in these both groups did not exceed 10% and in the higher dose groups (893 and 1446 mg/kg body weight) no mortality was observed, it was concluded that the mortality can be clearly not attributed to the test substance.

III. CONCLUSION

In an acute oral toxicity test with the canary (*Serinus canaria*), the LD_{50} of pyraclostrobin was found to be >1446 mg a.s./kg b.w. The NOEL was ≥ 1446 mg a.s./kg b.w.

CA 8.1.1.2 Short-term dietary toxicity to birds

The two short-term toxicity studies in bobwhite quail and mallard duck evaluated and accepted during the previous Annex I inclusion process are no longer part of the required data as outlined in EFSA/2009/1438 and the new EU Regulation 283/2013. For completeness the study details are summarised in the table below.

Table 8.1.1.2-1: Available short-term toxicity studies with pyraclostrobin

Test system	Test species	Results	Guideline	Reference (BASF DocID)
Short-term dietary toxicity	*Colinus virginianus*	LC_{50} > 5000 mg a.s./kg diet; LC_{50} > 1176 mg a.s./kg bw/d[1)]	US EPA FIFRA Guideline § 71-2 (Oct. 1984); OECD 205 (Apr. 1984)	1998/10932[2)]
	Anas platyrhynchos	LC_{50} > 5000 mg a.s./kg diet; LC_{50} > 1320 mg a.s./kg bw/d[1)]	US EPA FIFRA Guideline § 71-2 (Oct. 1984); OECD 205 (Apr. 1984)	1998/10933[3)]

2) Study title: "BAS 500 F - Avian Dietary LC_{50} test in chicks of the Bobwhite Quail (Colinus virginianus)"
3) Study title: "BAS 500 F - Avian Dietary LC_{50} test in chicks of the Mallard Duck (Anas platyrhynchos L.)"

CA 8.1.1.3 Sub-chronic and reproductive toxicity to birds

Two reproductive bird toxicity studies are available for pyraclostrobin, one in bobwhite quail and one in mallard duck. Both studies were already evaluated during the previous Annex I inclusion process and are still relevant for deriving the reproductive toxicity endpoint. Details on the studies are shown in M-CP 10.1 (e.g. Table 10.1.1.-2 in M-CP of BAS 500 06 F).

CA 8.1.2 Effects on terrestrial vertebrates other than birds

CA 8.1.2.1 Acute oral toxicity to mammals

Acute oral toxicity to mammals is discussed in M-CA 5.2.1. The studies previously evaluated during the Annex I inclusion process are considered to be still valid and sufficient. Therefore, no new studies have been conducted with the active substance. In the following two new 5 day dietary toxicity studies conducted with the representative formulation BAS 500 06 F are summarized.

Please note that the following studies CA 8.1.2.1/1 and CA 8.1.2.1/2 were erroneously listed as CP 10.1.2.1/1 and CP 10.1.2.1/2 in the Application submitted in January 2014 for the renewal of approval of pyraclostrobin.

Report:	CA 8.1.2.1/1 [redacted] et al., 2009a BAS 500 06 F: Acute toxicity testing study - Repeated dose oral toxicity study in Wistar rats 2009/1108893

Executive Summary

A 5-day mammal dietary toxicity test with the formulation BAS 500 06 F was conducted to determine mortality and sublethal effects in small mammals after oral dietary administration of BAS 500 06 F. In addition, the food avoidance behavior of small mammals was investigated. Behavior such as food avoidance, can reduce exposure by preventing animals from ingesting body burdens exceed harmful thresholds. Furthermore, the no observed effect concentration (NOEC) should be determined.

The test substance was administered at dietary concentrations of 5000 and 12000 ppm BAS 500 06 F. Five young female rats were used in each concentration group and in the control group. All groups were observed for mortality, water consumption, signs of clinical toxicity, impact on food consumption and body weight during the exposure period of 5 days and a treatment-free post-exposure period of 9 days. The animals received feed ad libitum.
No test substance related mortality was observed in any test group throughout the entire study period. No clinical signs of toxicity related to the test substance were observed in the treatment group of 5000 ppm test substance in the diet. In the highest treatment group of 12000 ppm test substance in the diet piloerection in all animals was observed from day 3 to 5. Significantly reduced food consumption was observed in all treated test groups during administration period. This effect was assessed as a problem of palatability resulting in avoidance of food contaminated with BAS 500 06 F containing the active ingredient pyraclostrobin. Impaired body weight data were obtained during administration period in all treated test groups. This finding was assessed as a consequence of the reduced food consumption rather than an incipient sign of general systemic toxicity.

All animals were examined macroscopically. No macroscopical findings were observed during the gross pathological examinations.

No test substance-related adverse effects of toxicological concern could be revealed. Reduced food consumption and body weight loss were clearly related to food avoidance. A NOEC could not be determined.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265, purity: content of a.s. in formulation: 202.7 g pyraclostrobin /L

Test species: rat, strain crl:WI (Han), female rats, age: 70-72 days at start of administration period; source: Charles River Laboratories, Research Models and Services GmbH, Germany.

B. STUDY DESIGN

Test design: Young female rats received different concentrations of the test substance offered in the diet on 5 consecutive days with a treatment-free post-exposure period of 9 days; 5 rats per test substance concentration and for the control group were used. All groups received ground diet and drinking water ad libitum. Assessment for mortality and clinical signs was carried out two times a day on working days (once a day on Saturdays, Sundays and public holidays) of the entire study period. Assessment of body weight was carried out once a day from study days 0 to 8 and on day 10, 12 and 14; food consumption was determined daily from study days 0 to 8 and on day 10, 12 and 14 and calculated as daily mean food consumption (g) per animal and day. Water consumption was observed daily by visual inspection of the water bottles for any overt changes in volume. Gross-pathological post-mortem examinations of all surviving specimens were carried out at the end of the study.

Endpoints: Mortality, clinical signs, feed consumption, water consumption, body weight (b.w.). Gross-pathological examinations were conducted on rats sacrificed at the definitive termination of the test. Calculation of NOEC.

Test concentrations: Dietary concentrations of 0 (Control), 5000 and 12000 ppm BAS 500 06 F in the diet. The corresponding actual mean daily intake rates were 0 (Control), 264 and 240 mg BAS 500 06 F/kg b.w./day.

Test conditions: Temperature: 20°C - 24°C, relative humidity: 30% - 70%; with only minimal deviations from these limits; the day/night cycle was a 12 hour light cycle photoperiod: 12 hours light: 12 hours dark.

Statistics: Descriptive statistic, Dunnett test for body weight data.

II. RESULTS AND DISCUSSION

Analytical measurements: The results of the analytical verification of the test substance concentration in the diet were within a range of 89.3% to 96.4% of the nominal concentrations during the test. The biological results are therefore based on the nominal values.

Biological results: The test substance was administered at dietary concentrations of 0 (Control), 5000 and 12000 ppm BAS 500 06 F. The corresponding actual mean daily intake rates are 0 (Control), 264 and 240 mg BAS 500 06 F/kg b.w./day.
No test substance related mortality was observed in any test group throughout the entire study period. No clinical signs of toxicity related to the test substance were observed in the treatment group of 5000 ppm test substance in the diet. In the highest treatment group of 12000 ppm test substance in the diet piloerection in all animals were observed from day 3 to 5. Statistical significant reduced food consumption was observed in all treated test groups during administration period. This effect was assessed as a problem of palatability resulting in avoidance of food contaminated with BAS 500 06 F containing the active ingredient pyraclostrobin. Impaired body weight data were obtained during administration period in all treated test groups. This finding was assessed as a consequence of the reduced food consumption rather than an incipient sign of general systemic toxicity.

All animals were examined macroscopically. No macroscopical findings were observed during the gross pathological examinations. Results are presented in the table below.

Table 8.1.2.1-1: Mammalian dietary toxicity of BAS 500 06 F to rats

Dose Group [ppm BAS 500 06 F in diet]	Control	5000	12000
Mean test substance intake (BAS 500 06 F mg/kg b.w./day)	--	264	240
Mortality [%]	0	0	0
Clinical signs	None	None	Yes[1)]

b.w. = body weight
1) Piloerection was observed in all animals on study day 3 to 5.

III. CONCLUSION

In conclusion, this study did not reveal test substance-related adverse effects of toxicological concern. Reduced food consumption and body weight loss were clearly related to food avoidance. A NOEC could not be determined.

BAS 500 06 F - Repeated dose oral toxicity study in Wistar rats - Administration via the diet over 5 days
2011/1146588
Guidelines: <none>
GLP: no

Executive Summary

With regard to the risk assessment for wild mammals, the standard acute tests using oral gavage as dosing method do not reflect the real pattern of exposure of wild mammals in the field following the application of several types of Plant Protection Products (for instance, those applied as foliar sprays). Laboratory testing using more realistic exposure routes (i.e., dietary) and dosing regimes (food available for brief daily intervals, not continuously, ensuring high feeding rates) would result in toxicity data better suitable for a more realistic assessment of the risk to wild mammals.

Hence, 5-day mammal dietary toxicity test with the formulation BAS 500 06 F was conducted to determine mortality and sublethal effects in small mammals after oral dietary administration of BAS 500 06 F under more realistic exposure conditions and dosing regimes than the standard acute toxicity tests.

Mortality and sublethal effects were determined in small mammals after oral dietary administration of BAS 500 06 F for 5 days. In addition, the food avoidance behavior of small mammals was investigated. Behavior such as food avoidance can reduce exposure by preventing animals from ingesting body burdens that exceed harmful thresholds.

BAS 500 06 F was administered over 5 days via the diet to groups of 5 young female Wistar rats as a homogeneous addition to the food. The test concentrations were chosen to cover field-relevant dietary concentrations of pyraclostrobin (BAS 500 F). Due to a transmission and calculation error the dietary concentrations applied in a first study part were too high (20859 ppm, 8773 ppm and 1883 ppm of BAS 500 06 F). Hence a second study part was conducted using the correct dietary concentrations in the diet (1495 ppm, 648 ppm and 149 ppm of BAS 500 06 F). Control rats were offered untreated diet. The administration period was followed by a treatment-free post-exposure period of 9 days.
In order to reflect the feeding behavior of wild animals and to ensure high feeding rates of the animals the feeding was restricted to 2 feeding periods of 2 hours. Two different control groups of 5 young female rats per group were included in the testing. One control group received untreated diet during the restricted feeding windows. Additionally, a second control group was offered untreated diet ad libitum to determine potential variations in food consumption due to restricted feeding.
All groups were observed for mortality, water consumption, signs of clinical toxicity, impact on food consumption and body weight during the exposure period of 5 days and a treatment-free post-exposure period of 9 days. Individual food consumption of animals was determined daily. On study day 0, the food consumption was in addition determined separately for each feeding interval after 20, 45, 70, 95, and 120 minutes for the dose groups as well as the control to estimate in reference to the controls the avoidance response time.

The experimental design was overall successful at training the rats to ingest the full daily intake during the only four hours (two periods of 2 hours each) where food was available. Detailed investigations of the feeding pattern at study day 0 revealed that the food was not ingested evenly throughout each of the 2-hour feeding intervals, but was largely ingested during the first feeding bout of 20 minutes. Hence the experimental designs is suitable to ensure high feeding rates of the test animals concentrated during two brief (<20 minutes) daily periods.
No test substance related mortality was observed in any test group throughout the entire study period. No clinical signs of toxicity related to the test substance were observed in any of the treatment groups. Reduced food consumption was observed in all treated test groups during administration period. This effect was caused by the avoidance of food treated with BAS 500 06 F containing the active ingredient pyraclostrobin. Impaired body weight data were obtained during administration period in all treated test groups. This finding was assessed as a consequence of the reduced food consumption rather than an incipient sign of general systemic toxicity. During the post-administration period a full recovery of food consumption and body weights was observed.
All rats were examined macroscopically. No substance-related abnormalities were detected in rats after sacrifice.

No test substance-related mortality or severe sublethal effects were observed. Reductions on food consumption and body weight loss were clearly related to avoidance of treated food.

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 500 06 F, batch no. 3223026, purity: content of a.s. in formulation: 200.7 g pyraclostrobin /L
Test species:	rat, strain crl:WI (Han), female rats, age: 69-71 days at start of administration period; source: Charles River Laboratories, Research Models and Services GmbH, Germany.

B. STUDY DESIGN

Test design:	Due to a transmission and calculation error the dietary concentrations applied in a first study part were too high (20859 ppm, 8773 ppm and 1883 ppm of BAS 500 06 F). Hence a second study part was conducted using the correct dietary concentrations in the diet (1495 ppm, 648 ppm and 149 ppm of BAS 500 06 F). Young female rats received different concentrations of the test substance offered in the diet on 5 consecutive days with a treatment-free post-exposure period of 9 days; 5 rats per test substance concentration and for the two control groups were used. Feeding time was restricted to 2 feeding periods of 2 hours in order to reflect the feeding behavior of wild animals and to ensure high feeding rates. Control group 5 with 5 animals was fed ad libitum, control group 6 was fed during restricted periods. Assessment for mortality and clinical signs was carried out two times a day on working days (once a day on Saturdays, Sundays and public holidays) of the entire study period. Assessment of body weight was carried out once a day on days -8, -2, 0 to 5, 7, 9, 11,13, and 14; food consumption was determined daily from study days -7 to 4 and 6 to 13. Individual food consumption was determined daily and calculated as daily mean food consumption (g) per animal and day. On study day 0, the food consumption was in addition determined separately for each feeding interval after 20, 45, 70, 95, and 120 minutes for the dose groups as well as the control to estimate in reference to the controls the avoidance response time. Water consumption was observed daily by visual inspection of the water bottles for any overt changes in volume. Gross-pathological post-mortem examinations of all surviving specimens were carried out at the end of the study.
Endpoints:	Mortality, clinical signs, feed consumption, water consumption, body weight (b.w.). Gross-pathological examinations were conducted on rats sacrificed at the definitive termination of the test.
Test concentrations:	Study part 1: Dietary concentrations of 0 (Control ad libitum and restricted), 1883, 8773, and 20859 ppm BAS 500 06 F. Study part 2: Dietary concentrations of 0 (Control ad libitum and restricted), 149, 648, and 1495 ppm BAS 500 06 F. The corresponding actual mean daily doses are 0 (Controls), 10.4, 44.4 and 96.8 mg BAS 500 06 F/kg b.w./day.
Test conditions:	Temperature: 20°C - 24°C, relative humidity: 30% - 70%; with only minimal deviations from these limits; the day/night cycle was an inverted 12 hour light cycle photoperiod: 12 hours light: 12 hours dark.
Statistics:	Descriptive statistics

II. RESULTS AND DISCUSSION

Analytical measurements: The results of the analytical verification of the test substance concentration in the diet were within a range of 87.66% to 98.1% of the nominal concentrations during the test. The biological results are therefore based on the nominal values.

Biological results: The test substance was administered in study part 1 at dietary concentrations of 0 (Control ad libitum and restricted), 1883, 8773, and 20859 ppm BAS 500 06 F and in study part 2 at dietary concentrations of 0 (Control ad libitum and restricted), 149, 648 and 1495 ppm BAS 500 06 F.
The experimental design was overall successful at training the rats to ingest the full daily intake during the only four hours (two periods of 2 hours each) where food was available. Detailed investigations of the feeding pattern at study day 0 revealed that the food was not ingested evenly throughout each of the 2-hour feeding intervals, but was largely ingested during the first about 20 minutes. Hence the experimental design is suitable to ensure high feeding rates of the test animals concentrated during two brief (<20 minutes) daily periods.
Dose-dependent reductions in food consumption were observed in all treated test groups during the administration period. This effect was caused by the clear avoidance of food treated with BAS 500 06 F containing the active ingredient pyraclostrobin by the laboratory rats. Impaired body weight data were obtained during administration period in all treated test groups. This finding was assessed as a consequence of the reduced food consumption rather than an incipient sign of general systemic toxicity. Marked reductions in food consumption [up to 96-99%] were observed in the highest treatment group (test group 4). This test group was terminated on treatment day 2 because of reduced nutritial condition of animals due to the very strong food avoidance. No test substance related mortality was observed in any test group throughout the entire study period. No severe clinical signs of toxicity related to the test substance were observed in any of the treatment groups. During the post-administration period a full recovery of food consumption and body weights was observed. All rats were examined macroscopically. No substance-related abnormalities were detected in rats after sacrifice. The results are presented in the tables below.

Table 8.1.2.1-2: Mammalian dietary toxicity of BAS 500 06 F to rats – Study part 1

Dose Group [ppm BAS 500 06 F in diet]	**Control 0** (feeding ad libitum)	**Control 1** (restricted feeding)	**1883**	**8773**	**20859**

b.w. = body weight
1) Reduced food consumption on study day 0
2) Reduced food consumption on study day 0 to 1

III. CONCLUSION

Dose-dependent reductions in food consumption were observed in all treated test groups during the administration period. Reductions in food consumption and body weight loss were clearly related to avoidance of treated food. No test substance-related mortality or severe sublethal effects were observed.

Please note that the following studies CA 8.1.2.1/3 and CA 8.1.2.1/4 were erroneously listed as CP 10.1.2.2/2 and CP 10.1.2.2/5 in the Application submitted in January 2014 for the renewal of approval of pyraclostrobin.

Report:	CA 8.1.2.1/3 [redacted] 2014a BAS 500 06 F: Study to assess avoidance and effects in wood mice (Apodemus sylvaticus) upon dietary exposure 2012/1129348
Guidelines:	<none>
GLP:	yes (certified by Department of Health of the Government of the United Kingdom, United Kingdom)

Executive summary

Study objective
A 3-day dietary toxicity test was conducted with the wood mouse (*Apodemus sylvaticus*) to determine toxicity in a risk assessment-relevant wild mammal species after oral dietary administration of the formulation BAS 500 06 F under field relevant conditions (i.e. rapid consumption of a limited resource via the dietary route, food available for brief daily intervals, not continuously).

Standard acute tests using oral gavage as dosing method do not reflect the real dietary pattern of exposure of wild mammals in the field following foliar spray applications. Hence the purpose of the study was to determine potential effects of BAS 500 06 F on wild mammals using exposure routes and dosing regimes better suitable for a more realistic assessment of the risk to wild mammals.

The study was deemed necessary as uncertainties were identified regarding a save use of the formulation BAS 500 06 F in the risk assessment for small mammals. The wood mouse was chosen as test organism, being a species representative of the small mammals likely exposed to the test item under normal use. The employed study design (i.e. length of the deprivation period, recovery times and lightning regime) was chosen to ensure the most stringent design while simultaneously considering animal welfare by alternating between exposure to treated food and exposure to non-treated food.

Besides the evaluation of potential effects of dietary exposure to BAS 500 06 F with respect to mortality, sublethal effects, feed consumption, and body weight, the objective of this study was to determine 1) the highest daily dietary ingestion rate of the test item that could be tolerated by a relevant wild mammal species), and 2) if animals show avoidance behavior in relation to the concentration of the test item. In this context an attempt was made to estimate the time of onset of avoidance using video recording.

Study design
The experiment was split into a pre-exposure period of 11 days, followed by an exposure period of 5 days (i.e. 3 exposure days alternating with 2 non-exposure days), and a treatment-free post-exposure period of 9 days.

During the exposure period (day 0 to day 4) BAS 500 06 F was administered over 3 exposure days (day 0, 2 and 4) via diet blocks to 3 treatment groups with 6 animals (3 males, 3 females) each. Within the exposure period animals received non-treated food on day 1 and 3. The test concentrations (i.e. 150, 1500 and 3000 mg BAS 500 06 F/kg diet; corresponding to 28.93, 289.30 and 578.60 mg a.s. pyraclostrobin/kg diet) were chosen to cover field-relevant dietary concentrations of pyraclostrobin (BAS 500 F) and a factor of 10 beyond to cover for interspecies variation. Treated diet blocks were prepared by first dissolving the test item in water and then adding the ground diet to ensure homogenous mixing prior to combining with untreated binding agent. A control group (3 males, 3 females) was offered untreated diet blocks. For ethical reasons, each of the three exposure days was followed by a non-exposure day with *ad libitum* access to untreated diet for recovery. In order to reflect the feeding behavior of animals in the wild and to ensure high feeding rates, the feeding on exposure days was restricted to 2 feeding periods of 4 hours separated by 2 h of non-exposure.

Mice were observed at least daily for mortality, signs of clinical toxicity, impact on food consumption and body weight during the exposure period and a treatment-free post-exposure period. Individual food consumption of animals was determined daily.

Results and conclusion
No mortalities, symptoms of poisoning (e.g. during pathological observations), and abnormal behavior were observed in any test group.

Dose-dependent reductions in food consumption were observed in all treated test groups during the administration period. The reduction in intake of treated diet blocks was significant at the 1500 and 3000 mg/Kg by wood mice compared to the control. The maximum dose of BAS 500 06 F consumed by mice during 8 hours of daily exposure was approximately 243 ± 25 mg formulation/ kg b.w./day, which is a factor of 2.2 less than the predicted total daily intake of 525.5 ± 25 mg formulation/ kg b.w./d recorded during the pre-exposure period on day -2.

Incorporation of BAS 500 06 F into diet blocks reduced food consumption of mice in the 150, 1500 and 3000 mg BAS 500 06 F/kg treatment groups by up to 40%, 59%, and 75% respectively, when compared to the control. This effect was consistent across the 3-days of exposure. This reduction in feeding on BAS 500 06 F treated blocks leads to clearly lower actual exposure levels as compared to predicted exposure levels based on pre-exposure consumption data.

Bodyweight loss on day 0 (i.e. first exposure day) and day 4 (i.e. last exposure day) was observed as a result of the experimental procedure similarly across the three treatment groups and the control.

During the treatment-free post-exposure period a full recovery of food consumption and body weight was observed, i.e. body weight was seen to exceed baseline weights (weights from day -2) on day 7 and day 9 during post-exposure.

In conclusion, there were no apparent significant adverse clinical or behavioral effects in wood mice exposed to dietary concentrations up to and including the highest test dose of 3000 mg BAS 500 06 F/kg diet.

Please note: the following detailed study summary presents data as given in the FERA report (BASF DocID 2012/1129348), as well as additional calculations. These additional calculations are fully based on the data presented in the FERA report, and are marked in the tables with a foot note. The calculations are included in the study summary in order to facilitate the comparison of the results from the present study with results from other acute toxicity studies with pyraclostrobin and BAS 500 06 F that are presented elsewhere.

I. MATERIAL AND METHODS

Test species: Wood mouse (*Apodemus sylvaticus*), age: over 6 weeks old; source: supplied from a FERA (Sand Hutton, York, YO41 1LZ, UK) breeding colony. Wood mice were housed individually throughout the study period

Test item: BAS 500 06 F, batch no. 0004863761, purity: content of a.s. in formulation: 201.0 g pyraclostrobin /L.

Test concentrations: Dietary concentrations of nominal 0 (control), 150, 1500 and 3000 mg BAS 500 06 F/kg diet (corresponding to analysed 0 (control), 33.04, 288.16 and 555.14 mg pyraclostrobin/kg diet).

Preparation of diet: Diet blocks of approx 10-15 g each were prepared from ground diet (Labdiet Certified Rodent Diet 5002) and egg white. The blocks were prepared to provide the test item incorporated at the required range of concentrations: 150, 1500 and 3000 mg BAS 500 06 F/kg diet.

Test design: 3 treatment groups and 1 control group with 6 animals (3 males and 3 females) per group were tested. Two replicates (one replicate = one mouse) of each treatment group and the control group were assessed on each test day. Note that, as the study did not need to be continuous, all mice began the acclimatization phase at the same time and continued up to day -2. Only two replicates (two mice) from each dose level were tested at a time and those mice not undergoing treatment remained on acclimatization conditions.

Pre-exposure period (-11 to -1): Wood mice were acclimatized to feeding on untreated diet blocks with two restricted 4 h feeding periods per day on 3 days (day -10 to day -6). To maximize their feeding rate wood mice were deprived of food for 12 h before the 1st 4 h feeding period, and between the 1st and 2nd feeding period. Wood mice that readily consumed untreated diet blocks were selected for the experiment. Normal intake rate was determined based on food consumption data for the untreated diet blocks. Based on the data gained over the pre-treatment period mice were randomly assigned to treatments on day -2.

Exposure period (day 0 to 4): Following a 12h period of food deprivation, animals were exposed on day 0 to BAS 500 06 F treated diet blocks for two 4 h periods separated by 2 hours food deprivation, and then access to untreated food for 6 hours for the remainder of the test day. To avoid disturbance, the intake of blocks was monitored remotely using video-recording of a balance reading and animal behaviour, where possible, simultaneously to determine behaviour during the 4 h exposure periods. The exposure day was then followed by a day of recovery (day 1) with ad libitum access to untreated food. This design (one day exposure, one day recovery) was repeated twice, but without video recording, so that each mouse had a total of three days of exposure, to reproduce the possible duration of exposure in the field and estimate the rate of food consumption.

Post-exposure period (day 5 to 9): The last exposure period on day 4 was followed by a recovery period where normal diet was available *ad libitum* for five days.

	Observations: Mice were observed at least daily during the test (when food was changed) until day 9. Assessment of weight of the untreated blocks at the beginning and end of exposure periods on days –10, -8, -6 and –2 in the pre-treatment period before the start of the test. The weight of test diet blocks (i.e. treated and untreated) at the beginning and end of treatment periods on the test day and on each of the 2 follow-on exposure days were assessed as well as the weight of normal ground diet consumed on Day 7 and 9 of the recovery period. The differences in weight of the food blocks at the beginning and end of relevant exposure and treatment periods, respectively, served as basis for the estimates of food consumption. Body weight of the mice was assessed at the beginning of the study (day –14), during the pre-trial period (day -7), before the test day (day -2), end of the test day (day 0), at the end of the follow-on period (day 4) and at the end of days 7 and day 9 during the recovery period.
Endpoints:	Mortality, feed consumption, body weight (b.w.).
Test conditions:	Room temperature was maintained at 16-20°C. Reversed daylight was used such that night corresponded to red light on from 09:00 PM to 01:00 AM (deprivation period starting on days before exposure, i,e. day -1, day 1 and day 3, respectively), dusk periods corresponded to low light on from 08:30 AM to 09:00 AM and 01:00 AM to 01:30 AM and the day period corresponded to main lights on from 01:30 AM to 08:30 AM (on exposure day 0, 2 and 4, respectively, with no food available). The change in light levels was monitored for each designated period at the beginning and end of the experimental phase.
Analytics:	The test substance concentrations in the diet blocks were analyzed using HPLC.
Statistics:	Descriptive statistic, in addition for each endpoint, food consumption (g), bodyweight (g) and time taken to start feeding on Day 0 (minutes) a repeated measures analysis was performed using a mixed-models approach to the analysis of covariance (ANCOVA).

II. RESULTS AND DISCUSSION

Analytical measurements

The results of the analytical verification of the concentration of the active substance pyraclostrobin in the diet were within a range of 89.2 to 106.2% of the nominal concentrations during the test (see Table 8.1.2.1-4). The biological results are based on the analytical values for the active substance.

Table 8.1.2.1-4: Summary of nominal and analysed concentrations of BAS 500 06 F and pyraclostrobin in test items

Nominal concentration of the formulation	Mean concentration of the formulation (n=3)	Nominal concentration of pyraclostrobin	Measured mean concentration of pyraclostrobin (n=3)	Verification of nominal concentration values
[mg BAS 500 06 F/kg]	[mg BAS 500 06 F/kg]	[mg a.s./kg]	[mg a.s./kg]	[%]
150[1)]	170[2)]	31.11[3)]	33.04[4)]	106.2[5)]
1500[1)]	1487[2)]	311.10[3)]	288.16[4)]	92.6[5)]
3000[1)]	2864[2)]	622.20[3)]	555.14[4)]	89.2[5)]

1) Values from Table S3 of the FERA report.
2) Values from Table S3 of the FERA report. Mean concentration of mg BAS 500 06 F/kg calculated based on 201.0 g/L and 1.037g/cm3 as stated in the foot note of table S3 of the FERA report.
3) Values specifically calculated for this study summary based on a density of 1.037g/cm^3 for the formulation and nominal 200 g a.s./L.
4) Values specifically calculated for this study summary from results as presented in Table S3 of the FERA report as mean value from three samples A, B and C for the respective test group concentration.
5) Values specifically calculated for this study summary by comparing nominal concentration values of the a.s. with the analytical values for the a.s.

Biological results

Mice were observed at least daily during the test (when food was changed) until day 9. There were no abnormal behaviour, mortalities and symptoms of poisoning (e.g. pathological observations in mortalities during the treatment period).

1. Food consumption

Incorporation of BAS 500 06 F in the diet lead to reduced mean food consumption by the wood mice. This effect did not change over the 3 days of exposure (day 0, day 2 and day 4). The mean food consumption was reduced up to 40%, 59%, and 75% compared with controls in the 150, 1500 and 3000 mg BAS 500 06 F/kg diet dose group, respectively. The mean food consumption on each of the exposure days (day 0, day 2 and day 4) and food consumption compared with controls (in percent) is shown in Table 8.1.2.1-5. Baseline consumption was defined as the amount eaten on day -2. The control group did show a slight increase in baseline consumption. The difference between control and treated groups was statistically significant for the 1500 mg BAS 500 06 F/kg ($p=0.009$) and 3000 mg BAS 500 06 F/kg ($p\leq0.0001$) treatment groups (Quantics Report_20140101, p. 10) however there was no significant difference between control and 150 mg BAS 500 06 F/kg treatment group.

Table 8.1.2.1-5: Mean food consumption across treatment groups (standard errors are in brackets)

Test group		Control	150 mg BAS 500 06 F/kg	1500 mg BAS 500 06 F/kg	3000 mg BAS 500 06 F/kg
Day 0	Consumption [g][3)]	2.94 (±0.2)	2.30 (±0.1)	1.74 (±0.2)	1.29 (±0.1)
	Compared with control [%][3)]	100	78.2	59.0	43.9
Day 2	Consumption [g][3)]	3.19 (±0.3)	2.40 (±0.2)	2.01 (±0.2)	1.54 (±0.2)
	Compared with control [%][3)]	100	75.0	63.3	48.3
Day 4	Consumption [g][3)]	3.16 (±0.3)	2.92 (±0.4)	1.98 (±0.3)	1.27 (±0.1)
	Compared with control [%][3)]	100	92.4	62.6	40.1

1) Based on a density of 1.037g/cm^3 for the formulation and nominal 200 g a.s./L.
2) Calculated from results as presented in Table S3 (FERA Report) as mean value from three samples A, B and C for the respective test group concentration.
3) Data from Table 4 of the FERA Report

In conclusion, this reduction in feeding on BAS 500 06 F treated blocks leads to clearly lower actual exposure levels as compared to the exposure levels predicted on pre-exposure consumption data, and could in turn be seen as a mechanism to reduce risk.

2. Intake of formulation and pyraclostrobin

While the mean consumption of diet treated with BAS 500 06 F by wood mice was reduced compared to controls due to lower initial consumption, the overall feeding pattern was similar between treatment and control groups.

Mean ingestion of BAS 500 06 F and pyraclostrobin over the two 4 h periods on each exposure day, as well as the highest intake within a 4 h period on each day, are shown below (Table 3 and 4). The estimated potential intake (predicted dose) for BAS 500 06 F based on the pre-exposure feeding rate for the same mice on day -2 is as well given for comparison.

The actually ingested mean daily dose over the treatment days is 19.0, 148.8, and 216.4 mg BAS 500 06 F/kg b.w./day for the treatment groups of 150, 1500, and 3000 mg formulation/kg diet, respectively (Table 8.1.2.1-6).

The actually ingested mean daily dose for pyraclostrobin over the treatment days is 3.7, 28.8, and 41.9 mg a.s./kg b.w./day for the treatment groups of 150, 1500, and 3000 mg formulation/kg diet, respectively (Table 8.1.2.1-6).

In comparison, the predicted mean daily dose over the treatment days was 4.4 mg a.s./kg b.w. (equivalent to 22.5 mg BAS 500 06 F/kg b.w.) for the 150 mg formulation/kg diet treatment group, 48.0 mg a.s./kg b.w. (equivalent to 247.4 mg BAS 500 06 F/kg b.w.) for 1500 mg formulation/kg diet treatment group and 101.9 mg a.s./kg b.w. (equivalent to 525.6 mg formulation/kg b.w.) for 3000 mg formulation/kg diet treatment group (see Table 8.1.2.1-6).

Table 8.1.2.1-6: Mean total daily intake of BAS 500 06 F and pyraclostrobin over two 4-hour periods in treatments and control on each treatment day (standard errors are in brackets)

Test group [Nominal concen-tration mg BAS 500 0 6 F/kg diet]	**Day 0**			**Day 2**			**Day 4**

1) Values for mean total daily intake from Table 2 of the FERA report.
2) Values for mean total daily intake of pyraclostrobin specifically calculated for this study summary from results *for* mg BAS 500 06 F/kg b.w. as presented in Table 2 of the FERA report considering 201 g a.s./L (analysed) and a density of 1.037g/cm^3.
3) Mean value (n=3, from day 0, day 2 and day 4).

The maximum mean intake of pyraclostrobin in any single 4-hour period in the 150 mg BAS 500 06 F/kg diet treatment group was 2.2 mg a.s./kg b.w. (equivalent to 11.1 mg BAS 500 06 F/kg b.w.) on day 2, in the 1500 mg BAS 500 06 F/kg diet treatment group was 16.0 mg a.s./kg b.w. (equivalent to 82.4 mg BAS 500 06 F/kg b.w.) on day 0 and in the 3000 mg BAS 500 06 F/kg diet treatment group was 23.9 mg a.s./kg b.w. (equivalent to 123.5 mg BAS 500 06 F/kg b.w.) on day 0 (see Table 8.1.2.1-7).

Table 8.1.2.1-7: Maximum mean intake of BAS 500 06 F and pyraclostrobin in any single 4-hour period in the treatment groups (standard errors are in brackets)

Test group [Nominal test item concentration [mg BAS 500 06 F/Kg diet]	**Day 0**		**Day 2**		**Day 4**		**Predicted dose** (Estimated 4-hour intake based on maximum day -2[1)] 4-hour intake rate)	
	[mg BAS 500 06 F/kg b.w.][1)]	**[mg pyraclostrobin/kg b.w.][2)]**	**[mg BAS 500 06 F/kg b.w.][1)]**	**[mg pyraclostrobin/kg b.w.][2)]**	**[mg BAS 500 06 F/kg b.w.][1)]**	**[mg pyraclostrobin/kg b.w.][2)]**	**[mg BAS 500 06 F/kg b.w.][1)]**	**[mg pyraclostrobin/kg b.w.][2)]**
150	10.2 (±1.88)	2.0	11.1 (±1.7)	2.2	10.7 (±1.6)	2.1	13.0 (±1.7)	2.5
1500	82.4 (±4.7)	16.0	78.4 (±15.1)	15.2	73.6 (±21)	14.3	154.6 (±22.7)	30.0
3000	123.5 (±15.5)	23.9	122.4 (±21.5)	23.7	99.2 (±13.8)	19.2	307.3 (±37.5)	59.6

1) Values for maximum mean intake from Table 3 of the FERA report.
2) Values for maximum mean intake of pyraclostrobin specifically calculated for this study summary from results for mg BAS 500 06 F/kg b.w. as presented in Table 3 of the FERA report considering 201 g a.s./L (analysed) and a density of 1.037g/cm^3.

The actual ingested dose per day compared with the predicted dose was a maximum of 39% on day 0, 46% on day 2 and 38% on day 4 in the 3000 mg/kg diet treatment, 54% on day 0, 65% on day 2 and 62% on day 4 in the 1500 mg/kg diet treatment and 78% on day 0, 81% on day 2 and 94% on day 3 in the 150 mg/kg diet treatment (see Table 8.1.2.1-8).

Table 8.1.2.1-8: Proportion of actual exposure compared with predicted exposure for BAS 500 06 F[1)]

Test group [Nominal test item concentration]	**150 [mg BAS 500 06 F/kg]**	**1500 [mg BAS 500 06 F/kg]**	**3000 [mg BAS 500 06 F/kg]**

Day 2	81%	65%	46%
Day 4	94%	62%	38%

1) Values from Table 1 of the FERA report

3. Post-trial recovery of diet intake

During the post-administration period a full recovery of food consumption was observed. Mean food consumption values during the recovery period (day 7 and day 9) are presented in Table 8.1.2.1-9 together with consumption values for day -2 (pre-exposure) and exposure days 0, 2 and 4. Consumption rates on day 7 and day 9 (post-exposure) were based on normal (ground) diet ad libitum for a 24h period. In contrast, consumption rates for pre-exposure (day -2) and exposure period (day -2, 0, 2 and 4) are based on restricted feeding for 8 hours (two-times of 4 h) within 24 h on a diet block.
Statistical analysis could not be performed on the recovery data as there was an incomplete data set for Day 9 data (Quantics Report_20140101, p. 7).

Table 8.1.2.1-9: Mean total daily diet intake of woodmice during the study from day -2 to day 9

Test group [Nominal test item concentration [mg BAS 500 06 F/kg diet]]	**Day -2[1)] [g diet]**	**Day 0[1)] [g diet]**	**Day 2[1)] [g diet]**	**Day 4[1)] [g diet]**	**Day 7[2)] [g diet]**	**Day 9[2)] [g diet]**
0	2.87	2.94	3.19	3.16	5.10	5.93[3)]
150	2.96	2.30	2.40	2.92	5.84	8.24[4)]
1500	3.27	1.73	2.02	1.98	4.87	4.39[3)]
3000	3.35	1.29	1.54	1.27	4.39	4.67[3)]

1) Mean total daily intake over two 4-hour periods. Data from Table 2 of the FERA Report.
2) Total consumption in a 24-hour period. Data from Table S1 of the FERA Report.
3) Based on data from only four individual wood mice (n=4). All other data are based on n=6 (see Quantics Report_20140101, p. 17, Appendix I)
4) Based on data from only three individual wood mice (n=3). All other data are based on n=6. (see Quantics Report_20140101, p. 17, Appendix I)

There was no evidence of any sustaining long-term effect of the treatment on the food consumption of the mice during the recovery period.

4. Body weight data

Bodyweight at day -2 was defined as the baseline weight for each woodmouse. Initial body weight on day -2 was found to be a significant factor (p = 0.01) in the longer term fluctuations in body weight and was therefore used as a covariate in all analysis (please refer to Table 6, Table 7 and Figure 4 of Quantics Report_20140101). There was no indication of a significant treatment (p=0.9044) or time by treatment effect (p=0.1933). Across all treatment groups and the control, a significant change in body weight with time (p < 0.0001) could be observed (Quantics Report_20140101, Table 6).

Body weight dropped below baseline levels on day 0 and rose slightly but remained below baseline on day 4. During recovery, when animals had unrestricted access to normal diet, weights peaked above baseline levels on day 7 and stayed around baseline levels on day 9. Please refer to Table 8.1.2.1-10 for mean bodyweight data. Woodmice appear to have over compensated for the initial weight loss and then stabilised. There was no significant difference between treatment groups (Quantics Report_20140101, Table 6) and although body weight does change with time the pattern of change is similar across treatment groups. This suggests that the drop in body weight seen on day 0 and day 4 is a result of the experimental procedure and not a result of exposure to BAS 500 06 F.

Table 8.1.2.1-10: Mean body weight of woodmice during the study from day -2 to day 9[1)]

Nominal test item concentration [mg BAS 500 06 F/kg diet]	Day -2 [g]	Day 0 [g]	Day 4 [g]	Day 7 [g]	Day 9 [g]
0	20.2	18.9	19.5	20.9	20.3
150	20.8	19.9	20.1	21.0	20.2
1500	19.7	18.7	18.9	19.7	19.4
3000	19.3	18.0	18.5	19.8	19.4

1) Values from Table E Appendix 6 of the FERA report.

In conclusion, bodyweight loss was observed during the treatment period (day 0 and 4) was attributed to the experimental procedure and are not considered as a result of exposure to BAS 500 06 F. The pattern of weight change was similar over time across treatment groups and control. There was no indication of any significant treatment or time by treatment effect.

During the post-administration period a recovery of body weights was observed. Body weight reached baseline weights (weights from day -2) on day 7 and day 9, indicating any sustaining long-term effect of the treatment on the body weight of the mice.

5. Time of feeding

There was no impact on the time to start feeding as assessed during the morning and afternoon on day 0, with respect to either treatment or time. Overall, a similar pattern of intake was present in the treatment groups and the control, but initial food consumption was lower in the treatments.

Feeding rate for the control animals peaked in the first 30 min of the first 4 h exposure period (9.0 g diet/kg b.w./15 min) and in 15 min of the second exposure period (20.9 g diet/kg b.w./15 min). Using these figures to predict exposure levels, the highest dose rate (3000 mg formulation/kg diet) would receive the equivalent of 27.1 mg formulation/kg b.w./15 min and 62.7 mg formulation/kg b.w./15 min, respectively. This was much higher than was actually seen, as the 3000 mg formulation/kg diet group received a maximum of 10.5 ± 3.9 mg formulation/kg b.w./15 min in the first and 9.3 ± 6.8 mg formulation/kg b.w./15 min in the second exposure. Therefore, predicting exposure levels from untreated consumption data would over estimate exposure levels.

III. CONCLUSION

There were no apparent significant adverse effects either clinical or behavioural from exposure of wood mice with dietary concentrations up to 3000 mg BAS 500 06 F/kg diet. No mortalities or symptoms of poisoning (e.g. pathological observations in mortalities during the treatment period) were observed.

Dose-dependent reductions in food consumption were observed in all treated test groups consistently during the exposure period.

This reduction in feeding on BAS 500 06 F treated blocks leads to clearly lower actual exposure levels as compared to the exposure levels predicted on pre-exposure consumption data. i.e. the maximum dose of BAS 500 06 F consumed by mice during 8 hours of daily exposure was approximately 243 ± 25 mg formulation/ kg b.w./d, which is a factor of 2.2 less than the predicted total daily intake of 525.5 ± 25 mg formulation/ kg b.w./d recorded during the pre-exposure period on day -2.

Bodyweight loss on day 0 and day 4 was observed as a result of the experimental procedure similarly across treatment groups and control.

During the post-exposure period (day 7 and 9) a full recovery of food consumption and body weights was observed, i.e. body weight was seen to exceed baseline weights on day 7 and day 9 during post-administration.

Report: CA 8.1.2.1/4
Mastitsky S. et al., 2014a
A body burden model to assess the acute dietary risk posed by formulated Pyraclostrobin (BAS 500 06 F) to the common vole, Microtus arvalis
2014/1001603
Guidelines: <none>
GLP: no

Executive Summary

A Tier 1 ecotoxicological risk assessment of the fungicidal product BAS 500 06 F (active substance pyraclostrobin) identified an uncertainty with respect to the acute risk to small herbivorous mammals. This study presents a refined risk assessment based on the body burden modeling approach, one of the higher tier options offered by the EFSA (2009) guidance document on risk assessment for birds and mammals. A body burden model is a mechanistic model that describes the internal content of a chemical in the body over time based on the knowledge about the toxicokinetic properties of that chemical and the foraging behavior of the species of interest. Considering the application timing of BAS 500 06 F in cereals (BBCH ≥ 40), the common vole is recommended by the EFSA guidance as a representative species of the guild of small herbivorous mammals. Thus, the body burden model presented herein focuses on the common vole and the active substance pyraclostrobin applied as a formulated product BAS 500 06 F in cereals.
The model developed in this study was a stochastic simulation model that predicted the internal content of pyraclostrobin in 1000 common voles, which started feeding on the contaminated diet composed of grass and cereal shoots immediately after application of the fungicide. The simulated period lasted for 48 hours. Due to the imposed heterogeneity with respect to their body weight, biokinetic parameters and foraging schedules, the voles demonstrated individual-specific temporal profiles of the internal content of pyraclostrobin, allowing for a quantitative probabilistic assessment of the acute risk. The risk was calculated as the percentage of individuals whose body burden exceeds a certain toxicological threshold. The employed toxicological threshold of 9.6 mg a.s./kg b.w. was derived from an acute oral rat laboratory study with the product BAS 500 06 F (BASF DocID 2007/1053390) by dividing the respective LD_{50} by a safety factor of 10. The latter safety factor was applied in order to cover the uncertainty associated with the interspecies extrapolation.
The selected toxicological threshold was not exceeded by any individual in any of the 2000 model runs (two-dimensional Monte Carlo simulations). This result suggests that the common voles feeding on grass and cereal shoots in a cereal field during 48 hours after treatment with 1.25 L/ha of BAS 500 06 F (corresponding to the rate of 250 g pyraclostrobin per ha) are highly unlikely to experience acute effects. Due to the high level of realism implemented in the foraging submodel, as well direct incorporation of the uncertainties about input model parameters into the calculations, the presented risk estimate can be characterized as robust.

I. MATERIAL AND METHODS

The body burden model presented herein is a stochastic simulation model allowing for conducting a probabilistic risk assessment. The model developed in this study was a stochastic simulation model that predicted the internal content of pyraclostrobin in 1000 common voles, which started feeding on the contaminated diet composed of grass and cereal shoots immediately after application of the fungicide. The simulated period lasted for 48 hours. Due to the imposed heterogeneity with respect to their body weight, biokinetic parameters and foraging schedules, the voles demonstrated individual-specific temporal profiles of the internal content of pyraclostrobin, allowing for a quantitative probabilistic assessment of the acute risk. The risk was calculated as the percentage of individuals whose body burden exceeds a certain toxicological threshold. The employed toxicological threshold of 9.6 mg a.s./kg b.w. was derived from an acute oral rat laboratory study with the product BAS 500 06 F (BASF DocID 2007/1053390, for detailed study summary please refer to chapter M-CP 7.1.1.1) by dividing the respective LD_{50} by a safety factor of 10. The latter safety factor was applied in order to cover the uncertainty associated with the interspecies extrapolation.

II. RESULTS AND DISCUSSION

Probabilistic assessment of the risk
Results show that this threshold was not exceeded in any of the simulated individuals, suggesting that the common voles feeding on a diet composed of grass and cereal shoots in a cereal field during 48 hours after foliar spray with BAS 500 06 F according to the GAP are highly unlikely to experience acute effects.

Sensitivity analysis
The conducted sensitivity analysis showed that most of the input model parameters had a very low or no influence on the calculated endpoints, suggesting that one would obtain stable risk estimates irrespective of the variation of these parameters within the specified ranges. The only (expected) exception was the biokinetic parameter, which is related to the elimination half-life of pyraclostrobin.

Evaluation of the non-modeled uncertainties
As explained in sections 3.2 Uncertainty and variability in the model inputs and 3.3 Two-dimensional Monte Carlo simulation of the study report, the uncertainty about model inputs was explicitly incorporated into the estimate of the acute risk posed by pyraclostrobin to the common vole. However, there were other, non-modeled, sources of uncertainty, which could potentially influence the estimate of risk. Sources deemed particularly important are summarized in Table 5 of the study report.

Validation of the model predictions
Comparing the model outputs with the available independent data suggests that the body burden model presented herein provides realistic predictions with regard to the acute risk posed by pyraclostrobin to the common voles feeding on the BAS 500 06 F-contaminated food.

III. CONCLUSION

This study aimed at conducting a probabilistic assessment of the acute risk posed by the active substance pyraclostrobin (applied as the fungicidal product BAS 500 06 F in cereal fields) to the common vole, a relevant focal species according to EFSA (2009). The assessment conducted using a specially developed body burden model showed that, when applied according to GAP, BAS 500 06 F is highly unlikely to cause acute effects in common voles feeding on the contaminated food for 48 hours after application. Due to a high level of realism with respect to the foraging behavior of common voles implemented in the model, as well as the direct incorporation of uncertainties about input model parameters into the calculations, the presented risk estimate can be characterized as robust. This assessment was conducted using the best data available.

CA 8.1.2.2 Long-term and reproductive toxicity to mammals

Long-term and reproductive toxicity to mammals is discussed in M-CA 5.6. The studies previously evaluated during the Annex I inclusion process are considered to be still valid and sufficient. Therefore, no new studies have been conducted with the active substance.

The following studies are no toxicity studies with mammals. However, these studies are summarised here as they provide data from new studies relevant for the mammalian long-term/reproductive risk assessments with the representative formulation BAS 500 06 F. The field study BASF DocID 2014/1000041 addresses acute and long-term effects of BAS 500 06 F on populations of small mammals. As only low numbers of voles were trapped in the first field effect study, a second field effect study (BASF DocID 2015/1126803) was conducted as follow-up. **The new study also shows no adverse acute and long-term effects of BAS 500 06 F on common vole populations in meadows.** The full summary of this new study has been added to this document (CA 8.1.2.2/2).

Please note that the following studies CA 8.1.2.2/1, CA 8.1.2.2/3 and CA 8.1.2.2/4 were erroneously listed as CP 10.1.2.2/1+3+4 in the Application submitted in January 2014 for the renewal of approval of pyraclostrobin.

Report:	CA 8.1.2.2/1 [redacted], 2014a Field study on the acute and long-term effects of a Pyraclostrobin formulation (BAS 500 06 F) applied as foliar spray in spring to cereals on populations of small mammals (wood mice and common voles) in Central Europe (Germany) 2014/1000041
Guidelines:	<none>
GLP:	yes (certified by Landesamt fuer Umwelt, Messungen und Naturschutz Baden Wuerttemberg, Karlsruhe, Germany)

Executive Summary

The study investigated the potential acute and long-term effects of the pyraclostrobin formulation BAS 500 06 F, applied as foliar spray to cereals in spring, on wood mouse and common vole populations. Long-term effects were investigated by comparing species abundance and population development in BAS 500 06 F – in treated winter cereal fields and untreated winter cereal fields over a period of six months.

This study showed no impacts of the fungicide BAS 500 06 F applied to winter cereal under field conditions on resident small mammal populations, of which eight different parameters (captures/individuals in- and off-crop, trapping efficiency, minimum number alive, population growth rate, percentage of reproductively active individuals, percentage of juveniles, percentage of females, and adult body weight) were monitored for the whole growth period of winter cereal in Germany. This could clearly be demonstrated for the resident wood mouse (*Apodemus sylvaticus*) populations. Although sample sizes were low for the common vole (*Microtus arvalis*) populations, no impacts of the fungicide BAS 500 06 F on a low-density population of common voles could be shown.

I. MATERIAL AND METHODS

Study site: The study was conducted between April 2013 and October 2013 in twelve winter cereal fields in the vicinity of the villages of Limburgerhof and Altrip in the federal state of Rhineland-Palatinate in Germany. The size of the study fields ranged between 2.0 ha and 5.5 ha.
Application: Six study fields were treated with the fungicide BAS 500 06 F (treatment fields). The first application was carried out at the early plant growth stage around BBCH stage 25 to 30, and the second application was conducted 20 days after the first application which was according to the use pattern. The remaining six study fields received no BAS 500 06 F treatment (control fields).

Test organisms: Test organisms were free-living, wild populations of the wood mouse (*Apodemus sylvaticus*) and the common vole (*Microtus arvalis*) naturally inhabiting the selected study fields and directly adjacent habitats.
Trapping: Live trapping (capture-mark-recapture) was carried out to compare the abundance and population dynamics of small mammal species in treated and untreated winter cereal fields and adjacent off-crop areas. Eighty Ugglan multiple-capture traps were set up in each study plot, with 60 traps placed inside the cereal field and 20 traps placed in the off-crop area adjacent to the study field. Study plots were defined as the area covered by the small mammal trapping grid. Captured individuals were marked with Passive Integrated Transponders (PIT) for individual identification. A total of ten trapping sessions, each trapping session consisting of three consecutive nights of trapping and one night of pre-baiting, were performed in each study field. Trapping commenced prior to the first application of BAS 500 06 F and continued until October 2013 in accordance with agricultural practice after harvest, crop rotation and the development of the following crop on the study fields. This monitoring method allowed assessing the trapping efficiency and Minimum Number Alive (MNA), the rate of population growth, the rate of reproduction, the proportion of juveniles, the sex ratio and the development of the body weight throughout the Field Phase. To assess whether the treatment with BAS 500 06 F had any effects on mice and vole species, the results of the above mentioned parameters of the six treatment fields were compared with those of the six control fields.

II. RESULTS AND DISCUSSION

a) Wood mouse (Apodemus sylvaticus)
The trapping efficiencies of wood mice in the in-crop habitats were comparable in treatment and control plots over the course of the Field Phase. The trapping efficiencies in the in-crop habitats of the treatment plots experienced a noticeable increase after the second application of BAS 500 06 F (after trapping session 3), while the trapping efficiencies in the in-crop habitats of the control plots increased only gradually. The relatively high trapping efficiencies in the in-crop habitats of treatment and control plots (trapping session 4 until trapping session 8) indicate that wood mice preferentially used the in-crop habitats during the times of advanced crop development. After the study fields were harvested there was a shift in habitat use from the in-crop habitat to the off-crop habitat.
The minimum number of individual wood mice alive (MNA) showed a similar pattern in control and treatment plots over the course of the Field Phase. However, MNAs in the treatment plots increased considerably until the population maximum was reached at trapping session 5 (mid-May). On the other hand, MNAs in the control plots increased only gradually and reached the population maximum at a later stage (trapping session 7; around end of June). Altogether, this also indicates that there are no acute effects of BAS 500 06 F on wood mouse populations, considering that MNAs increased even shortly after each application with BAS 500 06 F. The MNAs in the control plots never reached the maximum of the MNAs in the treatment plots. The population growth rate showed a similar pattern to the MNA values in control and treatment plots.

At the beginning of the trapping period, almost all individuals captured in treatment and control plots were reproductively active. Over the course of the reproductive season of wood mice and after treatments with BAS 500 06 F the percentage of reproductively active individuals in control and treatment plots followed an almost identical development from trapping session 3 until the end of the trapping period.
The mean percentage of juvenile wood mice over the course of the Field Phase followed a similar pattern in treatment and control plots. In treatment and control plots the percentage of juveniles was low during the first trapping sessions (early April), as expected at the beginning of the reproductive season of small mammals in Central Europe.
The percentage of female wood mice followed a similar pattern in control and treatment plots. The sex ratio remained below 50% in control and treatment plots in all trapping sessions except for the trapping session that was conducted after harvest (trapping session 9).
The development of the mean body weight of adult wood mice across all trapping sessions followed a similar pattern in treatment and control plots. Mean body weight decreased in the last two trapping sessions in both control and treatment plots, which reflects the normal development.
The mean recapture rate of marked wood mice was similar in treatment and control plots, indicating no difference in survival of wood mice. From trapping session 2 until 8 was the rate of recapture was in parts very high with almost 80%, but decreased after harvesting of the study fields (trapping session 9 and 10).

b) Common vole (Microtus arvalis)

The number of common voles captured was too low to infer any confident conclusions about abundance and population parameters in the treatment and control plots.

The trapping efficiencies of common voles in the in-crop habitats followed a very similar pattern in the treatment and control plots. Common voles were first trapped in in-crop habitats in trapping session 4 (beginning of May) after the second application of BAS 500 06 F. Thereafter numbers increased steadily until they reached a peak at trapping session 7 (around end of June) which was followed by a continuous decrease until the completion of the Field Phase. On the contrary, trapping efficiencies in the off-crop habitats of both treatment groups were very low, but showed a considerable increase during the last trapping session in October after the study fields were harvested. The low trapping efficiencies of common voles in the off-crop habitats reflect the low number of captured common voles in these habitats and may indicate the potential habitat preferences for this species.

The minimum number of common vole individuals alive (MNA) was similar in control and treatment plots throughout the trapping period. No common voles were captured in the first three trapping sessions in the treatment or in the control plots. The population maximum of common voles was reached at trapping session 7 (around end of June) at the time of high ground cover shortly before harvest. The population growth rate of common voles showed a similar pattern to the MNA values in control and treatment plots.

The mean percentage of reproductively active individuals fluctuated in control and treatment plots probably mainly due to the low number of individuals captured. In control and treatment plots the percentage of reproductively active common voles was highest in trapping session 8, coinciding with the time of highest ground cover. After harvest of the study fields the percentage of reproductively active individuals decreased again potentially reflecting the increased emigration from the study fields.

The mean percentage of juvenile common voles was low over the course of the Field Phase in control and treatment plots. In addition to the low number of juvenile captures, juveniles were not captured in all study fields. Thus no clear understandings of the dynamics of this parameter can be achieved due to the low sample size.

Meaningful statements on the development of the sex ratio of common voles cannot be made due to the sex ratio being based on very small sample sizes in control and treatment plots likewise.

Mean body weight of adult common voles was similar in control and treatment plots across trapping sessions. The body weight decreased slightly towards the end of the trapping period potentially indicating the potential decline in the number of pregnant females.

Some common voles were recaptured despite the overall low number of captured common voles in treatment and control plots.

III. CONCLUSION

In conclusion, this study showed no impacts of the fungicide BAS 500 06 F applied to winter cereal under field conditions on resident small mammal populations, of which eight different parameters (captures/individuals in- and off-crop, trapping efficiency, minimum number alive, population growth rate, percentage of reproductively active individuals, percentage of juveniles, percentage of females, and adult body weight) were monitored for the whole growth period of winter cereal in Germany. This could clearly be demonstrated for the resident wood mouse (*Apodemus sylvaticus*) populations. Although sample sizes were low for the common vole (*Microtus arvalis*) populations, no impacts of the fungicide BAS 500 06 F on a low-density population of common voles could be shown.

Report:	CA 8.1.2.2/2 Ziesemann B., 2016 a Field study on the acute and long-term effects of a Pyraclostrobin formulation (BAS 500 06 F) applied as foliar spray on meadows to populations of common voles in Central Europe (Germany) 2015/1126803
Guidelines:	OECD Principles of Good Laboratory Practice
GLP:	yes (certified by Landesanstalt fuer Umwelt, Messungen und Naturschutz Baden-Wuerttemberg, Karlsruhe, Germany)

Executive Summary

The present study aims to investigate potential acute and long-term effects of the fungicide BAS 500 06 F (containing the active substance pyraclostrobin) on common voles (*Microtus arvalis*) in agriculturally managed meadows. Meadows were used as a surrogate for other crop types to ensure sufficient numbers of common voles being exposed to the test item BAS 500 06 F. Acute and long-term effects were investigated by comparing common vole abundance and population parameters in BAS 500 06 F – treated and untreated meadows over a period that covered the reproductive season of common voles.

When applying BAS 500 06 F following the critical use pattern (2 x 250 g pyraclostrobin/ha), no negative effects were detected in any of the many investigated parameters throughout the study, i.e. no adverse acute and long-term effects of the fungicide BAS 500 06 F on common vole populations were found. This second field effect study therefore confirms the outcome of the first field effects study, and the result of the risk assessment presented in M-CP section 10.

I. MATERIAL AND METHODS

The study was conducted in agriculturally used meadows (study fields) in the vicinity of Dornburg in the Limburg-Weilburg district in Hessen, Germany, between May and October 2015. The size of the ten study fields ranged from 1.0 ha to 3.0 ha.

Five study fields were treated twice with BAS 500 06 F at a nominal application rate of 1.25 L product/ha (250 g pyraclostrobin/ha) in a spray volume of 200 L/ha. The first application was carried out on 08-11 June 2015 once common vole populations were large enough to ensure a sufficient part of the population to be exposed to the test item. The second application was conducted approximately three weeks later on 29 June - 04 July 2015. The remaining five study fields served as untreated control fields.

Live trapping (capture-mark-recapture) was carried out to compare abundance, population dynamics, age structure and reproduction of common voles in treated and untreated study fields. A total of 10 trapping sessions, each session consisting of one night of pre-baiting and three consecutive nights of trapping were performed.

Ugglan multiple-capture traps were used to live-trap small mammals. Sixty Ugglan multiple live capture traps were set up in each study field. Captured individuals were marked with Passive Integrated Transponders (PIT) for individual identification. All study fields were mowed before the trapping of common voles commenced and again in late summer (after trapping session 8 at the end of August 2015). This monitoring method allowed assessing the trapping success (number of captured animals and the number of individuals), the minimum number alive (MNA), the recapture rate, the sex ratio, the rate of reproduction, the proportion of juveniles, and the development of the body weight throughout the Field Phase which covered the majority of the reproductive season of common voles. In order to assess whether the treatment with BAS 500 06 F had any effects on common voles, the results of the above mentioned parameters of the five treatment fields were compared with those of the five control fields.

II. RESULTS

Overall, trapping success was high: 9161 captures of common voles were made in all study plots during the Field Phase of this study, including a total of 2495 individually marked animals.

Three abundance parameters were evaluated: number of captures and of individuals, minimum number of individuals alive (MNA) and recapture rate of marked individuals.

The number of individuals of common voles monitored was not statistically significantly different between control and treatment plots in any trapping session.

The minimum number of individual common voles alive (MNA) in the treatment and the control plots showed a similar pattern (Figure 1), and there were no statistically significant differences between the two groups.

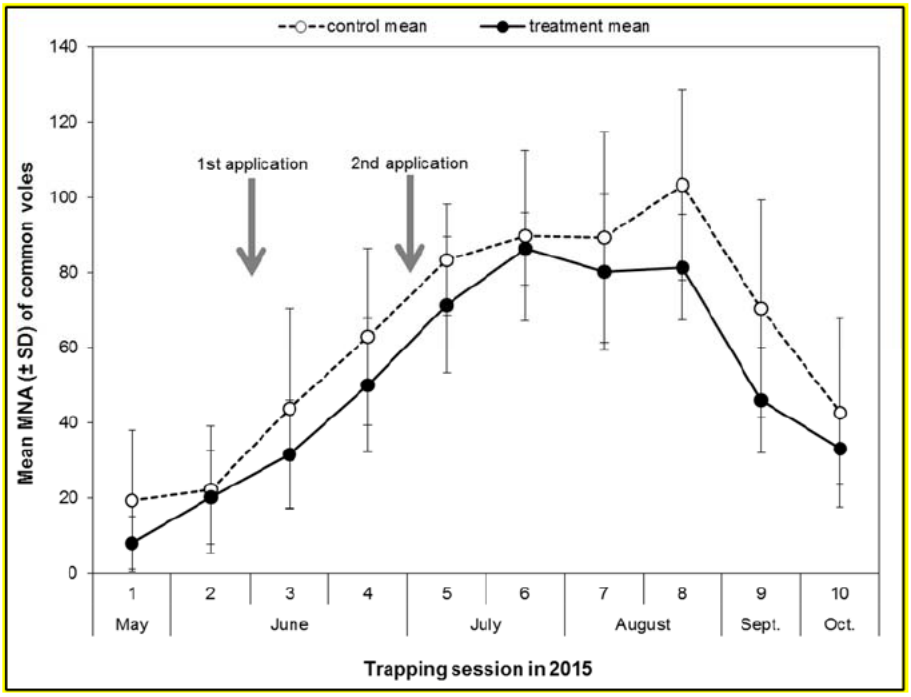

Figure 1: Mean of the minimum number of common voles alive (MNA) in control and treatment plots (the applications of BAS 500 06 F were conducted after trapping session 2 and 4. The error bars represent the standard deviation of the mean (± SD))

The mean recapture rate of marked common voles showed a similar development in treatment and control plots (Figure 2). The recapture rate of individuals exposed to BAS 500 06 F in the treatment plots was not statistically significantly different than the recapture rate of common voles in the control plots.

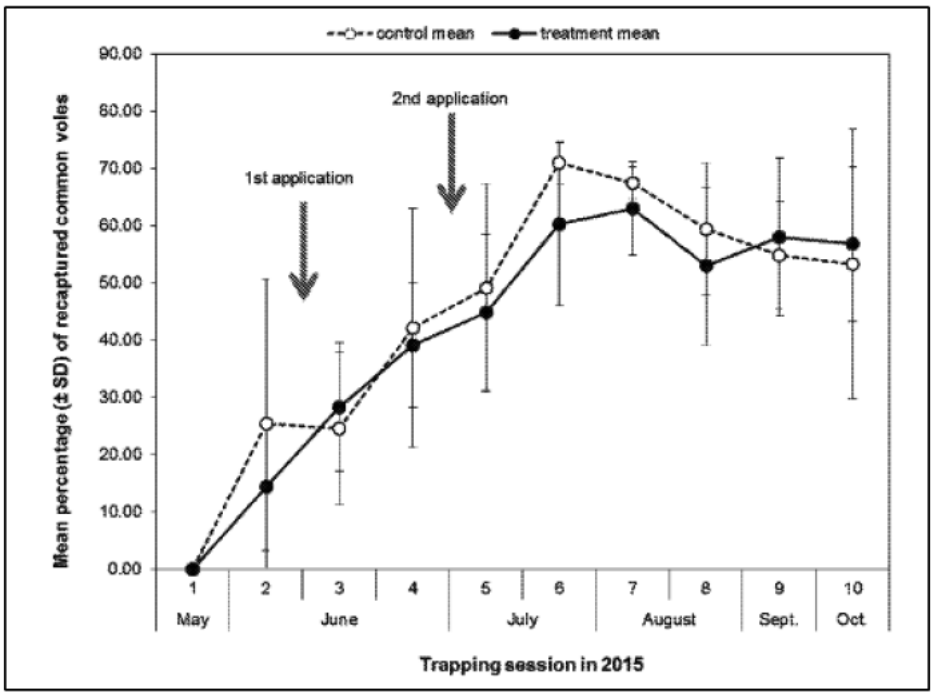

Figure 2: Mean recapture rate (%) of common vole individuals in control and treatment plots (legend as in Figure 1)

Four population parameters were evaluated: sex ratio (proportion of females and males), reproductive activity (proportion of reproductively active animals), age structure (proportion of juveniles), and bodyweight development.

The sex ratio of common voles was similar in treatment and control plots, and the proportion of females fluctuated almost consistently between 50-60% throughout the trapping period. No statistically significant differences in the percentage of female common voles were detected between control and treatment plots.

The proportion of reproductively active common voles followed a similar pattern in the control and treatment plots over the course of the study (Figure 3), with most trapping sessions without statistically significant differences between the two groups. After the second application of BAS 500 06 F, there was a marginal statistically significant difference (p=0.05) in trapping session no. 5, where the proportion of reproducing animals was even higher in the treatment plots than in the controls.

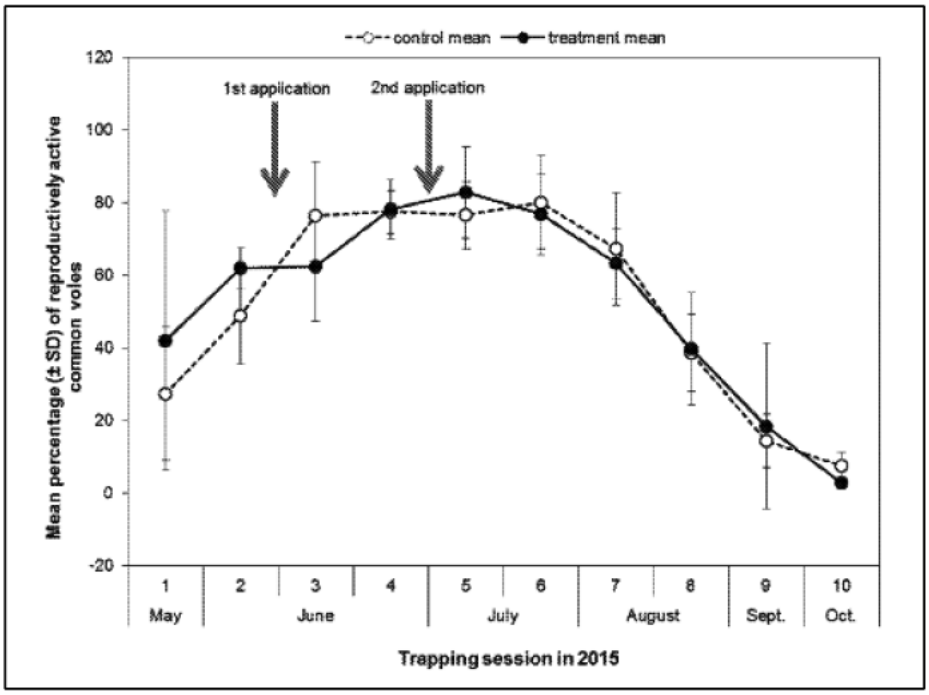

Figure 3: Mean percentage (%) of reproductively active common voles in control and treatment plots (legend as in Figure 1)

The pattern of the proportion of juveniles during the trapping period was similar in the control and treatments plots (Figure 4). The differences observed in trapping session no. 1 (before the application) was unrelated to treatment and likely biased by the low numbers of juveniles present at the early phases of the reproduction season.

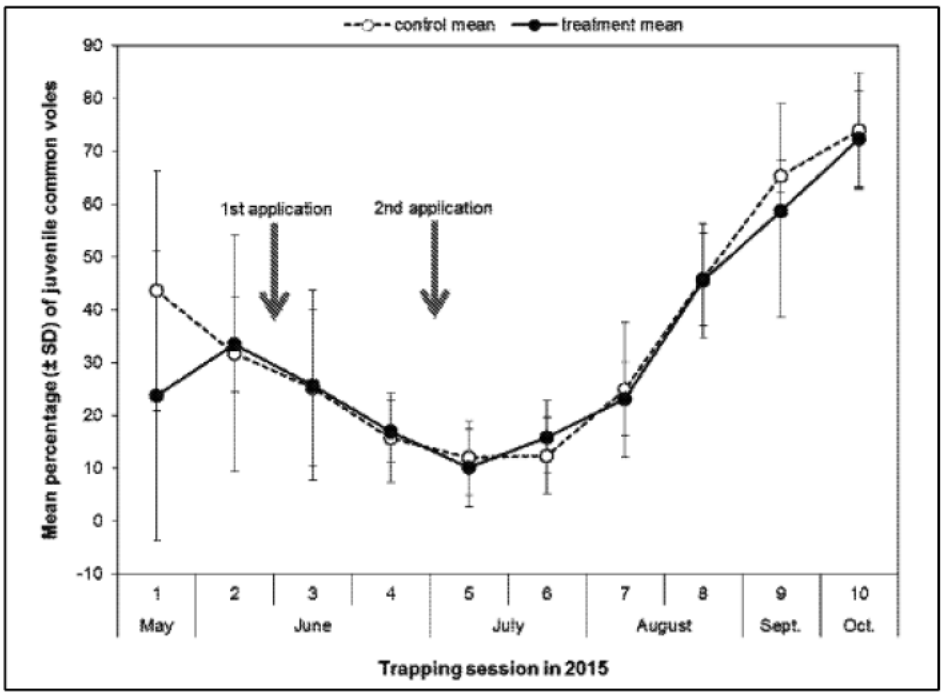

Figure 4: Mean percentage (%) of juvenile common voles in control and treatment plots (legend as in Figure 1)

The development of the mean body weight of adults (females and males) over the course of the trapping period was similar in control and treatment plots (Figure 5). The difference in the mean body weight of females and males was not statistically significant between control and treatment plots throughout the trapping period. The mean body weight of juveniles (females and males) was similar in both experimental groups throughout the trapping period (Figure 6). A decline in the mean body weight of juveniles after the second application of BAS 500 06 F occurred in both, control and treatment plots. Juvenile body weight was not statistically significantly different between control and treatment plots in any trapping session.

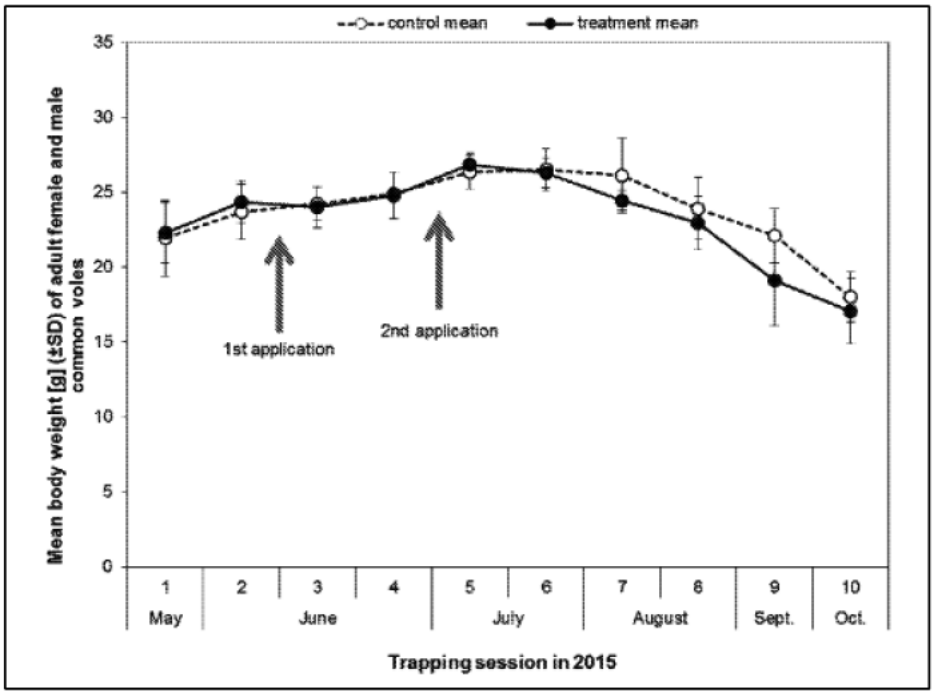

Figure 5: Mean body weight (g) of adult common voles (females and males) in control and treatment plots (legend as in Figure 1)

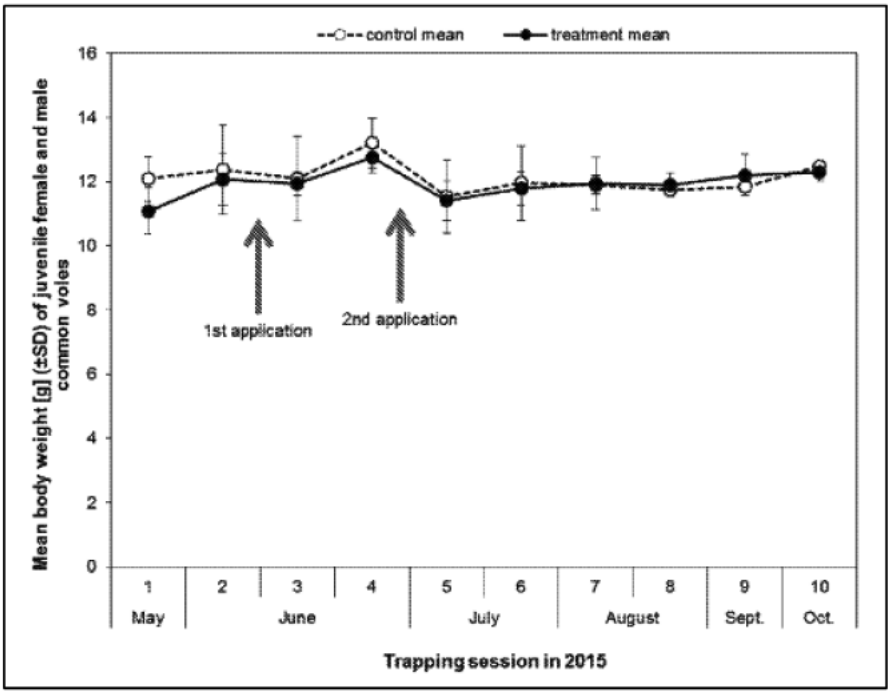

Figure 6: Mean body weight (g) of juvenile common voles (females and males) in control and treatment plots (legend as in Figure 1)

III. CONCLUSION

The study was conducted under realistic worst-case field conditions, i.e. in a preferred common vole habitat with high abundances of common voles. Therefore, the study is well appropriate to assess potential effects of pyraclostrobin (applied as BAS 500 06 F) on common voles on the population level.

When applying BAS 500 06 F following the critical use pattern (2 x 250 g pyraclostrobin/ha), no negative effects were detected in any of the many investigated parameters throughout the study, i.e. no adverse acute and long-term effects of the fungicide BAS 500 06 F (active substance pyraclostrobin) on common vole populations were found. This second field effect study therefore confirms the outcome of the first field effects study (BASF DocID 2014/1000041 shown above), and the result of the risk assessment presented in M-CP section 10.

Report:	CA 8.1.2.2/3 Moreno S., 2013a Study on the residue behaviour of Pyraclostrobin (BAS 500 F) on wheat (young plants) after treatment with BAS 500 06 F under field conditions in North and South Europe, season 2012 2013/1045207
Guidelines:	EEC 87/18 (No. L 15/29) 1986, International guidelines for distribution and pesticides application AEPLA FAO 1985, EC 1107/2009 of the European Parliament and of the Council of 21 Oct 2009, EEC 79/117, EEC 91/414, EEC 7029/VI/95 rev. 5 Appendix B, EEC 7525/VI/95 rev. 9 (March 2011)

Executive Summary

The objective of the study is to determine the magnitude of residues of pyraclostrobin (BAS 500 F) and the analyte 500M07 after one application of BAS 500 06 F carried out on wheat. The selected application rates, frequency and spray interval cover the Good Agricultural Practice (critical GAP).

I. MATERIAL AND METHODS

A. MATERIALS

Test item and application

The trial consisted of a control plot (untreated) and two treated plots (plot 2 and plot 3) without replication. No product containing the test item was used on the test plots during the season 2012.

The test item BAS 500 06 F (EC) was foliar applied on plot 2 at a nominal rate of 250 g pyraclostrobin/ha in a nominal spray volume of 200 L/ha at three leaves unfolded growth stage (BBCH 13) according to Good Laboratory Practice. The test item BAS 500 06 F (EC) was also foliar applied on plot 3 at a nominal rate of 100 g pyraclostrobin/ha in a nominal spray volume of 200 L/ha at three leaves unfolded growth stage (BBCH 13) according to Good Laboratory Practice.

B. STUDY DESIGN

Study site
During the 2012 growing season a total of nine trials were conducted in representative wheat growing areas in Germany, The Netherlands, The United Kingdom, Spain and Italy.

Sampling information
For this study specimens were collected as wheat whole plants without roots 1 hour after application as well as 1, 2, 3, 4, 5, 7, 10, 12 and 14 days thereafter. All specimens were sampled from the untreated, and from both treated plots. Untreated specimens were obtained prior to treated specimens at each sampling occasion. All specimens were transferred to freezer storage on the day of sampling and were then stored frozen (≤ -18ºC).

Residue analysis
All specimens were analyzed for pyraclostrobin (BAS 500 F) and its metabolite 500M07 (BF 500-3) using BASF method no. 535/1 (L0076/01). The method has a limit of quantitation of 0.01 mg/kg for both analyses.

2) conversion factor for calculation of 500M07 (BF 500-3) to parent BAS 500 F is 1.084
3) for residues < 0.010 mg/kg, value was set to 0.010 mg/kg for calculation of sum
4) HALA: hours after last application

III. CONCLUSION

In whole plant samples collected from plot 2 directly after the application (BBCH 13-14) residues of pyraclostrobin (BAS 500 F) ranged between 13 and 35 mg/kg. At the last sampling at 14 DALA (BBCH 13-31) residues decreased to a range of 0.028 – 5.5 mg/kg.
In whole plant samples collected from plot 3 directly after the application (BBCH 13-14) residues of pyraclostrobin ranged between 4.6 and 11 mg/kg. At the last sampling at 14 DALA (BBCH 13-31) residues decreased to a range of < 0.01 – 1.8 mg/kg. No residues of pyraclostrobin ≥ 0.01 mg/kg were present in control specimens.

Report:	CA 8.1.2.2/4 Martin T., 2013a Study on the residue behavior of Pyraclostrobin (BAS 500 F) on pea (young plants) after the application of BAS 500 06 F under field conditions in France (North), Germany, United Kingdom, Italy and Spain, 2012 2013/1044539
Guidelines:	EC 1107/2009 of the European Parliament and of the Council of 21 Oct 2009, EEC 79/117, EEC 91/414, EEC 7029/VI/95 rev. 5, EEC 7525/VI/95 rev. 7
GLP:	yes (certified by ENAC, Entidad Nacional de Acreditación, Madrid Spain)

Executive Summary

The objective of the study was to determine the residue level of pyraclostrobin (BAS 500 F) in or on young pea plants after one application of BAS 500 06 F.

I. MATERIAL AND METHODS

A. MATERIALS

Test item and application

Each trial consisted of a control plot (untreated) and two treated plots. All applications were made as foliar sprays, using commercial ground equipment or equipment which simulated commercial applications. No product containing the test item was used on the test plots during the year 2012. BAS 500 06 F was the test item used in this study. The actual application rates were within 10% of the nominal values.
The selected application rates, frequency and spray interval cover the Good Agricultural Practice (critical GAP), which will be defined by the label directions.

BAS 500 06 F (200 g/L of pyraclostrobin, EC) was foliar applied once on plot 2 at a rate equivalent to 250 g/ha of pyraclostrobin (1.25 L of formulated product /ha) and once on plot 3 at a rate equivalent to 100 g/ha of pyraclostrobin (0.5 L of formulated product /ha). The spray volume used was 200 L/ha and the application timing was at BBCH 12 - 13.

B. STUDY DESIGN

Study site
During the 2012 growing season, eight trials in peas were conducted in different representative growing areas in France (North), Germany, The United Kingdom, Italy and Spain.

Sampling information
Specimens of whole plant without roots were collected on plot 1 at the day of the application and 5 and 14 days thereafter. Specimens of whole plant without roots were collected on plot 2 and plot 3, 1 hour after the application and 1, 2, 3, 4, 5, 7, 10, 12 and 14 days thereafter.
Control (untreated) specimens were taken at every time point, and were collected prior to collection of the treated specimens to avoid contamination. Generally, the specimens were frozen within 6 hours of being taken, and remained frozen at or below -18°C, including during transportation, until analysis. The maximum storage interval from harvest until analysis was 188 days. Data indicate that residues were stable during the period of frozen storage prior to analysis.

Residue analysis
Specimens were analysed for pyraclostrobin (BAS 500 F) and its metabolite 500M07 (BF 500-3) using BASF method No. 535/1 (L0076/01). The method has a limit of quantitation of 0.01 mg/kg for both analytes.

1) days after last application
2) conversion factor for calculation of 500M07 (BF 500-3) to parent BAS 500 F is 1.084
3) for residues < 0.010 mg/kg, value was set to 0.010 mg/kg for calculation of sum
4) HALA: hours after last application

III. CONCLUSION

In whole plant samples collected from plot 2 directly after the application (BBCH 12-13) residues of pyraclostrobin (BAS 500 F) ranged between 11 - 23 mg/kg. Residues has been decreasing over the whole trial period and at last sampling at 14 DALA (BBCH 14-23) residues ranged between 0.14 - 1.4 mg/kg.

In whole plant samples collected from plot 3 directly after the application (BBCH 12-13) residues of pyraclostrobin ranged between 3.9 - 6.2 mg/kg. Residues has been decreasing over the whole trial period and at last sampling at 14 DALA (BBCH 14-23) residues ranged between 0.043 - 0.29 mg/kg.

No residues of pyraclostrobin ≥ 0.01 mg/kg were present in control specimens.

Please note, the following studies (CA 8.1.2.2/5 and CA 8.1.2.2/6), presenting the evaluation of residue data, were erroneously not listed in the Application submitted in January 2014 for the renewal of approval of pyraclostrobin. However, the two reports presenting the residue data, i.e. BASF DocID 2013/1045207 and BASF DocID 2013/1044539, were included in the Application (as CP 10.1.2.2/3 and 10.1.2.2/4) and are now submitted as CA 8.1.2.2/3 and CA 8.1.2.2/4.

Report:	CA 8.1.2.2/5 Erzgraeber B., 2013a Dissipation of BAS 500 F - Pyraclostrobin on young plants (wheat and peas) - Trials conducted in the Northern Zone of Europe - Calculation of DT50 / DT90 dissipation times 2013/1078114
Guidelines:	<none>
GLP:	no

Executive Summary

This modelling report provides kinetic analysis and estimation of dissipation times (DT_{50}, DT_{90} values) for pyraclostrobin on young plants.

The decline of pyraclostrobin residues on young plants was well described by this first order kinetics. The overall geometric mean DT_{50} of pyraclostrobin in young plants is 1.8 days (Northern Europe).

I. MATERIAL AND METHODS

Calculation of DT_{50} and DT_{90} values
The concentration time curves were described by a single first order (SFO) kinetic model, and this was fitted against the results of the individual trials using non-linear parameter estimation methods.

The goodness-of-fit of the kinetic models was assessed by visual inspection and statistical measures. For visual inspection, the recommended graphical representations of observed and modeled decline curves versus time and the residuals versus time are presented. As goodness-of-fit measures, the χ^2 minimum error level is provided.

II. RESULTS AND DISCUSSION

Table 8.1.2.2-3: Table DT_{50} and DT_{90} values of pyraclostrobin in young wheat plants and peas

[1)] and [2)] In 2012, BASF conducted 16 GLP field residue trials in the Northern Zone of Europe to obtain residue decline data in wheat and peas at early growth stages of the crops [Ref. 3, Ref. 4].
Wheat and peas were treated with either nominally 1.25 L (P2) or 0.5 L (P3) product BAS 500 06 F/ha. BAS 500 06 F contains 200 g pyraclostrobin/L, thus 250 g a.s./ha (P2) or 100 g a.s./ha were applied at BBCH 13 or 13/14 onto wheat and at BBCH 12-13 or 13 onto peas.

III. CONCLUSION

The decline of pyraclostrobin residues on young plants was well described by this first order kinetics. The overall geometric mean DT_{50} of pyraclostrobin in young plants is 1.8 days (Northern Europe).

[1)] and [2)] In 2012, BASF conducted 16 GLP field residue trials in the Southern Zone of Europe to obtain residue decline data in wheat and peas at early growth stages of the crops [Ref. 3, Ref.4].
Wheat and peas were treated with either nominally 1.25 L (P2) or 0.5 L (P3) product BAS 500 06 F/ha. BAS 500 06 F contains 200 g pyraclostrobin/L, thus 250 g a.s./ha (P2) or 100 g a.s./ha (P3) were applied at BBCH 13 or 13/14 onto wheat and at BBCH 12-13 or 13 onto peas.

[3)] In case of FOMC kinetic, a pseudo-SFO DT_{50} value for modeling is back-calculated from the DT_{90} as $DT_{50} = DT_{90}/3.32$.

[4)] trial discarded, since no acceptable fit could be achieved

III. CONCLUSION

The decline of pyraclostrobin residues on young plants was well described by this first order kinetics. The overall geometric mean DT_{50} of pyraclostrobin in young plants is 3.15 days (Southern Europe).

CA 8.1.3 Effects of active substance bioconcentration in prey of birds and mammals

The potential effects of active substance bioconcentration in prey of birds and mammals are addressed according to the guidance document EFSA/2009/1438 with the secondary poisoning risk assessments presented in the documents M-CP 10.1.1 and M-CP 10.1.2. All TER values exceed the trigger of 5 set by Commission regulation (EU) 546/2011 for acceptability of effects with considerable margins of safety. Consequently, no additional study is considered to be necessary.

CA 8.1.4 Effects on terrestrial vertebrate wildlife (birds, mammals, reptiles and amphibians)

According to the data requirements under regulation 1107/2009 (Commission Regulations (EU) 283/2013 and 284/2013 for the active ingredient and the plant protection products, respectively), the risk to amphibians and reptiles shall be addressed. However, there is no guidance or validated regulatory protocol yet available, neither on the type of the necessary regulatory testing nor how to conduct a risk assessment for amphibians and reptiles. Accordingly, specific toxicity tests for amphibian and reptile species are not requested.

Indications of a potential risk to amphibians and reptiles may be derived from findings or reports of adverse impacts and/or from literature data for existing substances.

An extensive literature search for pyraclostrobin and pyraclostrobin-containing plant protection products has not revealed any relevant information with respect to the risk of pyraclostrobin to reptiles. In addition, despite long-term extensive use of the substance worldwide, there has never been any reporting of adverse impacts on reptiles (or on adverse effects on birds and mammals) that the applicant is aware of. There is no indication from 'read across' that reptiles either could be particularly sensitive or would not be covered by the available vertebrate data and risk assessments. Accordingly, it can be concluded that applications of pyraclostrobin according to good agricultural practice will be of low risk to reptiles, too, analogous to birds and mammals.

However, there is literature on amphibians, which indicate that sensitive amphibian life stages may be vulnerable to pyraclostrobin, respectively to some of its formulations.
There are a few studies with aquatic life stages (tadpoles), which roughly reflect the toxicity observed with sensitive fish species. Summaries of these published studies are provided in M-CA 8.2.8). Some investigations indicate also toxicity to terrestrial life stages of amphibians. Summaries of the respective literature are provided below.

In addition, BASF has conducted own GLP laboratory and higher tier semi-field studies in order to assess the potential impact of pyraclostrobin applications to amphibians. These studies were conducted with the formulated product BAS 500 06 F (an EC-formulation considered to reflect the worst-case with respect to potential toxicity). The studies and a subsequent thorough risk assessment are provided in M-CP 10.1.3.

The following study investigates the acute toxicity of different fungicide formulations to juvenile Great Plains toad (*Bufo cognatus*) tadpoles and juveniles. In the following summary only the results for the pyraclostrobin containing formulation Headline® are presented.

Report:	CA 8.1.4/1 Belden J. et al., 2010a Acute toxicity of fungicide formulations to amphibians at environmentally relevant concentrations - Short communication 2014/1143801
Guidelines:	<none>
GLP:	no

Executive Summary

In a 72 h acute laboratory study tadpoles and juveniles of the Great Plains toad (*Bufo cognatus*) were exposed to Headline®, a fungicide with the active substance pyraclostrobin, at the following rates: 0.015, 0.15 and 1.50 mg a.s./L for tadpoles and 0.00022, 0.0022 and 0.0220 mg a.s./cm^2 for juveniles. Additionally, a dilution water control was set up for both tests. Each treatment consisted of three replicates. 9 - 10 juveniles per replicate were directly treated with an aerosol spray of formulation while contained in aquaria, whereas 20 tadpoles per replicate were exposed in water (static system).

Concentration of the active ingredient was measured within the spray mix used for juveniles and within the water used for tadpole testing at the beginning and end of the test. The mean concentration in the spray mix was between 89% and 102%.
For the highest treatment group no analysis of the concentration within the test water for tadpoles was done after 72 hours, because all individuals were dead within 24 hours. After 3 hours the mean measured value for pyraclostrobin within the test water for tadpoles was 80% of nominal. The following biological results are based on nominal concentrations of the active substance.

All aquatic concentrations resulted in 100% mortality of *B. cognatus* tadpoles. The medium and highest concentrations resulted in significant toxicity to juveniles ($F_{3,8} = 37.9$; $p < 0.001$). Most of the mortality occurred within the first 24 h (>90%) for both juveniles and tadpoles.

Acute laboratory studies with tadpoles (aquatic exposure) and juveniles (terrestrial exposure) of *Bufo cognatus* exposed to the formulation Headline® resulted in 100% mortality of tadpoles at concentrations equivalent to 0.015, 0.15 and 1.50 mg a.s./L in an aquatic system. Terrestrial exposure showed 100% juvenile mortality at 22 µg a.s./cm^2 and about 70% mortality at 2.2 µg µg a.s./cm^2 while 0.22 µg a.s./cm^2 caused no significant effect.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Headline® (EPA Reg. No. 7969-186; purchased from a local distributor) containing the active substance pyraclostrobin.

B. STUDY DESIGN

Test species: Great Plains toad (*Bufo cognatus*) tadpoles and juveniles, tadpoles: obtained from in-house culture, 7 days old, parents were wild caught; juveniles: wild caught near wetlands in western Texas, age: ≈ 60 d post-metamorphosis.

Test design: Test duration: 72 h, 3 test item concentrations plus a water control; each treatment consisted of three replicates; tadpoles: water exposure, static system, 20 tadpoles per aquarium and replicate; juveniles: directly treated with an aerosol spray of formulation (while contained in aquaria without water); 9 - 10 juveniles per aquarium and replicate; assessment of mortality every 12 hours; water quality was tested at test initiation and termination.

Endpoints: Mortality for tadpoles and juveniles of Great Plains toad (*Bufo cognatus*).

Test concentrations: Application rate to test chambers (spray mix): water control, 0.00022, 0.0022 and 0.022 mg a.s./cm^2;
Concentration in water: water control, 0.015, 0.15 and 1.50 mg a.s./L.

Test conditions: Aquaria (400 cm^2 floor surface area) for both life stages; juveniles: 1 cm sterilized soil; tadpoles: 16 cm carbon-filtered water, test volume: 6 L; temperature: 26 ± 1 C; pH: 7.0 - 7.2; dissolved oxygen: > 5.5 mg/L; photoperiod 13 h light : 11 h dark.

Analytics: Analytical verification of test item concentrations was conducted using a GC-method with MS detection.

Statistics: Descriptive statistics, one-way ANOVA, Tukey´s multiple range test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Concentration of the active ingredient was measured within the spray mix used for juveniles and within the water used for tadpole testing at the beginning and end of the test. The mean concentration in the spray mix was between 89% and 102% of nominal with standard deviations of less than 13%.
For the highest treatment group no analysis of the concentration within the test water for tadpoles was done after 72 hours, because all individuals were dead within 24 hours. After 3 hours the mean measured value for pyraclostrobin within the test water for tadpoles was 80% of nominal. The following biological results are based on nominal concentrations of the active substance.

Biological results: With respect to the aquatic exposure test, all concentrations resulted in 100% mortality of *B. cognatus* tadpoles ($F_{3,8} = 42.3$; $p < 0.001$). Within the terrestrial exposure test an application rate of 22 µg a.s./cm^2 resulted in 100% juvenile mortality and 2.2 µg µg a.s./cm^2 caused about 70% mortality while at 0.22 µg a.s./cm^2 no significant effect was observed. Most of the observed mortality occurred within the first 24 h (>90%) for both juveniles and tadpoles.

III. CONCLUSION

Acute laboratory studies with tadpoles (aquatic exposure) and juveniles (terrestrial exposure) of *Bufo cognatus* exposed to the formulation Headline® resulted in 100% mortality of tadpoles at concentrations equivalent to 0.015, 0.15 and 1.50 mg a.s./L in an aquatic system. Terrestrial exposure showed 100% juvenile mortality at 22 µg a.s./cm^2 and about 70% mortality at 2.2 µg µg a.s./cm^2 while 0.22 µg a.s./cm^2 caused no significant effect.

The following publication received only a reduced reliability index. For example, no analytical confirmation of test substances was conducted and no statistical analysis of the data was performed (i.e. the text indicates 20% mortality as a substance related effect, while similar mortality was observed in some of the control runs, and the same effect was seen at a factor of 10 different rates; for more details, see the literature evaluation). Thus, a reliability index of RI = 3 was assigned based on an evaluation according to Klimisch et al. 1997 (high reliability score = 1, not reliable = 4). Nonetheless, this publication is considered here, because it contains relevant information, which is in line with data from Belden et al. (2010). In the following summary only the results for the two pyraclostrobin containing formulations are presented (Headline® and a product coded BAS 500 18 F).

Report:	CA 8.1.4/2 Bruehl C. et al., 2013a Terrestrial pesticide exposure of amphibians: An underestimated cause of global decline? 2014/1143855
Guidelines:	<none>
GLP:	no

Executive Summary

The effects of the pyraclostrobin containing formulations Headline® and BAS 500 18 F on juvenile European common frogs (*Rana temporaria*) were tested in 7 day laboratory studies using direct overspray of young metamorphs. The test organisms were exposed to 0.1 x, 1 x and 10 x label rate. All test item concentrations had 3 or 5 replicates (depending on mortality within 24 h) with one frog per replicate container and the water control had 10 replicates. Assessment of mortality was performed one, two, and four hours after application and afterwards daily until the end of the study.

Mortality of juvenile European common frogs differed largely between the two pyraclostrobin formulations. The formulation Headline®, (naphta content 67%) caused 100% mortality just after 1 h at the test concentration of 880 ml formulation/ha. This test concentration corresponds to the maximum label rate for the product for commercial use. No effect was observed at 0.1x this rate. BAS 500 18 F, the formulation with the lower naphta content (<25%), revealed 20% mortality at 880 ml and at 8800 ml formulation/ha, i.e. the same level as the corresponding control run. In the four control runs mortality ranged from 0% to 20%. No statistical comparisons were carried out.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: 1. Headline® (EC-formulation with 250 g pyraclostrobin/L);
2. BAS 500 18 F (CS-formulation with 250 g pyraclostrobin/L)

B. STUDY DESIGN

Test species: European common frog (*Rana temporaria*), juveniles, wild caught from the nature protection area "Tal" between CH-4467 Rothenfluh and CH-4469 Anwil.

Test design: Test duration: 7 d; application: test organisms were confined to containers the floor of which covered by some sterilized soil substrate; applications were conducted with a laboratory track sprayer using commercial flat fan nozzles; spray volume of 200 L/ha on the soil substrate taking the interception of the wire cage into account; stepwise test design: first, three juvenile frogs were exposed individually to the 0.1x field rate; if they did not show any treatment effects after 24 h, two additional individuals were exposed; if the first three test organisms died, no further testing was conducted, 10x higher rates were tested accordingly; four parallel control with 10 individuals per run sprayed with water only; assessment of mortality: one, two and four hours after application and afterwards daily until the end of the study.

Endpoints: Mortality of juvenile European common frogs (*Rana temporaria*).

Test concentrations: Water control, 88 mL formulation/ha (equivalent to 0.1x of the max. label rate), 880 mL formulation/ha (1x max. label rate)

Test conditions: Macrolon containers Type II (area: 375 cm²), covered with a mesh, 2 cm layer of sterilized standard soil (Soil 2.3, LUFA Speyer, Germany), soil was kept moist containers were kept in climate chamber; temperature: 20 ± 2°C; relative humidity: 75 ± 15%; photoperiod: 16 h light : 8 h dark; feeding: every two days with fruit flies (*Drosophila hydei*) and crickets (*Acheta domestica*); Application equipment: laboratory track sprayer (Schachtner Fahrzeug- and Gerätetechnik, Germany); commercial flat fan nozzles (TeeJet 8001 EVS, Tee-Jet Spraying Systems Co., USA).

Analytics: No analytics were carried out.

Statistics: Descriptive statistics only, no statistical analysis of the data.

II. RESULTS AND DISCUSSION

Analytical measurements: No analytics were carried out.

Biological results: Mortality of juvenile European common frogs differed largely between the two pyraclostrobin formulations. The formulation Headline®, (naphta content 67%) caused 100% mortality just after 1 h at the test concentration of 880 ml formulation/ha. This test concentration corresponds to the maximum label rate for the product for commercial use. No effect was observed at 0.1x this rate. BAS 500 18 F, the formulation with the lower naphta content (<25%), revealed 20% mortality after 5 days at 880 ml formulation/ha and after 6 days at 8800 ml formulation/ha (*i.e*. the same level as the corresponding control run 'D'). In the four control runs mortality ranged from 0% to 20%. No statistic comparisons were carried out. The results are summarized in Table 8.1.4-1.

Table 8.1.4-1: Effects of Headline® (active substance: pyraclostrobin) and BAS 500 18 F (active substance: pyraclostrobin) on survival of juvenile *Rana temporaria*

Treat-ment	Nominal appli-cation rate	Corres-ponding control run	n*	Mortality (%)									
				1h	2h	4h	24h	2d	3d	4d	5d	6d	7d
Control Run A	--	--	10	0	0	0	0	0	0	0	0	0	0
Control Run B	--	--	10	0	0	0	0	0	0	10	10	10	10
Control Run C	--	--	10	0	0	0	0	0	0	0	0	0	0
Control Run D	--	--	10	0	0	0	10	20	20	20	20	20	20
Headline®													
0.1 x Label rate	88 mL/ha	D	5	0	0	0	0	0	0	0	0	0	0
Label rate	880 mL/ha	D	3	100	100	100	100	100	100	100	100	100	100
BAS 500 18 F													
0.1 x Label rate	88 mL/ha	B	5	0	0	0	0	0	0	0	0	0	0
Label rate	880 mL/ha	C	5	0	0	0	0	0	0	0	20	20	20
10 x Label rate	8800 mL/ha	D	5	0	0	0	0	0	0	0	0	20	20

* n = sample number

Considering the significant differences in toxicity of the two formulations containing the same level of the active substance pyraclostrobin the authors speculate that other chemicals in the formulation may play a major role in the effect size of pesticides.

III. CONCLUSION

The formulation Headline® (naphta content 67%) caused 100% mortality under laboratory conditions at an application rate of 880 ml formulation/ha. No effect was observed at 0.1x this rate. BAS 500 18 F, the formulation with the lower naphta content (<25%), revealed 20% mortality both at 880 ml formulation/ha and at 8800 ml formulation/ha, which is at the same level as the corresponding control run.

CA 8.1.5 Endocrine disrupting properties

An assessment of all available data in mammalian toxicology has come to the conclusion that there is no indication that pyraclostrobin has any potential to influence known endocrine mechanisms (for more detailed information please see M-CA 5.8.3).

Furthermore, neither the avian reproductive studies nor any studies conducted with fish give any indication for an endocrine activity of pyraclostrobin (for more detailed information please see M-CA 8.1.1.1, M-CP 10.1.1 and M-CP 10.2).

CA 8.2 Effects on aquatic organisms

Since Annex I inclusion of the active substance pyraclostrobin (BAS 500 F), new studies on aquatic organisms have been performed with the active substance and its major metabolites. As a result, there are new endpoints, which are considered in the aquatic risk assessment. Summaries of these new studies are provided below. For completeness this includes some older studies that had not been submitted during the previous Annex I inclusion process (e.g. because there is no respective data requirement in the EU) and also EU agreed studies that have been amended in the meantime (e.g. due to recalculations of endpoints or a new evaluation according to current guidelines). In addition, summaries are provided for peer-reviewed scientific literature that were considered to be of relevance (and reliable) for the aquatic risk assessment of pyraclostrobin.

Further information on the EU agreed studies, which have been already evaluated within the previous Annex I inclusion process of pyraclostrobin, can be found in the Monograph (Vol. 3, Annex B.9, August 2001) and the EU Review Report (SANCO/1420/2001-final, September 2004). Furthermore, the reports of these studies will be provided to RMS, co-RMS and EFSA and are available upon request for other member states.

References used within the following chapter, but not provided with the dossier, are given at the end of M-CA 8.2.

In general, different code numbers of different numbering systems are assigned to the metabolites of pyraclostrobin. In this chapter all metabolites are identified by the BF-code and synonym metabolite codes are given in brackets only where deemed to be helpful.

For better transparency and traceability of the active substance history, the results of all studies are summarized in Table 8.2-1.

Table 8.2-1: List of studies and endpoints with aquatic organisms and the active substance pyraclostrobin (BAS 500 F) and its major metabolites

Organism	Endpoint	Value [mg/L]	Reference (BASF DocID)	EU agreed

US-EPA = United States Environmental Protection Agency; ELS = early life stage; NO(E)AEC = No observed (ecologically) adverse effect concentration; LC = life cycle; TTE = Time-To-Effect/Event

1) Study has not been submitted during the Annex I inclusion process of pyraclostrobin. A study summary is provided below.
2) marine / saltwater species
3) Geometric mean plus corresponding LC_0 (>) and LC_{100} (<) values given in brackets.
4) Study was performed with the solo-formulation BAS 500 00 F (containing 250 g pyraclostrobin/L, nominally).
5) Spearman-Karber estimate of LC_{50} plus confidence limits given in brackets.
6) The 48-h LC_{50} obtained in the 96 h study is used in the risk assessment according to EU Regulation 283/2013 on the data requirements for active substances and the EFSA Aquatic Guidance (EFSA, 2013).
7) In accordance to recent guidelines (EFSA, 2013; OECD, 2011), the 72 h endpoints of the EU agreed study on the green alga have been (re-)calculated from original data. The re-calculated values are presented here and are used in the aquatic risk assessment; for details on these calculations please refer to the supplement. A summary of this study and the re-calculations is provided below.
8) In accordance to recent guidelines (EFSA, 2013; OECD, 2011), the 72 h endpoints obtained in the 96 h / 120 h alga studies are considered as relevant endpoint and are presented here
9) In this study the 24, 48, and 72 hour effective concentrations were not calculated because sufficient growth had not yet occurred in any of the test groups to allow for these calculations; thus the 96 h endpoints obtained in the 120 h alga studies are considered as relevant endpoint and are presented here.
10) Due to the reasoning given below, the study on this alga species is considered to be not valid.
11) based on frond numbers
12) based on dry weight
13) Endpoint obtained in the TTE study from respective exposure duration, i.e. the value in brackets (0.5, 2 or 8 hours exposure time).
14) The pyraclostrobin metabolites BF 500-6 and BF 500-7 do not occur to any significant extent in water; they are thus considered to be of relevance only in sediment and therefore, and also for animal welfare reasons, only studies on the sediment dwelling insect *C. riparius* have been performed.

CA 8.2.1 Acute toxicity to fish

An acute toxicity study with rainbow trout was already evaluated during the previous Annex I inclusion process. The following additional (flow through) study with rainbow trout (*Oncorhynchus mykiss*) performed with the active substance pyraclostrobin was conducted due to U.S. data requirements and is provided for completeness.

Report:	CA 8.2.1/1 [redacted].et al., 2000a Flow-through acute toxicity of BAS 500F to the rainbow trout, Oncorhynchus mykiss 2000/5034
Guidelines:	EPA 72-1(c), EPA 850.1075
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

In a 96-hour flow-through acute toxicity laboratory study, juvenile rainbow trout were exposed to a dilution water control, a solvent control and to nominal concentrations of 0.0013, 0.0022, 0.0036, 0.0060 and 0.010 mg pyraclostrobin/L (corresponding to mean measured concentrations of 0.0014, 0.0022, 0.0036, 0.0053 and 0.0090 mg a.s./L) in groups of 10 animals in glass aquaria containing 15 L water. Fish were observed for survival and symptoms of toxicity directly after start of exposure and 24, 48, 72 and 96 hours after start of exposure.

The biological results are based on mean measured concentrations of the test item. After 96 hours of exposure, no mortality was observed in the dilution water control, the solvent control and at test item concentrations of up to and including 0.0036 mg a.s./L, whereas 20% mortality was observed at 0.0053 mg a.s./L. At the highest tested concentration, all fish were dead after 96 hours of exposure.

In a flow-through acute toxicity study with rainbow trout the LC_{50} (96 h) of pyraclostrobin was 0.0062 mg a.s./L based on mean measured concentrations. The NOEC (96 h) was determined to be 0.0036 mg a.s./L (mean measured).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F; Reg. no.: 304 428), batch no. 27882/191/C, purity: 97.09%.

B. STUDY DESIGN

Test species: Rainbow trout (*Oncorhynchus mykiss*), juveniles; mean body length of control fish: 39.2 mm; mean wet weight of control fish: 0.55 g; supplied by Thomas Fish Company, Anderson, California, USA.

Test design: Flow through system (96 h); 5 test item concentrations plus a dilution water control and a solvent control, 2 replicates per treatment; 10 fish per aquarium (loading 0.37 g fish/L); assessment of mortality and sublethal effects directly after start of exposure and 24, 48, 72 and 96 hours after start of exposure.

Endpoints: LC_{50}, NOEC, mortality and sub-lethal effects.

Test concentrations: Control (dilution water), solvent control (0.1 mL dimethylformamide/L), 0.0013, 0.0022, 0.0036, 0.0060 and 0.010 mg pyraclostrobin/L (nominal), corresponding to mean measured concentrations of 0.0014, 0.0022, 0.0036, 0.0053 and 0.0090 mg a.s./L.

Test conditions: 20 L glass aquaria, test volume: 15 L; dilution water: deionized, carbon filtered and aerated water; flow rate: 6.1 volume additions per 24 hours on average in each test vessel; hardness: 40 mg $CaCO_3$/L; temperature: 11.1 - 13.0°C; pH 7.3 - 7.9; oxygen content: 10.4 mg/L - 10.6 mg/L; conductivity: 130 - 140 µmhos/cm; photoperiod 16 h light : 8 h dark; light intensity: approx. 52 foot candles; no aeration; no feeding.

Analytics: Analytical verification of test item concentrations was conducted using a HPLC-method with UV detection.

Statistics: Descriptive statistics; binomial/ nonlinear interpolation for calculation of LC_{50}.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of pyraclostrobin concentrations was conducted in each concentration at the beginning and at the end of the test. The analyzed contents of pyraclostrobin ranged from 86 to 115% of nominal at test initiation and from 88 to 111% of nominal at test termination. The following biological results are based on mean measured concentrations.

Biological results: After 96 hours of exposure, no mortality was observed in the dilution water control, the solvent control and at test item concentrations of up to and including 0.0036 mg a.s./L, whereas 20% mortality was observed at 0.0053 mg a.s./L. At the highest tested concentration, all fish were dead after 96 hours of exposure. Sub-lethal effects (i.e. change in coloration) were found at 0.0053 mg a.s./L after 96 hours. The results are summarized in Table 8.2.1-1.

Table 8.2.1-1: Acute toxicity (96 h) of pyraclostrobin to rainbow trout (*Oncorhynchus mykiss*)

Concentration [mg a.s./L] (nominal)	**Control**	**Solvent control**	**0.0013**	**0.0022**	**0.0036**	**0.0060**	**0.010**
Concentration [mg a.s./L] (mean measured)	**--**	**--**	**0.0014**	**0.0022**	**0.0036**	**0.0053**	**0.0090**
Mortality [%] (96 h)	0	0	0	0	0	20	100
Symptoms (after 96 h) *	none	none	none	none	none	C	n.d.
Endpoints [mg pyraclostrobin/L] (mean measured)							
LC_{50} (96 h)	**0.0062** (95% confidence limits: 0.0053 - 0.0090)						
NOEC (96 h)	0.0036						

n.d. = not determined; all fish dead
* Symptoms after 96 h: C = change in coloration.

III. CONCLUSION

In a flow-through acute toxicity study with rainbow trout the LC_{50} (96 h) of pyraclostrobin was 0.0062 mg a.s./L based on mean measured concentrations. The NOEC (96 h) was determined to be 0.0036 mg a.s./L.

The following acute toxicity study with bluegill sunfish (*Lepomis macrochirus*) performed with the active substance pyraclostrobin is not required for registration in the EU and it has not been evaluated previously on EU level. However, the study was conducted due to U.S. data requirements and is provided for completeness.

Report:	CA 8.2.1/2 [redacted] et al., 2000b Flow-through acute toxicity of BAS 500F to the bluegill sunfish, Lepomis macrochirus 2000/5033
Guidelines:	EPA 72-1(a), EPA 850.1075
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

In a 96-hour flow-through acute toxicity laboratory study, juvenile bluegill sunfish were exposed to a dilution water control, a solvent control and to nominal concentrations of 0.0065, 0.011, 0.018, 0.030 and 0.050 mg pyraclostrobin/L (corresponding to mean measured concentrations of 0.0061, 0.0095, 0.0159, 0.0269 and 0.0451 mg a.s./L) in groups of 10 animals in glass aquaria containing 15 L water. Fish were observed for survival and symptoms of toxicity directly after start of exposure and 24, 48, 72 and 96 hours after start of exposure.

The biological results are based on mean measured concentrations of the test item. After 96 hours of exposure, no mortality was observed in the dilution water control, the solvent control and at the lowest test item concentration of 0.0061 mg a.s./L, whereas 15% mortality was observed at 0.0095 mg a.s./L. At the three highest test item concentrations all fish were dead after 96 hours of exposure.

In a flow-through acute toxicity study with bluegill sunfish the LC_{50} (96 h) of pyraclostrobin was 0.0114 mg a.s./L based on mean measured concentrations. The NOEC (96 h) was determined to be 0.0061 mg a.s./L.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F; Reg. no.: 304 428), batch no. 27882/191/C, purity: 97.09%.

B. STUDY DESIGN

Test species: Bluegill sunfish (*Lepomis macrochirus*), juveniles; mean body length of control fish: 23.8 mm; mean wet weight of control fish: 0.11 g; supplied by "Osage Catfisheries", Osage Beach, Missouri, USA.

Test design: Flow through system (96 h); 5 test item concentrations plus a dilution water control and a solvent control, 2 replicates per treatment; 10 fish per aquarium (loading 0.073 g fish/L); assessment of mortality and sublethal effects directly after start of exposure and 24, 48, 72 and 96 hours after start of exposure.

Endpoints: LC_{50}, NOEC, mortality and sub-lethal effects.

Test concentrations: Control (dilution water), solvent control (0.1 mL dimethylformamide/L), 0.0065, 0.011, 0.018, 0.030 and 0.050 mg pyraclostrobin/L (nominal), corresponding to mean measured concentrations of 0.0061, 0.0095, 0.0159, 0.0269 and 0.0451 mg a.s./L.

Test conditions: 20 L glass aquaria, test volume: 15 L; dilution water: deionized, carbon filtered and aerated water, flow rate: 6.3 volume additions per 24 hours on average in each test vessel; hardness: 48 mg $CaCO_3$/L; temperature: 21.2°C - 22.5°C; pH 7.3 - 7.9; oxygen content: 8.7 mg/L - 9.4 mg/L; conductivity: 130 - 160 µmhos/cm; photoperiod: 16 h light : 8 h dark; light intensity: approx. 52 foot candles; no aeration; no feeding.

Analytics: Analytical verification of test item concentrations was conducted using an HPLC-method with UV-detection.

Statistics: Descriptive statistics; binomial/nonlinear interpolation for calculation of LC_{50}.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of pyraclostrobin concentrations was conducted in each concentration at the beginning and at the end of the test. The analyzed contents of pyraclostrobin ranged from 85 to 93% of nominal at test initiation and from 85% to 94% of nominal at test termination. The following biological results are based on mean measured concentrations.

Biological results: After 96 hours of exposure, no mortality was observed in the dilution water control, the solvent control and at the lowest test item concentration of 0.0061 mg a.s./L, whereas 15% mortality was observed at 0.0095 mg a.s./L. At the three highest test item concentrations, all fish were dead after 96 hours of exposure. After 96 hours of exposure, sub-lethal effects (i.e. lethargy and loss of equilibrium) were found at 0.0095 mg a.s./L. The results are summarized in Table 8.2.1-2.

Table 8.2.1-2: Acute toxicity (96 h) of pyraclostrobin to bluegill sunfish (*Lepomis macrochirus*)

Concentration [mg a.s./L] (nominal)	**Control**	**Solvent control**	**0.0065**	**0.011**	**0.018**	**0.030**	**0.050**
Concentration [mg a.s./L] (mean measured)	**--**	**--**	**0.0061**	**0.0095**	**0.0159**	**0.0269**	**0.0451**
Mortality [%] (96 h)	0	0	0	15	100	100	100
Symptoms (after 96 h) *	none	none	none	L	n.d.	n.d.	n.d.
Endpoints [mg pyraclostrobin/L] (mean measured)							
LC_{50} (96 h)	**0.0114** (95% confidence limits: 0.0095 - 0.0159)						
NOEC (96 h)	0.0061						

n.d. = not determined; all fish dead
* Symptoms after 96 h: L = lethargy and loss of equilibrium.

III. CONCLUSION

In a flow-through acute toxicity study with bluegill sunfish the LC_{50} (96 h) of pyraclostrobin was 0.0114 mg a.s./L based on mean measured concentrations. The NOEC (96 h) was determined to be 0.0061 mg a.s./L.

The following acute toxicity study with the marine fish species sheepshead minnow (*Cyprinodon variegatus*) performed with the active substance pyraclostrobin is not required for registration in the EU and it has not been evaluated previously on EU level. However, the study was conducted due to U.S. data requirements and is provided for completeness.

Report: CA 8.2.1/3
[redacted]., 2000c
Flow-through acute toxicity of BAS 500F to the sheepshead minnow, Cyprinodon variegatus
2000/5032
Guidelines: EPA 72-3(a), EPA 850.1075
GLP: yes
(certified by United States Environmental Protection Agency)

Executive Summary

In a 96-hour flow-through acute toxicity laboratory study, juvenile sheepshead minnow were exposed to a dilution water control, a solvent control and to nominal concentrations of 0.013, 0.022, 0.036, 0.060 and 0.10 mg pyraclostrobin/L (corresponding to mean measured concentrations of 0.0108, 0.0188, 0.0302, 0.0535 and 0.0879 mg a.s./L) in groups of 10 animals in glass aquaria containing 15 L water. Fish were observed for survival and symptoms of toxicity directly after start of exposure and 24, 48, 72 and 96 hours after start of exposure.

The biological results are based on mean measured concentrations of the test item. After 96 hours of exposure, no mortality was observed in the dilution water control, the solvent control and at test item concentrations of up to and including 0.0535 mg a.s./L, whereas 75% mortality was observed at the highest tested concentration of 0.0879 mg a.s./L.

In a flow-through acute toxicity study with sheepshead minnow the LC_{50} (96 h) of pyraclostrobin was 0.0769 mg a.s./L based on mean measured concentrations. The NOEC (96 h) was determined to be 0.0535 mg a.s./L.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F; Reg. no.: 304 428), batch no. 27882/191/C, purity: 97.09%.

B. STUDY DESIGN

Test species:	Sheepshead minnow (*Cyprinodon variegatus*), juveniles; mean body length of control fish: 21.0 mm; mean wet weight of control fish: 0.16 g; supplied by "Aquatic BioSystems", Fort Collins, Colorado, USA.
Test design:	Flow through system (96 h); 5 test item concentrations plus a dilution water control and a solvent control; 2 replicates per treatment; 10 fish per aquarium (loading 0.11 g fish/L); assessment of mortality and sublethal effects directly after start of exposure and 24, 48, 72 and 96 hours after start of exposure.
Endpoints:	LC_{50}, NOEC, mortality and sub-lethal effects.
Test concentrations:	Control (dilution water), solvent control (0.1 mL dimethylformamide/L), 0.013, 0.022, 0.036, 0.060 and 0.10 mg pyraclostrobin/L (nominal), corresponding to mean measured concentrations of 0.0108, 0.0188, 0.0302, 0.0535 and 0.0879 mg a.s./L.
Test conditions:	20 L glass aquaria, test volume: 15 L; dilution water: filtered natural seawater mixed with deionized water, salinity: 15 - 16 ‰; flow rate: 5.7 volume additions per 24 hours on average per test vessel; temperature: 21.8°C- 22.8°C; pH 7.8 - 7.9; oxygen content: 7.4 mg/L - 8.1 mg/L; photoperiod 16 h light : 8 h dark; light intensity: approx. 53 foot candles; no aeration; no feeding.
Analytics:	Analytical verification of test item concentrations was conducted using an HPLC-method with UV-detection.
Statistics:	Descriptive statistics; binomial/nonlinear interpolation for calculation of the LC_{50}.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of pyraclostrobin concentrations was conducted in each concentration at the beginning and at the end of the test. The analyzed contents of pyraclostrobin ranged from 82 to 89% of nominal at test initiation and from 83 to 89% of nominal at test termination. The following biological results are based on mean measured concentrations.

Biological results: After 96 hours of exposure, no mortality was observed in the dilution water control, the solvent control and at test item concentrations of up to and including 0.0535 mg a.s./L, whereas 75% mortality was observed at the highest tested concentration of 0.0879 mg a.s./L. No sub-lethal effects were found in the control groups and in all test item treatments after 96 hours. The results are summarized in Table 8.2.1-3.

Table 8.2.1-3: Acute toxicity (96 h) of pyraclostrobin to sheepshead minnow (*Cyprinodon variegatus*)

Concentration [mg a.s./L] (nominal)	**Control**	**Solvent control**	**0.013**	**0.022**	**0.036**	**0.060**	**0.10**
Concentration [mg a.s./L] (mean measured)	**Control**	**Solvent control**	**0.0108**	**0.0188**	**0.0302**	**0.0535**	**0.0879**
Mortality [%] (96 h)	0	0	0	0	0	0	75
Symptoms (after 96 h)	none	none	none	none	none	none	none
Endpoints [mg pyraclostrobin/L] (mean measured)							
LC_{50} (96 h)	**0.0769** (95% confidence limits: 0.0535 - 0.0879)						
NOEC (96 h)	0.0535						

III. CONCLUSION

In a flow-through acute toxicity study with sheepshead minnow the LC_{50} (96 h) of pyraclostrobin was 0.0769 mg a.s./L based on mean measured concentrations. The NOEC (96 h) was determined to be 0.0535 mg a.s./L.

The following acute toxicity study on rainbow trout (*Oncorhynchus mykiss*) performed with the metabolite BF 500-3 was requested by Canadian authorities and has not been evaluated previously on EU level.

Report:	CA 8.2.1/4 [redacted] 2007a Reg.No. 340266 (metabolite BF 500-3 of BAS 500 F): Acute toxicity study on the rainbow trout (Oncorhynchus mykiss) in a static system over 96 hours 2007/1010836
Guidelines:	OECD 203, EEC 92/69 A V C 1, EPA 72-1, EPA 850.1075
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a static acute toxicity laboratory study, juvenile rainbow trout were exposed to BF 500-3 (metabolite of pyraclostrobin) in two replicates per concentration with 10 animals in aquaria containing 50 L water at nominal concentrations of 0.0050, 0.010, 0.022, 0.050 and 0.10 mg/L (corresponding to mean measured concentrations of 0.0034, 0.0073, 0.018, 0.042 and 0.095 mg/L). Additionally, a solvent (acetone) control and a dilution water control were set up. Fish were observed for survival and symptoms of toxicity within 1 hour after start of exposure and after 4, 24, 48, 72 and 96 hours of exposure.

The biological results are based on mean measured concentrations of the test item. After 96 hours of exposure, no mortality or other symptoms of toxicity were observed including the highest test concentrations, which is at or even slightly above the maximum solubility of this metabolite.

In a static acute toxicity study with rainbow trout no mortality or other effects were observed up to the solubility limits of the test substance. The LC_{50} (96 h) of BF 500-3 (metabolite of pyraclostrobin) was determined to be > 0.0948 mg/L based on mean measured concentrations. The NOEC was ≥ 0.0948 mg/L.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BF 500-3 (Reg. No. 340 266, synonym: 500M07; metabolite of pyraclostrobin), batch no. 01311-150, purity: 100.0%.

B. STUDY DESIGN

Test species:	Rainbow trout (*Oncorhynchus mykiss*), juveniles, approx. 4 months old; body length 5.2 cm (4.0 - 6.0 cm); body weight 1.24 g (0.66 - 1.93 g); supplied by 'Forellenzucht Trostadt GbR', Trostadt, Germany.
Test design:	Static system (96 hours); 5 test item concentrations plus a dilution water control and a solvent control, 2 replicates per treatment; 10 fish per aquarium (loading 0.2 g fish/L); assessment of mortality and symptoms of toxicity within 1 hour after start of exposure and 4, 24, 48, 72 and 96 hours after start of exposure.
Endpoints:	LC_{50}, NOEC, mortality and sub-lethal effects.
Test concentrations:	Control (dilution water), solvent control (0.1 mL acetone/L), 0.0050, 0.010, 0.022, 0.050 and 0.10 mg BF 500-3/L (nominal); corresponding to mean measured concentrations of 0.0034, 0.0073, 0.018, 0.042 and 0.095 mg/L.
Test conditions:	Glass aquaria with stainless steel frame (0.60 x 0.35 x 0.40 m); water volume: 50 L; dilution water: non chlorinated charcoal filtered tap water mixed with deionized water; temperature: 11°C; pH 7.5 -7.8; oxygen content: 9.0 mg/L - 9.1 mg/L; total hardness: 100 mg $CaCO_3$/L; conductivity: approx. 250 µS/cm; acid capacity: approx. 2.5 mmol/L; photoperiod 16 h light : 8 h dark; light intensity: 36 - 191 lux; no aeration, no feeding.
Analytics:	Analytical verification of test item concentrations was conducted using an HPLC-method with MS-detection.
Statistics:	Descriptive statistics.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentration was conducted in each replicate at the beginning of the test, after 48 hours and at the end of the test. Measured values for BF 500-3 ranged from 107 to 116% of nominal at test initiation and from 36 to 56% at test termination. The following biological results are based on mean measured concentrations.

Biological results: After 96 hours of exposure, no mortality or other symptoms of toxicity were observed including the highest test concentrations, which is at or even slightly above the maximum solubility of this metabolite. The results are summarized in Table 8.2.1-4.

Table 8.2.1-4: Acute toxicity (96 h) of BF 500-3 (metabolite of pyraclostrobin) to rainbow trout (*Oncorhynchus mykiss*)

Concentration [mg/L] (nominal)	**Control**	**Solvent control**	**0.0050**	**0.010**	**0.022**	**0.050**	**0.10**
Concentration [mg/L] (mean measured)	**--**	**--**	**0.0034**	**0.0073**	**0.018**	**0.042**	**0.095**
Mortality [%] (96 h)	0	0	0	0	0	0	0
Symptoms (after 96 h)	none	none	none	none	none	none	none
Endpoints [mg BF 500-3/L] (mean measured)							
LC_{50} (96 h)	**> 0.0948**						
NOEC (96 h)	≥ 0.0948						

III. CONCLUSION

In a static acute toxicity study with rainbow trout no mortality or other effects were observed up to the solubility limits of the test substance. The LC_{50} (96 h) of BF 500-3 (metabolite of pyraclostrobin) was determined to be > 0.0948 mg/L based on mean measured concentrations. The NOEC was ≥ 0.0948 mg/L.

The following acute toxicity study on rainbow trout (*Oncorhynchus mykiss*) performed with the metabolite BF 500-5 is provided in support of the aquatic risk assessment. Due to new data requirements this new metabolite was identified and tested and has not been evaluated previously on EU level.

Report:	CA 8.2.1/5 [redacted] 2014a Acute toxicity of Reg.No. 298327 (BF 500-5, metabolite of Pyraclostrobin) to rainbow trout (Oncorhynchus mykiss) in a 96-hour static test 2013/1349200
Guidelines:	OECD 203 (1992), EC 440/2008 C.1 Acute Toxicity for Fish
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

In a static acute toxicity laboratory study, juvenile rainbow trout were exposed to BF 500-5 (metabolite of pyraclostrobin) at nominal concentrations of 1, 2, 4, 8 and 16 mg/L and a water control in one replicate per concentration with 7 animals in aquaria containing 14 L water. Fish were observed for survival and symptoms of toxicity 2, 24, 48, 72 and 96 hours after start of exposure.

The biological results are based on nominal concentrations. After 96 hours of exposure no mortality was observed in the control and at test item concentrations of up to and including 8 mg BF 500-5/L, whereas 100% mortality occurred at the highest tested concentration of 16 mg/L.

In a static acute toxicity study with rainbow trout the LC_{50} (96 h) of BF 500-5 (metabolite of pyraclostrobin) was 11.3 mg/L based on nominal concentrations. The NOEC (96 h) was determined to be 8 mg/L.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BF 500-5 (Reg.No. 298 327, synonym: 500M04, metabolite of pyraclostrobin); batch no.: L84-174; purity: 99.6% (± 1.0%)

B. STUDY DESIGN

Test species:	Rainbow trout (*Oncorhynchus mykiss*); juveniles; average body length 5.39 cm ± 0.4 cm; average body weight: 1.57 ± 0.29 g; supplied by "Forellenzuchtbetrieb Störk", Bad Saulgau, Germany.
Test design:	Static system (96 hours); 7 fish per aquarium (loading: 0.79 g fish/L) and per concentration, assessments of mortality and symptoms of toxicity 2, 24, 48, 72 and 96 hours after start of exposure.
Endpoints:	LC_{50}, NOEC, mortality and sub-lethal effects.
Test concentrations:	0 (control), 1, 2, 4, 8 and 16 mg BF 500-5/L (nominal).
Test conditions:	16 L glass aquaria; test volume: 14 L; deionized water with analytical grade salts (ISO Medium); temperature: 13.1°C - 13.5°C; pH 7.1 - 7.9; oxygen saturation: 85% - 100%; hardness: 250.0 mg $CaCO_3$/L; photoperiod: 16 h light: 8 h dark, light intensity: 480 - 1080 lux, gentle aeration, no feeding.
Analytics:	Analytical verification of the test item was conducted using an HPLC-method with MS/MS-detection
Statistics:	Descriptive statistics. Fisher`s Exact Binomial Test with Bonferroni Correction for determination of the NOEC; probit analysis for determination of the EC_{50} value.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each concentration at the beginning and at the end of the test. The mean analyzed contents of BF 500-5 ranged from 82 to 120% of nominal at test initiation and from 85 to 105% of nominal at test termination. As the initially measured concentrations confirmed the correct application of the test item, the following biological results are based on nominal concentrations.

Biological results: After 96 hours of exposure no mortality was observed in the control and at test item concentrations of up to and including 8 mg BF 500-5/L, whereas 100% mortality occurred at the highest tested concentration of 16 mg/L. After 96 hours of exposure, sub-lethal effects were observed at test item concentrations of 4 mg/L (i.e. mucus secretion) and 8 mg/L (i.e. tumbling during swimming, fish lying at the side or back, distended abdomen and dark coloration). Statistically significant differences in the mortality rates compared to the control were observed at the highest test item concentrations of 16 mg/L (Fisher's Exact Test, $\alpha = 0.05$). For results see Table 8.2.1-5.

Table 8.2.1-5: Acute toxicity (96 h) of BF 500-5 (metabolite of pyraclostrobin) on rainbow trout (*Oncorhynchus mykiss*)

Concentration [mg/L] (nominal)	**Control**	**1**	**2**	**4**	**8**	**16**
Mortality [%] (96 h)	0	0	0	0	0	100 *
Symptoms (96 h) $	none	none	none	MS	DA, DC, SB, TS	n.d.
Endpoints [mg BF 500-5/L] (nominal)						
LC_{50} (96 h) #	11.3 (95% confidence limits: 8 - 16)					
NOEC (96 h)	8					

n.d. = not determined; all fish dead

* Statistically significantly different compared to the control (Fisher's Exact Test, $\alpha = 0.05$)

$ Symptoms after 96 h: MS = mucus secretion, DA = distended abdomen; DC = dark coloration; SB = fish lying at the side or back, TS = tumbling during swimming

\# The LC_{50} was calculated as the geometric mean of the highest concentration causing no mortality and the lowest concentration resulting in 100% mortality.

III. CONCLUSION

In a static acute toxicity study with rainbow trout the LC_{50} (96 h) of BF 500-5 (metabolite of pyraclostrobin) was 11.3 mg/L based on nominal concentrations. The NOEC (96 h) was determined to be 8 mg/L (nominal).

To strengthen the ecotoxicological profile of pyraclostrobin and to justify the potential use of time weighted average concentrations (respectively the consideration of short-term exposure pulses), an acute time to effect study was conducted with different exposure pulses and rainbow trout. The study has been used in previous end-use product registrations, but has not been evaluated during the previous Annex I evaluation process.
This study had erroneously not been listed in the application submitted for renewal of approval.

Report:	CA 8.2.1/6 [redacted] 2000a BAS 500 F - Acute toxicity study on the rainbow trout (Oncorhychus mykiss) after short time exposure over 0.5, 2 and 8 hours in a flow-through system followed up by a post exposure period 2000/1014919
Guidelines:	EPA 72-1, EEC 92/69 A V C 1, OECD 203
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

The acute toxicity of pyraclostrobin to rainbow trout (*Oncorhynchus mykiss*) was evaluated after short time exposure over 0.5, 2 and 8 hours in a flow-through test system followed by a post-exposure period until 96 h after start of exposure. Fish were exposed to a water control and at nominal test item concentrations of 0.0080, 0.012, 0.018 and 0.027 mg a.s./L in groups of 30 animals per concentration in glass aquaria containing approximately 100 L water. After 0.5 hours one third, after 2 hours half and after 8 hours the rest of the surviving fish were transferred into new chambers with pure dilution water for the post-exposure period. Fish were observed for survival and symptoms of toxicity at test initiation, at the end of respective exposure periods, during the post-exposure period directly after transfer, in the earlier transferred exposure groups at each time when another exposure group was transferred and at 24, 48, 72 and 96 hours after study start.

The biological results are based on nominal concentrations of the test item. No mortality occurred in the controls and in all test item concentrations of the 0.5 h exposure group over the whole study period. After peak exposure over 2 hours, 2 out of 20 fish (10%) were found dead at the highest test item concentration of 0.027 mg a.s./L. After 8 hours of exposure, 8 out of 10 fish (80%) were found dead at the second highest test item concentration of 0.018 mg a.s./L and all fish were dead at the highest tested concentration. At the end of the post-exposure period, 1 out of 10 fish (10%) and 8 out of 9 fish (89%) had died in the 2 h exposure group at the two highest test item concentrations, respectively. In the 8 h exposure group, 1 out of 10 fish (10%) was found dead at 0.012 mg a.s./L whereas no further mortality occurred at 0.018 mg a.s./L during the post-exposure period.

In a flow-through acute toxicity study with rainbow trout, the LC_{50} values (96 h) of pyraclostrobin were > 0.027, 0.022 and 0.015 mg a.s./L after exposure durations of 0.5, 2 and 8 hours followed by a post-exposure period until 96 hours after study start (nominal). In general, shorter exposure times lead to a marked reduction of toxicity in comparison to the results of the 96 hours standard test with *O. mykiss*.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F; Reg. no.: 304 428), batch no. CP 029 053, purity: 99.0%.

B. STUDY DESIGN

Test species: Rainbow trout (*Oncorhynchus mykiss*), age: 4 - 5 months; mean body length: 5.6 cm (5.2 - 5.9 cm); mean body weight: 1.5 g (1.1 - 2.0 g); supplied by "Forellenhof Fredelsloh", Moringen, Germany.

Test design: Flow through system (96 h); 3 peak exposure groups: exposure over 0.5, 2 or 8 hours followed by a post-exposure period until 96 h after start of exposure; 4 test item concentrations plus a dilution water control, 1 replicate per treatment; 30 fish per concentration for the first (0.5 h) exposure period (loading: max. 0.45 g fish/L during exposure period, max. 1.67 g fish/L during post exposure period); after 0.5 hours one third, after 2 hours half and after 8 hours the rest of the surviving fish were transferred into new test chambers with pure dilution water for the post exposure period; assessment of mortality and sublethal effects each time, when fish were transferred to post exposure chambers, during post exposure period directly after transfer, in the earlier transferred exposure groups at each time when another exposure group was transferred and at 24, 48, 72 and 96 hours after study start.

Endpoints: LC_{50}, NOEC, mortality and sub-lethal effects.

Test concentrations: Control (dilution water), 0.0080, 0.012, 0.018 and 0.027 mg pyraclostrobin/L (nominal).

Test conditions:	Exposure period: glass aquaria (80 cm x 35 cm x 46 cm), test volume: approximately 100 L; flow rate: 20 L/hour/test vessel; no aeration; temperature: 13°C; pH 8.0 - 8.1; oxygen content: 10.2 mg/L - 10.7 mg/L. Post-exposure period: stainless steel aquaria (29 cm x 21 cm x 22 cm), dilution water volume: approximately 9 L; flow rate of dilution water: 6.5 L/hour/vessel; no aeration; temperature: 12°C; pH 8.0 - 8.1; oxygen content: 10.3 mg/L - 11.0 mg/L. Dilution water: carbon filtered and aerated non-chlorinated drinking water; hardness: approximately 250 mg $CaCO_3$/L. Photoperiod: 16 h light : 8 h dark.
Analytics:	Analytical verification of test item concentrations was conducted using an HPLC-method with UV-detection.
Statistics:	Descriptive statistics; probit analysis for calculation of LC_{50}.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of pyraclostrobin concentrations was conducted in each concentration at the beginning and at the end of the 8 hour peak exposure period. The analyzed contents of pyraclostrobin ranged from 93.7 to 101.1% of nominal concentrations at test initiation and from 86.7 to 97.2% of nominal after 8 hours. As the measured concentrations confirmed the correct application of the test substance, the following biological results are based on nominal concentrations.

Biological results: No mortality occurred in the controls and in all test item concentrations of the 0.5 h exposure group over the whole study period. After peak exposure over 2 hours, 2 out of 20 fish (10%) were found dead at the highest test item concentration of 0.027 mg a.s./L. At this concentration, only 9 instead of 10 fish could thus be transferred to the post-exposure chambers and only 9 fish remained in the exposure chamber for further exposure. After 8 h peak exposure, 8 out of 10 fish (80%) were found dead at the second highest test item concentration of 0.018 mg a.s./L and all fish were dead at the highest tested concentration.
At the end of the post-exposure period, 1 out of 10 fish (10%) and 8 out of 9 fish (89%) had died in the 2 h peak treatment at the two highest test item concentrations, respectively. In the 8 h exposure group, 1 out of 10 fish (10%) was found dead at 0.012 mg a.s./L whereas no further mortality occurred at 0.018 mg a.s./L during the post-exposure period.
At the end of 0.5 h peak exposure, sub-lethal effects (*i.e.* swimming at the bottom, tottering and swimming at the surface) were observed at the highest test item concentration of 0.027 mg a.s./L. In the 2 h exposure group, swimming at the bottom, tottering and apathy were observed at the three highest test item concentrations and in the 8 h exposure group, tottering and apathy were observed at 0.012 and 0.018 mg a.s./L at the end of the respective exposure peaks. After the post-exposure period, no sub-lethal effects were observed at up to and including the highest test item concentration in all peak exposure treatments.

The results are summarized in Table 8.2.1-6.

Table 8.2.1-6: Effect of pyraclostrobin on rainbow trout (*Oncorhynchus mykiss*) in an acute toxicity study after peak exposure over 0.5, 2 and 8 hours followed by a post-exposure period

2) Only 9 surviving fish could be transferred to post-exposure chambers of the 8 h peak treatment
3) Number of dead fish / total number of fish transferred to post-exposure chambers
* Symptoms: D = swimming at the bottom, T = tottering, N = apathy, C = swimming at the surface

III. CONCLUSION

In a flow-through acute toxicity study with rainbow trout, the LC_{50} values (96 h) of pyraclostrobin were > 0.027, 0.022 and 0.015 mg a.s./L after exposure durations of 0.5, 2 and 8 hours followed by a post-exposure period until 96 hours after study start (nominal). In general, shorter exposure times lead to a marked reduction of toxicity in comparison to the results of the 96 hours standard test with *O. mykiss*.

CA 8.2.2 Long-term and chronic toxicity to fish

CA 8.2.2.1 Fish early life stage toxicity test

The following early life-stage test on fathead minnow (*Pimephales promelas*) performed with the active substance pyraclostrobin is not required for registration in the EU and it has not been evaluated previously on EU level. The study was conducted due to U.S. data requirements and is provided for completeness.

Report:	CA 8.2.2.1/1 [redacted].et al., 2000i Early life stage toxicity of BAS 500 F to the fathead minnow, Pimephales promelas 2000/5053
Guidelines:	EPA 72-4(a), EPA 850.1400
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

The chronic toxicity of pyraclostrobin to fathead minnow (*Pimephales promelas*) was evaluated in a 36-day early life-stage test under flow-through conditions. Embryos were exposed to a dilution water control, a solvent control and to nominal concentrations of 0.0014, 0.0026, 0.0049, 0.010 and 0.020 mg pyraclostrobin/L (corresponding to mean measured concentrations of 0.000944, 0.00218, 0.00414, 0.00837 and 0.0161 mg a.s./L). Hatchability, survival rate and behavior of fathead minnow embryos and fry were assessed throughout the study. Individual fish lengths and weights were measured at test termination.

The results are based on mean measured concentrations. Egg hatch was complete on day 4 in the control groups and all test item treatments. Mean survival rates at hatch (day 4) and at test end (32 days post-hatch) were ≥ 90% in both the dilution water control, the solvent control and at test item concentrations up to and including 0.00837 mg a.s./L, whereas all fish had died before hatch (day 4) at the highest tested concentration of 0.0161 mg a.s./L. No statistically significant effects on survival, time to hatch, time to first feeding, total length, wet weight or dry weight compared to the pooled control were observed at concentrations of up to and including 0.00414 mg a.s./L. A slight sublethal effect on live, normal fathead minnow at 0.00414 mg/L was apparent on only 4% of the fish on one day (day 4), and although statistically significant, the effect was not considered to be of biological relevance.

In an early life-stage study with fathead minnow (*Pimephales promelas*) the overall NOEC (36 d) for pyraclostrobin was determined to be 0.00414 mg a.s./L based on mean measured concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F, Reg. No. 304 428), lot no. 27882/191/C, purity: 97.09%, dissolved in dimethylformamide (lot no. BV921).

B. STUDY DESIGN

Test species: Fathead minnow (*Pimephales promelas*), eggs less than 24 hours at test initiation, source: "Aquatic BioSystems, Inc.", Fort Collins, Colorado, USA.

Test design: Flow-through system (36 d); 5 test item concentrations plus a dilution water control and a solvent control; 4 replicate test chambers per treatment with 20 fertilized eggs in each; a proportional diluter system was used for intermittent introduction of the solutions to the test chambers. During the embryo stage, the developing embryos were incubated in glass cups. At the end of hatch (day 4), fish were released into the test chamber and randomly thinned to 10 fish per vessel. Daily assessment of hatch, survival, signs of toxicity and abnormal behavior. At test termination surviving animals were sacrificed and measured for length and weight.

Endpoints: NOEC values based on hatchability, survival, toxic signs and growth rates.

Test concentrations: Control (dilution water), solvent control (0.1 mL dimethylformamide/L), 0.0014, 0.0026, 0.0049, 0.010 and 0.020 mg a.s./L (nominal), corresponding to mean measured concentrations of 0.000944, 0.00218, 0.00414, 0.00837 and 0.0161 mg a.s./L.

Test conditions: Test vessels: 9 L glass aquaria (approx.15 x 30 x 20 cm) with a test volume of approx. 8.0 L; 4 replicate test chambers; glass incubation cups (used during embryo stage) closed on one end with Nitex® screen; two incubation cups per test chamber; dilution water: filtered deionized water sterilized with UV and aerated; temperature: 23.0°C - 26.4°C; pH 7.4 - 7.8; oxygen content: 8.0 mg/L - 9.4 mg/L; total hardness: 40 - 44 mg $CaCO_3$/L; conductivity: 130 - 180 µmhos/cm; light intensity: approx. 45 foot candles; photoperiod: 16 hours light : 8 hours dark; flow rate: approx. 6.6 volume additions per 24 hours per vessel; feeding: fish were fed 2-3 times daily *ad libitum* freshly hatched *Artemia salina* nauplii from day 5 onwards until 1 day before study termination; no aeration.

Analytics: Analytical verification of test item concentrations was conducted using an HPLC-method with UV-detection.

Statistics: Descriptive statistics; t-test for comparison of the dilution water control and solvent control data; ANOVA followed by Bonferroni's test or William's test to calculate NOEC values.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of the test item concentrations was conducted in all concentrations at test initiation, at regular intervals during the study and test end, except for the highest test item concentration, where analytical measurements were only conducted on days 0 and 7. Recoveries of pyraclostrobin ranged from 74.5 to 90.0% of nominal concentrations in all treatments at test initiation and from 80.9 to 88.5% of nominal in the 0.0026, 0.0049 and 0.010 mg/L (nominal) treatments at test termination. Measured contents in samples from the lowest test item treatment were below the limit of quantification (LOQ = 0.50 µg/L) on days 35 and 36; this is believed to be due to an unobserved diluter malfunction on test days 35 and 36. All analysis at this concentration prior to that time resulted in recoveries ranging from 75 to 84% of nominal. The following biological results are based on mean measured concentrations.

Biological results: No statistically significant differences were determined between the control and the solvent control data (t-test; $\alpha = 0.05$). Thus, the data from both control groups were pooled and the pooled data set was used for statistical evaluation of treatment related effects. Egg hatch was complete on day 4 in the control and all test item treatments. Mean survival rates at hatch (day 4) and at test end (32 days post-hatch) were ≥ 90% in both the dilution water control and solvent control and at test item concentrations up to and including 0.00837 mg a.s./L, whereas all fish had died before hatch (day 4) in the highest tested concentration of 0.0161 mg a.s./L. No statistically significant effects on survival, time to hatch, time to first feeding, total length, wet weight or dry weight compared to the pooled control were observed at concentrations of up to and including 0.00414 mg a.s./L (Bonferroni's test / William's test). Sublethal effects, observed as fish exhibiting lethargy and/or a loss of equilibrium or change in coloration, were noted at 0.0161 mg a.s./L on day 3 (complete mortality occurred on day 4 at this concentration), at 0.00837 mg a.s./L on days 4 - 6, 8 - 12, and on day 34, and at 0.00414 mg a.s./L on day 4. These effects were not observed at any other time during the test. As the effect on live, normal fathead minnow at 0.00414 mg/L was apparent on only 4% of the fish on one day (day 4), and although statistically significant, the effect was not considered to be of biological relevance. The results are summarized in Table 8.2.2.1-1.

Table 8.2.2.1-1: Chronic toxicity of pyraclostrobin to fathead minnow (*Pimephales promelas*) in a fish early life-stage test (36 d)

Concentration [mg a.s./L] (nominal)	**Control**	**Solvent control**	**0.0014**	**0.0026**	**0.0049**	**0.010**	**0.020**
Concentration [mg a.s./L] (mean measured)	**--**	**--**	**0.000944**	**0.00218**	**0.00414**	**0.00837**	**0.0161**
Embryo survival at hatch on day 4 [%]	98	99	99	99	94	90	0
Survival of larvae 32 days post hatch [%]	100	98	95	95	100	90	0
Percent live normal at hatch on day 4 [%]	98	99	99	99	90[#]	80	0
Percent live normal 32 days post hatch [%]	100	98	95	95	100	90	0

Mean wet weight [mg]	110.5	108.8	108.5	106.9	107.0	96.8	n.d.
Mean dry weight [mg]	23.6	23.0	23.2	22.7	23.3	22.4	n.d.
Endpoints [mg pyraclostrobin/L] (mean measured)							
$NOEC_{overall}$ (36 d)	0.00414						

n.d. = not determined; no fish survived at the concentration above 0.00837 mg a.s./L.

[#] Because the effect on live, normal fathead minnow at 0.00414 mg a.s/L was apparent on only 4% of the fish on one day (day 4), the effect was not considered to be of biological significance.

III. CONCLUSION

In an early life-stage study with fathead minnow (*Pimephales promelas*) the overall NOEC (36 d) for pyraclostrobin was determined to be 0.00414 mg a.s./L based on mean measured concentrations.

The following fish early life-stage test on sheepshead minnow (*Cyprinodon variegatus*) performed with the active substance pyraclostrobin is not required for registration in the EU and it has not been evaluated previously on EU level. The study was conducted due to U.S. data requirements and is provided for completeness.

Report:	CA 8.2.2.1/2 [redacted] et al., 2001j Early life stage toxicity of BAS 500 F to the Sheepshead Minnow, Cyprinodon variegatus 2000/5247
Guidelines:	EPA 72-4
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

The chronic toxicity of pyraclostrobin to sheepshead minnows (*Cyprinodon variegatus*) was evaluated in a 36-day early life-stage test under flow-through conditions. Embryos were exposed to a dilution water control, a solvent control and to nominal concentrations of 0.0034, 0.0065, 0.013, 0.025 and 0.050 mg pyraclostrobin/L (corresponding to mean measured concentrations of 0.00291, 0.00557, 0.0108, 0.0240 and 0.0445 mg a.s./L). Hatchability, survival rate and behavior of sheepshead minnow embryos and fry were assessed throughout the study. Individual fish lengths and weights were measured at test termination.

The results are based on mean measured concentrations. Egg hatch was complete on day 4 in the control groups and the three lowest test item treatments. At 0.0240 mg a.s./L, egg hatch was completed on day 5. In the highest test item concentration of 0.0445 mg a.s./L, all animals were dead before hatch (day 4). Mean survival rates at hatch (day 4) and at test end (32 days post-hatch) were ≥ 95% in both the dilution water control and the solvent control and in the test item concentrations of up to and including 0.0108 mg a.s./L. At 0.0240 mg a.s./L mean survival was 29% at hatch on day 4 and 55% on day 32 post-hatch. No statistically significant effects on survival, time to hatch, time to first feeding, total length, wet weight or dry weight compared to the pooled control were observed at concentrations of up to and including 0.0108 mg a.s./L.

In an early life stage study with sheepshead minnows (*Cyprinodon variegatus*) the overall NOEC (36 d) for pyraclostrobin was determined to be 0.0108 mg a.s./L based on mean measured concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F, Reg. No. 304 428), lot no. N68, purity: 93.5%, dissolved in dimethylformamide (lot no. BW660).

B. STUDY DESIGN

Test species:	Sheepshead minnow (*Cyprinodon variegatus*); eggs less than 24 hours before test initiation, source: "Aquatic BioSystems, Inc.", Fort Collins Colorado, USA.
Test design:	Flow-through system (36 d); 5 test item concentrations plus a dilution water control and a solvent control; 4 replicate test chambers per treatment with 20 fertilized eggs in each; a proportional diluter system was used for intermittent introduction of the solutions to the test chambers. During the embryo stage, the developing embryos were incubated in glass cups. At the end of hatch (day 4 and 5), fish were released into the test chamber and randomly thinned to 10 fish per vessel. Daily assessment of hatch, swim-up, survival, signs of toxicity and abnormal behavior. On day 36 surviving animals were sacrificed and measured for length and weight.
Endpoints:	NOEC values based on hatch rate, post-hatch survival, sublethal effects, growth and time spans to hatch.
Test concentrations:	Control (dilution water), solvent control (0.1 mL dimethylformamide/L) and 0.0034, 0.0065, 0.013, 0.025 and 0.050 mg pyraclostrobin/L (nominal); corresponding to mean measured concentrations of 0.00291, 0.00557, 0.0108, 0.0240 and 0.0445 mg a.s./L.
Test conditions:	Test vessels: 9 L glass aquaria (15 x 30 x 20 cm) with a test volume of approx. 7.0 L; 4 replicate test chambers; glass incubation cups (used during embryo stage) with 8.5 cm diameter closed on one end with Nitex® screen; two incubation cups per test chamber; dilution water: filtered natural seawater diluted with deionized water,; water temperature: 29.0°C - 30.8°C; pH 7.5 - 8.1; oxygen content: 5.4 mg/L - 7.9 mg/L; salinity: 15 - 16 ppt; light intensity: approx. 42 foot candles; photoperiod: 16 hours light : 8 hours dark; flow rate: approx. 6.7 volume additions per 24 hours per vessel; feeding: fish were fed 2-3 times daily *ad libitum* freshly hatched *Artemia salina* nauplii from day 6 onwards until 1 day before study termination; no aeration.
Analytics:	Analytical verification of test item concentrations was conducted using an HPLC-method with UV-detection.
Statistics:	Descriptive statistics; t-test for comparison of the dilution water control and solvent data ($\alpha = 0.05$); ANOVA followed by Bonferroni's test, William's test or Kruskal & Wallis's test to calculate NOEC values.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of the test item concentrations was conducted in all concentrations at test initiation, at regular intervals during the study and at test end, except for the highest test item concentration, where analytical measurements were only conducted on days 0 and 7. Recoveries of pyraclostrobin ranged from 75.3 to 103.1% of nominal concentrations at test initiation and from 79.4 to 84.0% of nominal at test termination. The following biological results are based on mean measured concentrations.

Biological results: No statistically significant differences were determined between the control and the solvent control data (t-test; $\alpha = 0.05$). Thus, the data from both control groups were pooled and the pooled data set was used for statistical evaluation of treatment related effects. Egg hatch was complete on day 4 in the control groups and the three lowest test item treatments. At 0.0240 mg a.s./L egg hatch was completed on day 5. In the highest test item concentration of 0.0445 mg a.s./L, all animals were dead before hatch (day 4). Mean survival rates at hatch (day 4) and at test end (32 days post-hatch) were $\geq$ 95% in both the dilution water control and the solvent control and in test item concentrations of up to and including 0.0108 mg a.s./L. At 0.0240 mg a.s./L, mean survival was 29% at hatch and 55% on day 32 post-hatch, respectively. No statistically significant effects on survival, time to hatch, time to first feeding, total length, wet weight or dry weight compared to the pooled control were observed at concentrations of up to and including 0.0108 mg a.s./L (Bonferroni's test / William's test / Kruskal & Wallis's test). Sublethal effects (i.e., lethargy and/or erratic swimming) were noted at 0.0108 mg a.s./L on day 4 (at hatch) and at 0.0240 mg a.s./L on days 4 and 5. These effects were not observed at any other time during the test. No other sublethal effects (other than delayed hatch) were observed at any test concentration at any time during the test. The results are summarized in Table 8.2.2.1-2.

Table 8.2.2.1-2: Chronic toxicity of pyraclostrobin to sheepshead minnow (*Cyprinodon variegatus*) in a fish early life stage test (36 d)

Concentration [mg a.s./L] (nominal)	**Control**	**Solvent control**	**0.0034**	**0.0065**	**0.013**	**0.025**	**0.050**
Concentration [mg a.s./L] (mean measured)	**--**	**--**	**0.00291**	**0.00557**	**0.0108**	**0.0240**	**0.0445**

[2] not determined; no fish survived at the concentration above 0.0240 mg a.s./L.

III. CONCLUSION

In an early life stage study with sheepshead minnows (*Cyprinodon variegatus*) the overall NOEC (36 d) for pyraclostrobin was determined to be 0.0108 mg a.s./L based on mean measured concentrations.

CA 8.2.2.2 Fish full life cycle test

As shown before the chronic toxicity to fish is fully addressed in a number of studies (partly already evaluated during the previous Annex I inclusion process, partly new studies performed for registration in the U.S.). No additional fish full life cycle study is required and no (new) study has been conducted.

CA 8.2.2.3 Bioconcentration in fish

Bioconcentration in fish was addressed in respective studies, which were evaluated already during the previous Annex I inclusion process. No further studies are required or were conducted.

CA 8.2.3 Endocrine disrupting properties

Based on the physical, chemical and structural characteristics of the active substance pyraclostrobin as well as based on results of available studies there is no indication of endocrine disrupting properties of this active substance. Thus, no studies are required.

CA 8.2.4 Acute toxicity to aquatic invertebrates

CA 8.2.4.1 Acute toxicity to *Daphnia magna*

The following acute toxicity study on *Daphnia magna* performed with the metabolite BF 500-3 is provided in support of the aquatic risk assessment. The study was requested by Canadian authorities and has not been evaluated previously on EU level.

Report:	CA 8.2.4.1/1 Bergtold M., Janson G., 2006a Acute toxicity of Reg.No. 340 266 (Metabolite of BAS 500 F) to Daphnia magna STRAUS in a 48 hour static test 2006/1038907
Guidelines:	OECD 202, EPA 850.1010
GLP:	yes (certified by Landesamt fuer Umweltschutz und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a static acute limit test, water flea neonates were exposed to BF 500-3 (metabolite of pyraclostrobin) at a single nominal concentration of 0.100 mg/L (limit test at a concentration above standard water solubility of this metabolite), a dilution water control and a solvent control (acetone) in 4 replicates per concentration containing 5 daphnids each. The test item was dissolved and tested with and without centrifugation (to check potential impact of potentially undissolved test item) of the test water prior to the addition of the daphnids. Daphnids were observed for immobility 24 hours and 48 hours after start of exposure.

The biological results are based on nominal concentrations of the test item. No mortality or other symptoms of toxicity were observed in the control, the solvent control and the test item treatments after 48 hours of exposure.

In a 48-hour static acute limit test with *Daphnia magna* the EC_{50} of BF 500-3 (metabolite of pyraclostrobin) was determined to be > 0.100 mg/L (concentration just above water solubility) based on nominal concentrations. The NOEC was ≥ 0.100 mg/L (nominal).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BF 500-3 (Reg. No. 340 266; synonym: 500M07; metabolite of pyraclostrobin), batch no. L74-118, purity: 99.9%.

B. STUDY DESIGN

Test species:	Water flea (*Daphnia magna* STRAUS), neonates from in-house culture (originally obtained from Institute National de Recherché Chimique Appliquée, France), > 2 < 24 hours old at test initiation.
Test design:	Static system (48 hours), limit test: 1 test concentration plus a control and a solvent control; the test item was dissolved and tested with and without centrifugation of the test water prior to the addition of the daphnids; 4 replicates with 5 daphnids in each; assessment of immobility after 24 and 48 hours.
Endpoints:	EC_{50} and NOEC based on immobility of daphnids.
Test concentrations:	Control (dilution water), solvent control (acetone), and 0.100 mg BF 500-3/L (nominal).
Test conditions:	Glass vessels, test volume 50 mL, dilution water: "M4" (Elendt medium); temperature: 20.6°C - 21.8°C; pH 7.92 - 8.00; oxygen content: 8.2 mg/L - 8.9 mg/L; total hardness: 2.39 mmol/L; conductivity: 665 µS/cm; photoperiod: 16 hours light : 8 hours dark; light intensity: 260 - 320 lux; no feeding and no aeration.
Analytics:	Analytical verification of test item concentrations was conducted using an HPLC-method with MS-detection.
Statistics:	Descriptive statistics.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentration was conducted in the controls and the test item treatment (standard and centrifuged test water) at the beginning and at the end of the test. Mean measured values for BF 500-3 in the non-centrifuged treatment were 101.8% of nominal at test initiation and 91.0% of nominal at test termination. In the centrifuged treatment mean measured concentrations of 95.7% of nominal at test initiation and 88.2% of nominal at test termination were determined. Hence, centrifugation had only a minor effect on the recovery of the test item though the test item was applied at a concentration just above its standard water solubility. As measured concentrations confirmed correct application of the test item, the following biological results are based on nominal concentrations.

Biological results: No mortality or other symptoms of toxicity were observed in the control, the solvent control and at the test item treatments after 48 hours of exposure. For results see Table 8.2.4.1-1.

Table 8.2.4.1-1: Effect of BF 500-3 (metabolite of pyraclostrobin) on *Daphnia magna* mobility

Concentration [mg/L] (nominal)	Control	Solvent control	0.100 (a)	0.100 (b)
Immobility (24 h) [%]	0	0	0	0
Immobility (48 h) [%]	0	0	0	0
Endpoints [mg BF 500-3/L] (nominal)				
EC_{50} (48 h)	> 0.100			
NOEC (48 h)	≥ 0.100			

(a) standard test water (non-centrifuged treatment); (b) centrifuged test water

III. CONCLUSION

In a 48-hour static acute limit test with *Daphnia magna* the EC_{50} of BF 500-3 (metabolite of pyraclostrobin) was determined to be > 0.100 mg/L (concentration just above water solubility) based on nominal concentrations. The NOEC was ≥ 0.100 mg/L (nominal).

The following acute toxicity study on *Daphnia magna* performed with the metabolite BF 500-5 is provided in support of the aquatic risk assessment. The study was conducted due to findings of this metabolite in new required e-fate studies and has not been evaluated previously.

Report:	CA 8.2.4.1/2 Kuhl R., Frank C., 2014b Acute toxicity of Reg.No. 298327 (BF 500-5, metabolite of Pyraclostrobin) to Daphnia magna in a static 48-hour immobilization test 2013/1349201
Guidelines:	OECD 202 (2004), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part C.2
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

In a static acute toxicity laboratory study, water flea neonates were exposed to BF 500-5 (metabolite of pyraclostrobin) at nominal concentrations of 0 (control), 0.625, 1.25, 2.5, 5.0 and 10.0 mg/L in 4 replicates per concentration containing 5 daphnids each. Daphnids were observed for immobility 24 hours and 48 hours after start of exposure.

The biological results are based on nominal concentrations of the test item. After 48 h of exposure, no immobility of daphnids was observed in the control and at test item concentrations of up to and including 5.0 mg/L, whereas 15% of the daphnids were immobile at the highest test item concentration of 10.0 mg/L. Statistically significant effects on mobility of daphnids after 48 h of exposure were observed at the highest test item concentration.

In a 48-hour static acute toxicity study with *Daphnia magna* the EC_{50} of BF 500-5 (metabolite of pyraclostrobin) was determined to be > 10.0 mg/L based on nominal concentrations. The NOEC was 5.0 mg/L (nominal).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BF 500-5 (Reg. No. 298 327, synonym: 500M04, metabolite of pyraclostrobin,), batch no. L84-174, purity: 99.6% (± 1.0%).

B. STUDY DESIGN

Test species:	Water flea (*Daphnia magna* STRAUS), neonates from in-house culture, < 24 hours old at test initiation and not first brood progeny.
Test design:	Static system (48 hours), 5 test concentrations plus dilution water control, 4 replicates with 5 daphnids in each; assessment of immobility after 24 and 48 hours.
Endpoints:	EC_{50} and NOEC based on immobility of daphnids.
Test concentrations:	Control (dilution water), 0.625, 1.25, 2.5, 5.0 and 10.0 mg BF 500-5/L (nominal).
Test conditions:	100 mL glass beakers, test volume 60 mL, dilution water: "M4" (Elendt medium); temperature: 19.3°C - 20.2°C; pH 7.7 - 7.8; oxygen content: 7.8 mg/L - 8.6 mg/L; photoperiod: 16 hours light : 8 hours dark; light intensity: 950 - 1100 lux; no feeding; no aeration.
Analytics:	Analytical verification of test item concentrations was conducted using an LC-method with MS/MS detection.
Statistics:	Descriptive statistics; Williams t-test for determination of the NOEC.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentration was conducted in each concentration at the beginning and at the end of the test. Mean measured values for BF 500-5 ranged from 89 to 98% of nominal concentrations at test initiation and from 86 to 99% at test termination. As analytical data confirmed correct application of the test item, the following biological results are based on nominal concentrations.

Biological results: After 48 h of exposure, no immobility of daphnids was observed in the control and at test item concentrations of up to and including 5.0 mg/L, whereas 15% of the daphnids were immobile at the highest test item concentration of 10.0 mg/L. Statistically significant effects on mobility of daphnids after 48 h of exposure were observed at the highest test item concentration (Williams t-test, $\alpha = 0.05$). For results see Table 8.2.4.1-2.

Table 8.2.4.1-2: Effect of BF 500-5 (metabolite of pyraclostrobin) on *Daphnia magna* immobility

Concentration [mg/L] (nominal)	Control	0.625	1.25	2.5	5.0	10.0
Immobility (24 h) [%]	0	0	0	0	0	5
Immobility (48 h) [%]	0	0	0	0	0	15 *
	Endpoints [mg BF 500-5/L] (nominal)					
EC_{50} (48 h)	> 10.0					
NOEC (48 h)	5.0					

* Statistically significantly different compared to the control (Williams t-test, $\alpha = 0.05$)

III. CONCLUSION

In a 48-hour static acute toxicity study with *Daphnia magna* the EC_{50} of BF 500-5 (metabolite of pyraclostrobin) was determined to be > 10.0 mg/L based on nominal concentrations. The NOEC was 5.0 mg/L (nominal).

CA 8.2.4.2 Acute toxicity to an additional aquatic invertebrate species

The following acute toxicity study on the saltwater mysid *Americamysis bahia* performed with the active substance pyraclostrobin is not required for registration in the EU and it has not been evaluated previously on EU level. However, the study was conducted due to U.S. data requirements and it is provided for completeness.
The 48-h LC_{50} obtained in the 96 h study on *A. bahia* is used for the risk assessment of pyraclostrobin according to EU Regulation 283/2013 (European Commission, 2013) which describes the data requirements for active substances. Also the recent EFSA Guidance on tiered risk assessment for plant protection products for aquatic organisms in edge-of-field surface waters (EFSA, 2013) advises to use the 48-h endpoint, which allows an easy comparison to the other standard acute invertebrate tests. Therefore, only the 48-h results are shown.

Report:	CA 8.2.4.2/1 Boeri R.L. et al., 2000d Flow-Through Acute Toxicity of BAS 500 F to the Mysid, Americanysis bahia 2000/5031
Guidelines:	EPA 850.1035, EPA 72-3(b)
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

In a flow-through acute toxicity laboratory study, saltwater mysids were exposed to a dilution water control, a solvent control and to nominal concentrations of 0.0010, 0.0018, 0.0029, 0.0048 and 0.0080 mg pyraclostrobin/L (nominal) (corresponding to mean measured concentrations of 0.00079, 0.0014, 0.0021, 0.0036 and 0.0060 mg a.s./L) in two replicates per treatment containing 10 mysids each. Saltwater mysids were observed for survival and symptoms of toxicity directly after start of exposure and 24, 48, 72 and 96 hours after start of exposure.

The biological results are based on mean measured concentrations of the test item. After 48 hours of exposure no mortality and no other toxic effects were observed in the control, the solvent control and in concentrations of up to and including 0.0036 mg/L, whereas 20% mortality was observed at the highest test item concentrations of 0.0060 mg a.s./L. After 48 hours, no sub-lethal effects were found.

In a flow-through acute toxicity study with saltwater mysids (*Americamysis bahia*) the LC_{50} (48 h) for pyraclostrobin was determined to be > 0.00597 mg a.s./L.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F; Reg. No. 304 428), batch no. 27882/191/C, purity: 97.09%.

B. STUDY DESIGN

Test species: Saltwater mysid (*Americamysis bahia*), juveniles, age: less than 24 hours old; average wet weight of control mysids: 0.88 mg; source: in-house cultures.

Test design: Flow-through system (96 hours); 5 test item concentrations plus a control and a solvent control, 2 replicates per treatment; 10 mysids per replicate (loading 0.00059 g mysid/L); assessment of mortality and symptoms of toxicity directly after start of exposure and 24, 48, 72 and 96 hours after start of exposure.

Endpoints: LC_{50} (48 h), mortality and sub-lethal effects.

Test concentrations: Control (dilution water), solvent control (0.1 mL dimethylformamide/L) and 0.0010, 0.0018, 0.0029, 0.0048 and 0.0080 mg pyraclostrobin/L (nominal), corresponding to mean measured concentrations of 0.00079, 0.0014, 0.0021, 0.0036 and 0.0060 mg pyraclostrobin/L.

Test conditions: Glass aquaria (20 L), test volume 15 L; test chambers: glass cylinders (8 cm in height and 8 cm in diameter) with mesh screen attached to the bottom; dilution water: filtered, sterilized and aerated natural seawater mixed with deionized water; flow rate: 6.5 volume additions per 24 hours on average; salinity: 16 - 17‰; temperature: 21.2°C - 22.9°C; pH 7.9 - 8.1; oxygen content: 7.9 - 8.3 mg/L; photoperiod 16 h light : 8 h dark with a 15 minute transition period between dark and light; light intensity: 55 foot-candles; feeding: juvenile mysids were fed daily with brine shrimps (*Artemia salina*); no aeration.

Analytics: Analytical verification of test item concentrations was conducted using an HPLC-method with UV-detection.

Statistics: Descriptive statistics; binomial/nonlinear interpolation method for calculation of the LC_{50}.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each concentration at the beginning and at the end of the test. The analytically determined concentrations of pyraclostrobin ranged from 66.8 to 78.0% of nominal concentrations at test initiation and from 66.8 to 83.2% of nominal at test termination. The following biological results are based on mean measured concentrations.

Biological results: After 48 hours of exposure no mortality and no other toxic effects were observed in the control, the solvent control and in concentrations of up to and including 0.0036 mg/L, whereas 20% mortality was observed at the highest test item concentrations of 0.0060 mg a.s./L. After 48 hours, no sub-lethal effects were found. The results are summarized in Table 8.2.4.2-1.

Table 8.2.4.2-1: Acute toxicity of pyraclostrobin to saltwater mysids (*Americamysis bahia*)

Concentration [mg a.s./L] (nominal)	**Control**	**Solvent control**	**0.0010**	**0.0018**	**0.0029**	**0.0048**	**0.0080**
Concentration [mg a.s./L] (mean measured)	**--**	**--**	**0.00079**	**0.0014**	**0.0021**	**0.0036**	**0.0060**
Mortality [%] (48 h)	0	0	0	0	0	0	20
Symptoms after 48 h	none	none	none	none	none	none	none.
Endpoints [mg pyraclostrobin/L] (mean measured)							
LC_{50} (48 h)	> 0.00597						

III. CONCLUSION

In a flow-through acute toxicity study with saltwater mysids (*Americamysis bahia*) the LC_{50} (48 h) for pyraclostrobin was determined to be > 0.00597 mg a.s./L.

The following acute toxicity study on the eastern oyster (*Crassostrea virginica*) performed with the active substance pyraclostrobin is not required for registration in the EU and it has not been evaluated previously on EU level. The study was conducted due to U.S. data requirements and it is provided for completeness.

Report:	CA 8.2.4.2/2 Boeri R.L. et al., 2000e Flow-through mollusc shell deposition test with BAS 500 F 2000/5042
Guidelines:	EPA 850.1025, EPA 72-3(c)
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

In a 96-hour acute toxicity laboratory study the effect of pyraclostrobin on shell deposition of eastern oysters was investigated under flow-through conditions. The eastern oysters were exposed to a dilution water control, a solvent control and to nominal concentrations of 0.0033, 0.0055, 0.0090, 0.015 and 0.025 mg pyraclostrobin/L (corresponding to mean measured concentrations of 0.0027, 0.0041, 0.0065, 0.0128 and 0.0215 mg a.s./L) in groups of 10 oysters per replicate with two replicates per treatment. Eastern oysters were observed for survival and symptoms of toxicity daily during the exposure period. Measurements of shell deposition for each oyster were made after 96 hours.

The biological results are based on mean measured concentrations of the test item. After 96 hours of exposure, survival of oysters was 95 and 100% in the control and the solvent control, respectively. No mortality occurred at test item concentrations of up to and including 0.0065 mg pyraclostrobin/L, whereas 5 and 10% mortality was observed at 0.0128 mg a.s./L and 0.0215 mg a.s./L, respectively. Statistically significant inhibition of shell growth compared to the pooled control / solvent control was observed at the three highest tested concentrations.

In a flow-through acute toxicity study with eastern oysters (*Crassostrea virginica*), the LC_{50} was > 0.0215 mg a.s./L; the EC_{50} (96 h) for pyraclostrobin was 0.0125 mg a.s./L based on mean measured concentrations. The NOEC (96 h) was determined to be 0.00406 mg a.s./L.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F; Reg. no.: 304 428), batch no. 27882/191/C; purity: 97.09%.

B. STUDY DESIGN

Test species:	Eastern oyster (*Crassostrea virginica*), juveniles, height: 30 - 50 mm; source: "P. Cummins Oyster Company", Baltimore, Maryland, USA.
Test design:	Flow-through system (96 hours); 5 test item concentrations plus a control and a solvent control, 2 replicates for each test item concentration and the controls with 10 oysters per replicate (20 animals per treatment); initially and daily assessment of mortality and symptoms of toxicity; measurements of shell deposition 96 hours after start of exposure.
Endpoints:	EC_{50} and NOEC for shell growth inhibition, mortality and symptoms of toxicity.
Test concentrations:	Control (dilution water: unfiltered seawater), solvent control (0.1 mL dimethylformamide/L); 0.0033, 0.0055, 0.0090, 0.015 and 0.025 mg pyraclostrobin/L (nominal), corresponding to mean measured concentrations of 0.0027, 0.0041, 0.0065, 0.0128 and 0.0215 mg a.s./L.
Test conditions:	20 L glass aquaria, test volume 15 L, natural unfiltered seawater, flow rate: average of 8.7 volume additions per 24 hours in each test vessel, 0.54 L per oyster per hour; salinity: 34‰; temperature: 20.2°C - 22.0°C; pH 7.8 - 8.1; oxygen content: 5.5 mg/L - 8.5 mg/L; photoperiod 16 h light : 8 h dark with a 15 minute transition period between dark and light; light intensity: 50 foot candles; no aeration; live marine phytoplankton as supplement to existing food in unfiltered seawater used as dilution water.
Analytics:	Analytical verification of test item concentrations was conducted using an HPLC-method with UV-detection.
Statistics:	Descriptive statistics; t-test (a = 0.05) for comparison of shell deposition data in the control groups; standard statistical techniques for calculation of EC_{50}, ANOVA followed by Bonferroni's test for shell deposition data of the test item treatments.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each concentration at test initiation and at test termination. Mean measured concentrations for pyraclostrobin ranged from 73 to 89% of nominal concentrations at test initiation and from 72 to 85% of nominal at test termination. The following biological results are based on mean measured concentrations.

Biological results: After 96 hours of exposure, survival of oysters was 95 and 100% in the control and the solvent control, respectively. No mortality occurred at test item concentrations of up to and including 0.0065 mg pyraclostrobin/L, whereas 5 and 10% mortality was observed at 0.0128 mg a.s./L and 0.0215 mg a.s./L, respectively. No sublethal effects were noted during the exposure period in the controls and the test item treatments. Control and solvent control oysters deposited an average of 2.3 and 2.5 mm of new shell during the test, respectively. No statistically significant difference in shell deposition was observed between the control groups (t-test, $\alpha = 0.05$). Subsequent statistical analyses were performed by comparing the pooled control and solvent control data to the treatment data. Statistically significant inhibition of shell growth compared to the pooled control / solvent control was observed at the three highest tested concentrations (Bonferroni's test). The results are summarized in Table 8.2.4.2-2.

Table 8.2.4.2-2: Acute toxicity (96 h) of pyraclostrobin to eastern oysters (*Crassostrea virginica*)

Concentration [mg a.s./L] (nominal)	**Control**	**Solvent control**	**0.0033**	**0.0055**	**0.0090**	**0.015**	**0.025**
Concentration [mg a.s./L] (mean measured)	**--**	**--**	**0.0027**	**0.0041**	**0.0065**	**0.0128**	**0.0215**

* Statistically significant difference compared to the pooled control / solvent control (Bonferroni's test).

III. CONCLUSION

In a flow-through acute toxicity study with eastern oysters (*Crassostrea virginica*), the LC_{50} was > 0.0215 mg a.s./L; the EC_{50} (96 h) for pyraclostrobin was 0.0125 mg a.s./L based on mean measured concentrations. The NOEC (96 h) was determined to be 0.00406 mg a.s./L.

CA 8.2.5 Long-term and chronic toxicity to aquatic invertebrates

CA 8.2.5.1 Reproductive and development toxicity to *Daphnia magna*

The reproductive and development toxicity to *Daphnia magna* has been addressed and evaluated already during the previous Annex I inclusion process. No further study is required or was conducted.

CA 8.2.5.2 Reproductive and development toxicity to an additional aquatic invertebrate species

The following life-cycle test on the saltwater mysid *Americamysis bahia* performed with the active substance pyraclostrobin is not required for registration in the EU and it has not been evaluated previously on EU level. The study was conducted due to U.S. data requirements and it is provided for completeness.
Note: This study had apparent deficiencies and has therefore not been accepted as valid by the US EPA.

Report:	CA 8.2.5/1 Wyskiel D.C. et al., 2004a BAS 500 F: A flow-through life-cycle toxicity test with the Saltwater Mysid Americamysis bahia 2004/5000004
Guidelines:	EPA 72-4 (b)
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

The chronic toxicity of pyraclostrobin to saltwater mysids (*Americamysis bahia*) was evaluated in a 28-day full-life cycle test under flow-through conditions. Mysids were exposed to a dilution water control, a solvent control and to nominal test item concentrations of 0.28, 0.52, 1.0, 2.0 and 4.0 µg pyraclostrobin/L (corresponding to mean measured concentrations of 0.27, 0.50, 0.93, 1.9 and 3.6 µg a.s./L). Survival, reproductive success and symptoms of toxicity were assessed throughout the study. Length, dry weight and wet weight of surviving mysids were determined at test termination.

The biological results are based on mean measured concentrations of the test item. Survival of unaffected saltwater mysids was statistically significantly affected compared to the pooled control at the three highest test item concentrations of 0.93, 1.9 and 3.6 µg pyraclostrobin/L. Reproductive success and mean total length was statistically significantly different to the pooled control data at the two highest test item concentrations. Mean dry and wet weight of surviving mysids at the test item concentrations of up to and including 1.9 µg a.s./L showed no statistically significant differences compared to the pooled control data.

In a flow-through chronic toxicity study with saltwater mysids (*Americamysis bahia*), the overall NOEC (28 d) for pyraclostrobin was determined to be 0.50 µg a.s./L based on mean measured concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F, Reg. no. 304 428), batch no. WF19407, purity: 99.7%.

B. STUDY DESIGN

Test species: Saltwater mysids (*Americamysis bahia*), juveniles, age: less than 24 hours old; source: in-house cultures, original culture obtained from "Aquatic BioSystems, Inc.", Fort Collins, Colorado, USA.

Test design: Flow-through system (28 days); 5 test concentrations plus control and solvent control, 2 replicates per test item concentration; 30 mysids per test vessel; 15 mysids per retention chamber; on day 14 when the sex of mysids could be determined, up to ten females were segregated from the population in each glass aquarium and paired with a male in the test chambers, unpaired mysids were sexually differentiated and placed in separate test chambers; daily assessment of survival and symptoms of toxicity, assessment of reproduction (number of offspring produced by each female) from day 17 on; determination of length, dry weight and wet weight of surviving mysids at test termination.

Endpoints: NOEC based on survival, reproductive success, length, dry and wet weight.

Test concentrations: Control (dilution water), solvent control (0.1 mL dimethylformamide/L) and 0.28, 0.52, 1.0, 2.0 and 4.0 µg pyraclostrobin/L (nominal), corresponding to mean measured concentrations of 0.27, 0.50, 0.93, 1.9 and 3.6 µg a.s./L.

Test conditions: 20 L glass aquaria (21 cm x 40 cm x 25 cm) containing two test chambers, test volume up to 7 L; test chambers: glass petri dishes with a 12 cm high collar of Nitex screen attached (from test initiation until day 14: petri dishes of 10 cm diameter, from day 14 on: petri dishes of 6 cm diameter); dilution water: filtered, aerated, sterilized and diluted seawater; flow rate: 13.6 volume additions per 24 hours on average; salinity: 15 - 17‰; temperature: 23.0°C - 26.7°C; pH 7.5 - 8.9; oxygen content: 5.0 - 7.9 mg/L; photoperiod 16 h light : 8 h dark with a 15 minute transition period between dark and light; light intensity: approx. 38 foot candles; feeding: newly hatched *Artemia salina nauplii* three times per day, no feeding during the final 24 hours; no aeration.

Analytics: Analytical verification of test item concentrations was conducted using an HPLC-method with UV-detection.

Statistics: Descriptive statistics, Bonferroni's or Williams's test for determination of NOEC values ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each concentration at test initiation, on days 7, 14, 21, and at test termination on day 28. Measured concentrations for pyraclostrobin were between 61.5 and 100.0% of nominal at test initiation. Measured concentrations after 7, 14, and 21 days ranged from 107.1 to 125.0%, from 80.0 to 119.2% and from 83.0 to 107.7% of nominal, respectively. At test termination, measured concentrations were between 73.1 and 85.0% of nominal. The following biological results are based on mean measured concentrations.

Biological results: The data from both control groups were pooled and the pooled data set was used for statistical evaluation of treatment related effects. Survival of unaffected (not lethargic) saltwater mysids was statistically significantly affected compared to the pooled control at the three highest test item concentrations of 0.93, 1.9 and 3.6 µg pyraclostrobin/L (Bonferroni's test / Williams's test; $\alpha = 0.05$). Reproductive success and mean total length was statistically significantly different to the pooled control data at the two highest test item concentrations (Bonferroni's test / Williams's test; $\alpha = 0.05$). Mean dry and wet weight of surviving mysids at the test item concentrations of up to and including 1.9 µg a.s./L showed no statistically significant differences compared to the pooled control data. The results are summarized in Table 8.2.5-1.

Table 8.2.5-1: Chronic toxicity (28 d) of pyraclostrobin to saltwater mysids (*Americamysis bahia*)

Concentration [µg a.s./L] (nominal)	**Control**	**Solvent control**	**0.28**	**0.52**	**1.0**	**2.0**	**4.0**
Concentration [µg a.s./L] (mean measured)	**--**	**--**	**0.27**	**0.50**	**0.93**	**1.9**	**3.6**
Survival (unaffected mysids) on day 28 [%]	88	80	83	82	73 *	52 *	0 *

	Endpoints [µg pyraclostrobin/L] (mean measured)						
$NOEC_{overall}$ (28 d)	0.50						

§ Defined as the sum of the total number of young each day divided by the number of surviving females on the respective day
* Statistically significant differences compared to pooled control (Bonferroni's test / Williams's test; $\alpha = 0.05$).

III. CONCLUSION

In a flow-through chronic toxicity study with saltwater mysids (*Americamysis bahia*), the overall NOEC (28 d) for pyraclostrobin was determined to be 0.50 µg a.s./L based on mean measured concentrations.

Note: This study had apparent deficiencies and has therefore not been accepted as valid by the US EPA.

The following life-cycle test on the saltwater mysid *Americamysis bahia* performed with the active substance pyraclostrobin is not required for registration in the EU and it has not been evaluated previously on EU level. The study was conducted due to U.S. data requirements following deficiencies in the first chronic mysid study. It is provided for completeness.

Report:	CA 8.2.5/2 Dinehart S., 2013a BAS 500 F: Life-cycle toxicity test of the saltwater mysid, Americamysis bahia, conducted under flow-through test conditions 2013/7002075
Guidelines:	EPA 850.1000, EPA 850.1350, EPA 72-4
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

The chronic toxicity of pyraclostrobin to saltwater mysids (*Americamysis bahia*) was evaluated in a 31-day full-life cycle test under flow-through conditions. Mysids were exposed to a dilution water control, a solvent control and to nominal test item concentrations of 0.25, 0.50, 1.0, 2.0, and 4.0 µg pyraclostrobin/L (corresponding to mean measured concentrations of 0.198, 0.365, 0.676, 1.28 and 2.57 µg a.s./L). Survival, reproductive success and symptoms of toxicity were assessed throughout the study. For the males and females of the parental generation, body length was determined after 14 days of exposure and at test termination. Additionally, dry weight was determined at test termination. The body length of the males and females of the filial generation was determined after 10 days of exposure

The biological results are based on mean measured concentrations. Survival of F_0-generation mysids was statistically significantly affected compared to the control at the highest test item concentration of 2.57 µg pyraclostrobin/L after 7 days of exposure. However, this effect was considered to be not biologically relevant, because the magnitude of the difference in percent survival was very small (i.e. 100% survival in the control compared to 97% survival at 2.57 µg a.s./L). There were no statistically significant differences among survival rates of the F_0-generation after 13, 14, 21, and 31 days of exposure compared to the control. There was a statistically significant reduction in the mean number of young produced per female at the highest test item concentration compared to the control. Length of F_0-males and females exposed for 14 days, length of F_0-males exposed for 31 days and weight of F_0-females exposed for 31 days was statistically significantly reduced at the highest test item concentration only. There was a slight but statistically significantly effect on the weight of F_0-males at the three highest test item concentrations. However, there was no impact on female weight and no impact on fecundity/reproductive performance (except for the highest treatment level). Therefore, though statistically significant, this impact is not of biological relevance and thus not considered an adverse effect. No statistically significant adverse effects on survival and growth of the F_1-generation mysids were detected in any of the test item concentrations tested.

In a flow-through chronic toxicity study with saltwater mysids (*Americamysis bahia*), the overall NOAEC (31 d) for pyraclostrobin was determined to be 1.28 µg a.s./L based on mean measured concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F; Reg. no.: 304 428), batch no. CD-001236, purity: 99.02%.

B. STUDY DESIGN

Test species:	Saltwater mysid (*Americamysis bahia*), juveniles, age: less than 24 hours old; source: in-house culture.
Test design:	Flow-through system (31 d); 5 test item concentrations plus a control and a solvent control, 3 replicates for each test item concentration, the control and the solvent control, two retention baskets per test vessel: one containing mysids for reproduction observations and one for growth observations. F_0-generation: 15 mysids per retention basket; 30 mysids per test vessel; pairing of mysids on day 13 by transferring male-female pairs from retention baskets into brood baskets (7 pairs per replicate); remaining mysids (after isolation of male-female pairs) were transferred to a single brood basket; determination of dry weight on day 31; measurement of body length after 14 days of exposure for mysids in the growth-retention baskets and on day 31 for paired mysids in brood baskets; assessment of survival on days 7, 13 (pre-pairing) and on days 14, 21 and 31 (post-pairing); reproduction (days to first brood release and number of young per female). F_1-generation: started with the first 15 post-larval F1-mysids; post-larval F1-mysids were assigned to retention baskets within the same test vessels as used for F0-mysid exposure; F1-mysids were exposed for 10 days; assessment of survival 4, 7 and 10 days after start of exposure; measurement of body length after 10 days of exposure.
Endpoints:	NOEC based on survival, reproductive success, body length and dry weight.
Test concentrations:	Control (dilution water), solvent control (approximately 25 µL dimethylformamide/L), 0.25, 0.50, 1.0, 2.0, and 4.0 µg pyraclostrobin/L (nominal), corresponding to mean measured concentrations of 0.198, 0.365, 0.676, 1.28 and 2.57 µg pyraclostrobin/L.

Test conditions:	Test vessels: glass aquaria (test volume: 20 L) with a glass pane in the middle of the tank containing two holes near the bottom; retention baskets: glass petri dish base (approximately 1.5 x 15 cm) with a nylon screen collar (mesh size: 355 µm); brood baskets: glass Petri dish base (approximately 1.5 x 10 cm) with a nylon screen collar (mesh size: 355 µm). Dilution water: artificial saltwater; salinity: 18.2 - 20.3 ‰; temperature: 24.1 - 25.0°C; pH 7.3 - 8.1; oxygen content: 4.1 mg/L - 7.3 mg/L. Flow rate: until day 5: approximately 5.3 volume exchanges/aquarium/24 h; from day 6 on: approximately 7.5 volume exchanges/aquarium/24 h. Photoperiod: 14 h light : 10 h dark with two 30-minute transition periods of lower light intensity; light intensity: 315 - 390 lux. Feeding: brine shrimp nauplii (*Artemia* sp.) supplemented with a mixture of commercially available enrichment products at least twice daily, saltwater rotifers once daily, F1 mysids on the last day of the study were fed only once. Aeration: from day 17 on.
Analytics:	Analytical verification of test item concentrations was conducted using an HPLC-method with UV detection.
Statistics:	Descriptive statistics; Williams's test for determination of NOEC values ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each concentration at test initiation, on days 9, 14, 21, and at test termination on day 31. Measured concentrations for pyraclostrobin were between 63 and 74% of nominal at test initiation. Measured concentrations after 9, 14, and 21 days ranged from 65 to 99%, from 62 to 84% and from 53 to 71% of nominal, respectively. At test termination, measured concentrations were between 67 and 76% of nominal. The following biological results are based on mean measured concentrations.

Biological results: Survival of F_0-generation mysids was statistically significantly affected compared to the control at the highest test item concentration of 2.57 µg pyraclostrobin/L after 7 days of exposure (William's test, $\alpha = 0.05$). However, this effect was considered to be not biologically relevant, because the magnitude of the difference in percent survival was very small (i.e. 100% survival in the control compared to 97% survival at 2.57 µg a.s./L). There were no statistically significant differences among survival rates of the F_0-generation after 13, 14, 21, and 31 days of exposure compared to the control. There was a statistically significant reduction in the mean number of young produced per female at the highest test item concentration compared to the control. Length of F_0-males and females exposed for 14 days, length of F_0-males exposed for 31 days and weight of F_0-females exposed for 31 days was statistically significantly reduced at the highest test item concentration (William's test, $\alpha = 0.05$). There was a slight but statistically significantly effect on the weights of F_0-males at the three highest test item concentrations (William's test, $\alpha = 0.05$). However, there was no impact on female weight and no impact on fecundity/reproductive performance (except for the highest treatment level). Therefore, though statistically significant, this impact is not of biological relevance and thus not considered an adverse effect. No statistically significant adverse effects on survival and growth of the F_1-generation mysids were detected in any of the test item concentrations tested. The results are summarized in Table 8.2.5-2.

Endpoint [mg pyraclostrobin/L] (mean measured)									
$NOAEC_{overall}$ (31 d)					1.28				

***** Statistically significant differences compared to the control (William's test, $\alpha = 0.05$).
# Values represent mean and standard deviation from all replicates.
a) The statistically significant difference in F0-mysid survival rate in the 2.57 µg/L treatment on day 7 was judged not to be biologically meaningful because of the magnitude of the difference in mean percent survival between the control and the solvent control.
b) The 0.198 µg/L treatment was excluded from statistical analyses for reproduction endpoints because of low reproductive output from F_0-female mysids in this treatment which did not appear to reflect a test substance treatment-related effect.
c) Paired females that produced no young were excluded from the mean calculation.
d) Slight impact on weight only without impact on length, on females or on reproduction; thus not considered to be a biologically relevant adverse effect.

III. CONCLUSION

In a flow-through chronic toxicity study with saltwater mysids (*Americamysis bahia*), the overall NOAEC (31 d) for pyraclostrobin was determined to be 1.28 µg a.s./L based on mean measured concentrations.

CA 8.2.5.3 Development and emergence in *Chironomus riparius*

A spiked water toxicity study with *Chironomus riparius* was already evaluated during the previous Annex I inclusion process. The following additional spiked sediment toxicity study with *C. riparius* was also performed with the active substance pyraclostrobin. It is provided in support of the aquatic risk assessment covering the exposure via sediment, and has not been evaluated previously on EU level.

Report:	CA 8.2.5.3/1 Kuhl R., Wydra V., 2013a Effects of BAS 500 F (Pyraclostrobin) on the development of sediment dwelling larvae of Chironomus riparius in a sediment-water system - Exposed via spiked sediment 2012/1185699
Guidelines:	OECD 218 (2004)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

In a 28-day static spiked sediment study, non-biting midge larvae (*Chironomus riparius*) were exposed to pyraclostrobin at nominal concentrations of 0.3, 0.6, 1.2, 2.4 and 4.8 mg a.s./kg dry sediment. Additionally, a solvent (acetone) control and a water control were set up. All test item concentrations and the water control had 4 replicates, whereas 6 replicates were tested for the solvent control. 20 larvae were added to each test vessel.

The biological results are based on nominal concentrations of the test item. Additionally, biological endpoints based on mean measured values are given. In the control and the solvent control mean emergence rates of 78.8 and 71.7% and mean development rates of 0.057 and 0.055 were observed, respectively. In the test item concentrations of up to and including 4.8 mg a.s./kg dry sediment, between 60 and 76% of the test animals emerged until day 28. Statistically significant differences compared to the pooled control were found for the emergence rates at the highest test item concentration. No statistically significant effect on the development was observed in any treatment group.

In a 28-day static sediment test with *Chironomus riparius* the NOEC values of pyraclostrobin were determined to be 2.4 mg a.s./kg dry sediment (nominal; equivalent to the mean measured concentration of 1.37 mg a.s./kg dry sediment) based on emergence rate and ≥ 4.8 mg a.s./kg dry sediment (nominal; equivalent to the mean measured concentration of ≥ 2.83 mg a.s./kg dry sediment) based on development rate.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F, Reg. No. 304 428), batch no. 10-510009, purity: 100% (analytical).

B. STUDY DESIGN

Test species: Non-biting midge (*Chironomus riparius*), first instar larvae, 3 days old at test initiation; source: in-house culture.

Test design: Static system (28 days); 5 test concentrations plus a solvent (acetone) control and a water control, 4 replicates per test item concentration and for the water control, 6 replicates for the solvent control; 20 larvae were added to each test vessel; assessment of emergence rate and development rate.

Endpoints: NOEC and EC_{50} (regarding emergence rate and development rate).

Test concentrations: Solvent (acetone) control, water control, 0.3, 0.6, 1.2, 2.4 and 4.8 mg a.s./kg dry sediment (nominal), corresponding to mean measured concentrations of 0.66, 1.37 and 2.83 mg a.s./kg dry sediment in the 1.2, 2.4 and 4.8 a.s./kg dry sediment treatments.

Test conditions: 600 mL glass vessels with 100 g spiked wet artificial sediment (according to OECD 218), 400 mL M4 water (Elendt medium) corresponding to a water layer of about 6.4 cm; pH 7.6 - 8.6; oxygen 62% to 100%; total hardness: 284.8 - 320.4 mg $CaCO_3$/L at test initiation and 311.5 - 329.3 mg $CaCO_3$/L at test termination; conductivity: 588 µS/cm; ammonia: 1.2 mg/L at test initiation and 2.0 mg/L at test termination; water temperature: 20°C - 21°C; light intensity: 620 - 720 lux; photoperiod: 16 h light : 8 h dark; continuous gentle aeration; food: TetraMin (days 0-10: 0.5 mg food/larva/day, days 11-27: 0.5 - 1.0 mg food/larva/day).

Analytics: Analytical verification of test item concentrations was conducted using a LC-MS/MS-method.

Statistics: Descriptive statistics, Student-t-test ($p < 0.05$) for comparison of the emergence and development rates in the control groups; ANOVA followed by one-sided Williams' t-test for determination of the NOEC based on emergence and development rate ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations in the overlying water, the pore water and the sediment was conducted in the test concentrations of 1.2 and 4.8 mg a.s./kg dry sediment at the beginning and the end of the test. Recoveries in the sediment were in a range between 86 and 101% of the nominal concentrations at test initiation, and < LOQ (limit of quantification = 0.57 mg a.s./kg dry sediment) and 17% of nominal at test termination. Pyraclostrobin concentrations found in the overlaying water ranged from < LOQ (LOQ = 0.001 mg/L) to 0.4% of nominal concentrations on day 0 and from < LOQ to 0.03% of nominal on day 28. Measured pore water concentrations were between 0.2% and 0.9% of nominal on test start and < LOQ (LOQ = 0.001 mg/L) in both test treatments on test end. The following biological results are based on nominal sediment concentrations. Additionally, biological endpoints based on mean measured values are given.

Biological results: In the control and the solvent control mean emergence rates of 78.8% and 71.7% and mean development rates of 0.057 and 0.055 were observed, respectively. In the test item concentrations of up to and including 4.8 mg a.s./kg dry sediment, between 60% and 76% of the test animals emerged until day 28. No statistically significant difference was observed between the controls (Student-t-test, $p < 0.05$). Hence, the controls were pooled and used as the reference in all evaluations. Statistically significant differences compared to the pooled control were found for the emergence rates at the highest test item concentration (Williams Multiple t-test, $\alpha = 0.05$). No statistically significant effect on the development was observed in any treatment group (Williams Multiple t-test, $\alpha = 0.05$). The results are summarized in Table 8.2.5.3-1.

Table 8.2.5.3-1: Effects of pyraclostrobin on emergence and development of Chironomus riparius

Concentration [mg a.s./kg dry sediment] (nominal)	**Control**	**Solvent control**	**0.3**	**0.6**	**1.2**	**2.4**	**4.8**
Emergence rate (ER) [% emerged midges] #	78.8 ± 19.7	71.7 ± 11.7	66.3 ± 13.1	75.0 ± 4.1	73.8 ± 12.5	76.3 ± 9.5	60.0 * ± 10.8
Development rate per day (DR) #	0.057 ± 0.001	0.055 ± 0.001	0.057 ± 0.003	0.056 ± 0.001	0.056 ± 0.002	0.059 ± 0.003	0.058 ± 0.002
	Endpoints [mg pyraclostrobin/kg dry sediment] (nominal)						
$EC_{50\ emergence\ rate}$ (28 d)	> 4.8 (mean measured: > 2.83)						
$NOEC_{emergence\ rate}$ (28 d)	2.4 (mean measured: 1.37)						
$NOEC_{development\ rate}$ (28 d)	≥ 4.8 (mean measured: ≥ 2.83)						

Values represent mean and standard deviation from all replicates, each with 20 larvae.
* Statistically significant difference compared to the pooled control (Williams Multiple t-test, $\alpha = 0.05$).

III. CONCLUSION

In a 28-day static sediment test with *Chironomus riparius* the NOEC values of pyraclostrobin were determined to be 2.4 mg a.s./kg dry sediment (nominal; equivalent to the mean measured concentration of 1.37 mg a.s./kg dry sediment) based on emergence rate and ≥ 4.8 mg a.s./kg dry sediment (nominal; equivalent to the mean measured concentration of ≥ 2.83 mg a.s./kg dry sediment) based on development rate.

The following spiked sediment toxicity study on non-biting midge larvae (*Chironomus riparius*) performed with the metabolite BF 500-3 is provided in support of the aquatic risk assessment of a sediment metabolite and has not been evaluated previously.

Report:	CA 8.2.5.3/2 Kuhl R., Wydra V., 2013b Effects of Reg.No. 340266 (metabolite of BAS 500 F (Pyraclostrobin), synonymous: 500M07, BF 500-3) on the development of sediment dwelling larvae of Chironomus riparius in a sediment-water system - exposed via spiked sediment 2013/1237446
Guidelines:	OECD 218 (2004)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

In a 28-day static spiked sediment study, non-biting midge larvae (*Chironomus riparius*) were exposed to BF 500-3 (metabolite of pyraclostrobin) at nominal test item concentrations of 1.0, 2.0, 4.0, 8.0 and 16.0 mg/kg dry sediment. Additionally, a solvent (acetone) control and a water control were set up. All test item concentrations and the water control had 4 replicates, whereas 6 replicates were tested for the solvent control. 20 larvae were added to each test vessel.

The biological results are based on nominal concentrations of the test item. In the control and the solvent control mean emergence rates of 90.0 and 88.3% were observed, respectively. The mean development rate was 0.059 in both control groups. In test item concentrations of up to and including 16.0 mg/kg dry sediment, between 87.5 and 95.0% of the test animals emerged until day 28. No statistically significant differences were found for the emergence and development rates at any test item concentration when compared to the pooled control.

In a 28-day static sediment test with *Chironomus riparius* the NOEC of BF 500-3 (metabolite of pyraclostrobin) was determined to be ≥ 16.0 mg a.s./kg dry sediment based on emergence and development rate (nominal).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BF 500-3 (Reg. No. 340 266; synonym: 500M07; metabolite of pyraclostrobin), batch no. L74-118, purity: 99.9%.

B. STUDY DESIGN

Test species: Non-biting midge (*Chironomus riparius*), first instar larvae, 3 days old at test initiation; source: in-house culture.

Test design: Static system (28 days); 5 test concentrations plus a solvent (acetone) control and a water control, 4 replicates per test item concentration and for the water control, 6 replicates for the solvent control; 20 larvae were added to each vessel; assessment of emergence rate and development rate.

Endpoints: NOEC and EC_{50} (regarding emergence rate and development rate).

Test concentrations: Solvent control, water control, 1.0, 2.0, 4.0, 8.0 and 16.0 mg/kg dry sediment (nominal).

Test conditions: 600 mL glass vessels with 100 g spiked wet artificial sediment (according to OECD 218), 280 mL M4 water (Elendt medium) corresponding to a water layer of about 6.0 cm; pH 8.1 - 8.7; oxygen saturation 86% - 102%; total hardness: 302.6 - 311.5 mg $CaCO_3$/L at test initiation and 302.6 - 329.3 mg $CaCO_3$/L at test termination; conductivity: 620 µS/cm; ammonia: 0.8 mg/L at test initiation and 0.6 - 0.8 mg/L at test termination; water temperature: 19°C - 21°C; light intensity: 670 - 870 lux; photoperiod: 16 h light : 8 h dark; continuous gentle aeration; food: TetraMin on workdays, 0-10 days: 0.5 mg food/larva/day, 11-27 days: 0.5 - 1.0 mg food/larva/day.

Analytics: Analytical verification of test item concentrations was conducted using a LC-MS/MS-method.

Statistics: Descriptive statistics, Student's t-test ($p < 0.05$) for comparison of the emergence and development rates in the control groups; ANOVA followed by Williams' Multiple Sequential t-test procedure for determination of the NOEC based on emergence and development rate ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations in the overlying water, the pore water and the sediment was conducted in the test concentrations of 2.0 and 16.0 mg/kg dry sediment at the beginning and the end of the test. Mean recoveries in the sediment were in a range between 96 and 101% of the nominal concentrations at test initiation and between 75 and 81% of nominal at test termination. Overlying water concentrations ranged from 2.18 to 11.23 µg/L at test start (= insertion of larvae) and < LoQ (limit of quantification) to 2.13 µg/L at test end. The pore water concentrations ranged from 8.62 to 66.58 µg/L at test start and from 2.51 to 13.62 µg/L at test termination. Since the analytical measurements of initial sediment concentrations confirmed the correct application of the test item, the following biological results are based on nominal sediment concentrations.

Biological results: In the control and the solvent control mean emergence rates of 90.0 and 88.3% were observed, respectively. The mean development rate was 0.059 in both control groups. In the test item concentrations of up to and including 16.0 mg/kg dry sediment between 87.5 and 95.0% of the test animals emerged until day 28. No statistically significant differences were observed between the control groups (Student's t-test, $p < 0.05$). Hence, the controls were pooled and used as the reference in all evaluations. No statistically significant differences were found for the emergence and development rates at any test item concentration when compared to the pooled control (Williams Multiple Sequential t-test procedure, $\alpha = 0.05$). The results are summarized in Table 8.2.5.3-2.

Table 8.2.5.3-2: Effects of BF 500-3 (metabolite of pyraclostrobin) on emergence and development of *Chironomus riparius*

Concentration [mg BF 500-3/kg dry sediment] (nominal)	**Control**	**Solvent control**	**1.0**	**2.0**	**4.0**	**8.0**	**16.0**

$NOEC_{emergence\ \&\ development\ rate}$ (28 d)	≥ 16.0						

Values represent mean and standard deviation from all replicates, each with 20 larvae.

III. CONCLUSION

In a 28-day static sediment test with *Chironomus riparius* the NOEC of BF 500-3 (metabolite of pyraclostrobin) was determined to be ≥ 16.0 mg a.s./kg dry sediment based on emergence and development rate (nominal).

The following spiked sediment toxicity study on non-biting midge larvae (*Chironomus riparius*) performed with the metabolite BF 500-6, which has not been evaluated previously, is provided in support of the aquatic risk assessment of a soil metabolite potentially contaminating sediments.

Report:	CA 8.2.5.3/3 Backfisch K., 2014b Chronic toxicity of Reg. No. 364380 (BF 500-6; metabolite of Pyraclostrobin) to the non-biting midge Chironomus riparius - A spiked sediment study 2014/1001481
Guidelines:	OECD 218 (2004)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a 28-day static spiked sediment study, non-biting midge larvae (*Chironomus riparius*) were exposed to BF 500-6 (metabolite of pyraclostrobin) at nominal test item concentrations of 2.0, 6.0, 18.0, 54.0 and 162.0 mg/kg dry sediment (corresponding to mean measured concentrations of 2.0, 6.5, 18.3, 48.7 and 151.5 mg/kg dry sediment). Even the highest test concentration did not cause 50% effect on emergence or development rate. However, no clear NOEC was reached in the first experiment. Therefore, a second test was conducted with lower nominal concentrations of 0.5, 1.0 and 2.0 mg/kg dry sediment (corresponding to mean measured concentrations of 0.6, 1.2 and 2.8 mg/kg dry sediment). Additionally, for each trial a solvent (acetone) control and a water control were set up. In the first experiment all test item concentrations and the water control had 4 replicates, whereas 6 replicates were tested for the solvent control. For the second experiment 4 replicates for each test item concentration and three replicates for each control were used. 20 larvae were added to each test vessel.

The biological results are based on mean measured concentrations of the test item. In the control and the solvent control of the first trial mean emergence rates of 0.9375 and 0.9583 were observed, respectively. The mean development rate was 0.0625 in the water control and 0.0617 in the solvent control. No statistically significant differences were found for the development rates at test item concentrations of up to and including the highest tested concentration when compared to the pooled control. The emergence rate was slightly, but statistically significantly reduced in all tested concentration groups. Therefore, a second test was added including some lower concentrations in order to derive a clear NOEC. Mean emergence rate in the second experiment was 0.8333 and 0.9333 in the control and the solvent control, respectively. The mean development rate was 0.0638 in the water control and 0.0626 in the solvent control. As expected, no statistically significant effect on the development rates was observed in any of the lower treatments whereas the emergence rate was significantly reduced at the highest test concentration of 2.8 mg/kg dry sediment.

In a 28-day spiked sediment test with *Chironomus riparius* the NOEC of BF 500-6 (metabolite of pyraclostrobin) was determined to be 1.2 mg/kg dry sediment based on emergence rate and ≥ 151.5 mg/kg dry sediment based on development rate (mean measured).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BF 500-6 (Reg. No. 346 380; synonym: 500M01, metabolite of pyraclostrobin); batch no. 01311-142; purity: 99.2%.

B. STUDY DESIGN

Test species: Non-biting midge (*Chironomus riparius*), first instar larvae from in-house culture (non-GLP), originally obtained from "the Zoological Institute of the J.W. Goethe University", Frankfurt, Germany.

Test design: Static system (28 days); first experiment: 5 test concentrations plus a solvent (acetone) control and a water control, 4 replicates per test item concentration and for the water control, 6 replicates for the solvent control; a second test was conducted with lower concentrations since no clear NOEC was reached in the first experiment: 3 test concentrations with four replicates plus a solvent (acetone) control and a water control with three replicates. 20 larvae were added to each vessel; assessment of emergence rate and development rate.

Endpoints: NOEC, EC_{50} values (regarding emergence rate and development rate).

Test concentrations: First experiment: solvent control, water control, 2.0, 6.0, 18.0, 54.0 and 162.0 mg/kg dry sediment (nominal); corresponding to mean measured concentrations of 2.0, 6.5, 18.3, 48.7 and 151.5 mg/kg dry sediment;
Second experiment: solvent control, water control, 0.5, 1.0 and 2.0 mg/kg dry sediment (nominal); corresponding to mean measured concentrations of 0.6, 1.2 and 2.8 mg/kg dry sediment.

Test conditions: 600 mL glass vessels with 100 g spiked wet artificial sediment (according to OECD 218), 400 mL M4 water (Elendt medium) corresponding to a water layer of about 8.0 cm; pH 7.52 - 8.17; oxygen content: 6.99 - 8.60 mg/L; total hardness: 2.48 mmol/L (1st trial) / 2.47 mmol/L (2nd trial); conductivity: 634 / 657 µS/cm; ammonia: 0.2 / 0.8 mg/L at test initiation and 0.5 / 2.0 mg/L at test termination; water temperature: 19.7°C - 20.6°C; light intensity: 361 - 461 lux; photoperiod: 16 h light : 8 h dark; continuous gentle aeration; food: finely ground and suspended TetraMin, 0.25 - 1.0 mg food/larva/day (i.e. 5 - 20 mg/vessel/day).

Analytics: Analytical verification of test item concentrations was conducted using an HPLC-method with MS-detection.

Statistics: Descriptive statistics, Probit analysis using linear maximum likelihood regression for determination of the EC_x values; ANOVA followed by Chi-square test with Bonferroni correction or Dunnett's Multiple t-test for determination of the NOEC based on emergence and development rate ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations in the overlying water, the pore water and the sediment was conducted in all test concentrations at the beginning and the end of the test for both trials. Mean recoveries in the sediment in the first experiment were in a range between 89% and 114% of the nominal concentrations at test initiation and between 92% and 109% of nominal at test termination. Overlying water concentrations ranged from < LoQ (limit of quantification = 1 µg/L) to 163.0 µg/L at test start (= insertion of larvae) and < LoQ to 2.42 µg/L at test end. The very high measurement in the overlying water in the highest treatment group at start of the test is likely due to some contamination of the sample (with sediment during sampling). The pore water concentrations ranged from < LoQ to 4.49 µg/L at test start and from < LoQ to 8.59 µg/L at test termination. Mean recoveries in the sediment during the second trial were between 120% and 141% of the nominal concentrations at test start and between 112% and 137% of nominal at test end. Mean measured test item concentrations in the overlying water and the pore water were < LoQ in all treatment groups at test start and at test end. The following biological results are based on mean measured sediment concentrations.

Biological results: In the control and the solvent control of the first trial mean emergence rates of 0.9375 and 0.9583 were observed, respectively. The mean development rate was 0.0625 in the water control and 0.0617 in the solvent control. No statistically significant differences were observed between the control groups (Chi-square test with Bonferroni correction, Dunnett's Multiple t-test procedure, $\alpha = 0.05$). Hence, the controls were pooled and used as the reference in all evaluations. No statistically significant differences were found for the development rates at test item concentrations of up to and including the highest tested concentration when compared to the pooled control (Chi-square test with Bonferroni correction, Dunnett's Multiple t-test procedure, $\alpha = 0.05$). The emergence rate was slightly, but statistically significantly reduced reduced in all tested concentration groups ($\alpha = 0.05$). Therefore, a second test was added including some lower concentrations in order to derive a clear NOEC. Mean emergence rate in the second experiment was 0.8333 and 0.9333 in the control and the solvent control, respectively. The mean development rate was 0.0638 in the water control and 0.0626 in the solvent control. Since there were no statistically significant differences observed between the control groups ($\alpha = 0.05$), the control data were pooled and used as the reference in all evaluations. As expected, no statistically significant effect on the development rates was observed in any of the lower treatments whereas the emergence rate was significantly reduced at the highest test concentration of 2.8 mg/kg dry sediment ($\alpha = 0.05$). The results are summarized in Table 8.2.5.3-3.

Table 8.2.5.3-3: Effects of BF 500-6 (metabolite of pyraclostrobin) on emergence and development of *Chironomus riparius* (trial 1 and 2)

III. CONCLUSION

In a 28-day spiked sediment test with *Chironomus riparius* the NOEC of BF 500-6 (metabolite of pyraclostrobin) was determined to be 1.2 mg/kg dry sediment based on emergence rate and ≥ 151.5 mg/kg dry sediment based on development rate (mean measured).

The following spiked sediment toxicity study on non-biting midge larvae (*Chironomus riparius*) performed with the metabolite BF 500-7, which has not been evaluated previously, is provided in support of the aquatic risk assessment of a soil metabolite potentially contaminating sediments.

Report:	CA 8.2.5.3/4 Backfisch K., 2014a Chronic toxicity of Reg.No. 369315 (BF 500-7; Metabolite of Pyraclostrobin) to the non-biting midge Chironomus riparius - A spiked sediment study 2014/1001482
Guidelines:	OECD 218 (2004)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a 28-day static spiked sediment study, non-biting midge larvae (*Chironomus riparius*) were exposed to BF 500-7 (metabolite of pyraclostrobin) at nominal test item concentrations of 2.0, 6.0, 18.0, 54.0 and 162.0 mg/kg dry sediment (corresponding to mean measured concentrations of 0.96, 4.55, 13.83, 47.15 and 123.5 mg/kg dry sediment). Additionally, a solvent (acetone) control and a water control were set up. All test item concentrations and the water control had 4 replicates, whereas 6 replicates were tested for the solvent control. 20 larvae were added to each test vessel.

The biological results are based on mean measured concentrations of the test item. Mean emergence rates in both controls were above 90%. The mean development rates were 0.0650 and 0.0644 for the water control and the solvent control, respectively. No statistically significant differences were found for the emergence and development rates at any test item concentration when compared to the water control and the solvent control.

In a 28-day static sediment test with *Chironomus riparius* the NOEC of BF 500-7 (metabolite of pyraclostrobin) was determined to be ≥ 123.5 mg a.s./kg dry sediment based on emergence and development rate (mean measured).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BF 500-7 (Reg. No. 369 315; metabolite of pyraclostrobin), batch no. L83-168, purity: 96.2%.

B. STUDY DESIGN

Test species:	Non-biting midge (*Chironomus riparius*), first instar larvae from in-house culture, originally obtained from "the Zoological Institute of the J.W. Goethe University" Frankfurt, Germany.
Test design:	Static system (28 days); 5 test concentrations plus a solvent (acetone) control and a water control, 4 replicates per test item concentration and for the water control, 6 replicates for the solvent control; 20 larvae were added to each vessel; assessment of emergence rate and development rate.
Endpoints:	NOEC and EC_{50} (regarding emergence rate and development rate).
Test concentrations:	Solvent control, water control, 2.0, 6.0, 18.0, 54.0 and 162.0 mg BF 500-7/kg dry sediment (nominal), corresponding to mean measured concentrations of 0.96, 4.55, 13.83, 47.15 and 123.5 mg/kg dry sediment.
Test conditions:	600 mL glass vessels with 100 g spiked wet artificial sediment (according to OECD 218), 400 mL M4 water (Elendt medium) corresponding to a water layer of about 8.0 cm; pH 7.41 - 8.11; oxygen content: 7.35 - 8.45 mg/L (saturation > 60%); total hardness: 2.53 mmol/L at test initiation; conductivity: 617 µS/cm at test initiation; ammonia: 0.8 mg/L; water temperature: 19.3°C - 20.1°C; light intensity: 397 - 592 lux; photoperiod: 16 h light : 8 h dark; continuous gentle aeration except during addition of the larvae and about 24 hours afterwards; food: TetraMin, until DAI 23: 0.25 - 1.0 mg food/larva/day.
Analytics:	Analytical verification of test item concentrations was conducted using an HPLC-method with MS-detection.
Statistics:	Descriptive statistics, Dunnett's Multiple t-test procedure ($p < 0.05$) for comparison of the water control, the solvent control and the treatment groups; ANOVA followed by Chi-square test with Bonferroni correction for determination of the NOEC based on emergence and development rate ($\alpha = 0.05$), Probit and Weibull analysis using linear max. likelihood regression for determination of EC_x values.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations in the overlying water, the pore water and the sediment was conducted in the controls and in each concentration at the beginning and the end of the test. Recoveries in the sediment were in the range between 66 and 87% of the nominal concentrations at test initiation and between 46 and 86% of nominal at test termination. Overlying water concentrations ranged from < LoQ (limit of quantification) to 5.32 µg/L at test start (= insertion of larvae) and from < LoQ to 2.7 µg/L at test end. The pore water concentrations ranged from < LoQ to 1.95 µg/L at test start and from < LoQ to 2.31 µg/L at test termination. The following biological results are based on the mean measured sediment concentrations.

Biological results: Mean emergence rates in both controls were above 90%. The mean development rates were 0.0650 and 0.0644 for the water control and the solvent control, respectively. No statistically significant differences were found for the emergence and development rates at any test item concentration when compared to the water control and the solvent control (Chi-square test with Bonferroni correction, $\alpha = 0.05$). The results are summarized in Table 8.2.5.3-4.

Table 8.2.5.3-4: Effects of BF 500-7 (metabolite of pyraclostrobin) on emergence and development of *Chironomus riparius*

Concentration [mg BF 500-7/kg dry sediment] (nominal)	**Control**	**Solvent control**	**2.0**	**6.0**	**18.0**	**54.0**	**162.0**

Endpoints [mg BF 500-7/kg dry sediment] (mean measured)							
$EC_{50\ emergence\ rate}$ (28 d)	> 123.5						
$NOEC_{emergence\ \&\ development\ rate}$ (28 d)	≥ 123.5						

[#] Values represent mean and standard deviation from all replicates, each with 20 larvae.

III. CONCLUSION

In a 28-day static sediment test with *Chironomus riparius* the NOEC of BF 500-7 (metabolite of pyraclostrobin) was determined to be ≥ 123.5 mg a.s./kg dry sediment based on emergence and development rate (mean measured).

CA 8.2.5.4 Sediment dwelling organisms

The following acute spiked sediment toxicity study on marine amphipods (*Leptocheirus plumulosus*) performed with the active substance pyraclostrobin is not required for registration in the EU and it has not been evaluated previously on EU level. The study was conducted due to U.S. data requirements and is provided for completeness.

Report:	CA 8.2.5.4/1 Gaertner K., 2013a BAS 500 F: Whole sediment acute toxicity to a marine amphipod (Leptocheirus plumulosus) 2013/7000055
Guidelines:	EPA 850.1740
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

In a 10-day static acute spiked sediment study, marine amphipods (*Leptocheirus plumulosus*) were exposed to pyraclostrobin at nominal concentrations of 0.63, 1.3, 2.5, 5.0 and 10 mg a.s./kg dry sediment (corresponding to mean measured concentrations of 0.771, 1.51, 2.74, 5.05 and 11.3 mg a.s./kg dry sediment). Additionally, a solvent control and a dilution water control were set up. All test item concentrations and the control groups had 8 replicates consisting of 20 amphipods per replicate. Assessment of survival and general health and behavior of the amphipods was performed at test end.

The biological results are based on mean measured sediment concentrations. After 10 days of exposure, the mean survival was 99 and 98% in the dilution water control and the solvent control, respectively. Survival rates at the test item concentrations of 0.771, 1.51, 2.74, 5.05 and 11.3 mg a.s./kg dry sediment were 98, 100, 97, 25 and 0.6%, respectively. Statistically significant differences compared to the dilution water control were observed at the two highest tested concentrations.

In a 10-day static acute sediment test with *Leptocheirus plumulosus*, the LC_{50} of pyraclostrobin was determined to be 4.412 mg a.s./kg dry sediment based on mean measured concentrations. The NOEC was 2.740 mg a.s./kg dry sediment.

I. MATERIAL AND METHODS

Test item:	Mixture of non-radiolabeled pyraclostrobin (BAS 500 F; Reg. no.: 304 428, batch no. COD-001236; purity: 99.02%) and ^{14}C-radiolabeled pyraclostrobin (batch no. 579-6009; specific activity: 64.4 MBq/g; radiochemical purity: 99.4%; chemical purity: 100%).
Test species:	Marine amphipod (*Leptocheirus plumulosus*), 2 - 4 mm length; source: "Chesapeake Cultures", Hayes, Virginia, USA.
Test design:	Static system (10 days); 5 test concentrations plus a control and a solvent control, 8 replicates per test item concentration and per control group, 20 amphipods per replicate; assessment of survival after 10 days.
Endpoints:	NOEC and LC_{50}.
Test concentrations:	Control (dilution water), solvent control, 0.63, 1.3, 2.5, 5.0 and 10 mg a.s./kg dry sediment (nominal); corresponding to geometric mean measured TRR concentrations (^{14}C-labeled pyraclostrobin equivalents) of 0.771, 1.51, 2.74, 5.05 and 11.3 mg a.s./kg dry sediment.
Test conditions:	1 L glass jars (17 cm height x 8.5 cm diameter) filled with 251.8 g natural marine sediment (27% sand, 55% silt, 18% clay, 6.4% organic matter), 600 mL dilution water (prepared by mixing a commercial sea salt mix to laboratory freshwater); salinity: 19.0 - 21.0‰; pH 7.6 - 8.5; oxygen content: 4.3 mg/L - 7.6 mg/L; water temperature: 24.3°C - 25.3°C; light intensity: 501 - 601 lux; photoperiod: 24 h light; continuous aeration.
Analytics:	Overlaying water, interstitial (pore) water and sediment were analyzed for total radioactive residues (TRR) using a liquid scintillation counting (LSC) method. The concentration of pyraclostrobin at the lowest treatment level was also measured in the overlying and interstitial water using an HPLC-method with UV-detection.
Statistics:	Descriptive statistics, Fisher's one-tailed exact test for determination of the NOEC value and for comparison of the dilution water control data and the solvent control data ($p = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of ^{14}C-labeled pyraclostrobin concentrations in the sediment, the overlying water and the interstitial water was conducted in the controls and in each concentration at the beginning and the end of the test via LSC analysis. Mean measured concentrations of ^{14}C-labeled pyraclostrobin TRR in the sediment were in a range between 117 and 125% of nominal concentrations at test initiation and between 89 and 120% of nominal at test termination. The geometric mean measured concentrations of ^{14}C-labeled pyraclostrobin in samples taken from the nominal concentrations of 0.63, 1.3, 2.5, 5.0 and 10 mg a.s./kg dry sediment were determined to be 0.771, 1.51, 2.74, 5.05 and 11.3 mg a.s./kg dry sediment, respectively, which represent 101 to 122% of nominal concentrations. The geometric mean measured concentrations of ^{14}C-labeled pyraclostrobin in the overlaying water samples were 0.000526, 0.00136, 0.00282, 0.00541 and 0.0115 mg TRR/L for the 0.63, 1.3, 2.5, 5.0 and 10 mg a.s./kg dry sediment samples, respectively. The respective geometric mean measured concentrations of ^{14}C-labeled pyraclostrobin in the interstitial water samples were 0.00169, 0.00338, 0.00625, 0.0115 and 0.0229 mg TRR/L.
Additionally, the concentration of pyraclostrobin in the controls and at the lowest treatment level was measured in overlying and interstitial water at test initiation and test termination via HPLC/UV analysis. Measured concentrations in overlaying water samples of two replicates of the 0.63 mg a.s./kg dry sediment treatment were 0.000128 and 0.000705 mg a.s./L at test initiation and 0.000342 and 0.0000492 mg a.s./L at test termination. In general, no residues of pyraclostrobin were detected in the control samples above the respective minimum quantifiable limits (MQL) in all measurements.
The following biological results are based on the geometric mean measured ^{14}C-labeled pyraclostrobin sediment concentrations. The TRR concentrations were corrected for dry weight of sediment.

Biological results: No statistically significant differences between the survival data in the dilution water control and the solvent control were detected (Fisher`s exact test; $p = 0.05$). The dilution control data were used for statistical evaluation of treatment related effects. After 10 days of exposure, the mean survival was 99 and 98% in the dilution water control and the solvent control, respectively. Survival rates at the test item concentrations of 0.771, 1.51, 2.74, 5.05 and 11.3 mg a.s./kg dry sediment were 98, 100, 97, 25 and 0.6%, respectively. Statistically significant differences compared to the dilution water control were observed at the two highest test concentrations (Fisher`s exact test; $p = 0.05$). The results are summarized in Table 8.2.5.4-1.

Table 8.2.5.4-1: Effect of pyraclostrobin on survival of *Leptocheirus plumulosus*

Concentration [mg a.s./kg dry sediment] (nominal)	**Control**	**Solvent control**	**0.63**	**1.3**	**2.5**	**5.0**	**10**
Concentration [mg a.s./kg dry sediment] (geometric mean measured)	**--**	**--**	**0.771**	**1.51**	**2.74**	**5.05**	**11.3**
Survival (10 d) [%]	99	98	98	100	97	25 *	0.6 *
	Endpoints [mg a.s./kg dry sediment] (geometric mean measured)						
LC_{50} (10 d)	4.412 (95% confidence limits: 4.192 - 4.643)						
NOEC (10 d)	2.740						

* Statistically significantly difference compared to the dilution water control (Fisher`s exact test; p = 0.05).

III. CONCLUSION

In a 10-day static acute sediment test with *Leptocheirus plumulosus*, the LC_{50} of pyraclostrobin was determined to be 4.412 mg a.s./kg dry sediment based on mean measured concentrations. The NOEC was 2.740 mg a.s./kg dry sediment.

CA 8.2.6 Effects on algal growth

CA 8.2.6.1 Effects on growth of green algae

The following 96-hour algae study on the freshwater green algae *Pseudokirchneriella subcapitata* has already been submitted and accepted during the previous Annex I inclusion process. Meanwhile the 72 h endpoints have been calculated from the original data for use in the aquatic risk assessment. The calculations and for completeness also the already submitted study are summarised below.

Report:	CA 8.2.6.1/1 Dohmen G.P., 1999a Effect of BAS 500 F on the growth of the green alga Pseudokirchneriella subcapitata 1999/11020
Guidelines:	OECD 201
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Report:	CA 8.2.6.1/2 Hoffmann F., 2009a Effect of BAS 500 F on the growth of the green alga Pseudokirchneriella subcapitata - Additional calculation of the inhibition values for growth rate and yield data after a test period of 72 h 2009/1037148
Guidelines:	OECD 201
GLP:	no

Executive Summary (originally submitted study, BASF DocID 1999/11020)

In a 96-hour static toxicity laboratory study, the effect of pyraclostrobin on the growth of the freshwater green algae *Pseudokirchneriella subcapitata* was investigated. The following nominal concentrations were applied: 0 (control), 0.008, 0.016, 0.031, 0.063, 0.125, 0.250, 0.5, 1.0 mg a.s./L (corresponding to mean measured concentrations of 0 (control), 0.007, 0.014, 0.027, 0.057, 0.113, 0.213, 0.448 and 0.843 mg a.s./L). Assessment of growth was conducted 48 h, 72 h and 96 h after test initiation. Mean measured concentrations of the test item were 90.4% of nominal at the beginning and 86.0% at the end of the test. The biological results are based on mean measured concentrations of the test item. No morphological effects on algae were observed in the control group and any test item concentration tested throughout the test.

The effects on algal growth are summarized in Table 8.2.6.1-1

Table 8.2.6.1-1: Effect (96 h) of pyraclostrobin on the growth of the freshwater green alga *Pseudokirchneriella subcapitata*

Concentration [mg a.s./L] (nominal)	**0.008**	**0.016**	**0.031**	**0.063**	**0.125**	**0.250**	**0.500**	**1.0**
Concentration [mg a.s./L] (mean measured)	**0.007**	**0.014**	**0.027**	**0.057**	**0.113**	**0.213**	**0.448**	**0.843**
Inhibition in 96 h [%] (based on growth rate)	-1.1	3.3	6.8	6.5	12.2	15.6	27.6	49.5
Inhibition in 96 h [%] (based on biomass)	0.2	12.5	28.4	26.1	42.6	51.9	68.2	87.2
Endpoints [mg pyraclostrobin/L] (mean measured)								
E_rC_{50} (0 - 96 h)	> 0.843 extrapolated: 1.282 (95% confidence limits: 1.110 - 1.482)							
E_rC_{10} (0 - 96 h)	0.078 (95% confidence limits: 0.071 - 0.087)							
E_bC_{50} (0 - 96 h)	0.152 (95% confidence limits: 0.143 - 0.162)							
E_bC_{10} (0 - 96 h)	0.014 (95% confidence limits: 0.013 - 0.015)							

In a 96-hour algae test with *Pseudokirchneriella subcapitata,* the E_rC_{50} of pyraclostrobin was determined to be > 0.843 mg a.s./L and the E_bC_{50} was 0.152 mg a.s./L (mean measured).

Executive Summary (recalculations; BASF DocID 2009/1037148)

The study BASF DocID 1999/11020 with the unicellular fresh water green alga *P. subcapitata* was conducted according to Good Laboratory Practice (GLP) following OECD Guideline 201, however, over a longer test duration than recommended (*i.e.* 96 h instead of 72 h). In the original study report only the 96 hour endpoints related to growth rate and biomass are reported.
Additional endpoints related to growth rate (r) and yield (y) after 72 hours of exposure were recalculated according to current recommendations (OECD 201, March, 2011). The following 72-hour endpoints were obtained based on mean measured concentrations of the test item:

E_rC_{50} (72 h) > 0.843 mg/L
E_rC_{10} (72 h) = 0.071 mg/L (95% confidence limits: 0.064 - 0.080 mg/L)
E_yC_{50} (72 h) = 0.148 mg/L (95% confidence limits: 0.140 - 0.158 mg/L)
E_yC_{10} (72 h) = 0.013 mg/L (95% confidence limits: 0.012 - 0.015 mg/L)

The following toxicity study on the freshwater green algae *Pseudokirchneriella subcapitata* performed with the metabolite BF 500-3 is provided in support of the aquatic risk assessment. The study was requested by Canadian authorities and has not been evaluated previously at the EU level.

Report:	CA 8.2.6.1/3 Hoffmann F., 2006a Effect of BF 500-3 (Reg.No. 340 266, metabolite of BAS 500 F) on the growth of the green alga Pseudokirchneriella subcapitata 2006/1038445
Guidelines:	OECD 201
GLP:	yes (certified by Landesamt fuer Umweltschutz und Gewerbeaufsicht, Mainz, Germany Fed.Rep.)

Executive Summary

In a 96-hour static toxicity laboratory study, the effect of BF 500-3 (metabolite of pyraclostrobin) on the growth of the green alga *Pseudokirchneriella subcapitata* was investigated. The following nominal concentrations were applied: 0.03, 0.075, 0.188, 0.469 and 1.172 mg BF 500-3/L. Additionally, a solvent (acetone) control and a dilution water control were set up. Assessment of growth was conducted 24, 48, 72 and 96 h after test initiation.

The biological results are based on nominal concentrations of the test item. No morphological effects on algae were observed in the control groups and at up to and including the highest test item concentration tested.

In a 96-hour algae test with *Pseudokirchneriella subcapitata,* the E_rC_{50} (96 h) of BF 500-3 (metabolite of pyraclostrobin) was determined to be > 1.172 mg/L based on nominal concentrations. After 72 hours of exposure, the respective E_rC_{50} was equally determined to be > 1.172 mg/L.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BF 500-3 (Reg. No. 340 266, synonym: 500M07; metabolite of pyraclostrobin), batch no. L74-118, purity: 99.9%.

B. STUDY DESIGN

Test species: Unicellular fresh water green alga, *Pseudokirchneriella subcapitata* (Reinsch) Korshikov (syn. *Selenastrum capricornutum* Prinz); specification: SAG 61.81; stock obtained from "Sammlung von Algenkulturen", Göttingen, Germany.

Test design: Static system (96 hours); 5 test concentrations with 5 replicates for each plus a control with 10 replicates and a solvent control with 5 replicates; daily assessment of growth.

Endpoints: EC_{10} and EC_{50} with respect to growth rate and yield after exposure over 72 and 96 hours.

Test concentrations: Control, solvent control (0.1 mL acetone/L), 0.03, 0.075, 0.188, 0.469 and 1.172 mg BF 500-3/L (nominal).

Test conditions: 100 mL Erlenmeyer flasks, test volume: 60 mL; nutrient solution according to OECD 201; pH 8.1 at test initiation and pH 7.80 - 7.98 at test termination; temperature: 22 ± 1°C; initial cell densities: 3 x 10^3 cells/mL; continuous light at about 8000 lux, continuous shaking at about 135 rpm.

Analytics: Analytical verification of test item concentrations was conducted using an HPLC-method with MS detection.

Statistics: Descriptive statistics, probit analysis for determination of EC_x values for growth rate and yield.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each test concentration at the beginning and at the end of the test. Mean measured values for BF 500-3 ranged from 74.0 to 98.8% of nominal concentrations at test initiation and from 20.6 to 56.5% of nominal at test termination. As the initially measured concentrations largely confirmed correct application of the test item, the following biological results are based on nominal concentrations.

Biological results: No morphological effects on algae were observed in the control groups and at up to and including the highest test item concentration tested. The effects on algal growth are summarized in Table 8.2.6.1-2.

Table 8.2.6.1-2: Effect of BF 500-3 (metabolite of pyraclostrobin) on the growth of the green algae *Pseudokirchneriella subcapitata*

Concentration [mg/L] (nominal)	**0.030**	**0.075**	**0.188**	**0.469**	**1.172**
Inhibition in 72 h (growth rate) [%]	0.9	6.2	5.8	9.0	12.2
Inhibition in 72 h (yield) [%]	3.5	22.6	20.8	31.4	40.0
Inhibition in 96 h (growth rate) [%] #	-0.5	1.2	4.3	11.9	11.9
Inhibition in 96 h (yield) [%] #	-2.5	5.9	19.7	45.9	45.9
Endpoints [mg BF 500-3/L] (nominal)					
E_rC_{50} (72 h)	> 1.172				
E_rC_{10} (72 h)	0.617 (95% confidence limits: 0.467 - 0.816)				
E_yC_{50} (72 h)	> 1.172				
E_yC_{10} (72 h)	0.038 (95% confidence limits: 0.030 - 0.047)				
E_rC_{50} (96 h)	> 1.172				
E_rC_{10} (96 h)	0.627 (95% confidence limits: 0.536 - 0.733)				
E_yC_{50} (96 h)	0.922 (95% confidence limits: 0.836 - 1.016)				
E_yC_{10} (96 h)	0.106 (95% confidence limits: 0.095 - 0.118)				

Negative values indicate stimulated growth compared to the control.

III. CONCLUSION

In a 96-hour algae test with *Pseudokirchneriella subcapitata,* the E_rC_{50} (96 h) of BF 500-3 (metabolite of pyraclostrobin) was determined to be > 1.172 mg/L based on nominal concentrations After 72 hours of exposure, the respective E_rC_{50} value was equally determined to be > 1.172 mg/L.

The following study on the freshwater green algae *Pseudokirchneriella subcapitata* performed with the metabolite BF 500-5 has not been evaluated previously and was conducted to address a new metabolite found in a newly required e-fate study.

Report:	CA 8.2.6.1/4 Kuhl R., Frank C., 2014c Toxicity of Reg.No. 298327 (BF 500-5, metabolite of Pyraclostrobin) to Pseudokirchneriella subcapitata in an algal growth inhibition test 2013/1349202
Guidelines:	OECD 201 (2011), (EC) No 761/2009 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH 2009 - Part C.3: Algal Inhibition Test, OECD Series on Testing and Assessment No. 23 (2000) - Aquatic Toxicity Testing of Difficult Substances and Mixtures
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

In a 72-hour static toxicity laboratory study, the effect of BF 500-5 (metabolite of pyraclostrobin) on the growth of the green alga *Pseudokirchneriella subcapitata* was investigated. The following nominal concentrations were applied: 0 (control), 0.10, 0.32, 1.0, 3.2 and 10.0 mg BF 500-5/L. Assessment of growth was conducted 24 h, 48 h and 72 h after test initiation.

The biological results are based on nominal concentrations of the test item. No morphological effects on algae were observed in the control group and at up to and including the highest test item concentration tested. Statistically significant differences for growth rate and yield compared to the control were observed at the two highest test item concentrations of 3.2 and 10.0 mg/L.

In a 72-hour algae test with *Pseudokirchneriella subcapitata,* the E_rC_{50} of BF 500-5 (metabolite of pyraclostrobin) was determined to be 5.33 mg/L based on nominal concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BF 500-5 (Reg. No. 298 327, synonym: 500M04; metabolite of pyraclostrobin), batch no. L84-174, purity: 99.6% ± 1%.

B. STUDY DESIGN

Test species:	Unicellular fresh water green alga, *Pseudokirchneriella subcapitata*; SAG 61.81; stock obtained from "Sammlung von Algenkulturen, Universität Göttingen", Göttingen, Germany.
Test design:	Static system (72 hours); 5 test concentrations with 3 replicates for each plus a control with 6 replicates; daily assessment of growth.
Endpoints:	EC_{10} and EC_{50} with respect to growth rate and yield after exposure over 72 hours.
Test concentrations:	Control, 0.10, 0.32, 1.0, 3.2 and 10.0 mg BF 500-5/L (nominal).
Test conditions:	50 mL Erlenmeyer flasks, test volume: 50 mL; nutrient solution according to OECD 201; pH 7.9 - 8.1 at test initiation and pH 8.0 - 9.7 at test termination; temperature: 22.1 - 22.7°C; initial cell densities: 5 x 10^3 cells/mL; continuous light at 4810 - 5870 lux.
Analytics:	Analytical verification of test item concentrations was conducted using an LC-method with MS/MS detection.
Statistics:	Descriptive statistics, probit analysis using linear max. likelihood regression for determination of EC_x values for growth rate and yield, Dunnett´s t-test for determination of the NOEC values ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each test concentration at the beginning and at the end of the test. Mean measured values for BF 500-5 ranged from 93 to 102% of nominal concentrations at test initiation. At test termination, the test item contents in the samples of all test item concentrations were below the LOQ (limit of quantification = 0.070 mg test item/L). As the initially measured concentrations confirmed correct application of the test item, the following biological results are based on nominal concentrations.

Biological results: No morphological effects on algae were observed in the control group and at up to and including the highest test item concentration tested. Statistically significant differences for growth rate and yield compared to the control were observed at the two highest test item concentrations of 3.2 and 10.0 mg/L (Dunnett´s t-test, $\alpha = 0.05$). The effects on algal growth are summarized in Table 8.2.6.1-2.

Table 8.2.6.1-3: Effect of BF 500-5 (metabolite of pyraclostrobin) on the growth of the green alga *Pseudokirchneriella subcapitata*

Endpoints [mg BF 500-5/L] (nominal)					
E_rC_{50} (72 h)	5.33 (95% confidence limits: 4.72 - 5.73)				
E_rC_{10} (72 h)	2.00 (95% confidence limits: 1.71 - 2.27)				
E_yC_{50} (72 h)	2.03 (95% confidence limits: 1.73 - 2.35)				
E_yC_{10} (72 h)	0.910 (95% confidence limits: 0.633 - 1.14)				

Negative values indicate stimulated growth compared to the control.
* Statistically significantly different compared to the control (Dunnett´s t-test, $\alpha = 0.05$)

III. CONCLUSION

In a 72-hour algae test with *Pseudokirchneriella subcapitata,* the E_rC_{50} of BF 500-5 (metabolite of pyraclostrobin) was determined to be 5.33 mg/L based on nominal concentrations.

CA 8.2.6.2 Effects on growth of an additional algal species

The following alga study on the freshwater diatom *Navicula pelliculosa* performed with the active substance pyraclostrobin is not required for registration in the EU. The study was conducted due to U.S. data requirements and has not been evaluated previously on EU level. It is submitted for completeness.

Report:	CA 8.2.6.2/1 Boeri R.L. et al., 2000f Growth and Reproduction Toxicity Test with BAS 500F and the Freshwater Alga, Navicula pelliculosa 2000/5046
Guidelines:	EPA 123-2, EPA 850.5400, EPA Subdivision J of the Pesticide Assessment Guidelines
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

The effect of pyraclostrobin on the growth of the freshwater diatom *Navicula pelliculosa* was investigated in a 120-hour static laboratory study. The following nominal concentrations were applied: 0.0013, 0.0025, 0.0050, 0.010 and 0.020 mg pyraclostrobin/L (corresponding to initial measured concentrations of 0.00118, 0.00240, 0.00486, 0.00908 and 0.0184 mg a.s./L). Additionally, a solvent control (dimethylformamide) and a dilution water control were set up. Assessment of growth was conducted 24, 48, 72, 96 and 120 h after test initiation.

The biological results are based on initial measured concentrations of the test item. Statistically significant differences compared to the pooled control were observed at the four highest test item concentrations after exposure over 120 hours.

In a 120 hour algae toxicity test with *Navicula pelliculosa,* the E_rC_{50} (120 h) for pyraclostrobin was determined to be > 0.0184 mg a.s./L. After 72 hours of exposure, the respective E_rC_{50} was determined to be 0.0158 mg a.s./.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F; Reg. no.: 304 428), batch no. 27882/191/C; purity: 97.09%.

B. STUDY DESIGN

Test species:	Freshwater diatom, *Navicula pelliculosa*, strain UTEX 664, stock originally obtained from the "Culture Collection of Algae", University of Texas, Austin, USA.
Test design:	Static system; test duration 120 hours; 5 test concentrations plus a dilution water control and a solvent control with 3 replicates for each; daily assessment of growth.
Endpoints:	EC_{50} with respect to biomass and growth rate after exposure over 72 and 120 hours.
Test concentrations:	Control (dilution water), solvent control (0.1 mL dimethylformamide/L), 0.0013, 0.0025, 0.0050, 0.010 and 0.020 mg pyraclostrobin/L (nominal), corresponding to initial measured concentrations of 0.00118, 0.00240, 0.00486, 0.00908 and 0.0184 mg a.s./L.
Test conditions:	250 mL glass flasks; test volume 50 mL; sterile enriched medium supplemented with 0.2 g/L Na_2SiO_3 x 9 H_2O; pH 7.4 at test initiation and pH 7.3 - 7.6 at test termination; temperature: 23.2°C - 23.7°C; initial cell densities 3 x 10^3 cells/mL; continuous light at 4100 - 4500 lux; constant shaking at 100 rpm.
Analytics:	Analytical verification of test item concentrations was conducted using an HPLC-method with UV detection.
Statistics:	Descriptive statistics; t-test (α = 0.05) for comparison of cell densities and growth rate data in the control and the solvent control; weighted least squares non-linear regression analysis for determination of EC_x values

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each concentration at the beginning and at the end of the test. The analyzed contents of pyraclostrobin ranged from 91 to 97% of nominal concentrations at test initiation and from 50 to 52% of nominal at test termination. The following biological results are based on initial measured concentrations.

Biological results: No statistically significant differences were determined between the control and the solvent control data (t-test; $\alpha = 0.05$). Thus, the data from both control groups were pooled and the pooled data set was used for statistical evaluation of treatment related effects. Statistically significant differences of the cell numbers and average specific growth rates compared to the pooled control were observed at the four highest test item concentrations after exposure over 120 hours (Bonferroni's test; $\alpha = 0.05$). The effects on algal growth are summarized in Table 8.2.6.2-1.

Table 8.2.6.2-1: Effect of pyraclostrobin on biomass development and growth of the freshwater diatom *Navicula pelliculosa*

Concentration [mg a.s./L] (nominal)	**Water control**	**Solvent control**	**0.0013**	**0.0025**	**0.0050**	**0.010**	**0.020**
Concentration [mg a.s./L] (initial measured)	**--**	**--**	**0.00118**	**0.00240**	**0.00486**	**0.00908**	**0.0184**
Mean cell density (72 h) [% of water control]	--	108	78	33	26	19	19

Growth rate (120 h) [% of water control]	--	96	96	72	68	70	68
Endpoints [mg pyraclostrobin/L] (initial measured)							
E_rC_{50} (72 h)	0.0158 (95% confidence limits: 0.00908 - > 0.0184)						
E_bC_{50} (72 h)	0.00165 (95% confidence limits: < 0.00118 - 0.00314)						
E_rC_{50} (120 h)	> 0.0184						
E_bC_{50} (120 h)	0.00150 (95% confidence limits: < 0.00118 - 0.00383)						
NOE_rC/NOE_bC (120 h)	0.00118						

III. CONCLUSION

In a 120 hour algae toxicity test with *Navicula pelliculosa,* the E_rC_{50} (120 h) for pyraclostrobin was determined to be > 0.0184 mg a.s./L. After 72 hours of exposure, the respective E_rC_{50} was determined to be 0.0158 mg a.s./L.

The following toxicity studies on the blue-green alga *Anabaena flos-aquae* and marine diatom *Skeletonema costatum* performed with the active substance pyraclostrobin are not required for registration in the EU. The studies were conducted due to U.S. data requirements and have not been evaluated previously on EU level.
Following the recommendations and validity criteria defined in the current OECD guideline 201 for alga testing (OECD, 2011) the 120 h studies on the algae *A. flos-aquae* and *S. costatum* are considered to be not valid. In both studies, at least one validity criterion is not met:

- the mean coefficients of variation (CV) for section by section specific growth rate in both the dilution water control and the solvent control were significantly > 35% after 0 - 72 hours, 0 - 96 hours and 0 - 120 hours in both studies;

- the CV of the average specific growth rate in the dilution water control was > 7% after 0 - 72 hours of exposure in the study on *A. flos-aquae* (i.e. 20%);

- the biomass increase was < 16 fold over the first 72 h in the dilution water control (*i.e.* 4-fold after 72 h) and over the first 96 h in the solvent control (*i.e.* 3-fold after 72 h and 13-fold after 96 h) in the study on *A. flos-aquae*; thus, no sufficient growth was demonstrated over the first 72 - 96 h of the test.

Nevertheless, summaries of the studies are provided for completeness.

Report:	CA 8.2.6.2/2 Boeri R.L. et al., 2000g Growth and reproduction toxicity test with BAS 500 F and the freshwater alga, Anabaena flos-aquae 2000/5036
Guidelines:	EPA 850.5400, FIFRA Subdivision J Series 123-2
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

In a 120-hour static toxicity laboratory study, the effect of pyraclostrobin on growth of the blue-green alga *Anabaena flos-aquae* was investigated. The following nominal concentrations were applied: 0.13, 0.25, 0.50, 1.0 and 2.0 mg pyraclostrobin/L (corresponding to mean measured concentrations of 0.118, 0.219, 0.466, 0.911 and 1.78 mg a.s./L). Additionally, a solvent control (dimethylformamide) and a dilution water control were set up. Assessment of growth was conducted 24 h, 48 h, 72 h, 96 h and 120 h after test initiation.

The biological results are based on mean measured concentrations of the test item. No statistically significant differences compared to the pooled control were observed at any test item concentrations after exposure over 120 hours.

In a 120-hour algae test with *Anabaena flos-aquae*, the E_rC_{50} (120 h) for pyraclostrobin was determined to be > 1.78 mg a.s./L, based on mean measured concentrations. After 96 hours of exposure, the respective E_rC_{50} value was determined to be 1.41 mg a.s./L.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F; Reg. no.: 304 428), batch no. 27882/191/C; purity: 97.09%.

B. STUDY DESIGN

Test species:	Freshwater blue-green alga, *Anabaena flos-aquae*; stock originally obtained from the University of Texas, Austin, USA; stock was maintained at test conditions for more than 14 days before the test.
Test design:	Static system (120 hours); 5 test concentrations plus a dilution water control and a solvent control with 3 replicates for each; daily assessment of growth.
Endpoints:	EC_{50} with respect to biomass and growth rate after exposure over 96 hours and 120 hours (72 h EC_{50} values could not be calculated because sufficient growth had not yet occurred during the first 72 hours in any of the test groups to allow the calculation to be made).
Test concentrations:	Control (dilution water), solvent control (0.1 mL dimethylformamide/L), 0.13, 0.25, 0.50, 1.0 and 2.0 mg pyraclostrobin/L (nominal), corresponding to mean measured concentrations of 0.118, 0.219, 0.466, 0.911 and 1.78 mg a.s./L.
Test conditions:	250 mL glass flasks; test volume: 50 mL; sterile enriched medium; pH 7.4 - 7.6 at test initiation and pH 7.8 - 8.0 at test termination; temperature: 23.7°C - 24.5°C; initial cell densities: 3 x 10^3 cells/mL; continuous light at about 2000 lux, continuous shaking at 100 rpm.
Analytics:	Analytical verification of test item concentrations was conducted using an HPLC-method with UV detection.
Statistics:	Descriptive statistics, t-test ($\alpha = 0.05$) for comparison of cell densities and growth rate in the control and solvent control; Bonferroni's test for determination of the NOEC values ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each test concentration at the beginning and at the end of the test. Mean measured concentrations of pyraclostrobin ranged from 96.4 to 102.8% of nominal concentrations at test initiation and from 78.4 to 83.6% of nominal at test termination. The following biological results are based on mean measured concentrations.

Biological results: No statistically significant differences were determined between the control and the solvent control data (t-test; $\alpha = 0.05$). Thus, the data from both control groups were pooled and the pooled data set was used for statistical evaluation of treatment related effects. No statistically significant differences compared to the pooled control were observed at any test item concentrations after exposure over 120 hours (Bonferroni's test; $\alpha = 0.05$). The effects on algal growth are summarized in Table 8.2.6.2-2.

Growth and reproduction toxicity test with BAS 500F and the marine alga, Skeletonema costatum
2000/5035
Guidelines: EPA 123-2
GLP: yes
(certified by United States Environmental Protection Agency)

Executive Summary

In a 120-h static toxicity laboratory study, the effect of pyraclostrobin on growth of the marine diatom *Skeletonema costatum* was investigated. The following nominal concentrations were applied: 0.013, 0.025, 0.050, 0.10 and 0.20 mg pyraclostrobin/L, corresponding to initial measured concentrations of 0.00973, 0.0194, 0.0381, 0.0816 and 0.159 mg a.s./L. Additionally, a solvent control (dimethylformamide) and a dilution water control were set up. Assessment of growth was conducted 24, 48, 72, 96 and 120 h after test initiation.

The biological results are based on initial measured concentrations of the test item. After 120 hours statistically significant differences compared to the pooled control were observed at the three and four highest test item concentrations for growth rate and mean cell density, respectively.

In a 120-h algae test with *Skeletonema costatum*, the E_rC_{50} (120 h) of pyraclostrobin was determined to be > 0.159 mg a.s./L based on initial measured concentrations. After 72 hours of exposure, the respective E_rC_{50} value was determined to be 0.0962 mg a.s./L.

Test item: Pyraclostrobin (BAS 500 F; Reg. no.: 304 428), batch no. 27882/191/C; purity: 97.09%.

B. STUDY DESIGN

Test species:	Marine diatom, *Skeletonema costatum*, strain UTEX LB 2308, in-house culture; stock originally obtained from the "Culture Collection of Algae", University of Texas, Austin, USA.
Test design:	Static system (120 hours); 5 test concentrations plus a dilution water control and a solvent control with 3 replicates for each; daily assessment of growth.
Endpoints:	EC_{50} with respect to biomass and growth rate after exposure over 72 hours and 120 hours.
Test concentrations:	Control (dilution water), solvent control (0.1 mL dimethylformamide/L), 0.013, 0.025, 0.050, 0.10 and 0.20 mg pyraclostrobin/L (nominal), corresponding to initial measured concentrations of 0.00973, 0.0194, 0.0381, 0.0816 and 0.159 mg a.s./L.
Test conditions:	250 mL glass flasks; test volume: 50 mL; enriched marine media; pH 8.0 at test initiation and pH 8.3 - 9.6 at test termination; temperature: 19.2°C - 21.1°C; initial cell densities: 1 x 10^3 cells/mL; photoperiod: 16 hours light : 8 hours dark, light intensity: 3900 - 4000 lux, continuous shaking at 100 rpm.
Analytics:	Analytical verification of test item concentrations was conducted using an HPLC method with UV detection.
Statistics:	Descriptive statistics, t-test (α = 0.05) for comparison of cell densities and growth rate in the control and the solvent control; weighted least squares non-linear regression estimation procedure for determination of EC_x values, Bonferroni's test (α = 0.05) for determination of the NOEC (120 h) values.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each test concentration at the beginning and at the end of the test. At test initiation, mean measured concentrations of pyraclostrobin ranged from 75 to 82% of nominal concentrations. At test termination mean measured concentrations of pyraclostrobin were between 15 and 66% of nominal. The following biological results are based on initial measured concentrations.

Biological results: No statistically significant differences were determined between the control and the solvent control data (t-test; α = 0.05). Thus, the data from both control groups were pooled and the pooled data set was used for statistical evaluation of treatment related effects. After 120 hours statistically significant differences compared to the pooled control were observed at the three and four highest test item concentrations for growth rate and mean cell density, respectively (Bonferroni's t-test; α = 0.05). The effects on algal growth are summarized in Table 8.2.6.2-3.

Table 8.2.6.2-3: Effect of pyraclostrobin on biomass development and growth of the marine diatom *Skeletonema costatum*

Concentration [mg a.s./L] (nominal)	**Water Control**	**Solvent control**	**0.013**	**0.025**	**0.050**	**0.10**	**0.20**
Concentration [mg a.s./L] (initial measured)	**--**	**--**	**0.00973**	**0.0194**	**0.0381**	**0.0816**	**0.159**
Mean cell density (72 h) [% of water control]	--	104	51	25	16	13	6
Growth rate (72 h) [% of water control]	--	100	85	71	62	59	41
Mean cell density (120 h) [% of water control]	--	98	99	86	59	51	15
Growth rate (120 h) [% of water control]	--	98	98	96	89	87	65
	Endpoints [mg pyraclostrobin/L] (initial measured)						
E_rC_{50} (72 h)	0.0962 (95% confidence limits: 0.0716 - 0.129)						
E_bC_{50} (72 h)	< 0.00973						
E_rC_{50} (120 h)	> 0.159						
E_bC_{50} (120 h)	0.0647 (95% confidence limits: 0.0498 - 0.0840)						
NOE_rC (120 h)	0.0194						
NOE_bC (120 h)	0.00973						

III. CONCLUSION

In a 120-h algae test with *Skeletonema costatum*, the E_rC_{50} (120 h) of pyraclostrobin was determined to be > 0.159 mg a.s./L based on initial measured concentrations. After 72 hours of exposure, the respective E_rC_{50} value was determined to be 0.0962 mg a.s./L.

CA 8.2.7 Effects on aquatic macrophytes

The following toxicity study on the aquatic plant *Lemna gibba* performed with the active substance pyraclostrobin is not required for registration in the EU. The study was conducted due to U.S. data requirements and has not been evaluated previously on EU level. It is submitted for completeness.

Report:	CA 8.2.7/1 Boeri R.L. et al., 2000h Growth and reproduction toxicity test with BAS 500F and the duckweed, Lemna gibba G3 2000/5037
Guidelines:	EPA 123-2, EPA 850.4400
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

In a 14-day static toxicity laboratory study, the effect of pyraclostrobin on the growth of the duckweed *Lemna gibba* was investigated. The following nominal concentrations were applied: 0.13, 0.25, 0.50, 1.0 and 2.0 mg pyraclostrobin/L (corresponding to initial measured concentrations of 0.120, 0.202, 0.422, 0.896 and 1.72 mg a.s./L). Additionally, a solvent control (dimethylformamide) and a dilution water control were set up. Assessment of plant growth and other effects was conducted 1, 4, 6, 8, 11 and 14 days after test initiation. Percent growth inhibition relative to the control was calculated for each test concentration based upon biomass for the parameters frond number and dry weight.

The biological results are based on initial measured concentrations of the test item. The duckweed population in the control vessels showed sufficient growth. At the end of the test, chlorotic fronds were observed in the control, the solvent control and in all test item concentrations tested. Statistically significant effects on the number of normal, non-chlorotic fronds and the plant biomass compared to the pooled controls were observed at the highest tested concentration of 1.72 mg a.s./L.

In a 14-day aquatic-plant test with *Lemna gibba,* the E_bC_{50} values of pyraclostrobin based on frond number and dry weight were determined to be > 1.72 mg a.s./L and 1.72 mg a.s./L, respectively, based on initial measured concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F; Reg. no.: 304 428), batch no. 27882/191/C; purity: 97.09%.

B. STUDY DESIGN

Test species:	Duckweed (*Lemna gibba* G3); inocula: 13 days old cultures; cultures maintained in-house; stock obtained from "Climate Stress Laboratory", USDA, Beltsville, Maryland, USA.
Test design:	Static system; test duration 14 days; 5 test item concentrations plus a control and a solvent control, 3 replicates for each test item concentration, the control and the solvent control; 3 plants with 3 - 4 fronds, total number of fronds at test initiation: 9 - 11 per replicate; assessment of growth and other effects on days 1, 4, 6, 8, 11 and 14.
Endpoints:	EC_{50} and NOEC with respect to biomass development after exposure over 14 days.
Test concentrations:	Control, solvent control (0.1 mL dimethylformamide/L), 0.13, 0.25, 0.50, 1.0 and 2.0 mg pyraclostrobin/L (nominal), corresponding to initial measured concentrations of 0.120, 0.202, 0.422, 0.896 and 1.72 mg a.s./L.
Test conditions:	500 mL glass flasks, test volume: 200 mL, M-Hoagland's media without sucrose or EDTA, pH 4.9 - 5.1 at test initiation and pH 5.5 - 5.7 at test termination; temperature: 24.7°C - 25.5°C, continuous light, light intensity: about 490 foot candles.
Analytics:	Analytical verification of the test item was conducted using an HPLC-method with UV-detection.
Statistics:	Descriptive statistics, t-test ($\alpha = 0.05$) for comparison of frond no. and dry weight in the control and solvent control, weighted least squares non-linear regression for determination of EC_x values based on frond no. and dry weight, Bonferroni's test for determination of the NOEC value ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each concentration at the beginning and at the end of the test. The analyzed contents of pyraclostrobin ranged from 81 to 92% of nominal at test initiation and from 17% to 34% of nominal at test termination. The following biological results are based on initial measured concentrations.

Biological results: No statistically significant differences were determined between the control and the solvent control data (t-test; $\alpha = 0.05$). Thus, the data from both control groups were pooled and the pooled data set was used for statistical evaluation of treatment related effects. The duckweed population in the control vessels showed sufficient growth, increasing from an average of 11 fronds per vessel to an average of 198 fronds per vessel, corresponding to an 18 x multiplication. At the end of the test, chlorotic fronds were observed in the control, the solvent control and in all test item concentrations tested. Statistically significant effects on the number of normal, non-chlorotic fronds and the plant biomass compared to the pooled controls were observed at the highest tested concentration of 1.72 mg a.s./L (Bonferroni's test; $\alpha = 0.05$). Effects on biomass development are summarized in Table 8.2.7-1.

Table 8.2.7-1: Effects of pyraclostrobin on the biomass development of duckweed *Lemna gibba*

Concentration [mg a.s./L] (nominal)	**Control**	**Solvent control**	**0.13**	**0.25**	**0.50**	**1.0**	**2.0**
Concentration [mg a.s./L] (initial measured)	**--**	**--**	**0.120**	**0.202**	**0.422**	**0.896**	**1.72**
Number of non-chlorotic fronds (14 d) [% of pooled control]	--	--	100	84	83	91	55
Mean dry weight of fronds [mg]	25.1	21.9	24.9	22.1	21.2	23.1	15.4
Endpoints [mg pyraclostrobin/L] (initial measured)							
E_bC_{50} (14 d) based on frond no	> 1.72						
E_bC_{50} (14 d) based on dry weight	1.72 (95% confidence limits: n.d.)						
NOEC (14 d)	0.896						

n.d. = not determined

III. CONCLUSION

In a 14-day aquatic-plant test with *Lemna gibba,* the E_bC_{50} values of pyraclostrobin based on frond number and dry weight were determined to be > 1.72 mg a.s./L and 1.72 mg a.s./L, respectively, based on initial measured concentrations.

CA 8.2.8 Further testing on aquatic organisms

The mesocosm study summarized below (BASF DocID 2000/1000011) was performed with the solo-formulation BAS 500 00 F (containing 250 g pyraclostrobin/L) and has already been submitted and accepted during the previous Annex I inclusion process for pyraclostrobin.

However, in recent years there was an increasing awareness of inconsistencies in both the way the same mesocosm data are interpreted and the AF applied by regulatory experts in different EU Member States. The Dutch Platform for Assessment of Higher-Tier Studies has produced a Guidance Document on how micro-/mesocosm data should be presented and evaluated in a uniform and transparent manner (de Jong et al., 2008; RIVM Guidance Document). The EFSA Aquatic Guidance Document (EFSA, 2013) proposes to largely use this document to present and evaluate micro-/mesocosm studies for regulatory purposes when placing plant protection products on the European market.
Therefore, the mesocosm study has been re-evaluated following the above mentioned RIVM Guidance Document.

This mesocosm study had been conducted under very conservative worst-case conditions with multiple test substance applications. Though conducted before certain additional guidances were published, which aid the assessment and evaluation of mesocosm studies, it covers all relevant requirements.
In order to further confirm this, an MDD analysis was conducted which is able to show that in this study far more than the required number of potentially sensitive species could be addressed with sufficient statistical power.

Executive summaries of the originally submitted study, the evaluation according to RIVM and the MDD analysis are provided below (for the detailed summary of the mesocosm study reference is made to the documents from the previous Annex I inclusion process for pyraclostrobin).

Report:	CA 8.2.8/1 Dohmen G.-P., 2000a The effect of BAS 500 00 F on aquatic ecosystems - An outdoor mesocosm investigation 2000/1000011
Guidelines:	EWOFFT, CLASSIC, HARAP, SETAC Europe, SETAC RESOLVE
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

A complex outdoor mesocosm study had been performed using multiple spray applications of the EC-formulated solo product BAS 500 00 F with eight applications of the test item in 14 day intervals and with rates increasing from 60 to 160 g a.s./ha during the season. A mixed, replicated ANOVA- regression approach was used with four treatment levels with concentrations reaching 0.9 to 24 µg a.s./L at the two last applications plus control, each with three replicate ponds. The mesocosm site consisted of 15 single ponds, each with a water volume of ca. 6.3 m^3. Water and sediment had been derived from a natural lake, which can be described as a holo/dimictic, meso- to slightly eutrophic, betameso-saprobic system. Parts of it are reserved as nature conservation area, and it is very rich in species. All relevant aquatic groups of phytoplankton, zooplankton, periphyton and benthic organisms were present in high diversity.

The results of this mesocosm study show, that most taxa were not affected even at the highest treatment level. Effects on a few species were observed at a concentration of 24 µg a.s./L. For all planktonic species these effects were found to be reversible. However, also fish and molluscs may be affected at this concentration. No clear effects were observed at 8 µg a.s./L. The multitude of endpoints and species and environmental conditions in this mesocosm study show clearly that at this (and lower) concentrations no adverse effects on aquatic communities can be expected even after multiple applications.

Parallel to the mesocosm study, the effects on fish under outdoor conditions were assessed using the same application scheme (omitting the first low application) in separate small ponds. Five ponds, each containing ca. 500 L water and sediment, were used for the control and the four pyraclostrobin treatments. Seven juvenile fish (*Cyprinus carpio*) were introduced initially into each of the ponds. Effects were only observed at the highest treatment level at the last application (during a period of high temperatures and low oxygen concentrations) causing fish mortality. No sublethal effects (behaviour, growth, gross pathological findings) were observed in any of the other treatments. Thus the outdoor fish study resulted in a NOEC = 8 µg a.s./L.

Based on the results of the mesocosm study, the NOEAEC for pyraclostrobin was determined to be between 8 µg a.s./L and 24 µg a.s./L; the NOEC of pyraclostrobin for aquatic ecosystems was 8 µg a.s./L.

Report: CA 8.2.8/2
Dohmen G.P., 2013a
Mesocosm study evaluation (BAS 500 00 F) - The effect of BAS 500 00 F on aquatic ecosystems - An outdoor mesocosm investigation
2012/1357084
Guidelines: none
GLP: no

Executive Summary

The mesocosm study was re-evaluated and presented according to the RIVM Guidance Document of the Dutch Platform for the assessment of higher tier studies (de Jong et al., 2008). The re-evaluation showed that the mesocosm test system is generally considered to allow very sensitive assessments of pesticide impact on aquatic ecosystems. Furthermore, the number of test substance applications is very much worst-case.
All relevant data are available and the study is considered acceptable and adequate for risk assessment. Given the data provided within the study report, a Reliability Index of 1 can be assigned.
The endpoints defined in the original study report were confirmed, i.e. the NOEAEC is between 8 µg a.s./L and 24 µg a.s./L; the NOEC of pyraclostrobin for aquatic ecosystems is 8 µg a.s./L.

Considering the multitude of endpoints covered, the inclusion of sensitive and relevant species, the worst case character of the study related to exposure and the realistic worst case test system applied, it can be concluded that this mesocosm study provides a sensitive, worst-case assessment of potential pyraclostrobin impacts on aquatic ecosystems.

Report: CA 8.2.8/3
Hommen U., 2016 a
MDD calculation for data sets of the BASF pond study on Pyraclostrobin (BASF DocID 2000/1000011)
2016/1345507
Guidelines: <none>
GLP: no

Executive Summary

- In 1999 BASF conducted an outdoor mesocosm study with the fungicide BAS 500 00 F (a.s.: pyraclostrobin). The test item was applied eight times every 14 days at four different treatment levels. Zooplankton, macroinvertebrates, emergence of insects and phytoplankton were monitored over up to 178 days after the first application.
- In the current 'Guidance on tiered risk assessment for plant protection products for aquatic organisms in edge-of-field surface waters' (EFSA, 2013) it is required to report minimum detectable differences (MDD) for taxa assessed in a micro- or mesocosm study. To derive a regulatory acceptable concentration (RAC) it is recommended that for at least eight populations of the sensitive group the MDDs should be sufficiently low to allow an evaluation of direct effects.
- MDDs for the taxa considered for the evaluation were calculated using the Williams-test for each combination of taxon and sampling date following the proposal outlined in Brock et al. (2015).
- Considering the fungicide mode of action of the test item and the available laboratory toxicity data, invertebrates (mainly zooplankton, partly macroinvertebrates) and to a lower extent algae (see EFSA pesticide dossiers, EFSA 2016) can be considered as sensitive groups. Therefore, the objective of this report was to provide MDDs for the data sets including these groups and to determine for how many potentially sensitive populations a reliable evaluation of direct effects is possible in this study.
- From each of the data sets with frequent samplings, i.e. zooplankton and phytoplankton, at least eight taxa fulfil the MDD criterion proposed by Brock et al. (2015). These taxa cover different taxonomic groups including Cladocera, Copepoda, Ostracoda, Rotifera, and different classes of algae.
- Also in the data sets with only three or four samplings (MASS and insect emergence), the MDDs indicate that for several taxa a reliable statistical analysis was possible (e.g. for different midges, mayflies, snails and mussels).
- Thus, the study meets the requirement by EFSA (2013) that for at least eight populations of the sensitive group(s) a statistical evaluation of direct effects should be possible.

Summary of Relevant Literature Data

The following literature data has not been used or evaluated during the previous Annex I inclusion process.
From the literature search the following peer-reviewed scientific study on *Chironomus dilutus* and *Hyalella azteca* was considered relevant and reliable (with restrictions, RI 2) for the aquatic risk assessment of pyraclostrobin. In this study, *C. dilutus* larvae and juveniles of *H. azteca* were exposed to nine different pesticides. In the following summary only the experimental data and results for pyraclostrobin are presented.

Report: CA 8.2.8/4
Ding Y. et al., 2010a
Toxicity of sediment associated pesticides to *Chironomus dilutus* and *Hyalella azteca*
2014/1143797
Guidelines: none
GLP: no

Executive Summary

Chironomus dilutus larvae and juveniles of *Hyalella azteca* were exposed to pyraclostrobin in a series of 10-day flow-through spiked sediment studies. In the tests with *C. dilutus* sediments were spiked with test item concentrations as high as necessary to obtain LC_{50} values. In the tests with *H. azteca*, nominal test item concentrations up to and including 20 mg/kg dry sediment were used. Additionally, a solvent (acetone) control and a water control were set up for all tests. The *C. dilutus* test was conducted with 5 replicates per test item concentration and the *H. azteca* tests were conducted with 3 replicates per test item concentration. 10 larvae were added to each test vessel in all tests. Three series of tests with *H. azteca* using 3 different sediments with different organic carbon (OC) contents (0.5, 2 and 2.8%) were conducted, while *C dilutus* was only tested with 1 type of sediment (2% organic carbon). Assessment of survival was performed at test end. In addition, a sublethal growth endpoint using average individual ash-free dry mass was measured for *C. dilutus*.

The biological results are based on mean measured sediment concentrations. Survival of *C. dilutus* in the control groups was higher than 88% and average ash-free dry weight (AFDM) values ranged from 0.58 to 0.67 mg for control organisms after the 10-day bioassays. Mean survival in the control groups of the *H. azteca* tests was 95%. *H. azteca* mortality did not reach 50% even at the highest test item concentration (20 mg/kg dry sediment). The apparent differences in endpoints between different OC contents are merely due to different analyzed concentrations (lower recovery at higher OC content).

In a 10-day flow-through spiked sediment test with *Chironomus dilutus* the LC_{50} of pyraclostrobin was determined to be 6.913 mg a.s./kg dry sediment (mean measured). In respective tests with *Hyalella azteca* the LC_{50} values for pyraclostrobin were > 21.6, > 19.3 and > 13.2 mg a.s./kg dry sediment (mean measured) using sediment with an organic carbon content of 0.5, 2.0 and 2.8%, respectively. The NOEC for growth in the test with *C. dilutus* was determined to be 3.2 mg a.s./kg dry sediment based on ash-free dry weight (mean measured).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F), CAS no.: 175013-18-0; supplier ChemService (West Chester, PA, USA), purity > 95%, log K_{ow}: 4.0, log K_{oc}: 3.8 - 4.2.

B. STUDY DESIGN

Test species: *Chironomus dilutus*, third instar larvae, source: in-house culture maintained at the Fisheries and Illinois Aquaculture Center, Southern Illinois University at Carbondale, originally obtained from "USEPA Environmental Research Laboratory", Duluth, MN, USA.
Hyalella azteca, juveniles, 7 - 14 days old; source: University of California, Berkeley, USA.

Test design: Flow-through system; exposure duration: 10 days; test substance was spiked into sediment; several test item treatments plus a solvent (acetone) control and a water control for both the *C. dilutus* and *H. azteca* tests. After a 12-day aging period, wet sediment was distributed into each test beaker and the sediment settled overnight. Ten organisms were randomly placed into each beaker.
C. dilutus: tests were performed with 4 - 6 test item concentrations; 5 replicates for all test item concentrations and controls, each replicate contained 10 animals; overlying water was renewed by addition of moderately hard water three times per day by an automatic water delivery system (total additions were approximately 180 ml/d), with the excess water overflowing of the beaker through a screened hole; *C. dilutus* was tested with 1 type of sediment only (2.0% organic carbon content).
H. azteca: tests were performed with 5 - 7 test item concentrations; 3 replicates for all test item concentrations and controls; each replicate contained 10 animals; overlying water was replaced by the addition of 500 ml water/d (each renewal was 100 ml, and five renewals were used daily); 3 series of tests were set up with *H. azteca* using 3 different sediments with different organic carbon content (0.5, 2.0 and 2.8%).

Assessment of survival and ash-free dry weight (AFDM) for *Chironomus dilutus* and assessment of survival for *H. azteca* was performed at test end.

Endpoints: NOEC and LC_{50} (regarding survival and growth) for *C. dilutus* and LC_{50} (regarding survival) for *H. azteca.*

Test concentrations:	Solvent control (< 700 µL acetone/kg wet sediment), water control for both test species; *C. dilutes*: 4 - 6 test item concentrations (as high as necessary to obtain LC_{50} values); *H. azteca:* 4 - 7 test item concentrations; nominal test item concentrations were not higher than 20 mg/kg dry sediment on the assumption that higher concentrations would be environmentally unrealistic.
Test conditions:	350 mL beakers with 60 g spiked wet sediment and approx. 300 ml overlying water; sediments were collected from drinking water reservoirs and a lake near Berkeley, California, USA with organic carbon contents of 0.5, 2.0 and 2.8%; temperature: 23°C; photoperiod: 16 h light : 8 h dark; food (daily): 1.0 mL of TetraFin suspension (6 g/L) for *C. dilutus* and yeast, cerophyll, and trout food mixture for *H. azteca*; some relevant information (pH, oxygen content, hardness and conductivity of dilution water) is missing in the study report.
Analytics:	Analytical verification of test item concentrations was conducted using a GC-method with micro-electron capture detection.
Statistics:	Descriptive statistics, probit analysis or trimmed Spearman–Karber analysis (Abbott's correction was applied in cases where the data were non-monotonic) for calculation of the LC_{50} values; ANOVA followed by Dunnett's test for determination of the NOEC values ($p < 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: The actual concentrations of the test items in the sediment were determined for each sediment type at the beginning and the end of the test. In the tests with *H. azteca* 95, 93 and 83% of nominal pyraclostrobin concentrations were found in sediments containing 0.5, 2 and 2.8% organic carbon, respectively. The measured pyraclostrobin content in the 2% organic carbon sediment used in the test with *C. dilutus* was 65% of nominal concentrations. The following biological results are based on mean measured sediment concentrations.

Biological results: Survival of *C. dilutus* in the control groups was higher than 88% and average ash-free dry weight values ranged from 0.58 to 0.67 mg for control organisms after the 10-day bioassays. There were no significant differences (Dunnett's test; $p < 0.05$) in the measurements between the negative and solvent controls. Mean survival in the control groups of the *Hyalella azteca* tests was 95% and no significant differences between control and solvent control were found. *Hyalella azteca* mortality did not reach 50% even at the highest test item concentration (20 mg/kg dry sediment). The apparent differences in endpoints between different OC contents are merely due to different analysed concentrations (lower recovery at higher OC content).
The results are summarized in Table 8.2.8-1.

Table 8.2.8-1: Effects of pyraclostrobin on survival and growth of *Chironomus dilutus* and survival of *Hyalella azteca*

Test organism	Organic carbon content of sediment [%]	Endpoint *	Value in mg a.s./kg dry sediment (mean measured)	Value in mg a.s./kg organic carbon content [1)] (mean measured)
Chironomus dilutus	2.0	10 d LC_{50}	6.913 (95% confidence limits: 4.958 - 8.443)	346 (95% confidence limits: 248 - 422)
		10 d NOEC [#]	3.2	160
Hyalella azteca	0.5	10 d LC_{50}	> 21.6	> 4330
	2.0	10 d LC_{50}	> 19.3	> 963
	2.8	10 d LC_{50}	> 13.2	> 470

III. CONCLUSION

In a 10-day flow-through sediment test with *Chironomus dilutus* the LC_{50} of pyraclostrobin was determined to be 6.913 mg a.s./kg dry sediment (mean measured). In respective tests with *Hyalella azteca* the LC_{50} values for pyraclostrobin were > 21.6, > 19.3 and > 13.2 mg a.s./kg dry sediment (mean measured) using sediment with an organic carbon content of 0.5, 2.0 and 2.8%, respectively. The NOEC for growth in the test with *C. dilutus* was determined to be 3.2 mg a.s./kg dry sediment based on ash-free dry weight (mean measured).

From the literature search the following peer-reviewed scientific study on *Hyalella azteca* was considered relevant and reliable (with restrictions; RI 2). In this study, *H. azteca* amphipods were exposed to two different strobilurin fungicide formulations and their active substances. In the following summary only the experimental data and results for pyraclostrobin and the pyraclostrobin containing formulation 'Headline' are presented.

Report: CA 8.2.8/5
Morrison S.A. et al., 2013a
Acute toxicity of Pyraclostrobin and Trifloxystrobin to Hyalella azteca
2014/1143857
Guidelines: none
GLP: no

Executive Summary

Hyalella azteca amphipods were exposed to the fungicide formulation Headline and its active substance pyraclostrobin solved in acetone in a 7-day static study. *Hyalella azteca* was exposed in a water-only exposure scenario and in microcosm tests including sediment. In the first microcosm exposure scenario the test item was added directly to the overlying water and in the second scenario the sediment was over-sprayed with test item 24 h prior to the addition of water. An additional microcosm test was conducted to determine the degree of pyraclostrobin partitioning to the sediment (fate test). These microcosm treatments were set up using the same methods as microcosm tests outlined above to include both sediment- and water-treated pathways. 3 replicates were used. Nominal test concentrations were 0.005, 0.012, 0.030, 0.070 and 0.150 mg a.s./L for the water-only tests and 0.005, 0.014, 0.039, 0.107 and 0.284 mg a.s./L for the microcosm tests. Additionally, a water control was set up for all tests. In the water-only tests all test item concentrations and the water control had 4 replicates, whereas in the microcosm tests 6 replicates were tested for each treatment. 10 amphipods were added to each test vessel. The assessment of mortality was performed after 7 days.

The biological results are based on nominal concentrations. Additionally, biological results are presented based on average measured water concentrations over 96 h.

Water-only tests: Control mortality was < 5% for all experiments. Most of the observed mortality (> 80%) occurred by 96 h for all treatments. After 96 h of exposure, statistically significant differences compared to the control were observed at the three highest and the four highest test item concentrations in the pyraclostrobin treatment and the Headline treatment, respectively. There was a significant difference, albeit slight, in mortalities between Headline and pyraclostrobin treatments. However, the LC_{50} and LC_{10} values were similar and 95% confidence intervals overlapped.

Microcosm tests: Control mortality was < 10% across all experiments. Observed toxicity was lower when Headline was applied to the overlying water in the microcosm, compared with the water-only tests. Sediment-water microcosm systems reduced the toxicity by a factor of 5 compared to the observed toxicity in water only tests when the overlying water was treated, based on the total amount of fungicide applied to the system (LC_{50} value of 0.017 mg/L compared to 0.0855 mg/L). No significant differences were observed in mortality between the controls and the sediment treated microcosms up to and including the highest tested concentration. Thus, water versus sediment application of Headline resulted in significantly different mortalities at the 2 highest test item concentrations and non-overlapping LC_{50} and LC_{10} values between exposure scenarios.

In a 7-day spiked water test (water-only exposure) with *Hyalella azteca* the LC_{50} values of pyraclostrobin were determined to be 0.022 and 0.017 mg a.s./L (nominal) for the pyraclostrobin solved in acetone and the pyraclostrobin formulation treatment, respectively (0.0251 and 0.021 mg a.s./L based on 96 h measured average water concentrations, respectively).
In a 7-day spiked water test including sediment (Headline water overspray) with *Hyalella azteca* the LC_{50} value of pyraclostrobin was 0.0855 mg a.s./L based on nominal concentrations (0.0183 mg a.s./L based on 96 h measured average water concentrations). In a 7-day sediment test (Headline sediment overspray) with *Hyalella azteca* the LC_{50} value of pyraclostrobin was > 0.284 mg a.s./L based on nominal concentrations (> 0.0087 mg a.s./L based on 96 h measured average water concentrations).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F), purchased from Sigma- Aldrich, purity: 99.9%.
Pyraclostrobin formulation Headline (US-EPA Reg. No. 7969-186);
some relevant information (batch no., density of pyraclostrobin formulation, content of a.s. in pyraclostrobin formulation) is missing in the study report.

B. STUDY DESIGN

Test species: *Hyalella azteca*, juveniles, size: 250 - 500 µm, source: in-house culture.

Test design: Static system (7 days); pyraclostrobin formulation Headline was suspended in dechlorinated water and added to experimental units; solutions containing the active substance were dissolved in acetone to achieve the same concentration of active substance as in formulation concentrations, based on percentages of active substance in the formulation; 10 amphipods per replicate.
Water-only tests: exposure to pyraclostrobin and pyraclostrobin formulation; 5 test item concentrations plus a water control, 4 replicates for each treatment; amphipods were introduced to the experimental units prior to the addition of fungicides, assessment of survival after 6 h and then every 12 h after the start of the exposure until test end.
Microcosm tests: exposure to pyraclostrobin formulation only; 6 replicates for each treatment; experimental units were treated with pyraclostrobin formulation in 2 ways: 1) pyraclostrobin formulation diluted in water was added directly to the overlying water and gently stirred into solution, 2) sediment was sprayed across the sediment surface 24 h prior to the addition of overlying water.
Amphipods were added to water-treated microcosms prior to treating the overlying water and were added to sediment-treated microcosms immediately following the addition of water to the system; assessment of mortality at 7 d.
Fate test: An additional test was conducted to determine the degree of pyraclostrobin partitioning to the sediment. Microcosm treatments were set up using the same methods as microcosm toxicity tests outlined above to include both sediment- and water-treated pathways except only 3 replicates were used. The amount of pyraclostrobin applied to the sediment and water system corresponded to a water concentration of 0.300 mg/L (assuming full water incorporation) or a sediment concentration of 0.230 mg/kg (assuming complete adsorption to the sediment). Three replicates and a control were destructively taken down for each treatment at 3 h, 12 h, 96 h and 168 h.

Endpoints: NOEC (regarding survival); LC_{10} and LC_{50}.

Test concentrations: Water-only tests: water control, 0.005, 0.012, 0.030, 0.070 and 0.150 mg pyraclostrobin/L.
Microcosm tests: water control, 0.005, 0.014, 0.039, 0.107 and 0.284 mg a.s./L, the given concentrations represent the concentration based on full water incorporation into 800 mL of overlying water.

Test conditions:	Water-only tests: 600 mL glass beakers containing 500 mL dechlorinated water. Microcosm tests: glass jars containing 800 mL dechlorinated water and 100 g of sediment. All tests: pH 7.2 - 7.5; oxygen content: 3.2 mg/L - 9.0 mg/L; temperature: 23 ± 1°C; photoperiod: 16 h light : 8 h dark; food: 1.0 mL of TetraMin fish food solution (1800 mg/L) per replicate daily. Dilution water: dechlorinated water obtained by carbon filtration of tap water (pH: 7.5 - 7.7; hardness: 80 - 100 mg $CaCO_3$/L; dissolved oxygen: 6.7 - 9.0 mg/L. Sediment: collected from a wetland from the Rainwater Basin of Central Nebraska, soil type: silty clay loam (16.2% sand, 50% silt and 33.8% clay), overall organic matter content: 6.78%; no detectable pesticides were found in sediment (<10 mg/kg). Some relevant information (light intensity, aeration) is missing in the study report.
Analytics:	Analytical verification of test item concentrations was conducted using a GC-method with selected ion monitoring detection.
Statistics:	Descriptive statistics, log probit analysis for calculation of LC_x values; ANOVA followed by Tukey's honestly significant difference test for determination of NOEC values ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in the water-only tests and the microcosm tests at multiple time points throughout the tests.
Water-only tests: measured water concentrations for pyraclostrobin in the water-only toxicity tests were 122 ± 28% of targeted concentrations over the entire test. On average, measured water concentrations of pyraclostrobin declined 13 ± 9% from initial concentrations over 168 h.
Microcosm - water overspray: At 4 h after test initiation, pyraclostrobin water concentrations in the spiked water microcosms across all treatment concentrations were 28 ± 2% of that expected based on full water incorporation. Water concentrations of pyraclostrobin continued to decline throughout the test, with 13 ± 8% remaining at 96 h and 9 ± 7% after 168 h. Based on the parallel fate experiment, pyraclostrobin water concentrations declined by 69%, whereas sediment concentrations increased by 56% from initial measurements by 168 h. However, no differences were observed in the total mass balance of pyraclostrobin in system from beginning (59 ± 6%) to the end (62 ± 4%) due to the dissipation from the water column. Thus, partitioning of pyraclostrobin into the sediment accounts for the majority of the declining water concentrations with other dissipation processes (e.g., biotic- or abiotic-transformations, hydrolysis, etc.) contributing to the 30 to 40% being lost from the system.

Microcosm - sediment overspray: Application of Headline to the sediment 24 h prior to adding water resulted in minimal partitioning of pyraclostrobin from the sediment into the water column. Highest pyraclostrobin water concentrations across all treatments (2 ± 3%) were observed at the first measurement (4 h), with concentrations decreasing to < 1% of the total concentration expected from full water incorporation for the remainder of the microcosm toxicity tests. Measured water and sediment concentrations declined to 65 and 45% of initial measured concentrations, respectively, by 168 h based on the parallel fate experiment. There was a pronounced loss of pyraclostrobin from the system when Headline was applied to the sediment with total mass balance recoveries declining from 81 ± 10% at 4 h to 43 ± 3% at 168 h.
The following biological results are based on nominal concentrations. Additionally, biological results are presented based on average measured water concentrations over 96 h.

Biological results:
Water-only tests: Control mortality was < 5% for all experiments. Most of the observed mortality (> 80%) occurred by 96 h for all treatments. After 96 h of exposure, statistically significant differences compared to the control were observed at the three highest and the four highest test item concentrations in the pyraclostrobin treatment and the Headline treatment, respectively (ANOVA followed by Tukey's honestly significant difference test; $p < 0.05$). There was a significant difference, albeit slight, in mortalities between Headline and pyraclostrobin treatments ($p = 0.035$). However, the LC_{50} and LC_{10} values were similar and 95% confidence intervals overlapped.
Microcosm tests: Control mortality was < 10% across all experiments. Observed toxicity was lower when Headline was applied to the overlying water in the microcosm, compared with the water-only toxicity tests. Sediment-water microcosm systems reduced the toxicity by a factor of 5 compared to the observed toxicity in water only tests when the overlying water was treated, based on the total amount of fungicide applied to the system (LC_{50} value of 0.017 mg/L compared to 0.0855 mg/L). No significant differences were observed in mortality between the controls and the sediment treated microcosms up to and including the highest tested concentration (ANOVA followed by Tukey's honestly significant difference test; $p < 0.05$). Thus, water versus sediment application of Headline resulted in significantly different mortalities at the 2 highest test item concentrations and non-overlapping LC_{50} and LC_{10} values between exposure scenarios.

The results are summarized in Table 8.2.8-2.

Table 8.2.8-2: Effects of pyraclostrobin and Headline on survival of *Hyalella azteca*

* 96-h average concentrations were calculated by averaging measurements from 6 h to 96 h.
# As pyraclostrobin formulation concentrations in the microcosm test declined throughout the exposures, 96 h weighted water concentration averages over time were calculated using an first-order exponential decay function.

III. CONCLUSION

In a 7-day spiked water test (water-only exposure) with *Hyalella azteca* the LC_{50} values of pyraclostrobin were determined to be 0.022 and 0.017 mg a.s./L (nominal) for the pyraclostrobin and the pyraclostrobin formulation treatment, respectively (0.0251 and 0.021 mg a.s./L based on 96 h measured average water concentrations, respectively).
In a 7-day spiked water test including sediment (Headline water overspray) with *Hyalella azteca* the LC_{50} value of pyraclostrobin was 0.0855 mg a.s./L based on nominal concentrations (0.0183 mg a.s./L based on 96 h measured average water concentrations). In a 7-day sediment test (Headline sediment overspray) with *Hyalella azteca* the LC_{50} value of pyraclostrobin was > 0.284 mg a.s./L based on nominal concentrations (> 0.0087 mg a.s./L based on 96 h measured average water concentrations).

From the literature search the following peer-reviewed scientific study on glochidia and juvenile life stages of freshwater mussels was considered relevant and reliable (with restrictions; RI 2). In this study, glochidia and juvenile life stages of freshwater mussels were exposed to different technical-grade current-use pesticides. However, in the following summary only the experimental data and results for pyraclostrobin are presented.

Report: CA 8.2.8/6
Bringolf R.B. et al., 2007a
Contaminant sensitivity of freshwater mussels - Acute and chronic toxicity of technial-grade pesticides to glochidia and juveniles of freshwater mussels (unionidae)
2014/1143854
Guidelines: none
GLP: no

Executive Summary

In an acute toxicity laboratory study, glochidia of the freshwater mussel *Lampsilis siliquoidea* were exposed over 48 hours under static conditions. Similarly, juvenile of *L siliquoidea* were exposed over 96 hours in a semi-static test system. Animals in both tests were exposed to a dilution water control, a solvent control and to up to 6 test item concentrations. Glochidia were exposed in groups of 100 - 200 individuals while juvenile test groups consisted of 7 mussels per replicate. Viability of glochidia was observed 24 and 48 hours after start of exposure. Survival of juveniles was assessed 48 and 96 hours after test initiation.

The biological results are based on mean measured concentrations of the test item. After 48 hours of exposure control viability was > 90% in the test with glochidia. Regarding the acute test with juvenile mussels control survival exceeded 93% after 96 hours of exposure. Juvenile mussels were more sensitive to pyraclostrobin than glochidia, at the end of the respective exposure times of 96 and 48 hours.

In an acute toxicity study with early life stages of the freshwater mussel *Lampsilis siliquoidea* the EC_{50} values of pyraclostrobin were 0.08 mg a.s./L (48 h) and 0.03 mg a.s./L (96 h) for glochidia and juveniles, respectively, based on mean measured concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Pyraclostrobin (BAS 500 F) purchased from Chem Service (West Chester, PA, USA), purity: 99%. Some relevant information (batch no.) is missing in the study report.

B. STUDY DESIGN

Test species:	Freshwater mussel (*Lampsilis siliquoidea)*, glochidia and juveniles; juveniles 8 weeks post-transformation and less than two months old; source: in-house culture, mussels originally collected from Silver Fork of Perche Creek, Boone County, Missouri, USA.
Test design:	Glochidia acute toxicity tests: Static system (48 h); 5 - 6 test item concentrations plus a dilution water control and a solvent control, 3 replicates per treatment; 100 - 200 glochidia in each replicate; assessment of viability 24 and 48 hours after start of exposure. Juvenile acute toxicity tests: Semi-static system (96 h); renewal of test solutions 48 hours after test initiation; 5 - 6 test item concentrations plus a dilution water control and a solvent control, 3 replicates per treatment; 7 mussels in each replicate; assessment of survival 48 and 96 hours after start of exposure.
Endpoints:	EC_{50} based on viability (glochidia) or survival (juveniles).
Test concentrations:	Control (dilution water), solvent control (acetone), 5 - 6 test item concentrations approaching water solubility of the test item.
Test conditions:	Test chambers: 90 x 50 mm glass crystallizing dishes, test volume: 100 mL; dilution water: reconstituted hard water; hardness: 170 - 192 mg $CaCO_3$/L; temperature: 20.1 - 21.9°C; pH 8.32 - 8.61; oxygen content: > 80% saturation; conductivity: 523 - 625 µS/cm; some relevant information (aeration; feeding) is missing in the study report.
Analytics:	Analytical verification of test item concentrations was conducted using a liquid chromatography-tandem mass spectrometry method.
Statistics:	Descriptive statistics; Trimmed Spearman-Karber method for calculation of EC_{50} values.

II. RESULTS AND DISCUSSION

Analytical measurements: Pesticide exposure concentrations were determined for at least two treatment concentrations in each toxicity test. The mean measured content of pyraclostrobin was 122.6 ± 5.7% of nominal concentrations for toxicity tests with glochidia and juvenile mussels. The following biological results are based on mean measured concentrations of the test item.

Biological results: After 48 hours of exposure control viability was > 90% in the test with glochidia. Regarding the acute test with juvenile mussels control survival exceeded 93% after 96 hours of exposure. Juvenile mussels were more sensitive to pyraclostrobin than glochidia, at the end of the respective exposure times of 96 and 48 hours. The results are summarized in Table 8.2.8-3.

Table 8.2.8-3: Acute toxicity of pyraclostrobin to early life stages of the freshwater mussel *Lampsilis siliquoidea*

Life stage	Endpoint	Value in mg a.s./L (mean measured)
Glochidia	EC_{50} (24 h)	0.48 (95% confidence limits: 0.19 - 1.21)
	EC_{50} (48 h)	0.08 (95% confidence limits: 0.04 - 0.19)
Juvenile mussels	EC_{50} (96 h)	0.03 (95% confidence limits: 0.03 - 0.04)

III. CONCLUSION

In an acute toxicity study with early life stages of the freshwater mussel *Lampsilis siliquoidea* the EC_{50} values of pyraclostrobin were 0.08 mg a.s./L (48 h) and 0.03 mg a.s./L (96 h) for glochidia and juveniles, respectively, based on mean measured concentrations.

In the following summary of a study with several substances only the results for pyraclostrobin and its formulation Headline® are presented.

Report: CA 8.2.8/7
Hooser E.A. et al., 2012a
Acute toxicity of three Strobilurin fungicide formulations and their active ingredients to tadpoles
2014/1143796
Guidelines: <none>
GLP: no

Executive Summary

In a 96-hour static acute toxicity laboratory study, tadpoles of Great Plains toad (*Bufo cognatus*) were exposed to pyraclostrobin and the formulation Headline® at nominal concentrations of 0 (solvent control), 0.0005, 0.0017, 0.0050 and 0.015 mg/L in 3 replicates per treatment each with 7 tadpoles per aquarium. Tadpoles were observed for survival every 2 hours for the first 12 hours and then every 12 hours through 96 hours after start of exposure.

The following biological results are based on nominal concentrations. Mortalities in the solvent control were < 2% for the entire experiment. Pyraclostrobin and the formulation caused 100% mortality at the highest concentration. Toxicity was comparable between pyraclostrobin and the formulation for all concentrations, with the exception of 0.005 mg/L, where formulation exposure resulted in 79% mortality versus no mortality from exposure to pyraclostrobin. The authors conclude that pyraclostrobin is toxic to tadpoles and that adjuvant(s) in the Headline® formulation also contribute to mortality. However, it has to be considered that spacing of concentrations was rather wide and that the dose response is rather steep.

In a static acute toxicity study with tadpoles of *Bufo cognatus*, the LC_{50} (72 h) of pyraclostrobin was determined to be 0.010 mg a.s./L based on nominal concentrations, while the LC_{50} (72 h) for the formulation Headline® was 0.0037 mg/L (nominal). The NOEC values were 0.005 mg a.s./L and 0.0017 mg/L (nominal) for pyraclostrobin and the formulation Headline®, respectively.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Headline®: EPA Reg. No. 7969-186; purchased from a local distributor. Pyraclostrobin: purchased from Sigma-Aldrich (St. Louis, MO, USA); analytical standard grade (Pestanal®); dissolved using HPLC grade acetone to produce the same concentrations as the formulations.

B. STUDY DESIGN

Test species: Great Plains toad (*Bufo cognatus*); exposure of 6 days old tadpoles, obtained from in-house culture; adults were captured in central Oklahoma, USA.

Test design: Static system; exposure duration: 96 hours; 4 test item concentrations plus solvent control; 7 tadpoles per aquarium; 3 aquaria per tank (3 replicates; 21 tadpoles per tank), 1 tank per concentration and control; assessment of mortality every 2 hours for the first 12 hours and then every 12 hours through 96 hours after start of exposure. Stock solution of the a.s. pyraclostrobin was prepared by dissolving in acetone; the stock solutions of the formulations was prepared with water.

Endpoints: LC_{50}, NOEC, based on mortality after 72 h.

Test concentrations: Solvent control (deionized water and 0.5 mL acetone per aquarium),and 0.0005, 0.0017, 0.005 and 0.015 mg a.s./L for both the active substance and the formulation, respectively.

Test conditions: 9.5 L glass aquaria, test volume: 6 L, dilution water: dechlorinated water; temperature: 25 ±°2°C; dissolved oxygen: > 5.4°mg/L; photoperiod 13 h light : 11 h dark.

Analytics: Analytical verification of test item concentrations was conducted using a GC-method with MS detection.

Statistics: Descriptive statistics, one-way ANOVA, Tukey´s multiple range test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentration was conducted in the lowest treatment groups for both the formulation treatment and the active substance treatment after 3 and 96 hours and also in the highest treatment group for the formulation after 3 hours (value for active substance is missing). For the highest treatment group no analysis was done after 96 hours, because all individuals were dead within 24 hours for pyraclostrobin and Headline®. After 3 hours the mean measured values for pyraclostrobin and Headline® in the lowest treatment group were 84% and 126% of nominal values, respectively. After 96 hours the mean measured values for pyraclostrobin and Headline® were 22% and 91% of nominal, respectively. In the highest treatment group, the mean measured value of Headline® was 98% of nominal after 3 hours.
The following biological results are based on nominal concentrations.

Biological results: Mortalities in the solvent control were < 2%. 100% mortality was observed at the highest tested concentration for the a.s. and the formulation. Statistically significant differences in toxicity between pyraclostrobin and formulation exposure occurred at 0.005 mg/L only. The results are summarized in Table 8.2.8-4.

The authors speculate that constituents of the formulation may be responsible for the observed difference in toxicity at 0.005 mg/L. However, it has to be considered that spacing of concentrations was rather wide and that the dose response is rather steep.

Table 8.2.8-4: Acute toxicity of the active substance pyraclostrobin and the formulation Headline® to tadpoles of Bufo cognatus

Test substance	Endpoint	Value in mg a.s./L (nominal)
Pyraclostrobin	LC_{50} (72 h)	0.010
	NOEC (72 h)	0.005
Headline®	LC_{50} (72 h)	0.0037
	NOEC (72 h)	0.0017

III. CONCLUSION

In a static acute toxicity study with tadpoles of *Bufo cognatus*, the LC_{50} (72 h) of pyraclostrobin was determined to be 0.010 mg a.s./L based on nominal concentrations, while the LC_{50} (72 h) for the formulation Headline® was 0.0037 mg/L (nominal). The NOEC values were 0.005 mg a.s./L and 0.0017 mg/L (nominal) for pyraclostrobin and the formulation Headline®, respectively.

The following study investigated sublethal and chronic effects of three different strobilurin-containing fungicide formulations to *Bufo cognatus* tadpoles. In the following summary only the results for pyraclostrobin and the pyraclostrobin containing solo formulation Headline® are presented.

Report: CA 8.2.8/8
Hartman E.A.H. et al., 2014a
Chronic effects of Strobilurin fungicides on development, growth and mortality of larval great plains toads (Bufo cognatus)
2014/1143856
Guidelines: <none>
GLP: no

Executive Summary

In a 90-day semi-static chronic limit test, tadpoles of Great Plains toad (*Bufo cognatus*) were exposed throughout metamorphosis to the formulation Headline® at a single nominal concentration of 0.0017 mg pyraclostrobin/L and a dilution water control in 6 replicates per treatment each with 21 tadpoles per aquarium. Aquaria were checked daily for metamorphosed individuals and mortality. With the onset of metamorphosis the time to metamorphosis was recorded and weight and snout-vent length (SVL) were measured. At test termination surviving tadpole larvae were measured, staged and counted as incomplete metamorphosis.

The following biological results are based on nominal concentrations. Mortalities in the control were < 15% for the entire experiment. Mean body mass and snout-vent length of tadpoles in the control were 19.3 g and 11.4 mm. The average time to metamorphosis was 68.8 days for animals in the control, which is significantly longer than observed normally in the field (18-49 days). The time to metamorphosis of tadpoles in the Headline® treatment was statistically significantly reduced (it was also reduced non significantly in another treatment group). Headline® exposure caused no mortality and no statistically significant effects on body mass and snout-vent length were observed. In conclusion, headline exposure did not result in any adverse effects, and it may be speculated whether the observed difference to the control might be due to a particular poor performance of the control group.

In a semi-static chronic test with tadpoles of *Bufo cognatus*, application of the formulation Headline®, corresponding to a nominal test concentration of 0.0017 mg pyraclostrobin/L, resulted in a shorter development time as compared to the control. There was no impact on mortality or on biomass development or snout-vent length and accordingly no adverse effect of the Headline® treatment.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Headline® (EPA Reg. No. 7969-186; purchased from a local distributor) containing the active substance pyraclostrobin.

B. STUDY DESIGN

Test species: Great Plains toad (*Bufo cognatus*); tadpoles were captive breed from three pairs of adults captured in central Oklahoma (USA) in spring 2012.

Test design: Semi-static system; renewal of test water every 96 hours with fresh spike solutions; limit test: 1 test item concentration plus a water control; 21 six day old tadpoles per aquarium; 6 aquaria per treatment (n = 6 replicates). Tadpoles were allowed to acclimate to the test chambers 24 hours prior to test initiation; exposure duration: up to 90 days; daily assessment of mortality (failure to move after gentle probing with a glass rod) and metamorphosed individuals. Individuals that reached Gosner stage 44 were removed and placed into a tank with dilution water and substrate and allowed to absorb their tail and complete metamorphosis (Gosner stage 46). Time to metamorphosis was recorded and mass and snout–vent length (SVL) were measured at this time. Animals that had not finished metamorphosis after 90 days were measured, staged and counted as incomplete metamorphosis.

Endpoints: Mortality, time to metamorphosis, body mass and snout–vent length (SVL)

Test concentrations: Water control and 0.0017 mg pyraclostrobin/L (nominal).

Test conditions: 9.5 L glass aquaria, test volume: 6 L of dechlorinated water with continuous aeration, dilution water: dechlorinated water; temperature: 25 ±°2°C; dissolved oxygen: > 5.4°mg/L; photoperiod 13 h light: 11 h dark; feeding: tadpoles were fed *ad libitum* a mixture of commercial rabbit food and TetraMin® fish flakes (Tetra).

Analytics: Analytical verification of test item concentrations was conducted using a GC-method with MS detection. Please note, due to volume limitations of collected test water, pyraclostrobin measurements of the test items could not be achieved

Statistics: Descriptive statistics, one-way ANOVA, Wilcoxon test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of the test item concentration was conducted in fresh and old solutions (i.e. 2 and 96 hours after spiking) at each test water renewal in two of the six replicates. Due to volume limitations of collected test water, pyraclostrobin measurements could not be achieved. In addition, spiking solutions were confirmed to be within 10% of expected, which is similar to the precision of the instrument. The following biological results are reported using nominal concentrations.

Biological results: Mortalities in the control were < 15% for the entire experiment. Mean body mass and snout-vent length of tadpoles in the control were 19.3 g and 11.4 mm. The average time to metamorphosis was 68.8 days for animals in the control, which is significantly longer than observed normally in the field (18-49 days). The time to metamorphosis of tadpoles in the Headline® treatment was statistically significantly reduced (it was also reduced non significantly in another treatment group). Headline® exposure caused no mortality and no statistically significant effects on body mass and snout-vent length were observed. In conclusion, headline exposure did not result in any adverse effects, and it may be speculated whether the observed difference to the control might be due to a particular poor performance of the control group.

III. CONCLUSION

In a semi-static chronic test with tadpoles of *Bufo cognatus*, application of the formulation Headline®, corresponding to a nominal test concentration of 0.0017 mg pyraclostrobin/L, resulted in a shorter development time as compared to the control. There was no impact on mortality or on biomass development or snout-vent length and accordingly no adverse effect of the Headline® treatment.

CA 8.3 Effects on arthropods

CA 8.3.1 Effects on bees

Since Annex I inclusion of the active substance pyraclostrobin (BAS 500 F), new studies on honeybees and bumblebees have been performed with the active substance. As a result, there are new endpoints, which are considered in the honey bee risk assessment. Summaries of these new studies are provided below and an overview on studies and endpoints is given in Table 8.3.1-1.

Table 8.3.1-1: List of studies and endpoints with bees and the active substance pyraclostrobin (BAS 500 F)

Substance	Test species	Endpoint	Value	Reference (BASF DocID)	EU agreed
Pyraclostrobin	honeybee	48 h acute oral LD_{50}	> 73.1 µg a.s./bee	1999/11457	yes
		48 h acute contact LD_{50}	> 100.0 µg a.s./bee		
	honeybee	48 h acute oral LD_{50}	> 110 µg a.s./bee	2013/1003210	no, new study
		48 h acute contact LD_{50}	> 100 µg a.s./bee		
	bumblebee	96 h acute oral LD_{50}	> 97.2 µg a.s./bee	2016/1000530	no, new study
		96 h acute contact LD_{50}	> 100 µg a.s./bee		
Pyraclostrobin (tested as Pristine)[3)]	honeybee	honeybee development	No unacceptable effects in queen development, queen survival and adult worker bee health using 400 ppm Pristine treated (measured concentration: 22 ppm pyraclostrobin)	2013/1416303	no, new study
Pyraclostrobin[1)]	--	residues in honeybee feed items (sunflower)	Applied rate: 143 g pyraclostrobin/ha Highest residue: 16.6 mg pyraclostrobin/kg (90^{th} percentile, found in pollen)	2014/1000204	no, new study
Pyraclostrobin[1)]	--	residues in honeybee feed items (oilseed rape)	Applied rate: 143 g pyraclostrobin/ha Highest residue: 6.7 mg pyraclostrobin/kg (90^{th} percentile, found in pollen)	2014/1000182	no, new study
Pyraclostrobin[2)]	honeybee	semi-field tunnel test	No unacceptable lethal or sublethal effects on honeybee colonies exposed to 250 g a.s./ha	2011/1112669	no, new study

1) Study was carried out with BAS 556 03 F as a surrogate for pyraclostrobin. BAS 556 03 F contains 130 g pyraclostrobin/L and 80 g metconazole/L and is an EC formulation like BAS 500 06 F. The study is presented as additional information.
2) Study was carried out with BAS 500 06 F as a surrogate for pyraclostrobin because active substances can only be applied as formulated products.
3) Peer-reviewed scientific study was carried out with Pristine containing 25.2% boscalid and 12.8% pyraclostrobin (a formulation similar to BAS 516 07 F). The study summary is shown in M-CP 10.3.1.3 of the BAS 516 07 F dossier.

Report:	CA 8.3.1/1 Mack P., 2014a Determination of residues of BAS 556 03 F in nectar, pollen and flowers of sunflowers after one application in 2013 2014/1000204
Guidelines:	EEC 7029/VI/95 rev. 5, EU Regulation 1107/2009 with Regulation 283/2013, EU Regulation 1107/2009 with Regulation 284/2013
GLP:	yes (certified by Landesamt fuer Umwelt, Messungen und Naturschutz Baden Wuerttemberg, Karlsruhe, Germany)

Executive Summary

The purpose of the study was to collect samples for later determination of residues in nectar, pollen and flowers from sunflowers treated once with BAS 556 03 F under field conditions. During the 2013 growing season five separate field trials were conducted in different representative growing areas in Southern Germany, Italy and Greece. Actual applied rates of pyraclostrobin in the five trials were 145.9, 144.3, 146.0, 144.3, and 137.4 g a.s./ha. The results were compared to an untreated control.

In the control treatments no residues of pyraclostrobin were detected in pollen, nectar and flower matrices. The matrices with the highest residues analyzed over all trials were pollen samples. Residues ranged from 2.20 to 17.00 mg/kg at the first sampling (0-1 DAA) and from 0.05 to 1.3 mg/kg at the second sampling (6-7 DAA). In flower samples residues of all trials ranged from 0.68 mg/kg to 1.50 mg/kg at the first sampling (0-1 DAA). At the second sampling (6-7 DAA) residues were between 0.04 mg/kg and 0.32 mg/kg. In nectar samples lowest residues of all matrices were analysed and ranged from 0.04 mg/kg to 0.53 mg/kg at the first sampling (0-1 DAA). At the second sampling the residues were < 0.010 mg/kg (below LOQ).

Based on the application rate of 143 g pyraclostrobin/ha (applied as BAS 556 03 F) the highest residues (90th percentile), found in pollen, was determined to be 16.6 mg pyraclostrobin/kg at the first sampling with an average value of 9.76 mg pyraclostrobin/kg.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 556 03 F, batch no. 380014, content: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 130.0 g/L nominal (132.6 g/L analyzed); metconazole (BAS 555 F, Reg. No. 4 056 343): 80.0 g/L nominal (80.2 g/L analyzed); density: 1.077 g/cm^3.

B. STUDY DESIGN

Test design: Nectar, pollen and flower samples collected from sunflowers were analyzed for residues of the test item BAS 556 03 F. The study comprised five trials, three in Southern Germany (trials -*01* to -*03*), one in Italy (trial -*04*) and one in Greece (trial -*05*). For the trials -*01* and -*03* to -*05* two treatment groups were set up per trial, one test item treatment and one untreated control.

Field site: The three German fields were located in the region of Baden-Wuerttemberg; the two fields in Italy in the region of Emilia-Romagna. All fields were cropped with sunflowers.

Sampling: Two samplings were performed per trial, one within 24 hours after application of the treatment field and one six to seven days after application. For trial -*02* one field site was used, where one sampling was performed before application and used as control and two further samplings were performed one and seven days after application. For pollen and nectar samples, on each sampling day a pooled sample of approx. 0.4 g was collected and divided into two subsamples samples (A and R) of at least 0.2 g, if enough material was available. For flower samples on each sampling day 12 flower heads from at least 12 different locations across the plot were collected. Depending on the size of the flower head they were cut into pieces and at least 1/8 of the flower head was taken for a pooled sample. The samples were divided into two subsamples (A and R) of at least 12 flower heads, each.

Application rates: Actual applied rates of pyraclostrobin: trial -*01*: 145.9 g a.s./ha, trial -*02*: 144.3 g a.s./ha, trial -*03*: 146.0 g a.s./ha, trial -*04*: 144.3 g a.s./ha and trial -*05*: 137.4 g a.s./ha. All applications were carried out between BBCH 63 and 65 with 300 L water/ha.

II. RESULTS AND DISCUSSION

In the control treatments no residues of pyraclostrobin were detected in pollen, nectar and flower matrices. The matrices with the highest residues analyzed over all trials were pollen samples. Residues ranged from 2.20 to 17.00 mg/kg at the first sampling (0-1 DAA) and from 0.05 to 1.3 mg/kg at the second sampling (6-7 DAA). In flower samples residues of all trials ranged from 0.68 mg/kg to 1.50 mg/kg at the first sampling (0-1 DAA). At the second sampling (6-7 DAA) residues were between 0.04 mg/kg and 0.32 mg/kg. In nectar samples lowest residues of all matrices were analysed and ranged from 0.04 mg/kg to 0.53 mg/kg at the first sampling (0-1 DAA). At the second sampling the residues were < 0.010 mg/kg (below LOQ). The results are presented in Table 8.3.1-2.

Table 8.3.1-2: Analyzed residues of pyraclostrobin in nectar, pollen and flower samples

Matrix	Treatment	Sampling	Timing [DAA[1)]]	Range of residues over all trials [mg/kg]	90th percentile over all trials [mg/kg]
Nectar	Control	S1[2)]	-1 – 1	< LOQ	--
		S2[2)3)]	7		
	BAS 556 03 F	S1[2)]	0 – 1	0.04 – 0.53	0.42
		S2[2)]	7	< LOQ	--
Pollen	Control	S1	-3 – 1	< LOQ	--
		S2[3)]	0 – 7		
	BAS 556 03 F	S1	0 – 1	2.20 – 17.00	16.60
		S2	6 – 7	0.05 – 1 3	1.07
Flowers	Control	S1	-3 – 1	< LOQ	--
		S2[3)]	6 – 7		
	BAS 556 03 F	S1	0 – 1	0.68 – 1.50	1.46
		S2	6 – 7	0.04 – 0.32	0.31

< LOQ (below limit of quantification): < 0.010 mg/kg
1) Days after application
2) Nectar samples of four trials (no sample in trial *-04*)
3) No sample for trial *-02*

For all matrices a reduction between the first and second sampling is visible. Table 8.3.1-3 shows the residue reduction from the 1st to the 2nd sampling in percent, calculated from the average residue values from all 5 trials.

Table 8.3.1-3: Reduction of pyraclostrobin residues in nectar, pollen and flowers between samplings

Matrix	Sampling	Timing [DAA [1)]]	Average residue [mg/kg]	Reduction [%]
Nectar	S1[2)]	0 – 1	0.20	--
	S2[2)3)]	7	< 0.01	95.00
Pollen	S1	0 – 1	9.76	--
	S2	6 – 7	0.51	94.77
Flowers	S1	0 – 1	1.13	--
	S2	6 – 7	0.19	83.19

1) Days after application
2) Nectar samples of four trials (no sample in trial *-04*)
3) Values below the limit of quantification (0.010 mg/kg) were set to 0.01 mg/kg.

III. CONCLUSION

Based on the application rate of 143 g pyraclostrobin/ha (applied as BAS 556 03 F) the highest residues (90th percentile), found in pollen, was determined to be 16.6 mg pyraclostrobin/kg at the first sampling with an average value of 9.76 mg pyraclostrobin/kg.

Report:	CA 8.3.1/2 Barth M., 2014a Determination of residues of BAS 556 03 F in oilseed rape inflorescences and their respective honeybee food items 2014/1000182
Guidelines:	EEC 1607/VI/97 rev. 2 10.06.1999, EU Regulation 1107/2009 with Regulation 283/2013, EU Regulation 1107/2009 with Regulation 284/2013, SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

The purpose of the study was to collect samples for later determination of residues in nectar, pollen and flowers from winter oilseed rape treated once with BAS 556 03 F under field conditions. During the 2013 growing season five separate field trials were conducted in different representative growing areas in Europe. Trial FR 13 044 01 was performed in East Germany, trials FR 13 044 02 and -03 were performed in South Germany and trial FR 13 044 04 was located in West Germany. Trial FR 13 044 05 was performed in Poland. Actual applied rates of pyraclostrobin in the five trials were 134.7, 138.6, 139.5, 142.4 and 149.3 g a.s./ha. The results were compared to an untreated control.

In the control treatments no residues at or above the limit of quantification of pyraclostrobin were detected in pollen, nectar and flower matrices. The matrices with the highest residues analyzed over all trials were flower samples. Residues ranged from 8.557 to 20.994 mg/kg at the first sampling (0 DAA) and from 0.361 to 2.915 mg/kg at the second sampling (7 DAA). In pollen samples residues of all trials ranged from 1.075 mg/kg to 7.787 mg/kg at the first sampling (0 DAA). At the second sampling (7 DAA) residues were between 0.010 mg/kg and 0.222 mg/kg. In nectar samples lowest residues of all matrices were analyzed and ranged from 0.057 mg/kg to 0.231 mg/kg at the first sampling (0 DAA). At the second sampling the residues were < LOD to 0.023 mg/kg.

Based on the application rate of 143 g pyraclostrobin/ha (applied as BAS 556 03 F) the highest residues (90th percentile), found in pollen, was determined to be 6.7 mg pyraclostrobin/kg at the first sampling with an average value of 3.3 mg pyraclostrobin/kg.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 556 03 F, batch no. 380014, content: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 130.0 g/L nominal (132.6 g/L analyzed); metconazole (BAS 555 F, Reg. No. 4 056 343): 80.0 g/L nominal (80.2 g/L analyzed); density: 1.077 g/cm^3.

B. STUDY DESIGN

Test design: Nectar, pollen and flower samples collected from winter oilseed rape were analyzed for residues of the test item BAS 556 03 F. The study comprised five trials, which covered different geographical regions in Europe. Each trial comprised a test item treatment and an untreated control. The minimum distance between test item treatment and control was at least 10 m. Two samplings were performed per trial, one on day of application and one seven days after application.

Field site: The four German fields were located in East Germany near Motterwitz (Saxony), in South Germany (Kleinrheinfeld and Traustadt, Bavaria) and in West Germany near Goch-Nierswalde (North Rhine Westfalia); the field in Poland was located near Urbanowice. All fields were cropped with winter oilseed rape.

Sampling: For determination of residues in *Brassica napus* L. the flower samples and the respective bee food items (pollen and nectar) were sampled in the test item treatment and the respective control of each trial. For pollen and nectar samples, on each sampling day a pooled sample of approx. 2 g was collected and divided into two subsamples samples (A and R) of at least 1 g for analysis. For flower samples on each sampling day a pooled sample of at least 10 g of winter oil seed rape inflorescences were collected divided into two subsamples samples (A and R) of at least 5 g, each. The sampling on DAA 0 was performed within 24 hours after application of the test item. The second sampling took place on DAA 7.

Application rates: Actual applied rates of pyraclostrobin: trial -*01*: 134.7 g a.s./ha, trial -*02*: 138.6 g a.s./ha, trial -*03*: 139.5 g a.s./ha, trial -*04*: 142.4 g a.s./ha and trial -*05*: 149.3 g a.s./ha. All applications were carried out at BBCH 65 with 300 L water/ha.

II. RESULTS AND DISCUSSION

In the control treatments no residues at or above the limit of quantification of pyraclostrobin were detected in pollen, nectar and flower matrices. The matrices with the highest residues analyzed over all trials were flower samples. Residues ranged from 8.557 to 20.994 mg/kg at the first sampling (0 DAA) and from 0.361 to 2.915 mg/kg at the second sampling (7 DAA). In pollen samples residues of all trials ranged from 1.075 mg/kg to 7.787 mg/kg at the first sampling (0 DAA). At the second sampling (7 DAA) residues were between 0.010 mg/kg and 0.222 mg/kg. In nectar samples lowest residues of all matrices were analyzed and ranged from 0.057 mg/kg to 0.231 mg/kg at the first sampling (0 DAA). At the second sampling the residues were < LOD to 0.023 mg/kg. The results are presented in Table 8.3.1-4.

Table 8.3.1-4: Analyzed residues of pyraclostrobin in nectar, pollen and flower samples

Matrix	Treatment	Sampling	Timing [DAA[1)]]	Range of residues [mg/kg]	90th percentile [mg/kg][2)]
Nectar	Control	S1	0	< LOQ	--
		S2	7		
	BAS 556 03 F	S1	0	0.057 - 0.231	0.211
		S2	7	< LOQ - 0.023	0.021
Pollen	Control	S1	0	< LOQ	--
		S2	7		
	BAS 556 03 F	S1	0	1.075 – 7.787	6.727
		S2	7	0.010 - 0.222	0.186
Flowers	Control	S1	0	< LOQ	--
		S2	7		
	BAS 556 03 F	S1	0	8.557 – 20.994	29.602
		S2	7	0.361 - 2.915	2.012

< LOQ (below limit of quantification): < 0.01 mg/kg.
1) Days after application.
2) 90th percentile over all trails.

For all matrices a reduction between the first and second sampling is visible. Table **8.3.1-3** shows the residue reduction from the 1st to the 2nd sampling in percent, calculated from the average residue values from all 5 trials:

Table 8.3.1-5: Reduction of pyraclostrobin residues in nectar, pollen and flowers between samplings

Matrix	Sampling	Timing [DAA[1)]]	Average residue [mg/kg]	Reduction [%]
Nectar	S1	0	0.14	--
	S2[2)]	7	0.01	91.4
Pollen	S1	0	3.30	--
	S2	7	0.11	96.6
Flowers	S1	0	19.26	--
	S2	7	1.00	94.8

1) Days after application.
2) Values below the limit of quantification (0.010 mg/kg) were set to 0.01 mg/kg.

III. CONCLUSION

Based on the application rate of 143 g pyraclostrobin/ha (applied as BAS 556 03 F) the highest residues (90th percentile), found in pollen, was determined to be 6.7 mg pyraclostrobin/kg at the first sampling with an average value of 3.3 mg pyraclostrobin/kg.

CA 8.3.1.1 Acute toxicity to bees

In the original dossier the study BASF DocID 1999/11457 had been included. However, since the effect of the toxic reference item was slightly out of range, the study was repeated for the renewal of approval. The results of the new study confirm the outcome of the original study. For risk assessment purposes the values of the new study are used.

CA 8.3.1.1.1 Acute oral toxicity

Report:	CA 8.3.1.1.1/1 Sekine T., 2013a Effects of BAS 500 F (acute contact and oral) on honey bees (Apis mellifera L.) in the laboratory 2013/1003210
Guidelines:	OECD 213 (1998), OECD 214 (1998)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

In a limit test, young adult worker bees (*Apis mellifera carnica*) were exposed orally to pyraclostrobin (BAS 500 F). Therefore, a nominal dose of 100.0 µg a.s./bee was tested, resulting in an actual uptake of 110.0 µg a.s./bee. Additionally, honeybees were treated with dimethoate as reference item at 0.05 to 0.32 µg/bee (nominal) or with water and solvent as control treatments. The test was conducted with 5 replicates per treatment group; each replicate contained 10 bees. Assessment of mortality was done after 4, 24 and 48 hours.

No mortality was observed after 48 hours in the control and the test item treatments. The LD_{50} was determined to be > 110.0 µg a.s./bee. No behavioral abnormalities of the bees could be observed.

The oral LD_{50} value (48 h) for pyraclostrobin was > 110.0 µg a.s./bee.

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 500 F, batch no. 10-510009, content: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 100% (± 1.0%).
Test species:	Honeybee *Apis mellifera carnica*; young adult worker bees; derived from a healthy and queen-right colony, source: in-house culture; collected on the morning of use.

B. STUDY DESIGN

Test design: Limit test for oral toxicity; duration 48 h; 3 treatment groups (water control, solvent control, test item and 4 concentrations of the reference item) with 5 replicates per treatment group, each replicate consisting of 10 bees per cage; assessment of mortality after 4, 24 and 48 hours.

Endpoints: Mortality, resulting in an LD_{50} value; behavioral abnormalities.

Reference item: Dimethoate (nominal 400 g/L).

Test doses: Water control, solvent control and 100.0 µg a.s./bee (nominal) resulting in an actual uptake of 110.0 µg a.s./bee.

Test conditions: Temperature: 24 – 25 °C; relative humidity: 56% – 81%; photoperiod: 24 h darkness.

Statistics: Descriptive statistics.

II. RESULTS AND DISCUSSION

No mortality was observed after 48 hours in the control and the test item treatments. The LD_{50} was determined to be > 110.0 µg a.s./bee. No behavioral abnormalities of the bees could be observed. The results are summarized in Table 8.3.1.1.1-1.

Table 8.3.1.1.1-1: Toxicity of pyraclostrobin to honeybees (Apis mellifera) in an oral toxicity test

Consumed dosage [µg a.s./bee]	**Mortality [%]**		
	4 h	**24 h**	**48 h**
Water control	0.0	0.0	0.0
Solvent control	0.0	0.0	0.0
110.0	0.0	0.0	0.0
Endpoint [µg a.s./bee]			
LD_{50} (48 h)	> 110.0		

The LD_{50} value (24 h and 48 h) for the reference item in the oral toxicity test was determined to be 0.23 µg a.s./bee.

III. CONCLUSION

The oral LD_{50} value (48 h) for pyraclostrobin was > 110.0 µg a.s./bee.

Report:	CA 8.3.1.1.1/2 Amsel K., 2016 a Acute toxicity of BAS 500 F to the bumblebee Bombus terrestris L. under laboratory conditions 2016/1000530
Guidelines:	Van der Steen (1996), Van der Steen (2001), OECD 213 (1998), OECD 214 (1998), Hanewald et al. (2013)
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

In an acute oral limit test, young adult worker bumblebees (*Bombus terrestris*) were exposed to pyraclostrobin (BAS 500 F). The toxicity of the test item was determined at a dose rate of 100.0 µg a.s./bumblebee; the resulting oral uptake was 97.2 µg a.s./bumblebee (based on analyzed purity). Additionally, bumblebees were treated with Dimethoate EC 400 (a.s. dimethoate) as a reference item at dose rates ranging from 0.25 to 1.47 µg consumed dimethoate/bumblebee (analyzed), and furthermore with a 50% (w/v) sucrose solution and 50% (w/v) sucrose solution including 5% acetone as controls.

After 96 hours of oral exposure, no mortality occurred in the control group fed with 50% (w/v) sucrose solution or with the sucrose solution including 5% acetone. In the test item treatment, slight mortality of 1.7 % was observed after oral consumption of 97.2 µg a.s./bumblebee after 96 hours.

No behavioral effects of bumblebees were observed at all tested dose rates in the oral toxicity test.

In the acute oral toxicity test with pyraclostrobin (BAS 500 F), the resulting LD_{50} after 96 hours was estimated to be > 97.2 µg consumed a.s./bumblebee.

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 500 F, batch no. COD-001236, content: pyraclostrobin (BAS 500 F, Reg.No. 304428): purity: 99.02% analyzed.
Test species:	*Bombus terrestris* L. (bumblebee), young adult worker bumblebees derived from healthy and queen-right hives; source: Biobest Belgium N.V., Westerlo, Belgium; collected on the morning prior to use.

B. STUDY DESIGN

Test design:	In a 96-hour test, adults of *Bombus terrestris* were exposed to 1 dose of BAS 500 F in treated food (50% (w/v) sucrose solution including 5% acetone). In total, the test design consisted of 1 dose rate of the test item, 2 control groups (1 dose rate each) and 4 dose rates of the reference item. 60 replicates were used for the test item and sucrose control including 5% acetone. 30 replicates were used for the sucrose control and the reference item. 1 bumblebee was used per replicate. Assessments of bumblebee mortality and behavioral effects were done after 4, 24, 48, 72 and 96 hours.
Endpoints:	Mortality, behavioral impairments
Reference item:	Dimethoate EC 400 (dimethoate, 400 g/L nominal)
Test doses:	Control: 50% (w/v) sucrose solution; acetone control: 50% (w/v) sucrose solution including 5% acetone; BAS 500 F: 100.0 µg/bumblebee (resulting in an actual uptake of 97.2 µg BAS 500 F/bumblebee); reference item: 0.25, 0.45, 0.80 and 1.47 µg dimethoate/bumblebee
Test conditions:	Temperature: 24.9 – 25.1 °C, relative humidity: 59.6 – 60.5%, photoperiod: 24 h darkness; food: 50% (w/v) sucrose solution
Statistics:	Descriptive statistics; Fisher's Exact Binomial Test with Bonferroni Correction for mortality data (one-sided greater, $\alpha = 0.05$)

II. RESULTS AND DISCUSSION

After 96 hours of oral exposure, no mortality occurred in the control group fed with 50% (w/v) sucrose solution or with the sucrose solution including 5% acetone. In the test item treatment, slight mortality of 1.7% was observed after oral consumption of 97.2 µg a.s./bumblebee after 96 hours. The results are summarized below.

Table 8.3.1.1.1-2: Toxicity of BAS 500 F to *Bombus terrestris* (bumblebee) in an oral toxicity test

Treatment	Dosage	Mortality [%]			
		24 h	48 h	72 h	96 h
Control	Sucrose	0.0	0.0	0.0	0.0
	Sucrose + 5% acetone	0.0	0.0	0.0	0.0
BAS 500 F [µg consumed a.s./bumblebee]	97.2	1.7	1.7	1.7	1.7
Endpoint [µg consumed a.s./bumblebee]					
LD_{50} (96 h)	> 97.2				

III. CONCLUSION

In the acute oral toxicity test with pyraclostrobin (BAS 500 F), the resulting LD_{50} after 96 hours was estimated to be > 97.2 µg consumed a.s./bumblebee.

CA 8.3.1.1.2 Acute contact toxicity

Report:	CA 8.3.1.1.2/1 Sekine T., 2013a Effects of BAS 500 F (acute contact and oral) on honey bees (Apis mellifera L.) in the laboratory 2013/1003210
Guidelines:	OECD 213 (1998), OECD 214 (1998)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

In a limit test, young adult worker bees (*Apis mellifera carnica*) were exposed to pyraclostrobin (BAS 500 F). The toxicity was determined in a contact limit test at a nominal dose of 100.0 µg a.s./bee. Additionally, honeybees were treated with dimethoate as reference item at 0.10 to 0.30 µg/bee or with water and solvent as a control groups. The test was conducted with 5 replicates per treatment group, each replicate contained 10 bees. Assessment of mortality was done after 4, 24 and 48 hours.

No mortality was observed in the control and test item treatments. The LD_{50} was determined to be >100.0 µg a.s./bee. One single bee showed a moving coordination problem during the 48 hours assessment. This was the only occurrence of test item related behavioral abnormalities during the entire time of the contact test.

The contact LD_{50} value (48 h) for pyraclostrobin was > 100.0 µg a.s./bee.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 F, batch no. 10-510009, content: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 100% (± 1.0%).

Test species: Honeybees *Apis mellifera carnica*; young adult worker bees; derived from a healthy and queen-right colony, source: in-house culture; collected on the morning of use.

B. STUDY DESIGN

Test design: Limit test for contact toxicity; duration 48 h; 4 treatment groups (water control, solvent control, test item and 4 concentrations of the reference item) with 5 replicates per treatment group, each replicate consisting of 10 bees per cage; assessment of mortality after 4, 24 and 48 hours.

Endpoints: Mortality, resulting in a LD_{50} value; behavioral abnormalities.

Reference item: Dimethoate (nominal 400 g/L).

Test doses: Water control, solvent control and 100.0 µg a.s./bee.

Test conditions: Temperature: 24 – 25 °C; relative humidity: 56% – 81%; photoperiod: 24 h darkness.

Statistics: Descriptive statistics.

II. RESULTS AND DISCUSSION

No mortality was observed in the control and test item treatments. The LD_{50} was determined to be >100.0 µg a.s./bee. One single bee showed a moving coordination problem during the 48 hours assessment. This was the only occurrence of test item related behavioral abnormalities during the entire time of the contact test. The results are summarized in Table 8.3.1.1.2-1.

Table 8.3.1.1.2-1: Toxicity of pyraclostrobin to honeybees (Apis mellifera) in a contact toxicity test

Treatment [µg a.s./bee]	Mortality [%]		
	4 h	24 h	48 h
Water control	0.0	0.0	0.0
Solvent control	0.0	0.0	0.0
100.0	0.0	0.0	0.0
	Endpoint [µg a.s./bee]		
LD_{50} (48 h)	> 100.0		

The LD_{50} value (24 h) for the reference item in the contact toxicity test was determined to be 0.27 µg a.s./bee.

III. CONCLUSION

The contact LD_{50} value (48 h) for pyraclostrobin was > 100.0 µg a.s./bee.

Report:	CA 8.3.1.1.2/2 Amsel K., 2016 a Acute toxicity of BAS 500 F to the bumblebee Bombus terrestris L. under laboratory conditions 2016/1000530
Guidelines:	Van der Steen (1996), Van der Steen (2001), OECD 213 (1998), OECD 214 (1998), Hanewald et al. (2013)
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

In an acute contact limit test, young adult worker bumblebees (*Bombus terrestris*) were exposed to pyraclostrobin (BAS 500 F). The toxicity of the test item was determined at a dose rate of 100.0 µg a.s./bumblebee (based on analyzed purity). Additionally, bumblebees were treated with Dimethoate EC 400 (a.s. dimethoate) as a reference item at dose rates ranging from 2.5 to 10.1 µg dimethoate/bumblebee (analyzed), and furthermore with deionized water, TritonX solution and acetone as controls.

After 96 hours, 3.3% mortality occurred in the control group treated with deionized water and no mortality occurred in the control groups treated with TritonX solution and acetone. In the test item treatment, no mortality occurred after thoracic application of 100.0 µg a.s./bumblebee after 96 hours.

No behavioral effects of bumblebees were observed at all tested dose rates in the contact toxicity test.

In the acute contact toxicity test with pyraclostrobin (BAS 500 F), the resulting LD_{50} after 96 hours was estimated to be > 100.0 µg a.s./bumblebee.

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 500 F, batch no. COD-001236, content: pyraclostrobin (BAS 500 F, Reg. No. 304 428): purity: 99.02% analyzed

B. STUDY DESIGN

Test species:	*Bombus terrestris* L. (bumblebee), young adult worker bumblebees derived from healthy and queen-right hives; source: Biobest Belgium N.V., Westerlo, Belgium; collected on the morning prior to use.
Test design:	In a 96 hour test, adults of *Bombus terrestris* were exposed to 1 dose rate of BAS 500 F in an appropriate carrier (acetone) placed on the dorsal bumblebee thorax. In total, the test design consisted of 1 dose rate of the test item, 3 control groups (1 dose rate each) and 4 dose rates of the reference item. 60 replicates were used for the test item and the acetone control and 30 replicates for the reference item, water and TritonX control (1 bumblebee per replicate). Assessments of bumblebee mortality and behavioral effects were done after 4, 24, 48, 72 and 96 hours.
Endpoints:	Mortality, behavioral impairments
Reference item:	Dimethoate EC 400 (dimethoate, 400 g/L nominal)
Test doses:	Control: deionized water; acetone control: pure acetone; TritonX control: 0.5% (v/v) TritonX solution; BAS 500 F: 100.0 µg/bumblebee (the test item was solved in acetone); reference item: 2.5, 4.0, 6.4 and 10.1 µg dimethoate/bumblebee
Test conditions:	Temperature: 24.9 – 25.1 °C, relative humidity: 59.6 – 60.5%, photoperiod: 24 h darkness; food: 50% (w/v) sucrose solution
Statistics:	Descriptive statistics; Fisher's Exact Binomial Test with Bonferroni Correction for mortality data (one-sided greater, $\alpha = 0.05$)

II. RESULTS AND DISCUSSION

After 96 hours, 3.3% mortality occurred in the control group treated with deionized water and no mortality occurred in the control groups treated with TritonX solution and acetone. In the test item treatment, no mortality occurred after thoracic application of 100.0 µg a.s./bumblebee after 96 hours. The results are summarized below.

Table 8.3.1.1.2-2 Toxicity of BAS 500 F to *Bombus terrestris* (bumblebee) in a contact toxicity test

Treatment	Dosage	Mortality [%]			
		24 h	48 h	72 h	96 h
Control	deionized water	0.0	0.0	3.3	3.3
	0.5% TritonX	0.0	0.0	0.0	0.0
	acetone	0.0	0.0	0.0	0.0
BAS 500 F [µg a.s./ bumblebee]	100	0.0	0.0	0.0	0.0
Endpoint [µg a.s./bumblebee]					
LD_{50} (96 h)	> 100.0				

III. CONCLUSION

In the acute contact toxicity test with pyraclostrobin (BAS 500 F), the resulting LD_{50} after 96 hours was estimated to be > 100.0 µg a.s./bumblebee.

CA 8.3.1.2 Chronic toxicity to bees

Based on uncertainties with regard to the implementation process of the EFSA Guidance Document on Honey Bee Risk Assessment, the applicant had decided to conduct a study on the chronic toxicity of pyraclostrobin to honeybees. Due to technical problems of keeping the test item sufficiently stable in the feed solution, results are currently not available. Investigations on chronic toxicity of pyraclostrobin to bees will be continued.
Due to the situation described above, the study is not part of the supplemental dossier, although it was included in the study list of the application for renewal of approval as data point KCA 8.3.1.2/1 (BASF DocID 2013/1235056).
It should be considered that a study on chronic toxicity to honeybees is not required for AIR 3 substances submitted before January 1st, 2015 according to SANCO/10606/2014 (May 16th, 2014). Furthermore, a bee brood tunnel study conducted with BAS 500 06 F (CP 10.3.1.5/1, BASF DocID 2011/1112669) is available, which is a higher tier option to address this data point.

CA 8.3.1.3 Effects on honeybee development and other honeybee life stages

Since this study type requires exposure of bees to sprayed flowering plants, the test item used needs to be formulated in a way suitable for spray applications. Therefore, the study was conducted with the representative solo-formulation BAS 500 06 F. The study is intended to address the active substance, but is summarized in the dossier of BAS 500 06 F (CP 10.3.1.5/1, BASF DocID 2011/1112669).

CA 8.3.1.4 Sub-lethal effects

A tunnel study is available, which covers sublethal effects to honeybees (see CP 10.3.1.5/1).
All standard and higher tier studies demonstrate that pyraclostrobin does not pose an unacceptable risk to honeybees. Consequently, further tests are not necessary.

CA 8.3.2 Effects on non-target arthropods other than bees

CA 8.3.2.1 Effects on Aphidius rhopalosiphi

No new studies available with the active substance, because studies have been carried out with the formulated products (please refer to M-CP 10.3.2.1).

CA 8.3.2.2 Effects on *Typhlodromus pyri*

No new studies available with the active substance, because studies have been carried out with the formulated products (please refer to M-CP 10.3.2.1).

CA 8.4 Effects on non-target soil meso- and macrofauna

Since Annex I inclusion of the active substance pyraclostrobin (BAS 500 F), new studies on soil macro organisms have been performed with the active substance and its soil metabolites. As a result, there are new endpoints, which are considered in the respective risk assessment. Summaries of these new studies are provided below and an overview on studies and endpoints is given in Table 8.4-1.

Table 8.4-1 Toxicity to non-target soil meso- and macrofauna of pyraclostrobin and relevant metabolites

Substance	Species	Endpoint	Value [mg/kg dry soil]	Reference (BASF Doc ID)	EU agreed
Pyraclostrobin	*Eisenia fetida*	NOEC	11.6 *	2014/1000461	no, new study
BF 500-6	*Eisenia fetida*	NOEC	≥ 160 *	2013/1003174	no, new study
BF 500-7	*Eisenia fetida*	NOEC	≥ 160 *	2013/1224029	no, new study
BF 500-6	*Folsomia candida*	NOEC	≥ 1000	2013/1068054	no, new study
BF 500-7	*Folsomia candida*	NOEC	≥ 800	2013/1224030	no, new study
Pyraclostrobin[1)]	*Folsomia candida*	NOEC	23.9	2008/1037495	no, new study
	Hypoaspis aculeifer	NOEC	≥ 17.3	2012/1129444	no, new study

* Toxicity endpoint is re-adjusted using a soil factor of 2 to address the organic content of the soil (peat 10%), and the log P_{ow} of the substance is > 2.

1) Study was carried out with BAS 500 06 F as a surrogate for pyraclostrobin. For a study summary please refer to the formulation dossier of BAS 500 06 F, M-CP 10.4.2.1.

CA 8.4.1 Earthworms – sub-lethal effects

Report: CA 8.4.1/1
Friedrich S., 2014a
Sublethal toxicity of BAS 500 F (Pyraclostrobin) to the earthworm Eisenia fetida in artificial soil
2014/1000461
Guidelines: OECD 222 (2004)
GLP: yes
(certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

The effects of BAS 500 F on mortality, biomass development and reproduction of the earthworm *Eisenia fetida* (Annelida: Oligochaeta) were investigated in a 56-day reproduction study. Five concentrations of the test item (8.0, 13.6, 23.1, 39.3 and 66.8 mg a.s./kg dry soil) were incorporated into the soil (10% peat) with 4 replicates per treatment and 8 replicates for the solvent control (each containing 10 worms). Assessment of adult worm mortality, biomass development and feeding activity was carried out after 28 days, assessment of reproduction (number of juveniles) was carried out after 56 days.

The mortality of adult worms was about 0 – 5.0% in the five test item treatments and 1.3% in the solvent control group. No statistically significant differences compared to the solvent control were observed at any test item concentration. The weight change of adult worms was about -6.8 – 36.4% in the test item treatments and 35.2% in the solvent control group. Statistically significant differences on worm weight of *Eisenia fetida* were determined at concentrations of 39.3 and 66.8 mg a.s./kg dry soil. The reproduction rate was statistically significantly different compared to the solvent control at concentrations of 39.3 and 66.8 mg a.s./kg dry soil. No behavioral abnormalities were observed in any of the treatment groups. The feeding activity of adult worms was reduced at the concentrations of 39.3 and 66.8 mg a.s./kg dry soil.

In a 56-day earthworm reproduction study with BAS 500 F on earthworms (*Eisenia fetida*), the NOEC for mortality was determined to be 66.8 mg a.s./kg soil dry weight. The NOEC for biomass and reproduction was determined to be 23.1 mg test item/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 F, Reg. No. 304 428, batch No. COD-001236; purity: 99.2% (tolerance ± 1.0 %).

Test species: Earthworm (*Eisenia fetida*), adult worms (with clitellum); weight: 301 mg – 498 mg), age: approximately 3 months old; source: "W. Neudorff GmbH KG" followed by in-house culture.

B. STUDY DESIGN

Test design:	56-day test in treated artificial soil according to OECD 222 (10 % peat); 5 different concentrations of the test item were incorporated into the soil; 6 treatment groups (5 test item concentrations, solvent control); 4 replicates for the test item treatments, 8 replicates for the solvent control, 10 worms each. Assessment of adult worm mortality, behavioral effects and biomass development was done after 28 days. Reproduction rate was determined after additional 28 days (assessed 56 days after application).
Endpoints:	NOEC; effects on mortality, weight change, reproduction rate, feeding activity.
Reference item:	Nutdazim 50 FLOW (carbendazim, SC 500). The effects of the reference item were investigated in a separate study.
Test concentrations:	Control, 8.0, 13.6, 23.1, 39.3 and 66.8 mg a.s./kg dry soil.
Test conditions:	Artificial soil according to OECD 222 (with 10% peat); pH 5.99 - 6.06 at test initiation, pH 5.70 – 5.76 at test termination; water content: 56.4% - 56.5% of maximum water holding capacity (WHC) at test initiation, 55.6% - 56.2% of WHC at test termination; temperature: 18.6 °C – 21.8 °C; photoperiod: 16 h light : 8 h dark, light intensity: 580 lux; food: horse manure.
Statistics:	Descriptive statistics, Fisher's Exact Binomial Test for mortality ($\alpha = 0.05$), Williams-t-test for weight change and reproduction ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

The mortality of adult worms was about 0 – 5.0% in the five test item treatments and 1.3% in the solvent control group. No statistically significant differences compared to the solvent control were observed at any test item concentration (Fisher's Exact Binomial Test with Bonferroni Correction, $\alpha = 0.05$, one-sided greater). The weight change of adult worms was about -6.8 – 36.4% in the test item treatments and 35.2% in the solvent control group. Statistically significant differences on worm weight of *Eisenia fetida* were determined at concentrations of 39.3 and 66.8 mg a.s./kg dry soil (Williams-t-test, $\alpha = 0.05$, one-sided smaller). The reproduction rate was statistically significantly different compared to the solvent control at concentrations of 39.3 and 66.8 mg a.s./kg dry soil (Williams-test, $\alpha = 0.05$, one-sided smaller). No behavioral abnormalities were observed in any of the treatment groups. The feeding activity of adult worms was reduced at the concentrations of 39.3 and 66.8 mg a.s./kg dry soil. The results are summarized below (see Table 8.4.1-1).

Table 8.4.1-1: Effects of BAS 500 F on earthworms (*Eisenia fetida)* in a 56-day reproduction study

BAS 500 F [mg/kg dry soil]	Solvent control	8.0	13.6	23.1	39.3	66.8
Mortality (day 28) [%]	1.3	0.0	0.0	2.5	5.0	2.5
Weight change (day 28) [%]	35.2	36.4	32.7	28.0	9.4 *	-6.8 *
Mean no. of juveniles (day 56)	118.8	127.8	123.8	107.5	36.8 *	14.8 *
Reproduction (day 56) [% of control]	--	107.6	104.2	90.5	30.9 *	12.4 *
Endpoints [mg BAS 500 F/kg dry soil]						
$NOEC_{mortality}$ (day 28)	66.8					
$NOEC_{weight}$ (day 28)	23.1					
$NOEC_{reproduction}$ (day 56)	23.1					

* Statistically significantly different from solvent control (Williams-t-test, $\alpha = 0.05$, one-sided smaller).

III. CONCLUSION

In a 56-day earthworm reproduction study with BAS 500 F on earthworms (*Eisenia fetida*), the NOEC for mortality was determined to be 66.8 mg a.s./kg soil dry weight. The NOEC for biomass and reproduction was determined to be 23.1 mg test item/kg dry soil.

Report:	CA 8.4.1/2 Ganssmann M., 2013a Effects of Reg.No. 364380 (metabolite of BAS 500 F, Pyraclostrobin) on reproduction and growth of earthworms Eisenia fetida in artificial soil 2013/1003174
Guidelines:	OECD 222 - Earthworm Reproduction Test (2004), ISO 11268-2 (1998), EC 1107/2009 (14 June 2011)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

The effects of BF 500-6 (Reg. No. 364 380, synonym: 500M01), a metabolite of pyraclostrobin, on mortality, biomass development and reproduction of the earthworm *Eisenia fetida* (Annelida: Oligochaeta) were investigated in a 56-day reproduction study. Five concentrations (20, 40, 80, 160 and 320 mg BF 500-6/kg dry soil) were incorporated into the soil (10% peat) with 4 replicates per treatment (each containing 10 worms). An untreated control with 8 replicates was included. Assessment of adult worm mortality, biomass development and feeding activity was carried out after 28 days, assessment of reproduction (number of juveniles) was carried out after 56 days.

After 28 days of exposure a slight mortality of 2.5% was observed at the test item treatment concentration of 80 mg BF 500-6/kg dry soil, which was not statistically significantly different compared to the control. The body weight changes and reproduction rates were also not statistically significantly different compared to the control up to and including the highest concentration tested. Neither behavioral abnormalities nor effects on feeding activity were observed in any of the treatment groups.

In a 56-day earthworm reproduction study with BF 500-6 (Reg. No. 364 380, a metabolite of pyraclostrobin) on earthworms (*Eisenia fetida*), the NOEC for mortality, biomass, feeding activity and reproduction was determined to be ≥ 320 mg BF 500-6/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Reg. No. 364 380 (metabolite of pyraclostrobin, BF 500-6, synonym: 500M01) batch no. 01311-142; purity: 99.2% (tolerance ± 1.0 %).

Test species: Earthworm (*Eisenia fetida*), adult worms (with clitellum); weight: 300 mg – 592 mg), age: approximately 10 to 11 months old; source: in-house culture.

B. STUDY DESIGN

Test design:	56-day test in treated artificial soil according to OECD 222 (10% peat); different concentrations of the test item were incorporated into the soil; 6 treatment groups (5 test item concentrations, control); 4 replicates for the test item treatments, 8 replicates for the control, 10 worms each. The artificial soil was treated and filled into test vessels, before the earthworms were introduced on the top of the soil. Assessment of worm mortality, behavioral effects and biomass development after 28 days; assessment of reproduction rate (number of offspring) after another 28 days (56 days after application).
Endpoints:	NOEC; effects on mortality, weight change, reproduction rate, feeding activity.
Reference item:	Luxan Carbendazim 500 FC (carbendazim, 500 g/L nominal). The effects of the reference item were investigated in a separate study.
Test concentrations:	Control, 20, 40, 80, 160 and 320 mg Reg. No. 364 380/kg dry soil.
Test conditions:	Artificial soil according to OECD 222 (with 10% peat); pH 6.4 - 6.5 at test initiation, pH 6.0 - 6.1 at test termination; water content: 54.3% - 54.9% of maximum water holding capacity (WHC) at test initiation, 52.5% - 58.5% of WHC at test termination; temperature: 18 °C - 22 °C; photoperiod: 16 h light : 8 h dark, light intensity: 400 lux to 800 lux; food: cattle manure.
Statistics:	Descriptive statistics, Fisher's Exact Test for mortality ($\alpha = 0.05$), Williams t-test for weight change and reproduction ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

After 28 days of exposure a slight mortality of 2.5% was observed at the test item treatment concentration of 80 mg BF 500-6 /kg dry soil, which was not statistically significantly different compared to the control (Fisher`s Exact Test, $\alpha = 0.05$). The body weight changes and reproduction rates were also not statistically significantly different compared to the control (Williams t-test, $\alpha = 0.05$) up to and including the highest concentration tested. Neither behavioral abnormalities nor effects on feeding activity were observed in any of the treatment groups. The results are summarized below (see Table 8.4.1-2).

Table 8.4.1-2: Effects of BF 500-6 (Reg. No. 364 380), a metabolite of pyraclostrobin, on earthworms (Eisenia fetida) in a 56-day reproduction study

BF 500-6 [mg/kg dry soil]	Control	20	40	80	160	320
Mortality (day 28) [%]	0.0	0.0	0.0	2.5	0.0	0.0
Weight change (day 28) [%]	51.7	52.7	52.4	55.9	56.7	50.1
Mean no. of juveniles (day 56)	276	324	330	308	293	303
Reproduction (day 56) [% of control]	--	117.4	119.5	111.5	106.2	109.7
Food consumption [g]	25.0	25.0	25.0	25.0	25.0	25.0
Endpoints [mg BF 500-6/kg dry soil]						
$NOEC_{mortality, weight}$ (day 28)	≥ 320					
$NOEC_{reproduction}$ (day 56)	≥ 320					

III. CONCLUSION

In a 56-day earthworm reproduction study with BF 500-6 (Reg. No. 364 380, a metabolite of pyraclostrobin) on earthworms (*Eisenia fetida*), the NOEC for mortality, biomass, feeding activity and reproduction was determined to be ≥ 320 mg BF 500-6/kg dry soil.

Report:	CA 8.4.1/3 Ganssmann M., 2013b Effects of Reg.No. 369315 (metabolite of BAS 500 F, Pyraclostrobin) on reproduction and growth of earthworms Eisenia fetida in artificial soil with 10% peat 2013/1224029
Guidelines:	OECD 222 - Earthworm Reproduction Test (2004), ISO 11268-2 (2012)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

The effects of BF 500-7 (Reg. No. 369 315, synonym: 500M02), a metabolite of pyraclostrobin, on mortality, biomass development and reproduction of the earthworm *Eisenia fetida* (Annelida: Oligochaeta) were investigated in a 56-day reproduction study. Five concentrations (20, 40, 80, 160 and 320 mg BF 500-7/kg dry soil) were incorporated into the soil (10% peat) with 4 replicates per treatment (each containing 10 worms). An untreated control with 8 replicates was included. Assessment of adult worm mortality, biomass development and feeding activity was carried out after 28 days, assessment of reproduction (number of juveniles) was carried out after 56 days.

After 28 days of exposure a slight mortality of 2.5% was observed at the test item treatment concentrations of 20, 40 and 320 mg BF 500-7/kg dry soil, respectively, which was not statistically significantly different compared to the control, where 1.3% of the worms died. The body weight changes and reproduction rates were also not statistically significantly different compared to the control up to and including the highest concentration tested. Neither behavioral abnormalities nor effects on feeding activity were observed in any of the treatment groups.

In a 56-day earthworm reproduction study with BF 500-7 (Reg. No. 369 315, a metabolite of pyraclostrobin) on earthworms (*Eisenia fetida*), the NOEC for mortality, biomass, feeding activity and reproduction was determined to be ≥ 320 mg BF 500-7 /kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Reg. No. 369 315 (metabolite of pyraclostrobin, BF 500-7, synonym: 500M02) batch no. L83-168; purity: 96.2%.

Test species: Earthworm (*Eisenia fetida*), adult worms (with clitellum); weight: 301 mg – 598 mg), age: approximately 7 months old; source: in-house culture.

B. STUDY DESIGN

Test design:	56-day test in treated artificial soil according to OECD 222 (10% peat); different concentrations of the test item were incorporated into the soil; 6 treatment groups (5 test item concentrations, control); 4 replicates for the test item treatments, 8 replicates for the control, 10 worms each. The artificial soil was treated and filled into test vessels, before the earthworms were introduced on the top of the soil. Assessment of worm mortality, behavioral effects and biomass development after 28 days; assessment of reproduction rate (number of offspring) after another 28 days (56 days after application).
Endpoints:	NOEC; effects on mortality, weight change, reproduction rate, feeding activity.
Reference item:	Luxan Carbendazim 500 FC (carbendazim, 500 g/L nominal). The effects of the reference item were investigated in a separate study.
Test concentrations:	Control, 20, 40, 80, 160 and 320 mg Reg. No. 369 315/kg dry soil.
Test conditions:	Artificial soil according to OECD 222 (with 10% peat); pH 6.0 at test initiation and termination; water content: 51.2% - 53.7% of maximum water holding capacity (WHC) at test initiation, 55.4% - 61.5% of WHC at test termination; temperature: 18 °C - 22 °C; photoperiod: 16 h light : 8 h dark, light intensity: 400 lux to 800 lux; food: cattle manure.
Statistics:	Descriptive statistics, Fisher's Exact Test for mortality ($\alpha = 0.05$), Williams t-test for weight change and reproduction ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

After 28 days of exposure a slight mortality of 2.5% was observed at the test item treatment concentrations of 20, 40 and 320 mg BF 500-7/kg dry soil, respectively, which was not statistically significantly different compared to the control, where 1.3% of the worms died (Fisher`s Exact Test, $\alpha = 0.05$). The body weight changes and reproduction rates were also not statistically significantly different compared to the control (Williams t-test, $\alpha = 0.05$) up to and including the highest concentration tested. Neither behavioral abnormalities nor effects on feeding activity were observed in any of the treatment groups. The results are summarized below (see Table 8.4.1-3).

Table 8.4.1-3: Effects of BF 500-7 (Reg. No. 369 315), a metabolite of pyraclostrobin, on earthworms (Eisenia fetida) in a 56-day reproduction study

BF 500-7 [mg/kg dry soil]	**Control**	**20**	**40**	**80**	**160**	**320**

Reproduction (day 56) [% of control]	--	97.6	125.9	130.5	122.8	105.8
Food consumption [g]	25.0	25.0	25.0	25.0	25.0	25.0
Endpoints [mg BF 500-7/kg dry soil]						
$NOEC_{mortality, weight}$ (day 28)	≥ 320					
$NOEC_{reproduction}$ (day 56)	≥ 320					

III. CONCLUSION

In a 56-day earthworm reproduction study with BF 500-7 (Reg. No. 369 315, a metabolite of pyraclostrobin) on earthworms (*Eisenia fetida*), the NOEC for mortality, biomass, feeding activity and reproduction was determined to be ≥ 320 mg BF 500-7 /kg dry soil.

CA 8.4.2 Effects on non-target soil meso- and macrofauna (other than earthworms)

Report:	CA 8.4.2/1 Ganssmann M., 2013c Effects of Reg.No. 364380 (metabolite of BAS 500 F, Pyraclostrobin) on reproduction of the collembola Folsomia candida in artificial soil with 5% peat 2013/1068054
Guidelines:	OECD 232 (2009), ISO 11267 (1999)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

The effects of BF 500-6 (Reg. No. 364 380, synonym: 500M01), a metabolite of pyraclostrobin, on mortality and reproduction of Collembola *(Folsomia candida)* were investigated in a laboratory study over 28 days. Five concentrations (62.5, 125, 250, 500 and 1000 mg BF 500-6 /kg dry soil) were incorporated into the soil with 4 replicates per test item treatment. An untreated control with 8 replicates was included. All replicates contained 10 collembolans. Assessment of mortality, reproduction rate (number of juveniles) and behavior was carried out after 28 days.

After 28 days of exposure a slight mortality of up to 15% was observed in the test item treated groups, which was not statistically significantly different compared to the control, where 8% of the Collembola died. Reproduction of the collembolans exposed to BF 500-6 was not statistically significantly different compared to the control up to and including the highest test concentration of 1000 mg/kg dry soil. No behavioral abnormalities were observed in any of the treatment groups.

In a 28-day Collembola reproduction study with BF 500-6 (Reg. No. 364 380, a metabolite of pyraclostrobin) the NOEC based on mortality and reproduction was determined to be ≥ 1000 mg BF 500-6/kg dry soil, the highest concentration tested.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Reg. No. 364 380 (metabolite of pyraclostrobin, BF 500-6, synonym: 500M01) batch no. 01311-142; purity: 99.2% (tolerance ± 1.0 %).

Test species: Collembola (*Folsomia candida)*, juveniles (10 - 12 days old); source: in-house culture.

B. STUDY DESIGN

Test design: 28-day chronic laboratory test in treated artificial soil (5% peat) according to OECD 232 and ISO 11267; different concentrations of the test item were mixed homogenously into artificial soil and filled into glass vessels after which collembolans were introduced on top of the soil; 6 treatment groups (5 test item concentrations, control); 4 replicates for each test item treatment and 8 replicates for the control, each containing 10 collembolans. Assessment of adult mortality, reproduction (number of juveniles) and behavioral effects after 28 days.

Endpoints: Mortality, reproduction rate after 28 days.

Reference item: Boric acid (100.3 % analyzed). The effects of the reference item were investigated in a separate study.

Test rates: Control, 62.5, 125, 250, 500 and 1000 mg Reg. No. 364 380/kg dry soil.

Test conditions: Artificial soil according to OECD 232 (peat: 5 %); pH 6.1 at test initiation, pH 5.9 - 6.0 at test termination; water content at study initiation 52.2 % - 54.6 % of maximum water holding capacity and 46.6 % - 52.7 % of maximum WHC at test termination; temperature: 18 C – 22 C; photoperiod: 16 h light : 8 h dark, light intensity: 400 lux - 800 lux; food: 2 mg granulated dry yeast at the start of the test and after 14 days.

Statistics: Descriptive statistics; Fisher's Exact Test for mortality ($\alpha = 0.05$), Williams t-test for reproduction data ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

After 28 days of exposure a slight mortality of up to 15% was observed in the test item treated groups, which was not statistically significantly different compared to the control, where 8% of the Collembola died (Fisher's Exact test, $\alpha = 0.05$, one-sided greater).
Reproduction of the collembolans exposed to BF 500-6 was not statistically significantly different compared to the control up to and including the highest test concentration of 1000 mg/kg dry soil (Williams t-test, $\alpha = 0.05$, one-sided smaller).
No behavioral abnormalities were observed in any of the treatment groups. The results are summarized in Table 8.4.2-1.

Table 8.4.2-1: Effect of BF 500-6 (Reg. No. 364 380) on Collembola (Folsomia candida) in a 28-day reproduction study

BF 500-6 [mg/kg dry soil]	**Control**	**62.5**	**125**	**250**	**500**	**1000**
Mortality (day 28) [%]	8	8	5	10	15	10
No. of juveniles (day 28)	437	471	467	527	451	419
Reproduction (day 28) [% of control]	--	108	107	121	103	96
Endpoints [mg BF 500-6/kg dry soil]						
$NOEC_{mortality,\ weight}$ (day 28)	≥ 1000					
$NOEC_{reproduction}$ (day 28)	≥ 1000					

III. CONCLUSION

In a 28-day Collembola reproduction study with BF 500-6 (Reg. No. 364 380, a metabolite of pyraclostrobin) the NOEC based on mortality and reproduction was determined to be ≥ 1000 mg BF 500-6/kg dry soil, the highest concentration tested.

Report:	CA 8.4.2/2 Ganssmann M., 2013d Effects of Reg.No. 369315 (metabolite of BAS 500 F, Pyraclostrobin) on reproduction of the collembola Folsomia candida in artificial soil with 5% peat 2013/1224030
Guidelines:	OECD 232 (2009)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

The effects of BF 500-7 (Reg. No. 369 315, synonym: 500M02, a metabolite of pyraclostrobin, on mortality and reproduction of Collembola *(Folsomia candida)* were investigated in a laboratory study over 28 days. Five concentrations (50, 100, 200, 400 and 800 mg BF 500-7/kg dry soil) were incorporated into the soil with 4 replicates per test item treatment. An untreated control with 8 replicates was included. All replicates contained 10 collembolans. Assessment of mortality, reproduction rate (number of juveniles) and behavior was carried out after 28 days.

After 28 days of exposure a slight mortality of up to 15% was observed in the test item treated groups, which was not statistically significantly different compared to the control, where 6% of the Collembola died. Reproduction of the collembolans exposed to BF 500-7 was not statistically significantly different compared to the control up to and including the highest test concentration of 800 mg/kg dry soil. No behavioral abnormalities were observed in any of the treatment groups.

In a 28-day Collembola reproduction study with BF 500-7 (Reg. No. 369 315, a metabolite of pyraclostrobin) the NOEC based on mortality and reproduction was determined to be ≥ 800 mg BF 500-7/kg dry soil, the highest concentration tested.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Reg. No. 369 315 (metabolite of pyraclostrobin, BF 500-7, synonym: 500M02) batch no. L83-168; purity: 96.2%.

Test species: Collembola (*Folsomia candida)*, juveniles (10 - 12 days old); source: in-house culture.

B. STUDY DESIGN

Test design:	28-day chronic laboratory test in treated artificial soil (5% peat) according to OECD 232 and ISO 11267; different concentrations of the test item were mixed homogenously into artificial soil and filled into glass vessels after which collembolans were introduced on top of the soil; 6 treatment groups (5 test item concentrations, control); 4 replicates for each test item treatment and 8 replicates for the control, each containing 10 collembolans. Assessment of adult mortality, reproduction (number of juveniles) and behavioral effects after 28 days.
Endpoints:	Mortality, reproduction rate after 28 days.
Reference item:	Boric acid (100.3 % analyzed). The effects of the reference item were investigated in a separate study.
Test rates:	Control, 50, 100, 200, 400 and 800 mg Reg. No. 369 315/kg dry soil.
Test conditions:	Artificial soil according to OECD 232 (peat: 5 %); pH 6.1 - 6.2 at test initiation, pH 6.0 - 6.1 at test termination; water content at study initiation 43.6 % - 45.7 % of maximum water holding capacity and 41.4 % - 44.3 % of maximum WHC at test termination; temperature: 18 C – 22 C; photoperiod: 16 h light : 8 h dark, light intensity: 400 lux - 800 lux; food: 2 mg granulated dry yeast at the start of the test and after 14 days.
Statistics:	Descriptive statistics; Fisher's Exact Test for mortality ($\alpha = 0.05$), Williams t-test for reproduction data ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

After 28 days of exposure a slight mortality of up to 15% was observed in the test item treated groups, which was not statistically significantly different compared to the control, where 6% of the Collembola died (Fisher's Exact test, $\alpha = 0.05$, one-sided greater).
Reproduction of the collembolans exposed to BF 500-7 was not statistically significantly different compared to the control up to and including the highest test concentration of 800 mg/kg dry soil (Williams t-test, $\alpha = 0.05$, one-sided smaller).
No behavioral abnormalities were observed in any of the treatment groups. The results are summarized in Table 8.4.2-2.

Table 8.4.2-2: Effect of BF 500-7 (Reg. No. 369 315) on Collembola (Folsomia candida) in a 28-day reproduction study

BF 500-7 [mg/kg dry soil]	**Control**	**50**	**100**	**200**	**400**	**800**
Mortality (day 28) [%]	6	8	10	10	13	15
No. of juveniles (day 28)	886	861	1041	921	873	860
Reproduction (day 28) [% of control]	--	97	117	104	98	97
Endpoints [mg BF 500-7/kg dry soil]						
$NOEC_{mortality,\ weight}$ (day 28)	≥ 800					
$NOEC_{reproduction}$ (day 28)	≥ 800					

III. CONCLUSION

In a 28-day Collembola reproduction study with BF 500-7 (Reg. No. 369 315, a metabolite of pyraclostrobin) the NOEC based on mortality and reproduction was determined to be ≥ 800 mg BF 500-7/kg dry soil, the highest concentration tested.

CA 8.4.2.1 Species level testing

Further studies are not triggered.

CA 8.5 Effects on nitrogen transformation

Since Annex I inclusion of the active substance pyraclostrobin (BAS 500 F) a new study on nitrogen transformation has been performed with the new representative formulation BAS 500 06 F. As a result, there is a new endpoint, which is considered in the risk assessment. A summary of this new study is provided in the formulation dossier of BAS 500 06 F (M-CP 10.5). An overview on studies and endpoints is given in Table 8.5-1.

Table 8.5-1 Toxicity to nitrogen transformation of pyraclostrobin and its metabolites

Substance	Endpoint	NOEC [mg/kg dry soil]	Reference (BASF DocID)	EU agreed
BF 500-6	Effects on nitrogen transformation	1.0	1999/11311	yes
BF 500-7	Effects on nitrogen transformation	0.5	1999/11311	yes
pyraclostrobin [1)]	Effects on nitrogen transformation	3.33	2012/1129443	no, new study

[1)] Study was carried out with BAS 500 06 F as a surrogate for pyraclostrobin. For the study summary please refer to the formulation dossier of BAS 500 06 F, M-CP 10.5.

CA 8.6 Effects on terrestrial non-target higher plants

CA 8.6.1 Summary of screening data

Non-target plant GLP studies with the representative formulations are available. Further screening data are not required.

CA 8.6.2 Testing on non-target plants

Studies have been conducted with the representative formulations and are described in M-CP 10.6.2.

CA 8.7 Effects on other terrestrial organisms (flora and fauna)

Studies with the active substance are not required. Studies conducted with the representative formulations are described in M-CP 10.7 (including studies which are not required under 1107/2009).

CA 8.8 Effects on biological methods for sewage treatment

The results of the already peer-reviewed and accepted study are still valid and they are summarized in Table 8.8-1. No new study has been performed.

Table 8.8-1: Effects on biological methods for sewage treatment

Test item	Study type	Endpoint [mg a.s./L]	Reference (BASF DocID)	EU agreed
BAS 500 F (pyraclostrobin)	Respiration inhibition test (inhibition of oxygen consumption activated sludge from wastewater plant)	EC_{20} (0.5 h) > 1000	1999/10656	yes

CA 8.9 Monitoring data

According to the knowledge of the applicant, there are currently no published ecotoxicological monitoring data available for pyraclostrobin or its metabolites, which would provide additional knowledge on the ecotoxicological assessment not covered by this dossier.

During literature search a few publications were found dealing with environmental monitoring of various pesticides in surface water, groundwater and/or sediment outside EU (e.g. US, Australia, Costa Rica) mentioning also pyraclostrobin. The results showed that pyraclostrobin could be detected in local areas characterized by intensive fungicide use during the spraying season, however, frequency of detection as well as measured concentrations were usually very low.

CA 9 LITERATURE DATA

A literature search on pyraclostrobin and the common product trade names was performed by the BASF Group Information Center. The Literature Search Report on pyraclostrobin describes the general search and evaluation process as well as details on search profiles, search histories and summary tables.

The complete search report is provided in K-CA 9 (BASF DocID 2014/1172994).

The first step of the search result processing based on summary records was done by the Information Center and involved the separation into "hits" and "ballast" (obviously irrelevant records). The "ballast" was not further processed.

The "hits" were further evaluated by the scientific experts and categorized into "not relevant", "relevant, but not reliable", and "used for dossier". The result of this evaluation is documented in different EXCEL files which are contained on the CADDY CD as additional attachments to the search report in K-CA 9 with the file names as listed below (alphabetical order):

Analytics:	Pyraclostrobin Literature Analytics
Ecotoxicology:	Pyraclostrobin Literature Ecotox aquatic
	Pyraclostrobin Literature Ecotox general
	Pyraclostrobin Literature Ecotox terrestric
	Pyraclostrobin Literature Ecotox wildlife
E-fate:	Pyraclostrobin Literature E-fate
Consumer Safety:	Pyraclostrobin Literature Metabolism and Residues in Animals
	Pyraclostrobin Literature Metabolism and Residues in Plants
Product Chemistry:	Pyraclostrobin Literature Product Chemistry
Toxicology:	Pyraclostrobin Literature Toxicology (including the search topics operator exposure, toxicology in animals and humans, mode of action and QSAR as shown in the Literature Search Report)

All literature seen as both, relevant and reliable, has been discussed in Doc M. The respective articles are part of the reference lists of the different sections as contained in Doc L.

The hits in Ecotox general, Ecotox wildlife (not including amphibians), E-Fate, Metabolism and Residues in Animals as well as Product Chemistry did not contribute to the risk assessment and were therefore not further discussed in the dossier.

Table of Contents

CA 10 CLASSIFICATION AND LABELLING OF THE ACTIVE SUBSTANCE

The following harmonized classification and labelling was adopted for pyraclostrobin:

Legislation	**Classification**	**Labelling**	**Concentration limits**
Directive 67/548/EEC	T, N R: 23-38-50-53	T, N R: 23-38-50/53 S: 1/2-45-60-61-63	None
Regulation (EC) No 1272/2008	Hazard class and category code: Acute Tox. 3 Skin Irrit. 2 Aquatic Acute 1 Aquatic Chronic 1 Hazard statement code: H331, H315, H400, H410	Pictogram signal word code: GHS06 GHS09 Danger Hazard statement code: H331, H315, H410	M-factor = 100

Single accidental exposure of humans to spray mist of pyraclostrobin containing formulations resulted in symptoms of respiratory irritation (see M-CA 5.9.3). Based on this direct observation in humans and supportive evidence for respiratory irritation observed in subchronic inhalation studies in rats (see CA 5.3.3/1 and 5.3.3/2), BASF self-classified pyraclostrobin with STOT SE Category 3 (H335, May cause respiratory irritation). Consequently BASF proposes for pyraclostrobin the classification and labelling as shown below.

Legislation	**Classification**	**Labelling**	**Concentration limits**
Directive 67/548/EEC	T, N R: 23-37-38-50-53	T, N R: 23-37/38-50/53 S: 1/2-45-60-61-63	None
Regulation (EC) No 1272/2008	Hazard class and category code: Acute Tox. 3 Skin Irrit. 2 Aquatic Acute 1 Aquatic Chronic 1 STOT SE 3 Hazard statement code: H331, H315, H400, H410, H335	Pictogram signal word code: GHS06 GHS09 Danger Hazard statement code: H331, H315, H410, H335	M-factor = 100

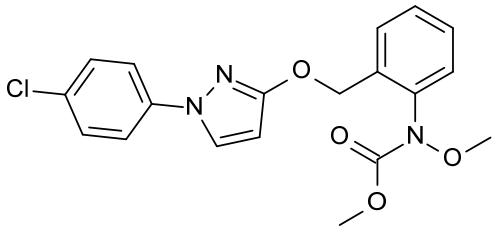
Table of Contents

1 IDENTITY

1.1 Summary of identity

Pyraclostrobin, chemical name (IUPAC) methyl N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl] oxymethyl}phenyl)-(N-methoxy)carbamate, is a fungicide and belongs to the chemical class of strobilurines.



BASF Number:	BAS 500 F
BASF Registry Number:	Reg.No. 304428
Molecular formula:	$C_{19}H_{18}ClN_3O_4$
Molecular mass:	387.8 g/mol
CAS No.:	175013-18-0
CIPAC No.:	657
EC No.:	not assigned

BAS 500 06 F is an emulsifiable concentrate (EC) containing 200 g/L of the active ingredient pyraclostrobin.

BAS 516 07 F is a water dispersible granule (WG) containing 6.7% w/w pyraclostrobin and 26.7% w/w boscalid.

2 PHYSICAL AND CHEMICAL PROPERTIES

2.1 Summary of physical and chemical properties of the active substance

Purified pyraclostrobin is a white to light beige crystalline solid, while the commercially produced technical material is an amber-coloured glass-like solid.
Pyraclostrobin is neither flammable, nor explosive, nor corrosive, nor oxidising. The pure active ingredient (PAI) has a vapour pressure of 2.6 x 10^{-8} Pa at 20°C. It is slightly soluble in pure water (1.9 mg/L at 20°C and pH 5.8). Its n-octanol/water partition coefficient (log Pow) is 3.99. Due to the lack of acidic protons, pyraclostrobin does not dissociate. The active substance absorbs light in the UV area (absorption bands around 205 and 275 nm), showing sensitivity to photolysis (measured with PAI).

2.2 Summary of physical and chemical properties of the plant protection product

The product BAS 500 06 F is an EC formulation. It is a dark yellow clear liquid with a moderate naphthalene-like odour. It is not explosive, has no oxidising properties and is not considered to be a self-heating substance. It has a self-ignition temperature of 450°C. The product is not considered to be highly flammable. In aqueous solution it has a pH value around 6-7. The stability data indicate a shelf life of at least 2 years at ambient temperature. Its technical characteristics are acceptable for an EC formulation.

The product BAS 516 07 F is a WG formulation. It is a brown fine granule with a smoky odour. It is not explosive, has no oxidising properties and is not considered to be a self-heating substance. It has a self-ignition temperature of 246°C. The product is not considered to be highly flammable. In aqueous solution it has a pH value around 5. The stability data demonstrate a shelf life of at least 2 years at ambient temperature. Its technical characteristics are acceptable for a WG formulation.

3 DATA ON APPLICATION AND EFFICACY

3.1 Summary of effectiveness

Pyraclostrobin is a strobilurine fungicide which is used worldwide in many crops for the control of a broad range of important pathogens from the classes of ascomycetes, basidiomycetes, deuteromycetes and oomycetes. Pyraclostrobin is active against different fungal stages both on the plant surface and in the plant tissue. After application to the plant, the active ingredient is taken up via the leaf and then translocated at low rates via the transpiration flow. Due its relatively low mobility, it shows local systemic and translaminar activity. Because of its very high intrinsic activity, pyraclostrobin has been observed to have systemic effects in a number of authorized uses. By that, it can control fungal stages which have already become established in deeper tissue layers. Pyraclostrobin is thus suitable for preventative and curative treatments.

Pyraclostrobin belongs to the QoI group of fungicides. The mode of action is the inhibition of mitochondrial respiration resulting from a blockage of the mitochondrial electron transport chain, thus blocking phosphorylation further down in the respiratory chain. In consequence, this leads to a reduction of energy-rich ATP which is required to support a range of essential processes in the fungal cell. In the end, the various fungal development processes of spore germination, formation of infection structures, mycelium growth and sporulation are permanently disrupted.

In addition to its fungicidal effects, plant physiology is also affected by the application of pyraclostrobin. Among these effects higher yield and better product quality in absence of diseases as well as improvement of the assimilation rate and delayed senescence have been reported. Some studies showed better stress tolerance to abiotic stresses (e.g. drought or frost). Furthermore, a reduction of physiological leaf spots in cereals has been observed after treatment with pyraclostrobin-containing products.

3.2 Summary of information on the development of resistance

Pyraclostrobin belongs to the QoI group of fungicides. Most important resistance mechanisms to QoIs are target site mutations, in particular the G143A in the cytochrome *b*. G143A leads to strong resistance and reduced field efficacy. Two other mutations, F129L and G137R, have been described, which lead to lower resistance factors.

All QoI fungicides are in the same cross-resistance group and should be managed accordingly. QoI resistance has developed in some diseases (www.frac.info). However, several fungal species were not yet able to develop field resistance to QoI fungicides, which can be explained by the structure of the target gene (“intron pathogens”). In such pathogens, development of G143A resistance is unlikely and thus long-term efficacy of pyraclostrobin is expected.

3.3 Summary of adverse effects on treated crops

Pyraclostrobin has been applied in all EU member states since many years with several different formulations across a wide range of crops without reports of phytotoxic effects on target or succeeding crops. Consequently, no negative impact is expected on treated crops.

3.4 Summary of observations on other undesirable or unintended side-effects

There is no evidence of any undesirable or unintended side-effect.

4 FURTHER INFORMATION

4.1 Summary of methods and precautions concerning handling, storage, transport or fire

Handle in accordance with good industrial hygiene and safety practice. Use appropriate personal protective equipment, e.g. particle filter with high efficiency for solid and liquid particles, suitable chemical resistant safety gloves, safety glasses with side-shields, protecting boots and chemical-protection suits. Store work clothes separately.

Ensure thorough ventilation of stores and work areas. Protect the product from direct sunlight, temperatures above 40 °C and moisture. Segregate the product from foods and animal feeds.

For transport consider hazard class 9, packing group III, ID number UN 3077 and hazard label 9, EHSM. As proper shipping name use “Environmentally hazardous substance, solid, N.O.S. (contains pyraclostrobin)”.

Prevent electrostatic charge and keep fire extinguishers handy.

In case of fire wear self-contained breathing apparatus and chemical-protective clothing. Do not breathe fumes. Keep containers cool by spraying with water if exposed to fire. Dispose of fire debris and contaminated extinguishing water in accordance with official regulations. Collect contaminated extinguishing water separately, do not allow to reach sewage or effluent systems.

4.2 Summary of procedures for destruction or decontamination

Clean contaminated floors and objects thoroughly with water and detergents, observing environmental regulations. Cleaning operations should be carried out only while wearing breathing apparatus.
Collect waste in suitable containers, which can be labeled and sealed. Waste must be sent to a suitable incineration plant, observing local regulations. Contaminated packaging should be emptied as far as possible and disposed of in the same manner as the product.

4.3 Summary of emergency measures in case of an accident

Use personal protective clothing and avoid contact of product with skin, eyes and clothing. Do not allow the product to reach drains or surface waters.

First aid personnel should pay attention to their own safety.

Treat patients according to symptoms (no specific antidote is known) and seek for medical attention. If the patient is likely to become unconscious, place and transport in stable sideways. Immediately remove contaminated clothing. After skin contact, wash thoroughly with soap and water. In case of contact with eyes, wash affected eyes for at least 15 minutes under running water with eyelids held open. If inhaled, keep patient calm and move to fresh air. If ingested, rinse mouth and then drink 200-300 ml of water.

5 METHODS OF ANALYSIS

5.1 Methods used for the generation of pre-authorisation data

5.1.1 Analysis of the active substance as manufactured

Pyraclostrobin
Pyraclostrobin is determined by reverse phase high performance liquid chromatography with UV detection and external calibration. The separation of the samples is achieved by using gradient elution and quantification of the active ingredient by UV-detection at 275 nm and comparison with reference material. This method was evaluated during the previous Annex I inclusion process.

Dimethyl sulfate (relevant impurity)
Dimethyl sulfate is determined by solid-phase microextraction (SPME) coupled to GC/MS and external calibration. This method was evaluated during the previous Annex I inclusion process.

5.1.2 Formulation analysis

Analytical methods for BAS 500 06 F

The method CF-A 669 is applicable for the determination of **pyraclostrobin** in the EC formulation BAS 500 06 F. A reversed phase HPLC method is used, utilizing a 4µm J'sphere ODS-H80 column. Detection is done by a UV detector at 230 nm and quantification is made by external standard.

Dimethyl sulfate: A method of analysis was developed in order to determine the relevant impurity dimethyl sulfate in BAS 500 06 F. The method applied is a Headspace GC method, MS detection with quantification by means of standard addition. The method was developed and validated in accordance with current GLP regulations.

Analytical methods for BAS 516 07 F

The active substances of BAS 516 07 F can be quantified using the analytical reversed phase-HPLC method CF-A 598. This method was developed and validated for quantifying **pyraclostrobin and boscalid** in BAS 516 00 F, but specific chromatograms prove the applicability for BAS 516 07 F as well. This method is a reversed phase-HPLC method with UV-detection and external calibration to determine pyraclostrobin and boscalid in water dispersible granules (WG).

Dimethyl sulfate: The GC method AM/01120/01e was developed to determine the relevant impurity dimethyl sulfate in BAS 516 07 F. Quantification is done by means of standard addition. This analytical method is a GC method equipped with headspace autosampler and a mass spectrometer detector.

5.1.3 Methods for Risk Assessment

Plants and plant products

The analytical methods for the determination of pyraclostrobin in foodstuffs of plant origin were evaluated in the previous Annex I inclusion process and during more recent evaluations performed by EFSA in the context of MRL applications. Pyraclostrobin residues in commodities of plant origin can be determined by LC/MS-MS with LOQs of 0.02 mg/kg or 0.01 mg/kg. The BASF methods 421/0, 445/0, 535/1 (synonym: L0076/01) allow the determination of pyraclostrobin and its metabolite 500M07 (synonym: BF 500-3) in multiple crops. The metabolite 500M07 is not part of the residue definition in Europe.

The data generation methods are fully validated in separate GLP studies. Furthermore, an extensive set of concurrent fortification experiments exist from supervised field trials or processing studies. They are also supported by extractability investigations performed in the context of metabolism studies. The general suitability of these methods has been already confirmed by EFSA in the recently published Reasoned Opinion on MRLs (Review of established MRLs according to Reg. 396/2005 (Art. 12); EFSA Journal 2011;9(8):2344).

Due to the broad use of pyraclostrobin containing formulations, the scope of the methods has been considerably expanded over the past years. In 2011, EFSA re-evaluated the safety of the established EU MRLs according to Reg. 396/2005, Art. 12. In the context of this evaluation a data gap for a validated method in coffee beans has been identified. The method 445/0 (SOP-PA.0243) has been used for the analysis of the samples generated during the supervised field trials in Brazil.

In addition, a method was developed for the analysis of representative samples generated during supervised field trials. It is intended to support the dietary risk assessment for metabolite 500M04 and its conjugates. For proving the suitability of the enzymatic cleavage step applied, the glycoside 500M79 was selected.

Summaries of the validation studies for the new methods are presented in M-CA 4.1.2 and a summary of the methods including the respective reference in the dossier is listed in the table below:

Method	LOQ (mg/kg)	Matrices	Analyte(s)	Detection
SOP-PA.0243 (CA 4.1.2/13)	0.02	Coffee (grain), soybean (grain) and wheat (grain)	Pyraclostrobin and its metabolite BF 500-3 (500M07)	LC-MS/MS
L0220/01 (CA 4.1.2/14) (CA 4.1.2/15)	0.01	Lettuce (head), white cabbage and leek	Metabolite 500M04 (BF 500-5) and its glycoside conjugate 500M79 (Reg.No. 597091)	LC-MS/MS
L0076/09 (CA 4.1.2/16)	0.01	Dry beans, soya bean (grain), citrus, wheat, tomato	Pyraclostrobin and its metabolite BF 500-3 (500M07)	LC-MS/MS

Food of animal origin

The analytical methods for the determination of pyraclostrobin in foodstuffs of animal origin were evaluated in the previous Annex I inclusion process.

Pyraclostrobin parent residues can be determined by LC-UV method with a validated LOQ of 0.01 mg/kg in milk and 0.05 mg/kg in muscle, liver, kidney, fat and eggs. In the context of this dossier, method L0151/01 is provided. In order to allow an efficient enforcement of pyraclostrobin parent residues using up-to-date technology (LC-MS/MS), it replaces the previously submitted LC-UV method 439/0. It was also validated in blood. As required in SANCO 825/00 and the relevant OECD guidance document, the validation data include a confirmatory technique (second transition).

For data generation purposes, a common moiety method was developed in the context of the previous Annex I inclusion process. It is based in the hydrolytic degradation of BAS 500 F and its metabolites to 500M04 and 500M85. For proving the suitability of the method, which has been used in the cow feeding study, the common moiety has been newly validated for key metabolites identified in the livestock metabolism studies (BASF Method no. 446/2, L0058/03). The principle of the common moiety approach from 2000 was kept; only the final quantitation technique (LC-MS/MS instead of GC-MS) was changed.

In order to support the poultry feeding study, the common residue analytical method (D9902) used for sample analysis is provided as supplemental information. The poultry feeding study was submitted to US EPA.

Summaries of the validation studies for the new methods are presented in M-CA 4.1.2 and a summary of the methods including the respective reference in the dossier is listed in the table below:

Method	LOQ (mg/kg)	Matrices	Analyte(s)	Detection
L0058/03 (CA 4.1.2/17) (CA 4.1.2/18)	0.01	Muscle, kidney, fat, liver, milk and egg	Pyraclostrobin and metabolites 500M04 (BF 500-5), 500M85 (BF 500-8) – common moiety approach	LC-MS/MS
L0151/01 (CA 4.1.2/19) (CA 4.1.2/20)	0.01	Cow: muscle, kidney, fat, liver, milk, skim milk, cream hen: egg swine: blood	Pyraclostrobin	LC-MS/MS
D9902 (CA 4.1.2/21)	0.05	Hen: egg, liver, muscle, fat	Pyraclostrobin and metabolite BF 500-16 [hydrolysed into BF 500-5 and BF 500-9] – common moiety approach	LC-MS/MS

Soil

BASF method L0166/01 fulfilling the European requirements for data generation was developed for the quantitation of pyraclostrobin and its metabolites (shown below) in soil. Additionally, another validated method for parent in soil is provided as supplemental information. This method has been used to analyse petri dish samples collected in a new field dissipation study.

A summary of the methods including the respective reference in the dossier is listed in the table below:

Method	LOQ (mg/Kg)	Matrices	Analyte(s)	Detection
L0166/01 (CA 4.1.2/1)	0.001	soil	Pyraclostrobin and its metabolites BF 500-6 (500M01), BF 500-7 (500M02) and BF 500-3 (500M07)	LC-MS/MS
L0161/01 (CA 4.1.2/2)	0.001	soil	Pyraclostrobin	LC-MS/MS

Water

Two methods fulfilling the European requirements for data generation were developed for the quantitation of pyraclostrobin and its metabolites (shown below) in water. Additionally, another validated method for parent in water is provided as supplemental information. This method has been used to analyse spray solution samples collected in a new field dissipation study.

A summary of the methods including the respective reference in the dossier is listed in the table below:

Method	LOQ (µg/L)	Matrices	Analyte(s)	Detection
L0182/02 (CA 4.1.2/4)	0.003 for BAS 500 F and 0.03 for metabolites	Water (ground/ surface and tap)	Pyraclostrobin (BAS 500 F) and its metabolites BF 500-11 (500M60), BF 500-12 (500M59), BF 500-13 (500M62), BF 500-14 (500M76) and BF 500-15 (500M78)	LC-MS/MS
L0182/02 (CA 4.1.2/5)	0.03	Water (ground/ surface)	BF 500-5 (500M04)	LC-MS/MS
APL0500/01 (CA 4.1.2/3)	1	Water	Pyraclostrobin	LC-MS

Air

The method L0197/01 fulfilling the European requirements for data generation was developed for the quantitation of pyraclostrobin in air. A summary of the method including the respective reference in the dossier is listed in the table below:

Method	**LOQ (ng/L)**	**Matrices**	**Analyte(s)**	**Detection**
L0197/01 (CA 4.1.2/6)	4.44	Air	Pyraclostrobin	LC-MS/MS

5.2 Methods for post-authorisation control and monitoring purposes

Plants and plant products

Based on the residue definition for MRL setting and enforcement, a residue analytical method is required for the parent molecule pyraclostrobin in food of plant origin. For this purpose, residue analytical method 421/0 was already provided in the previous Annex I inclusion process. The method was found to be suitable to quantify residues in different commodity groups, but also in crop matrices which are considered as "difficult" to analyse. Due to an extended use pattern of pyraclostrobin, an Independent Laboratory Validation study in coffee is provided in M-CA 4.2.

In addition, the QuEChERS method (determination using GC-MS and/or LC-MS/MS) is sufficiently validated at the LOQ of 0.01 mg/kg for the determination of pyraclostrobin in plant matrices. The use of the multi residue method for the determination of pyraclostrobin residues is widely published in the Internet.

A summary of the methods including the respective reference in the dossier is listed in the table below:

Method	LOQ (mg/kg)	Matrices	Analyte(s)	Detection
421/0 (CA 4.2/1)	0.02	Multiple commodities	Pyraclostrobin	LC-MS/MS
QuEChERS	0.01	Multiple commodities	Pyraclostrobin	LC-MS/MS

Food of animal origin

Based on the residue definition for MRL setting and enforcement, a residue analytical method is required for the parent molecule Pyraclostrobin in food of animal origin. In order to allow an efficient enforcement of Pyraclostrobin parent residues using up-to-date technology (LC-MS/MS) method L0151/01 replaces the previously submitted LC-UV method 439/0. It was also validated in blood. As required in SANCO 825/00 and the relevant OECD guidance document, the validation data include a confirmatory technique (second transition).

A summary of the methods including the respective reference in the dossier is listed in the table below:

Method	LOQ (mg/kg)	Matrices	Analyte(s)	Detection
L0151/01 (CA 4.2/3)	0.01	Cow: muscle, kidney, fat, liver, milk, skim milk, cream hen: egg swine: blood	Pyraclostrobin	LC-MS/MS

Soil

The soil methods developed for risk assessment as listed in chapter 5.1.3 can also be used for monitoring purposes.

Method	LOQ (mg/Kg)	Matrices	Analyte(s)	Detection
L0166/01 (CA 4.1.2/1)	0.001	soil	Pyraclostrobin and its metabolites BF 500-6 (500M01), BF 500-7 (500M02) and BF 500-3 (500M07)	LC-MS/MS
L0161/01 (CA 4.1.2/2)	0.001	soil	Pyraclostrobin	LC-MS/MS

Water

The water method developed for risk assessment as listed in chapter 5.1.3 can also be used for monitoring purposes. For confirmation, an independent laboratory validation was performed.

Method	LOQ (µg/L)	Matrices	Analyte(s)	Detection
L0182/02 (CA 4.2/5)	0.003 for parent 0.03 for metabolites	Water (surface/drinking)	Pyraclostrobin and its metabolites BF 500-5 (500M04), BF 500-11 (500 M60), BF 500-12 (500M59), BF 500-13 (500M62), BF 500-14 (500M76) and BF 500-15 (500M78)	LC-MS/MS

Air

The air method developed for risk assessment as listed in chapter 5.1.3 can also be used for monitoring purposes.

Method	LOQ (ng/L)	Matrices	Analyte(s)	Detection
L0197/01 (CA 4.1.2/6)	4.44	Air	Pyraclostrobin	LC-MS/MS

Methods used in support of toxicological studies

Methods developed for supporting toxicological studies as listed in M-CA 5.1.3.

Method	LOQ	Matrices	Analyte(s)	Detection
13/0173_04 (CA 4.1.2/7)	50 ng/mL	plasma	Reg.No. 5916421 (500M24)	LC-MS/MS
99/0251_01-0 (CA 4.1.2/8)	50 ng/mL	plasma	Reg.No. 411847 (500M60)	LC-MS/MS
99/0249_01 (CA 4.1.2/9)	50 ng/mL	plasma	Reg.No. 413038 (500M76)	LC-MS/MS
14/0701_04 (CA 4.1.2/10)	50 ng/mL	plasma	Reg.No. 399379 (500M106) Reg.No. 298327 (500M04)	LC-high resolution MS
14/0701_03-01 (CA 4.1.2/11)	0.1 mg/mL	CMC	Reg.No. 399379 (500M106)	LC-UV
14/0701_03-01 (CA 4.1.2/12)	0.5 mg/mL	CMC	Reg.No. 399379 (500M106)	LC-UV

6 IMPACT ON HUMAN AND ANIMAL HEALTH

In the EU Review Report for pyraclostrobin (8 September 2004; SANCO/1420/2001-final) the toxicological properties of pyraclostrobin were fixed. The endpoints are still valid. The database has been extended with studies fulfilling new data requirements, studies conducted to fulfil data requirements of other authorities, updated metabolism studies using state of the art metabolite identification, by inclusion of additional toxicological evaluation on significant metabolites and by assessment of impurities and theoretical impurities for potential toxicological relevance.

6.1 Effects Having Relevance to Human and Animal Health

6.1.1 Summary of adsorption, distribution, metabolism and excretion

Pyraclostrobin has been extensively studied for absorption, distribution, metabolism and excretion. Endpoints set during the previous Annex I inclusion process reflect the rapid absorption and excretion as well as the extensive metabolism in mammalian systems.

In addition, a new rat study focussing on detailed metabolism in plasma is now available, which extends the knowledge obtained during previous studies. Given the degree of metabolism of pyraclostrobin, it is not to be expected to match all metabolites or percentage between the old and new study. In the recently performed plasma study in rats, several metabolites have been reconfirmed and some new metabolites (500M104, 500M106, 500M107 and 500M108) have been identified. The relevant pathways are provided in Figure 6.1.1-1 and Figure 6.1.1-2.

Since the submission of the supplemental dossier in July 2014, further investigations have been performed. Main purpose of these studies was to get a better understanding of the formation, but also the metabolism of metabolites 500M106, 500M107 and 500M02 which were predominantly found in human and rabbit cell cultures, but only in minor amounts in rats.

When all studies (including the comparative *in-vitro* metabolism and the subsequent investigations on 500M106) are compared, the following general conclusions can be drawn:

- Pyraclostrobin is rapidly excreted via urine and feces.
- Excretion of radioactivity is similar for both sexes. The majority of the radioactivity was excreted via feces (>80% of the dose) and smaller amounts via urine <15% of the dose). Via bile, about 35% of dose is excreted resulting in a bioavailability of approximately 50%.
- There is no evidence of any cumulative potential of pyraclostrobin. Throughout the time course of the experiments, highest radioactivity concentrations were found in the GI tract. Most organs and tissues had values similar to the ones of the plasma. Liver (factor: 4 – 5) and to a smaller extent kidneys (factor: 2) were tissues with higher values than plasma. Radioactivity concentrations were lowest in bone and brain.
- The metabolite patterns in feces, urine, bile, liver, kidney and plasma were largely comparable for both sexes and for all dose groups investigated.

- In total six transformation steps were observed in rats; they are also depicted in the figure below:

  - Desmethoxylation of the side chain
  - Hydroxylation of the chlorophenyl pyrazole ring system
  - Hydroxylation of the tolyl ring system
  - Cleavage of the ether bond resulting in chlorophenyl pyrazole or anthranilic acid derivatives
  - Desmethylation of the side chain
  - Cleavage of the amide bond in the side chain

- The combination of these reactions followed by conjugation steps results in a huge number of metabolites.

In accordance with the new data requirements for active substances of Commission Regulation No 283/2013 of 1 March 2013, and in alignment with RMS Germany a comparative *in-vitro* metabolism study of pyraclostrobin was conducted. There is no guideline for this type of study available yet, therefore the study was conducted according to an internal protocol, which was aligned with RMS Germany.

- Pyraclostrobin was found to be extensively metabolized by liver hepatocytes or microsomes of humans, rabbits, rats and dogs (microsomes only).
- The study showed no human metabolites which were not also observed in at least one of the animal species.
- The same key metabolic degradation steps were observed as under *in-vivo* conditions. Metabolites as 500M04, 500M73, 500M108, 500M103, 500M104 and 500M88 are common to all test species. Some quantitative differences were noted between the different test species. In human and rabbit, the formation of metabolite 500M106 is the major degradation pathway. Subsequently, 500M106 is further metabolized by conjugation with glucuronic acid to 500M107. In human and rabbit, metabolite 500M02 (which is formed by dimerization) has been also identified.
- Based on these results, three metabolites require further consideration. For metabolites 500M106 and 500M02, further toxicological studies have been performed (see M-CA 5.8). The glucuronic acid conjugate 500M107 is covered by the investigations of 500M106. The relevant endpoints are considered for estimating the dietary exposure (see M-CA 6.9) as the conversion of parent into the three metabolites cannot be excluded under *in-vivo* conditions.
- For improving the understanding of the formation and metabolism of 500M106, additional investigations were performed.
- In a rat metabolism study where 500M106 was dosed to male rats, the same excretion pattern was found as for pyraclostrobin. The metabolic pathway is presented in Figure 6.1.1-3. The results of the metabolism study demonstrate that rats are an appropriate species for further toxicological testing, but they also show that metabolite 500M02 is covered by the investigations on 500M106 as it has been found in considerable amounts.
- By means of further *in-vitro* investigations, the enzyme resulting in the formation of 500M106 has been identified as human carboxylesterase 1. This type of enzymes is also present in rats.

Altogether and taking the results summarized in M-CA 5.8 into account, the new studies support the use of the previous studies for end point setting (ADI, ARfD) and also the resulting interpretation of consumer risk.

6.1.2 Summary of acute toxicity

Since the last evaluation new acute inhalation toxicity studies and a NRU-Phototoxicity study have been conducted. In the dossier update of 27-Feb-2017 the range finding toxicity study of the in-vivo mouse micronucleus assay has been added. The mortality data in this study are suitable to derive an acute oral toxicity value in mice, which is considerably lower than the value derived from the acute oral rat study. Reasons are discussed in M-CA 5.2.

Pyraclostrobin is characterized by a rather low dermal toxicity. The toxicity by the inhalation route is to a great extent dependent on the vehicle/solvent used to generate an inhalable aerosol. Whereas for pyraclostrobin dissolved in acetone LC_{50} values of 0.31 mg/L < LC_{50} < 1.07 mg/L and 0.58 mg/L were derived, indicating that pyraclostrobin is toxic by inhalation, the generation of an aerosol with pyraclostrobin dissolved in Solvesso revealed a value of 4.07 mg/L < LC_{50} < 7.3 mg/L. Pyraclostrobin is irritant to the skin, but not irritant to the eye. In a Maximisation test pyraclostrobin was not sensitising.
No indications for a phototoxic potential was observed in an in vitro NRU Phototoxicity Test in Balb/c 3T3 cells.

6.1.3 Summary of short-term toxicity

The short-term toxicity of pyraclostrobin was investigated in dietary 3-month studies in rats, mice, and dogs. Additionally, a dietary 28-day study in rats and a dietary 1-year dog study were performed. The short-term dermal toxicity was determined in a 28-day study in rats. Based on the acute toxicity of BAS 500 F, two 28-day inhalation studies in rats were performed. The results of the short-term toxicity studies are shown in Table 6.1.3-1.

The signs of toxicity observed in the three species tested were overall similar and consisted of reduction of absolute body weight and body weight gain at the high dose levels. The observed clinico-chemical findings can be linked to the (severely) reduced body weight gain. The effects observed typically included reduced total protein, globuline, glucose, tryglycerides and creatinine. The increase in urea may suggest a slightly impaired kidney function at the high dose level in rats and mice. In addition, in rats and mice haematological changes indicative of an anaemic process with compensatory reactions were observed. In rats a higher incidence and/or severity of extramedullary hematopoiesis in the spleen was noted at higher dose levels. In rats and mice, the hemosiderin deposition in spleen seemed to be of slightly lower severity at higher dose levels. Concerning white blood cell parameters, rats demonstrated an increase in white blood cells at the higher dose levels tested, whereas in mice a leukopenia was noted at higher dose levels. The latter was accompanied by effects in lymphatic organs (thymus atrophy, increased apoptotic bodies in mesenteric lymph nodes).
With the exception of the dietary 1-year dog study, the pathology indicated the duodenum mucosa to be the only consistent target organ in all three species tested. The changes (mucosal hypertrophy) were characterised by an increased ratio of cytoplasm to the nuclei in the villi, and a hyperplastic aspect in the epithelial cells.
Only in rats a slight hepatocellular hypertrophy was observed. Secondary to the substantial effects on body weight in rats and mice at higher dose levels, a lower incidence and/or severity of hepatocellular fat storage was noted.

Feeding of BAS 500 F to dogs for one year resulted in clinical signs of toxicity, initially vomitus and diarrhea at the high dose level. At this dose level body weight and food consumption were impaired. Additionally, slight haematological and clinico-chemical changes were observed. There were no specific signs of toxicity or changes in histopathological parameters.

In a 4-week dermal toxicity study in rats no substance-related systemic toxicity was detected up to the highest dose level tested of 250 mg/kg bw. Due to the irritant properties of pyraclostrobin dose dependent signs of local dermal irritation were noted at all dose levels tested.

After subchronic inhalatory exposure of rats to pyraclostrobin dissolved in acetone (6 hours per day on a 5 days/week basis), mortality was observed at 0.3 mg/L. This is in the same range as observed for pyraclostrobin dissolved in acetone in acute inhalation studies, which revealed a 4h LC_{50} of 0.58 mg/L. The respiratory tract (nasal cavity, larynx and lungs) and the duodenum were identified as target organs as indicated by dose dependent atrophy/necrosis and regeneration/repair of the olfactory epithelium, hyperplasia of the respiratory epithelium of nasal cavity and the larynx, perivascular inflammation of the lungs as well as hyperplasia / weight increase of the duodenal mucosal. The reversibility of the observed findings was confirmed after a 28-day treatment-free period.

Table 6.1.3-1: Summary of short-term NOAELs and LOAELs observed in rats, mice and dogs

Study	NOAEL	LOAEL
4-week, oral rat	100 ppm (9.0 mg/kg bw/day)	500 ppm (42.3 mg/kg bw/day)
13-week, oral rat	150 ppm (10.7 mg/kg bw/day)	500 ppm (34.7 mg/kg bw/day)
13-week, oral mouse	< 50 ppm (9.3 mg/kg bw/day) (NOAEL ~ 4 mg/kg bw/day (30 ppm) based on effects observed after 90-day in the mouse carcinogenicity study)	50 ppm (3.5 mg/kg bw/day)
13-week, oral dog	200 ppm (5.8 mg/kg bw/day)	450 ppm (5.8 mg/kg bw/day)
52-week, oral dog	200 ppm (2.7 mg/kg bw/day)	400 ppm (10.8 mg/kg bw/day)
28-day, dermal rat	250 mg/kg bw/day	No systemic toxicity observed
28-day, inhalation rat	0.01 mg/L	0.03 mg/L

6.1.4 Summary of genotoxicity

Pyraclostrobin was evaluated for its potential genotoxicity in vitro using bacterial and mammalian cell mutagenicity tests, a chromosome damage (clastogenicity) test and an unscheduled DNA synthesis test. The results of these studies demonstrated the absence of a genotoxic effect.
In vivo, the test substance was assessed for the induction of micronuclei in mice. The result of this study showed that BAS 500 F has no chromosome-damaging potential. In order to prove the exposure of the target organ in the mouse micronucleus assay (i.e. the bone marrow), a kinetic study using radioactive pyraclostrobin was conducted in mice and the report summary has been added in M-CA 5.4.

It is therefore concluded, that pyraclostrobin has no mutagenic or genotoxic properties both *in vitro* and *in vivo*.

6.1.5 Summary of long-term toxicity and carcinogenicity

The results of a two-year chronic toxicity study and a two-year carcinogenicity study in rats indicate that a maximum tolerated dose was achieved at the high dose level. This is demonstrated by a body weight gain depression of approximately 10% in both sexes. Food consumption was marginally affected at the high dose level and there were slight reductions of clinical chemistry parameters. In high dose males an increased incidence in liver cell necrosis was observed.
There was no evidence of a carcinogenic effect of pyraclostrobin in rats at any dose level.

A carcinogenicity study in mice was conducted up to a maximum tolerated dose as evidenced by significant body weight depression (13% in both sexes) and a reduced body weight gain of 27 – 29%. There were no other signs of toxicity and no test substance related effects were noted in the differential blood count as well as gross- and histopathology investigations.
There was no evidence of a carcinogenic effect of pyraclostrobin in mice at any dose level.

In summary, long-term feeding studies with pyraclostrobin in rats and mice resulted in reduction of body weight and body weight gain. Occasionally clinical chemistry parameters were affected. In high dose male rats an increased incidence of liver cell necrosis was observed. In mice no specific target organ was identified. Pyraclostrobin was not carcinogenic.

6.1.6 Summary of reproductive toxicity

The reproduction toxicity of pyraclostrobin was investigated in a 2-generation reproduction study in rats as well as in prenatal toxicity studies in rats and rabbits.

Parental toxicity was indicated by impaired body weight development and/or reduced food consumption. Reproductive function was not affected in the two generation study in rats including sperm and ovarian parameters as well as the estrus cycle of the rats of both generations. Developmental effects in F1 and F2 pups consisted of a slightly impairment of body weight development. Secondary to the effects on pup body weight development, organ weight changes were noted for a number of organs. Most probably for the same reason a slight, but statistically significant delay of vaginal opening was observed at the high dose. However, the mean number of days for vaginal opening was well within the historical control range and no high dose pup reached the criterion vaginal opening later than the latest control pup.
Accordingly, the NOAEL for reproductive function was identified at the highest dose tested of (300 ppm equivalent to 32.6 mg/kg bw/day). The NOAEL concerning general systemic toxicity for the parental animals was 75 ppm (8.2 mg/kg bw). The NOAEL for developmental toxicity in the F1 and F2 litters also was 75 ppm (8.2 mg/kg bw).

In the prenatal toxicity study in rats no teratogenicity was observed up to the highest dose tested (50 mg/kg bw/day). A slight increase of visceral and skeletal variations at the high dose – even though within the historical control range – was considered to be related to treatment. Maternal toxicity was indicated by reduced food consumption and impaired absolute and corrected body weight development. In conclusion, pyraclostrobin was not teratogenic in rats.
The NOAEL for maternal toxicity was 10 mg/kg bw/day, whereas the developmental NOAEL was set at 25 mg/kg bw/day.

In the rabbit prenatal toxicity study severe maternal toxicity was observed as indicated by dose- and time-dependent decrease of mean food consumption down to 11% of the control, body weight loss and clinical signs. Secondary to the severe maternal toxicity during and shortly after implantation, fetal toxicity at the high dose consisted of an increased post-implantation loss due to an increased number of early resorptions. A slight increase of skeletal malformations of the axial skeleton was within the historical control range and considered unlikely to represent a specific effect of pyraclostrobin treatment.
The NOAEL for developmental toxicity was set at 5 mg/kg bw. The NOAEL for maternal toxicity was established in a supplemental rabbit maternal toxicity study and set at 3 mg/kg bw/d, based on reduced feed consumption and slightly reduced body weight observed at the next higher dose level of 5 mg/kg bw/day. Pyraclostrobin was not teratogenic in rabbits.

The lowest NOAEL for maternal/parental toxicity was 3 mg/kg bw (maternal toxicity study in rabbits) and 5 mg/kg bw/d for developmental toxicity (rabbit prenatal toxicity study).

6.1.7 Summary of neurotoxicity

Pyraclostrobin was tested for potential neurotoxicity in acute and subchronic neurotoxicity studies in rats. These studies included extensive functional observation batteries as well as specific neurohistopathological investigations. In these studies, as well as in other studies with pyraclostrobin, no indications for a neurotoxic potential were observed.

6.1.8 Summary of further toxicological studies on the active substance

6.1.8.1 Supplemental studies in the active ingredient

Additionally, to the studies available for Annex I inclusion of pyraclostrobin, immunotoxicity studies in mice were conducted upon request of US EPA. The studies investigated the cellular mediated immunity as assessed by the functional NKC assay (cellular immune response) as well as the T-cell dependent IgM antibody response (TDAR) to sheep red blood cells (humoral immune response). Like in the subchronic mouse study, lower spleen and thymus weights were observed. For the thymus a stress related reduction of thymus weights can be assumed based on the substantial effects on body weight development. The lower spleen weights correlated to a lower number of spleen cells, which however did not result in an adverse effect on the cellular immune response. In the TDAR study the number of haemolytic plaques per spleen was not affected by treatment up to the highest dose tested. However, based on the lower number of spleen cells per organ, the specific activity (plaques/10^6 spleen cells) as statistically increased compared to the control. While a decrease in the AFC response has been recognized as an indicator that a test substance has the potential of being immunosuppressive; at the present time, the consequences of an increase in the specific AFC response have not been established and thus the adversity of this change cannot be assessed. The NOEL in this study was therefore set at 200 ppm, which was equivalent to a daily dose of 55 mg/kg bw/day.

The effects of pyraclostrobin on serum and urine levels of iron were determined in a 14 day study. A dose- and time dependent decrease of serum iron concentrations was noted. In contrast, serum transferrin levels or urinary iron excretion were not affected by treatment. Based on the decrease of serum iron concentration, the no observed effect level was determined at 3.8 mg/kg bw/day.

6.1.8.2 Endocrine disrupting properties

There is no indication for an endocrine disruption potential of pyraclostrobin from pivotal animal studies. The organ weight changes of male and female sexual organs and endocrine glands observed in subchronic studies at higher dose levels were secondary to the observed decrease of terminal body weights and typically not accompanied by histopathological findings. The decrease of absolute and relative adrenal weights in female mice was accompanied by a decrease of lipid deposition in the x-zone, which is specific to mice and of unknown function. The decreased lipid content is considered secondary to the impaired body weight development. No histopathological effects on the thyroid were observed in rodents and dogs. Likewise, long-term administration of pyraclostrobin did not indicate treatment-related effects on neoplastic or non-neoplastic findings in sexual organs or endocrine tissues. In the 2-generation study administration of pyraclostrobin had no effect on the estrous cycle, the number, morphology and motility of sperm as well as on male or female fertility.
The only potential indication for a sex-hormone mediated effect is a slight delay of vaginal opening in the 2-generation study. However, the mean day of vaginal opening at the high dose level (33.3 days) was well within the historical control range of 29.9 to 34.9 days. The slight delay of vaginal opening is considered to be secondary to a delay of physical development due to a lower body weight gain at the high dose.

In a study by Orton et al. pyraclostrobin was tested for anti-androgenic activity in the MDA-kb2 assay. No anti-androgenicity was observed. As many other pesticides and chemicals, pyraclostrobin is part of the US ToxCast program. Several assays react to varying doses of pyraclostrobin, however, no conclusive picture has emerged.

As a conclusion, there is no evidence for endocrine disruption properties of pyraclostrobin.

6.1.9 Summary of toxicological data on impurities and metabolites

There are three groups of plant or livestock animal metabolites, which were considered no to be adequately covered by the metabolism of pyraclostrobin in rats and thus investigated toxicologically.

Metabolite 500M04 (and its conjugation derivatives; Group 2 of 6) is a metabolite found in all compartments, i.e. soil, water, plants, livestock, fish, rat as well as in in-vitro metabolism studies. 500M04 is of low acute toxicity, is not irritant to the rabbit skin or eye and was negative in a Maximization assay for skin sensitizing effects. In a subchronic rat study at the high dose level an increased water consumption accompanied by a higher volume of discharged urine was noted, which contained high amounts of unidentified crystals. The above changes were in line with the histopathological findings observed in the kidneys at this dose level. However, there was no indication of renal dysfunction as indicated by the absence of respective clinical chemistry alterations. Additionally, a slight regenerative anemia accompanied by an adaptive increase of extramedullary hematopoiesis in the spleen was observed. The NOAEL in this study was 103 mg/kg bw/day and thus about 10-fold higher than the respective NOAEL for pyraclostrobin. 500M04 is not genotoxic as evident from in vitro and in vivo genotoxicity studies. Based on the above findings 500M04 is not considered to be toxicologically relevant. An ADI of 0.52 mg/kg bw/day was calculated.

Metabolites 500M24, 500M49 and 500M51 (Group 3) were tested negative for genotoxicity in a battery of 3 in vitro and one in vivo genotoxicity studies (500M24 only). The metabolites are therefore considered not to be toxicologically relevant. This essentially holds true for Metabolite 500M76 (synonym: BF 500-14; Group 6).

Metabolites 500M02 and 500M106 were found in newly performed metabolism studies. Metabolite 500M02 did not show any genotoxic potential in-vitro, while metabolite 500M106 showed the same outcome in two in-vivo genotoxicity studies. A 28-day rat study with 500M106 showed a NOAEL of 300 mg/kg bw/day. An ADI of 0.5 mg/kg bw/day was calculated covering also 500M02. Based on the toxicological data an ARfD is not needed. Consequently, both metabolites are considered not to be of toxicologically relevance.

The water photolysis metabolites 500M60 (synonym BF 500-11) and 500M62 (synonym BF 500-13) are not considered to be toxicologically relevant based on the results of genotoxicity studies.

Impurities and theoretical impurities have been evaluated for their toxicological relevance in J-CA.

6.1.10 Summary of medical data and information

The information on human data was updated by a recent literature search as well as by inclusion of all internal medical information, which became available since the last submission

All persons handling crop protection products at BASF are surveyed by regular medical examinations. There are no specific parameters available for effect monitoring of pyraclostrobin. Thus, the medical monitoring program is designed as a general health check-up.

Some cases of eye irritation deriving from pyraclostrobin in combination with other substances in the course of production, transportation, formulation and packaging have been reported to BASF. Literature research revealed a report on 5 cases of accidental exposure to pyraclostrobin containing aerial spray mist. The most severe incident pertained 27 Hispanics, which were exposed to off-target drift originating from an air craft treating a nearby field. The most common symptom reported by the exposed workers was upper respiratory tract pain or irritation (26 patients), followed by chest pain (20 patients). These observations in combination with supportive evidence from animal studies led to the proposal to classify pyraclostrobin with H335 (STOT SE Category 3, May cause respiratory irritation).

No epidemiological studies are available. No specific signs of poisoning or specific antidotes are available.

For first aid measures and medical treatment following intoxication by pyraclostrobin or pyraclostrobin containing products, it is advised to follow the instructions given in the Safety Data Sheets.

6.2 Toxicological end point for assessment of risk following long-term dietary exposure - ADI

Pyraclostrobin:

No additional data have been provided for renewal of pyraclostrobin that would affect the derivation of reference value agreed upon for Annex I inclusion of pyraclostrobin as laid down in the EU Review Report (SANCO/1420/2001-final, 8 September 2004) and approved in the Commission Directive 2004/30/EC of 10 March 2004.

NOAEL from the chronic dietary toxicity study in the rat was considered to be most relevant for establishing the Acceptable Daily Intake (ADI). The NOAEL in the chronic dietary toxicity study was 75 ppm, which is equivalent to a mean daily dose of 3 mg/kg bw. Pyraclostrobin has no genotoxic or carcinogenic potential, is not teratogenic and has no effects on fertility. Therefore, a safety factor of 100 is applied, resulting in an **ADI of 0.03 mg/kg bw for pyraclostrobin**.

Metabolite 500M04:

Metabolite 500M04 is not genotoxic and has a substantially lower subchronic toxicity compared to pyraclostrobin. As it is a major metabolite consumers may be exposed to, an ADI was derived from the NOAEL observed in the 90-day rat study (103 mg/kg bw/day) and a safety factor of 200. The use of an extra two fold safety factor for extrapolation from subchronic to chronic exposure is in line with the EFSA Scientific Opinion 'Guidance on selected default values to be used by the EFSA Scientific Committee, Scientific Panels and Units in the absence of actual measured data' and also with the values discussed in the ECHA 'Guidance on information requirements and chemical safety assessment, Chapter R.8: Characterization of dose [concentration]-response for human health' (Version 2.1, Nov. 2012).

Accordingly, the proposed **ADI for 500M04** is calculated as **0.52 mg/kg bw/day.**

6.3 Toxicological end point for assessment of risk following acute dietary exposure - ARfD (acute reference dose)

Pyraclostrobin:

No additional data have been provided for renewal of pyraclostrobin that would affect the derivation of reference values agreed upon for Annex I inclusion of pyraclostrobin as laid down in the EU Review Report (SANCO/1420/2001-final, 8 September 2004) and approved in the Commission Directive 2004/30/EC of 10 March 2004.

The ARfD was derived based on the NOAEL of 3 mg/kg bw/d for maternal toxicity from the rabbit prenatal toxicity study. Reduced food consumption and slightly reduced body weight were seen at the next higher tested dose level. Using the NOAEL of 3 mg/kg bw/d and the standard assessment factor of 100, the acute reference dose **(ARfD) is 0.03 mg/kg bw for pyraclostrobin.**

Metabolite 500M04:

For the determination of an ARfD, results for oral studies that used acute or sub-acute (up to 28-day) short-term exposure are the most relevant studies to be considered, provided the study design is sufficient to derive a NOAEL. No such study is available for 500M04. The only study suitable for deriving a NOAEL for short-term exposure effects is the 90-day feeding study. However, as there were no effects on body weight or food consumption, no effects were observable. The only clinically observable effect was an increased water consumption, which was first noted after about 35 days of exposure. It can be assumed that the histopathological changes in the kidneys and ureters likewise did not occur earlier. As hematology and clinical chemistry parameters were determined at study termination only, it is unknown when change of the affected red blood cell and clinical chemistry parameters took place. As a conclusion, no effects of a single or a few administrations of 500M04 can be identified. Accordingly, no ARfD is derived for 500M04.

6.4 Toxicological end point for assessment of occupational, bystander and residents risks – AOEL

There are new data that affect the derivation of the AOEL. These consisted of the newly submitted 28-day inhalation studies in rats and the immunotoxicity studies in female mice.

According to the principles of Annex VI to Directive 91/414 EEC, the proposed AOEL should be based on the highest level at which no adverse effect is observed in tests in the most sensitive relevant animal species.

For the risk assessment of the operator or worker as well as bystander and resident the results of the short-term toxicity including neurotoxicity and immunotoxicity studies and reproduction/developmental toxicity studies are considered the most relevant in order to calculate an AOEL.

The NOAELs and LOAELs of up to 90-day repeated-dose studies including endpoint specific studies for neurotoxicity and immunotoxicity and reproductive toxicity studies are summarized in the following table:

Table 6.4-1: NOAELs and LOAELs from repeated dose studies potentially relevant for AOEL setting

Study	NOAEL	LOAEL
4-week, oral rat	100 ppm (9.0 mg/kg bw/day)	500 ppm (42.3 mg/kg bw/day)
13-week, oral rat	150 ppm (10.7 mg/kg bw/day)	500 ppm (34.7 mg/kg bw/day)
13-week, oral mouse	< 50 ppm (9.3 mg/kg bw/day) (NOAEL ~ 4 mg/kg bw/day (30 ppm) based on effects observed after 90-day in the mouse carcinogenicity study)	50 ppm (3.5 mg/kg bw/day)
13-week, oral dog	200 ppm (5.8 mg/kg bw/day)	450 ppm (5.8 mg/kg bw/day)
52-week, oral dog	200 ppm (2.7 mg/kg bw/day)	400 ppm (10.8 mg/kg bw/day)
28-day, dermal rat	250 mg/kg bw/day	No systemic toxicity observed
28-day, inhalation rat	0.01 mg/L	0.03 mg/L
2-generation rat	75 ppm (8.2 mg(dg bw/day)	300 ppm (32.6 mg/kg bw/day)
Acute neurotox rat	1000 mg/kg bw	Not obtained
90-day neurotox rat	49.9 mg/kg bw/day	Not obtained
Developmental toxicity rat	10 mg/kg bw/day (maternal) 25 mg/kg bw/day (developmental)	25 mg/kg bw/day (maternal) 50 mg/kg bw/day (developmental)
Developmental toxicity rabbit	3 mg/kg bw/day (maternal) 5 mg/kg bw/day (developmental)	5 mg/kg bw/day (maternal) 10 mg/kg bw/day (developmental)
28-day immunotoxicity mouse	200 ppm (50 mg/kg bw/day)	750 ppm (191 mg/kg bw/day)

In the Annex I inclusion process the **AOEL of 0.015 mg/kg bw/day** was set based on the NOAEL of 3 mg/kg bw/day for the maternal toxicity in the rabbit developmental toxicity studies applying a safety factor of 100 and considering a 50% systemic absorption (see Pyraclostrobin Review Report (SANCO/1420/2001-final, 8 September 2004)).

The new immunotoxicity studies revealed a NOEL of 50 mg/kg bw/day which is considerably higher than the NOAEL of 3 mg/kg bw/day used for the derivation of the AOEL. Thus, the immunotoxicity studies in mice do not affect the AOEL setting.

The 28-day inhalation studies revealed a systemic NOAEC of 0.03 mg/L (30 mg/m³) and a local NOAEC of 0.01 mg/L (10 mg/m³). Thus these studies may affect the AOEL setting.

According to Snipes (Crit. Rev. Toxicol., 20(3):175-211, 1989) a respiratory minute volume of 0.2 L for a 250 g rat. Using the standard assumption of a 100% systemic absorption after inhalative exposure, a systemic inhalative dose of 2.88 mg/kg bw/day can be calculated for a 6 hour (360 min) exposure period. Using the safety factor of 100 an inhalative AOEL of 0.029 mg/kg bw/day can be calculated. As this inhalative AOEL is about two fold higher than the AOEL derived in the Annex I inclusion process, i.e. the AOEL of 0.015 mg/kg bw/day is protective for inhalative exposure, too.

Thus it is proposed to set only one **AOEL of 0.015 mg/kg bw/day**.

6.5 Summary of product exposure and risk assessment

Two representative formulations were evaluated in support of the renewal process of pyraclostrobin: **BAS 500 06 F**, an EC formulation containing 200 g/L pyraclostrobin, and **BAS 516 07 F**, a WG formulation containing 67 g/kg pyraclostrobin and 267 g/kg boscalid.
Operator, bystander, resident and worker risk evaluations for both formulations are presented below. Exposure and risk assessments were performed considering the maximum application rate of 0.25 kg/ha pyraclostrobin (1.25 L/ha BAS 500 06 F) for cereals covering the less critical use in maize. For BAS 516 07 F the considered maximum application rate was 0.25 kg/ha corresponding to 0.017 and 0.067 kg/ha for pyraclostrobin and boscalid, respectively.

6.5.1 Operators

BAS 500 06 F
BAS 500 06 F will be applied in field crops (cereals and maize), which is professional use only. The relevant application scenario is outdoor tractor operated boom sprayer with hydraulic nozzles. For operators exposed to pyraclostrobin when applying BAS 500 06 F a safe use could be demonstrated based on BBA model assessment if protective equipment (gloves during mixing/loading as well as gloves, coverall and sturdy footwear during application) is used, but no safe use could be demonstrated based on UK POEM assessments. Therefore, a refined risk assessment with higher tier data on the basis of two field exposure studies was performed.
For the refined assessment the predicted systemic exposure is within the acceptable limit thus demonstrating a safe use for pyraclostrobin when applied in cereal crops and maize at the maximum recommended application rate (predicted systemic exposure: 0.31% of AOEL).

BAS 516 07 F
BAS 516 07 F will be applied in potatoes, which is professional use only. The relevant application scenario is outdoor tractor operated boom sprayer with hydraulic nozzles. For operators exposed to pyraclostrobin and boscalid when applying BAS 516 07 F a safe use could be demonstrated based on BBA model and UK POEM assessments if no protective equipment is used. The predicted exposure corresponds to 23% of the AOEL for pyraclostrobin and 12% of the AOEL for boscalid based on UK POEM assessments, for BBA assessments the predicted exposure is less.
In conclusion operators are considered to be at acceptable risk when exposed to pyraclostrobin and boscalid under the use conditions of BAS 516 07 F in potatoes.

6.5.2 Bystander and resident exposure

The exposure assessment presented in the following is based on the German guidance paper for evaluation of bystander and resident exposure (Martin et al., 2008) for bystander and residents with adopted drift distances of 1 m for field crops.

BAS 500 06 F

For the exposure of a **bystander** passing by a cereal field treated with BAS 500 06 F, the systemic exposure to pyraclostrobin was assessed based on 5 minutes exposure applying generic spray drift deposits of 2.77% of the application rate at 1 meter distance. This estimate results in a predicted systemic exposure for adults of 5.4% of the AOEL for pyraclostrobin. For children the estimate is 4.2% of the AOEL for pyraclostrobin.

Thus, adult and child bystanders passing by a cereal or maize field treated with BAS 500 06 F are considered to be at acceptable risk.

For the exposure of **residents** located next to a cereal field treated with BAS 500 06 F the systemic exposure to pyraclostrobin was assessed based on 2 hour exposure to spray drifts via dermal route. Oral exposure of children and toddlers was considered in addition for ingestion of contaminated plant material and hand to mouth transfer of residues. Exposure to airborne concentration of vapour for non-volatile compounds such as pyraclostrobin is not considered.

This estimate results for adults in 0.7 and for children in 1.5% of the AOEL for pyraclostrobin. Thus, the exposure of adult and child residents living next to a field treated with BAS 500 06 F is considered to be safe.

In conclusion, residents are not at risk if exposed to spray drift of pyraclostrobin under the use conditions of BAS 500 06 F in cereals and maize.

BAS 516 07 F

For the exposure of a **bystander** passing by a field of potatoes treated with BAS 516 07 F, the systemic exposure was assessed based on 5 minutes exposure applying generic spray drift deposits of 2.77% of the application rate at 1 meter distance. This estimate results in a predicted systemic exposure for adults of 0.26 and of 0.12% of the AOEL for pyraclostrobin and boscalid, respectively. For children the estimate is 0.21% of the AOEL for pyraclostrobin and 0.1% of the AOEL for boscalid.

Thus, adult and child bystanders passing by a field of potatoes treated with BAS 516 07 F are considered to be at acceptable risk.

For the exposure of **residents** located next to a field of potatoes treated with BAS 516 07 F, the systemic exposure was assessed based on 2 hour exposure to spray drifts via dermal route. Oral exposure of children and toddlers was considered in addition for ingestion of contaminated plant material and hand to mouth transfer of residues. Exposure to airborne concentration of vapour for non-volatile compounds such as pyraclostrobin and boscalid is not considered.

This estimate results for adults in 0.033 and in 0.02% of the AOEL for pyraclostrobin and boscalid, respectively. For children the estimate is 0.09% of the AOEL for pyraclostrobin and 0.04% of the AOEL for boscalid. Thus, the exposure of adult and child residents living next to a field of potatoes treated with BAS 516 07 F is considered to be safe.

In conclusion, residents are not at risk if exposed to spray drift of pyraclostrobin under the use conditions of BAS 516 07 F in potatoes.

6.5.3 Workers

Estimations of potential worker exposure have been undertaken for both products based on the intended use and the following guidance for exposure prediction: EUROPOEM - Re-entry exposure model final draft, amended by more specific US EPA agricultural transfer coefficients.

BAS 500 06 F

For field crop re-entry in cereals and maize, crop inspection and scouting with a re-entry period of 2 hours was considered to be the adequate scenario. The predicted systemic exposure is about 35% of the AOEL.

It is concluded that there is no unacceptable risk anticipated for the worker wearing adequate working clothing when re-entering cereal crops and maize treated with BAS 500 06 F after the spray dilute has dried.

BAS 516 07 F

For field crop re-entry in potatoes crop inspection and scouting with a re-entry period of 2 hours was considered to be the adequate scenario. The predicted systemic exposure is about 3.3% of the AOEL for pyraclostrobin and 1.6% of the AOEL for boscalid.

It is concluded that there is no unacceptable risk anticipated for the worker wearing adequate working clothing when re-entering potatoes treated with BAS 516 07 F after the spray dilute has dried.

7 RESIDUES

7.1 Summary of storage stability of residues

Plant matrices

Freezer storage stability investigations are available for plant matrices and processed fractions. In the relevant study, the stability of pyraclostrobin and its metabolite 500M07 (synonym: BF 500-3) was investigated up to a period of 18 – 25 months. As representative commodities, peanut nutmeat, peanut oil, wheat grain, wheat straw, sugar beet tops, sugar beet roots, tomatoes and grape juice were fortified with the test items at levels of 1 mg/kg. Pyraclostrobin and 500M07 were found to be stable up to 18 – 25 months.

Animal matrices

In order to investigate the storage stability of the of BAS 500 F residues in matrices of animal origin, investigations were performed in liver, muscle and milk. These matrices are considered as representative for the matrices stored during the residue transfer study in cows, but also to a great extent for poultry.
For fortification experiments the parent compound BAS 500 F and a mixture of BAS 500 F and BF 500-10 were used. The test items selected allow analyzing according to the residue definitions for monitoring and for risk assessment purposes. Whereas for method 439/0 the parent compound is the analyte, for method 446/1, BAS 500 F and BF 500-10 are the "model" substances for the analytes 500M04 (BF 500-5) and 500M85 (BF 500-8). Samples were spiked at a 0.5 mg/kg level (liver, muscle) and at a 0.1 mg/kg level (milk) and stored below -18°C. BAS 500 F residues proved to be stable in all matrices (demonstrated by application of two methods), while BF 500-10 showed some degradation during the course of the study. As all samples from the cow feeding study were analysed within 6 months, residues were sufficiently stable during that period of storage.

7.2 Summary of metabolism, distribution and expression of residues in plants, poultry, lactating ruminants, pigs and fish

7.2.1 Plant Metabolism Studies

In the context of the previous submission, plant metabolism studies have been submitted in grapes, potatoes and wheat covering the crop categories of fruits, root & tuber vegetables and cereals (all foliar application). According to the results of these studies, BAS 500 F is intensively metabolized by mainly three key transformation steps:

- N-Desmethoxylation and O-desmethylation of the side chain
- Hydroxylation of the aromatic ring systems
- Cleavage between the ring systems

The contribution of these reactions followed by subsequent conjugation leads to a large number of metabolites.

For covering a broader use spectrum and a different application type, two new crop metabolism studies have been conducted. They were performed in wheat (seed treatment application) and in paddy rice. Besides these new studies, a cabbage metabolism study is newly submitted in the EU. This study was performed for achieving the registration in Japan.

Chinese cabbage (foliar application)
For the investigation of the metabolism of BAS 500 F, Chinese cabbage plants were treated 3 x at rates of 130 g as/ha using material labeled either in the tolyl or the chlorophenyl ring system. Leaf-ball and outer leaves samples of both labels were mainly extracted with methanol. The extractable radioactivity was characterized and quantified by radio HPLC. In addition, liquid/liquid partitioning experiments using benzene and methanol were carried out. The metabolites were identified by comparison with reference substances. Where possible, they were isolated by HPLC and their structures elucidated by LC-MS/MS.
Predominant residue in outer leaves and leaf ball consists of the parent compound pyraclostrobin and its metabolite 500M07. Some other components which were identified as products formed by cleavage of the molecule, O-glucosylation or methoxylation turned out to be of minor importance, because their respective amount is far below 10% of the TRR (amounts ranged between <0.16 and 3.65% of the TRR). The pathway in Chinese cabbage is presented in Figure 7.2.1-1.

Wheat (seed treatment)
The active substance was applied to the seeds using BAS 662 XI F blank formulation, for each label at a nominal rate of 1 x 10 g as/ha. In general, the levels of total radioactive residues (TRR) were very low (<0.010 mg/kg) in all wheat matrices (straw, hay, forage, grain) for both labels (chlorophenyl and tolyl label) indicating low translocation behavior of parent and its metabolites. Due to the low radioactivity levels only straw samples were extracted with solvent. The extractability of the radioactive residues from straw with methanol and water was moderate for both labels (63.3% TRR for the chlorophenyl label and 46.4% TRR for the tolyl label). Due to low levels of radioactivity in the Residual Radioactive Residues (RRR) after solvent extraction no further solubilization steps were performed. The nature of the residues was examined by HPLC analyses of fractions isolated from the methanol extracts of straw (both labels). Retention time comparison with authentic reference compounds suggests that the only significant peak detected most probably represents the parent compound pyraclostrobin and/or its desmethoxylated metabolite 500M07, which are co-eluting using the applied HPLC methods.
As only parent and metabolite 500M07 were detected in context of this study, no separate pathway is presented.

Paddy rice (foliar application)
For investigating the metabolism in paddy rice, two foliar spray applications were performed with BAS 500 GG F (CS formulation), each with a nominal application rate of 100 g a.s./ha. The first application was carried out at growth stage BBCH 39, the second at BBCH 69. Forage samples of both labels were taken one day before the second application. Straw, grain and spelts were sampled from mature rice plants at BBCH 89. The highest levels of total radioactive residues (TRR) were found in rice straw, in rice grain lower levels were detected for both labels. The lowest values were found in rice forage, sampled one day before the second application. The extractability with methanol and water was high in rice forage; for rice straw and grain, it was slightly lower. From all matrices the major part of the radioactivity was extracted with methanol. The nature of the residues was examined by HPLC analysis of the methanol and water extracts. Metabolites were identified by mass spectrometric analysis and/or co-chromatography experiments.

The by far predominant residues of ^{14}C-pyraclostrobin in rice consisted of the unchanged parent compound and its desmethoxy metabolite 500M07. In rice forage, straw and grain of both labels pyraclostrobin was the main component identified, ranging from 41.5% - 73.3% TRR. Metabolite 500M07 was found in all matrices as the second most prominent compound (from 8.0% to 17.3% TRR). Some further polar and medium polar components were characterized by their HPLC elution behavior and were all clearly below 10% TRR. The Residual Radioactive Residue (RRR) after solvent extraction was characterized using a sequential solubilization procedure with aqueous ammonia solution and enzymes that released further portions of 4.9% - 16.7% TRR. The ammonia and enzyme solubilizates of straw (both labels) were analyzed by HPLC. Like in the water extracts several components eluting in the range between 15 min and about 30 min were detected and characterized by their HPLC elution behavior. Higher levels of non-extractables found in straw and grain, are partially incorporated in or associated with cellulose, lignin, starch or protein. The pathway in rice is shown in Figure 7.2.1-2.

The newly performed studies did not result in the formation of any new metabolite. The metabolic pathways are indicating the same degradation behavior with BAS 500 F as key component, followed by the desmethoxy metabolite 500M07 (synonym: BF 500-3).
An overall proposed pathway for all the plant matrices analyzed (foliar application: grapes, potatoes, Chinese cabbage, rice, wheat; seed treatment: wheat) is presented in Figure 7.2.1-3.

Besides these new studies, a supplementary document (non-GLP) to the grape metabolism study was prepared upon request of Japanese authorities. Purpose of the document was to clarify the way of metabolite identification, which is based on extracts from grape leaves.

7.2.2 Livestock Metabolism Studies

Poultry

For Annex I inclusion (Directive 91/414/EEC) a poultry metabolism study was carried out after dosing of tolyl-^{14}C and chlorophenyl-^{14}C labeled pyraclostrobin.

The metabolism and distribution of ^{14}C-BAS 500 F in laying hens was investigated following repeated oral administration of ^{14}C-BAS 500 F at one dose level. The test items were administered to two groups of hens using two different radiolabels. The chlorophenyl label was applied at a dose of 12 mg/kg feed, and the tolyl label was fed at a dose of 13 mg/kg feed, both by gavage and on seven consecutive days. The dose levels corresponded to 0.70 mg/kg body weight (chlorophenyl label) and 0.88 mg/kg body weight (tolyl label).

Pyraclostrobin (BAS 500 F) is rapidly absorbed, distributed and excreted. In hens dosed with 12 mg/kg feed, the residues in muscle were below 0.010 mg/kg. Consequently, no further investigations were carried out. In fat and eggs, pyraclostrobin and the desmethoxy metabolite 500M07 formed the major part of the residue, whereas in liver hydroxylation reactions partly followed by conjugation were predominant.

In detail, five routes of biotransformation were detected: First, the predominant transformation was the desmethoxylation step. Second, the desmethoxylated metabolite 500M07 was hydroxylated at the tolyl ring followed by conjugation with glucuronic acid. Third, the desmethoxylated metabolite was hydroxylated at the chlorophenyl ring or at the pyrazole ring again followed by a conjugation reaction with glucuronic acid. Fourth, the parent compound was hydroxylated at the chlorophenyl ring in para-position whereby the Cl-atom was shifted to the meta-position. Fifth, the parent compound was cleaved at the methylene ether bridge. A specific variation was the substitution of the Cl-atom by glucuronic acid.

These metabolic degradation steps are in accordance with the metabolic transformation steps known from plants but also from other species. The metabolic pathway in hen is included in Figure 7.2.2-4.

Lactating ruminants

For Annex I inclusion (Directive 91/414/EEC) a goat metabolism study was carried out after dosing of the tolyl-^{14}C and chlorophenyl-^{14}C labeled test substance.

The metabolism and distribution of ^{14}C-BAS 500 F was investigated in lactating goats following repeated oral administration of ^{14}C-BAS 500 F at two dose levels. The test compound was administered daily on 5 consecutive days at nominal dose levels of 12 mg/kg and 50 mg/kg feed. The intention of the low dose level was to simulate a dose which would be close to the expected residue level in plant parts to be used as feed items. This dose level would allow judgement whether residues are likely to occur in ruminants under normal agricultural practice. The additional high dose level was added in order to facilitate metabolite identification and characterisation. Following administration of ^{14}C-BAS 500 F to lactating goats, the radioactivity was rapidly and almost completely excreted; excretion mainly occurred via faeces. There was no indication of accumulation of ^{14}C-BAS 500 F in goat milk and tissues. The total radioactive residues in the edible portions of the 12 mg/kg dose group, which is close to the residue level in plant parts to be fed, were low.

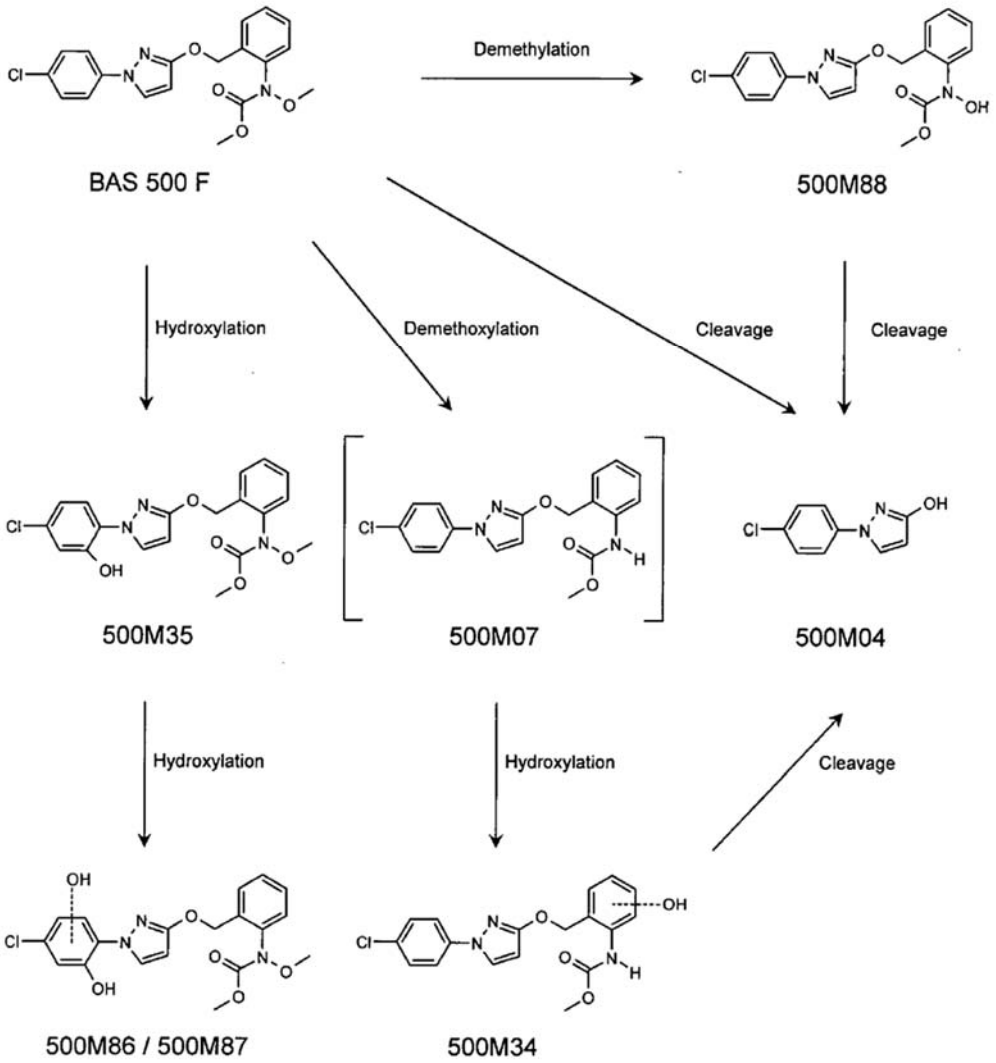
In goats, ^{14}C-BAS 500 F is metabolised by three key transformation steps which are identical to the ones found in hen: (1) desmethoxylation at the oxime ether bond (2) hydroxylation of the chlorophenyl, the pyrazole and/or the tolyl ring system and (3) cleavage between both ring systems and subsequent oxidation of the two resulting molecule parts.

In muscle and fat, BAS 500 F and the desmethoxy metabolite 500M07 were detected as the only residue. In milk, liver and kidney the situation was more complex. In milk, metabolites derived from the cleavage reaction (as 500M04, 500M05 and 500M85) were predominant besides BAS 500 F. In liver and kidney, hydroxylation reaction in various positions of the aromatic ring systems led to the metabolites 500M08, 500M39, 500M45, 500M64, 500M66 and 500M67. In liver the cleavage reaction is less pronounced, whereas in kidney the cleavage product 500M51 was found. The metabolic pathway in goat is included in Figure 7.2.2-4. The non-extractable residues of liver and kidney (high dose) were further characterised by pronase treatment and acid hydrolysis.

Upon request of the Australian authority, an *in vitro* comparison study was performed for goat and cow cell cultures. In order to allow a comprehensive overview, the study summary of these supplemental investigations are provided in context of this dossier.

Goat and cow microsomes and hepatocytes were incubated with the chlorophenyl-^{14}C labeled test substance. BAS 500 F was similarly metabolized by goat and cow microsomes. All metabolites identified in samples from incubations with cow microsomes were also found in the experiments with goat microsomes. The appearance of the main metabolite 500M04 was independent from the microsomes` origin and resulted from cleavage of the ether bond. It was already identified in a previous *in vivo* goat study as one of the key degradation products of BAS 500 F. The metabolites 500M88 (demethylation of the N-methoxycarbamate group) and 500M34 (desmethoxylation of the N-methoxycarbamate group and hydroxylation of the benzylic ring) were further common metabolites found after incubation of BAS 500 F with goat or cow microsomes. Hydroxylation reactions of the chlorophenyl moiety played only a minor role in the *in vitro* biotransformation route of BAS 500 F. The pathway in cow and goat microsomes is presented in Figure 7.2.2-1.

Figure 7.2.2-1: Proposed metabolic pathway of pyraclostrobin in *in vitro* investigations of goat and cow



Pigs

According to Reg. 283/2013, pig metabolism studies shall be provided where the plant protection product is used in crops whose parts or products, also after processing, are fed to pigs and where it becomes apparent that metabolic pathways differ significantly in the rat as compared to ruminants and where the intake is expected to exceed 0.004 mg/kg bw/day.
For pyraclostrobin, no metabolism study was performed in pigs, since the metabolite patterns in rodents (rats) and ruminants (goats) did not show any difference.

Fish

In order to fulfill the requirements of Reg. 283/2013, two studies are submitted in this dossier. According to Reg. 283/2013, metabolism studies on fish may be required where the plant protection product is used in crops whose parts or products, also after processing, are fed to fish and where residues in feed may occur from the intended applications. Pyraclostrobin is registered in the majority of crops being intended as fish feed item. In most of these crops residue levels above LOQ occur.

The bioaccumulation study in bluegill sunfish has been performed in 1999 and was already evaluated as part of the ecotox section during the previous Annex I inclusion process. In the study the tolyl-^{14}C and chlorophenyl-^{14}C labeled test substance was applied to water. The study includes the identification of metabolites in edible and inedible portions of bluegill sunfish.
After exposure of fish to BAS 500 F at a nominal exposure level of 300 ng/L, apparent steady state was reached after 2 - 4 days. After termination of the exposure, radioactivity levels in fish tissues decreased rapidly with a half-life of *ca.* 0.7 – 1.0 days. Bioconcentration factors based on total radioactivity were relatively low in edibles (232 - 262) and relatively high in inedible (1169 - 1221). For unchanged parent compound, the BCF values were considerably lower in all tissues, which is an indication for an intensive metabolic clearance of BAS 500 F. Only minor differences were observed between the two labelled forms of the test compound with regard to the kinetic parameters.
In the edible tissues pyraclostrobin formed the major part of the residue, followed by 500M07. Cleavage of the ether bond resulting in the formation of the metabolite 500M04 occurred to a minor extent and mainly in the inedible portion of fish (see Figure 7.2.2-2).

For fulfilling Reg. 283/2013, a fish metabolism study was performed in which rainbow trouts were dosed orally via feed. During the study, the test item was dosed to the fish for 10 consecutive days for both labels at a nominal level of 10 mg/kg. After 10 days, the fish were killed and edible tissues (liver, filet and filet skin) and pyloric caeca removed post mortem.
The investigation of the samples of both labels showed comparable TRR levels. In all matrices (filet, filet skin, liver) and in both labels (chlorophenyl and tolyl) most of the extracted residues consisted of unchanged parent (70.4-93.1% TRR; 0.210-0.409 mg/kg). Only minor amounts of the metabolite 500M89 (Reg.no. 334089) were detected in extracted residue (1-4% TRR; 0.006-0.011 mg/kg). Taking the actual feed burden and the overdosing factor (8x) into account, no significant residues of 500M89 will occur when fish are fed with commodities being treated with pyraclostrobin. Reactions leading to a cleavage of the molecule between the ring systems did not occur. A degradation to polar residues occurred to a minor extent and at ranges of 1-7% TRR (0.005-0.037 mg/kg). In liver ca. 8-11% TRR (0.044-0.054 mg/kg) were incorporated in the tissue and just releasable with digestive enzymes. The pathway is presented in Figure 7.2.2-3. The results are in accordance with those obtained during the BCF study and they are included in Figure 7.2.2-4.

7.3 Definition of the residue

The residue definitions currently established in the EU, but also supported in future, are compiled in the table below. In sections M-CA 6.7 and M-CA 6.9, detailed justifications for BASF's proposal are provided. The proposal is based on a careful evaluation of all studies being available at the time point of submission. Consequently, it includes considerations for all those crops for which an EU MRL is established. It is not limited to the intended uses in potatoes, cereals and maize.

7.3.1 Plant Matrices

For pyraclostrobin, plant metabolism studies have been performed in fruits, root & tuber vegetables, leafy vegetables and cereals (wheat, paddy rice) covering both, foliar and seed treatment applications. During these investigations, samples/matrices were analyzed which serve either as animal feed or human food. Two confined rotational crop studies were additionally conducted. After application of pyraclostrobin to bare soil, representative crops (typically small grain, leafy crops and root vegetables) were investigated at different replant intervals (emergency plant back, fall plant back, annual plant back).

In general, pyraclostrobin follows a common pathway in all crops and independent from the type of application. The following metabolic conversion steps were observed in the plant metabolism, hydrolysis (simulating processing) and the succeeding crop studies:

- Desmethoxylation of the side chain resulting in the metabolite 500M07
- Cleavage between the ring systems resulting in the metabolites 500M04 (followed by conjugation reactions)
- Cleavage between the ring systems resulting in the metabolites 500M24, 500M49 and 500M72 (tryptophan)
- Hydroxylation of the chlorophenyl pyrazole moiety (followed by conjugation)
- Hydroxylation of the tolyl moiety (followed by conjugation)
- Photolytic rearrangement reaction resulting in the metabolite 500M76

In almost all samples investigated from metabolism studies, the parent molecule forms by far the predominant residue followed by the metabolite 500M07. All other metabolites are present in significantly lower amounts, but also not consistently in all crops or commodities.

Residue definition for monitoring purposes

The analyte(s) to be selected for monitoring purposes should occur in large quantities, and should be common to all commodities in which residues are expected. Ideally, the monitoring method should be based on one single analyte (‘marker or indicator compound’).

In case of pyraclostrobin and its metabolites in food of plant origin, there is only one component which meets all criteria listed in the OECD guidance document. Based on the studies available, the following residue definition is proposed for monitoring purposes in plant commodities (including processing fractions thereof):

Pyraclostrobin, parent only

Residue definition for data generation / risk assessment purposes

In order to propose a suitable residue definition for risk assessment purposes, the pyraclostrobin metabolites found in the plant metabolism studies and during processing were grouped in total into six different groups.

- Group 1: Desmethoxy metabolite 500M07 (synonym: BF 500-3)
- Group 2: Chlorphenyl pyrazole derivatives
- Group 3: Anthranilic acid derivatives 500M24 and 500M49
- Group 4: Hydroxylated metabolites (chlorphenyl pyrazole moiety)
- Group 5: Hydroxylated metabolites (tolyl moiety)
- Group 6: Photo metabolite 500M76

The dietary exposure for each group was assessed separately for identifying the contributions of the plant metabolites to the total dietary risk. Due to obvious reasons no assessment has been performed for the metabolite 500M72, which has been identified as the natural amino acid tryptophan. Due to their absence in succeeding and root crops even at exaggerated rates, the same applies for the aerobic soil metabolites 500M01 and 500M02. The assessments were limited to those target crops from which a contribution to the dietary risk could be expected.

For deriving residue levels to be used in chronic and acute exposure assessments, the following studies were additionally considered:

- Magnitude of residue studies in target crops (supervised field trials)
- Magnitude of residues in processed commodities

Table 7.3.1-1: Contribution of pyraclostrobin plant metabolites to chronic dietary risk

Metabolite group - Metabolites	ADI used [mg/kg bw / day]	ADI utilization [%]	Comment
1 - 500M07	0.03	< 2%	Indicative assessment covering all target crops (worst case)
2 - 500M04 and conjugated	0.52	< 0.1%	
3 - 500M24	0.0015 (TTC)	< 9%	Cereal grain
3 - 500M49	0.0015 (TTC)	0.1%	Oilseeds
3 - 500M51	0.0015 (TTC)	n.a.	Metabolite only found in livestock metabolism studies
4 - Hydroxylated metabolites (chlorphenyl pyrazole moiety)	0.03	0.6%	
5 - Hydroxylated metabolites (tolyl moiety)	0.03	0.6%	
6 - 500M76	0.0015 (TTC)	0.2%	

Table 7.3.1-2: Contribution of pyraclostrobin plant metabolites to acute dietary risk

Metabolite group - Metabolites	ARfD used [mg/kg bw / day]	ARfD utilization [%]	Comment
1 - 500M07	0.03	max. 30% (celery, onions)	Refined for table grapes, apples and scarole
2 - 500M04 and conjugated	n.a.	n.a.	
3 - 500M24	0.005 (TTC)	not relevant	Metabolite only found in wheat metabolism study (grain)
3 - 500M49	0.005 (TTC)	0%	
3 - 500M51	0.005 (TTC)	n.a.	Metabolite only found in livestock metabolism studies
4 - Hydroxylated metabolites (chlorphenyl pyrazole moiety)	0.03	8% (melons) 7% (water melons) 5% (table grapes)	Refined for table grapes, apples and scarole
5 - Hydroxylated metabolites (tolyl moiety)	0.03	11% kale 8% (melons) 7% (water melons)	Refined for table grapes, apples and scarole
6 - 500M76	0.005 (TTC)	15% (kale) 9% (globe artichoke) 8% (Chinese cabbage)	Refined for scarole

The data show that the contributions of the metabolites to the dietary risk are small even under unrealistic worst case assumptions. None of the groups should be included in the residue definition for dietary risk assessment. Due to the favorable outcome, no further refinement than indicated above was performed (e.g. by inclusion of processing factors for vegetable crops, which are always cooked prior to consumption).

Following this indicative assessment based on an in-depth analysis of all metabolism, residue and processing fraction studies, the residue definition shown below is proposed for risk assessment in plant commodities (including processing fractions thereof):

Pyraclostrobin, parent only

7.3.2 Animal matrices

In general, pyraclostrobin follows a common pathway in different livestock species, which is also comparable to the one observed in rats. As in plant matrices, the following metabolic conversion steps were observed in the relevant studies:

- Desmethoxylation of the side chain resulting in the metabolite 500M07
- Cleavage between the ring systems resulting in the metabolites 500M04, 500M05 and 500M85
- Cleavage between the ring systems resulting in the metabolites 500M49 and 500M51
- Hydroxylation of the chlorophenyl pyrazole moiety (followed by conjugation)
- Hydroxylation of the tolyl moiety (followed by conjugation)

Besides these steps, metabolite 500M89 was identified in fish in very low amounts; it is formed by desmethylation.

In the majority of samples investigated (poultry: fat and eggs, goat: milk, meat and fat), the parent molecule forms a predominant part of the residue followed by the metabolite 500M07. In milk, the cleavage products 500M04 and 500M05 are present in the same amounts as parent. Especially in goat liver, but also kidney, relatively high amounts of radioactivity were incorporated into tissues, which could be at least partly released by enzymatic techniques. After applying harsh conditions (refluxing with hydrochloric acid), the metabolites 500M04 and 500M85 were detected in the hydrolyzate. All other metabolites are present in significantly lower amounts, but also not consistently in all livestock commodities.

Residue definition for monitoring purposes

For the residue definition in animal commodities the same criteria apply as for plants. The analyte(s) to be selected for monitoring purposes should occur in large quantities, and should be common to all commodities in which residues are expected. Ideally, the monitoring method should be based on one single analyte (‘marker or indicator compound’).

In case of pyraclostrobin and its metabolites in food of animal origin, there is only one component which meets most of the criteria listed in the OECD guidance document. Based on the studies available, where unchanged pyraclostrobin formed a considerable part of the residue in food items being highly consumed (milk for small children, meat and fat for all subpopulation groups), the following residue definition is proposed for monitoring purposes in animal commodities:

Pyraclostrobin, parent only

Residue definition for data generation / risk assessment purposes

In order to propose a suitable residue definition for risk assessment purposes, the pyraclostrobin metabolites found in livestock metabolism studies were grouped in total into five different groups. The grouping followed the same principles as for plants, but without group 6 ("photo metabolite").

- Group 1: Desmethoxy metabolite 500M07 (synonym: BF 500-3)
- Group 2: Chlorphenyl pyrazole derivatives
- Group 3: Anthranilic acid derivatives 500M49 and 500M51
- Group 4: Hydroxylated metabolites (chlorphenyl pyrazole moiety)
- Group 5: Hydroxylated metabolites (tolyl moiety)

The dietary exposure for each group was assessed separately for identifying the contributions of the livestock metabolites to the total dietary risk. For deriving residue levels to be used in chronic and acute exposure assessments, the following studies were additionally considered:

- Magnitude of residue study in cows
- Magnitude of residue study in hens

Table 7.3.2-1: Contribution of pyraclostrobin livestock metabolites to chronic dietary risk

Metabolite group - Metabolites	ADI used [mg/kg bw / day]	ADI utilization [%]	Comment
1 - 500M07	0.03	< 0.1%	
2 - 500M04 and conjugates	0.52	< 0.1%	
3 - 500M24	0.0015 (TTC)	n.a.	Metabolite only found in wheat metabolism study (grain)
3 - 500M49	0.0015 (TTC)	0%	
3 - 500M51	0.0015 (TTC)	0%	
4 - Hydroxylated metabolites (chlorphenyl pyrazole moiety)	0.03	0.1%	
5 - Hydroxylated metabolites (tolyl moiety)	0.03	< 0.1%	

Table 7.3.2-2: Contribution of pyraclostrobin livestock metabolites to acute dietary risk

Metabolite group - Metabolites	ARfD used [mg/kg bw / day]	ARfD utilization [%]	Comment
1 - 500M07	0.03		
2 - 500M04 and conjugates	n.a.	n.a.	
3 - 500M24	0.005 (TTC)	n.a.	Metabolite only found in wheat metabolism study (grain)
3 - 500M49	0.005 (TTC)	max. 0.2% (poultry liver)	
3 - 500M51	0.005 (TTC)	max. 0.2% (bovine kidney)	
4 - Hydroxylated metabolites (chlorphenyl pyrazole moiety)	0.03	< 1% (milk)	
5 - Hydroxylated metabolites (tolyl moiety)	0.03	< 0.5% (milk)	

The data demonstrate that the contributions of the individual metabolites to the dietary risk at realistic dose levels are considerably lower than for parent.

The proposal below is based on the indicative assessment, but also takes the findings of the cow feeding study into account, where residues of 500M04 and 500M85 were found in liver (realistic feed burden), milk and kidney (10x to 20x).

Accordingly, the following residue definition is proposed for risk assessment in animal commodities:

Pyraclostrobin and its metabolites analysed as the hydroxypyrazoles 500M04 (synonym BF 500-5) and 500M85 (synonym BF 500-8), sum expressed as pyraclostrobin

7.4 Summary of residue trials in plants and identification of critical GAP

Pyraclostrobin is registered in multiple crops belonging to different EU crop groups. Within this dossier, residue data are only provided for the representative uses supporting the renewal process. As formulations the solo EC formulation BAS 500 06 F and the mixed WG formulation BAS 516 07 F (containing pyraclostrobin and boscalid) were selected.

In this dossier section the relevant data for the following crops are summarized:

- Potatoes (BAS 516 07 F)
- Wheat, barley (BAS 500 06 F)
- Maize (BAS 500 06 F)

According to the European Commission guidance on extrapolation and group tolerances (SANCO 7525/VI/95-rev 9, March 2011), the data provided allow extrapolation to other crops such as triticale, rye and oats.

The studies provided for potatoes and cereals in this dossier have been submitted before in context of national or zonal registration dossiers. They have not been evaluated within the MRL re-evaluation process according to Reg. 396/2005, Art. 12. Consequently, they are not considered as peer-reviewed. In case of maize and sweet corn and driven by the high importance of maize silage as feed item, parts of the studies had been provided to EFSA in context of the MRL evaluation process. The studies, which had been assessed before, are clearly indicated so that a differentiation between “old” and new data should be possible.

In chapter M-CA 6.7 the residue levels found in samples destined for human food or for animal feed are compared with the data already being evaluated by EFSA. For the desmethoxy metabolite, the codes 500M07 and BF 500-3 are used synonymously.

7.4.1 Target crops

7.4.1.1 Root and tuber vegetables: Potatoes

The formulation BAS 516 07 F is registered in the Northern part of the EU. Due to the favorable residue behavior in potatoes with residues consistently below the LOQ of 0.02 mg/kg at all sampling intervals, only a reduced number of residue data is required.

In order to allow a more comprehensive evaluation in potatoes, the residue trials with the formulation BAS 536 01 F are additionally summarized. As shown in the table below, the mixed formulation containing pyraclostrobin and dimethomorph is registered at higher rates (100 g BAS 500 F / ha compared to 17 g BAS 500 F / ha) and also in more countries. The results obtained confirm the favorable residue behavior since even at the higher rates the residues found in tuber were well below the LOQ of 0.02 mg/kg.

Table 7.4.1.1-1: Summary of the critical GAP for the proposed use in potatoes for BAS 516 07 F

Crop	Outdoor/ Protected	Growth stage (BBCH)	Maximum Number of Applications	Minimum Application Interval (days)	Maximum		Minimum PHI (days)
					Rate* (kg as/ha)	Water (L/ha)	
Potatoes (N-EU)	O	41 – 89	4	5 - 10	0.017	150-1000	0-3

* amount of pyraclostrobin per ha and application

Table 7.4.1.1-2: Summary of the critical GAP for the proposed use in potatoes for BAS 536 01 F (supplemental information)

Crop	Outdoor/ Protected	Growth stage (BBCH)	Maximum Number of Applications	Minimum Application Interval (days)	Maximum		Minimum PHI (days)
					Rate* (kg as/ha)	Water (L/ha)	
Potatoes (N-EU)	O	10 – 89	3	5	0.100	100-400	7
Potatoes (S-EU)	O	10 - 89	3	5	0.100	100-1000	3

* amount of pyraclostrobin per ha and application

In 2003, in total six trials were performed with the formulation BAS 516 00 F. In these trials, an application rate of 20 g as/ha was applied 4 times.

In the growing season 2005, in total ten field trials were performed in Northern Europe (Germany, Belgium, Denmark and Northern France) and Southern Europe (Italy, Spain, Greece and Southern France). The trials were conducted with formulation BAS 536 01 F according to the critical GAP of this formulation (± 25%).

In the growing season 2015, in total four field trials were performed in Southern Europe (Italy, Spain, Greece and Southern France). The trials were conducted with formulation BAS 516 07 F according to the critical GAP of this formulation (± 25%).

For deriving a MRL proposal, the more critical GAP which is applied with BAS 536 01 F was considered.

Northern Europe (n=5): 5 x <0.02 mg/kg

Southern Europe (n=5): 5 x <0.02 mg/kg

In none of the trials any detectable residue above the limit of quantitation (LOQ) of 0.02 mg/kg was found.

7.4.1.2 Cereals

Multiple residue studies had been performed in cereals for the active substance pyraclostrobin using solo and mixed formulations. The residue data were evaluated during the previous Annex I inclusion process, various national submissions, but also in context of the EU MRL re-evaluation according to Reg. 396/055 Art. 12. They were considered as suitable for establishing an EU MRL for wheat (including triticale), rye, barley and oats. Between 1998 and 2005 more than 70 trials were conducted in representative growing areas of the Northern and Southern part of Europe. In the trials, two applications were performed at 250 g as/ha.

Despite the broad coverage, new residue trials in cereals have been performed between 2009 and 2012. The purpose of these trials was to provide a consistent residue data package for the formulation BAS 500 06 F, but also to ensure that the residue levels in grain are covered by the established EU MRLs. The trials were performed in accordance with the most critical registered GAP (see table below).

Table 7.4.1.2-1: Summary of the critical GAP for the proposed use in cereals for BAS 500 06 F

Crop	Outdoor/ Protected	Growth stage (BBCH)	Maximum Number of Applications	Minimum Application Interval (days)	Maximum		Minimum PHI (days)**
					Rate* (kg as/ha)	Water (L/ha)	
Barley	O	25 - 69	2	21	0.25	100 – 400	35
Oats	O	25 - 69	2	21	0.25	100 – 400	35
Wheat	O	25 - 69	2	21	0.25	100 – 400	35
Triticale	O	25 - 69	2	21	0.25	100 – 400	35
Rye	O	25 - 69	2	21	0.25	100 – 400	35

* amount of pyraclostrobin per ha and application
** for cereal crops the actual preharvest interval is defined by the latest growth stage of application (which is BBCH 69)

Cereals: Barley

In the growing seasons 2009 - 2012, in total 28 barley field trials comprising 36 plots were performed in Northern Europe (Germany, The Netherlands, Denmark, Northern France and United Kingdom) and Southern Europe (Italy, Spain, Greece and Southern France). The trials were conducted with formulations BAS 500 06 F, BAS 702 01 F and BAS 703 04 F according to the critical GAP of formulation BAS 500 06 F (± 25%).

The following parent compound residues were found in barley grain samples at a PHI of 35 days or later:

Northern Europe (n=18): 0.02, 0.039, 0.043, 0.056, 0.06, 0.065, 0.07 (2x), 0.08, 0.09 (2x), 0.10, 0.11, 0.21, 0.22, 0.25, 0.35, 0.82 mg/kg

Southern Europe (n=18): <0.01 (3x), 0.02 (2x), 0.029, 0.03 (3x), 0.039, 0.06, 0.09, 0.11, 0.13, 0.14, 0.15, 0.27, 0.54 mg/kg

Cereals: Wheat

In the growing seasons 2010 - 2012, in total 24 wheat field trials comprising 28 plots were performed in Northern Europe (Germany, The Netherlands, Denmark, Northern France and United Kingdom) and Southern Europe (Italy, Spain, Greece and Southern France). The trials were conducted with formulations BAS 500 06 F and BAS 703 04 F according to the critical GAP of formulation BAS 500 06 F (± 25%).

The following parent compound residues were found in wheat grain samples at a PHI of 35 days or later:

Northern Europe (n=14): <0.01 (7x), 0.016, 0.02 (3x), 0.03, 0.039, 0.14 mg/kg

Southern Europe (n=14): <0.01 (7x), 0.01 (2x), 0.011, 0.015, 0.017, 0.02 (2x) mg/kg

7.4.1.3 Maize

The use in maize was not part of the previous Annex I inclusion process. It was submitted for the first time in Europe in summer 2010. The dRR was intended to achieve the registration of the mixed formulation BAS 512 16 F (containing the active ingredients pyraclostrobin and epoxiconazole) in maize. Subsequently to this submission, further draft Registration Reports were provided to countries acting as zonal RMS. The trials supporting a registration of the solo formulation BAS 500 06 F were partly included since the trials were performed side-by-side at the same locations.

After submission, Germany has prepared an evaluation report on the MRLs for maize, which was provided to EFSA in summer 2011. Based on the evaluation report EFSA has published a Reasoned Opinion (Feb 2012), in which the use in maize and its impact on the dietary feed burden calculations were investigated.

In order to allow a comprehensive evaluation of the formulation BAS 500 06 F, the old and the new data are summarized in M-CA 6.3.3.

Table 7.4.1.3-1: Summary of the critical GAP for the proposed use in maize and sweet corn for BAS 500 06 F

Crop	Outdoor/ Protected	Growth stage (BBCH)	Maximum Number of Applications	Minimum Application Interval (days)	Maximum		Minimum PHI (days)
					Rate (kg as/ha)	Water (L/ha)	
Maize	O	65	1	n.a.	0.2	100 - 400	F
Sweet corn	O	65	1	n.a.	0.2	100 - 400	F

n.a. = not applicable
F = defined by application at last growth stage

In the period from 2008 to 2009, in total 16 residue trials were performed in maize in the EU; 8 trials were located in the Northern Region and 8 in the Southern Region. The formulations BAS 512 04 F (133 g/L pyraclostrobin and 50 g/L epoxiconazole, SE) and BAS 500 06 F (200 g/L of pyraclostrobin, EC) were applied once at a rate of 1.5 L/ha and 1 L/ha, respectively, according to GAP ± 25%. Maize grain was collected at crop maturity (BBCH 89) corresponding to 49 - 99 DALA.

Additionally, in the growing seasons 2012 and 2013, five trials were performed in Northern Europe (Germany, The Netherlands, United Kingdom, Northern France and Belgium) and four were performed in Southern Europe (Italy, Spain, Greece and Southern France). In these trials, formulation BAS 500 06 F was applied according to the critical GAP. Maize grain was collected at crop maturity (BBCH 89) corresponding to 34 - 85 DALA.

The trials fulfill the requirements concerning the geographical and the seasonal distribution. The evaluation of the residue data led to the conclusion that there is no significant difference of the residue behavior regarding different seasons, formulations or regions in North and South EU.

In none of the trials any detectable residue above the limit of quantitation (LOQ) was found.

Sweet corn, barley straw, maize (as feed item) and wheat straw
For all these commodities sufficient residue values were determined and MRLs or pseudo-MRLs could be calculated. The collected relevant residue values and MRL calculations can be found in chapter M-CA 6.7.2.

7.5 Summary of feeding studies in poultry, ruminants, pigs and fish

Poultry

A hen feeding study was performed for registration purposes in the US. In the study hens were dosed at three different dose levels (0.3, 0.9 and 3.0 mg/kg feed) corresponding to approximately 0.5x, 1.5x and 5x of the expected maximum EU feed burden. The samples were analysed using the common moiety approach which covers parent type metabolites and metabolites hydroxylated in the chlorophenyl ring system. The study is only considered as supplemental information as the results from the hen metabolism study indicate a low likelihood of any detectable residues in hen tissues or eggs. The outcome of the study confirmed the conclusions drawn from the metabolism study. Even at the highest dose level (3.0 mg/kg), pyraclostrobin total residues were below the level of quantitation of the common moiety approach applied (LOQ, 0.05 mg/kg per analyte). As the parent molecule is fully covered by the common moiety approach, the residues of pyraclostrobin in hen tissues and eggs were also <0.05 mg/kg. Based on these results, the samples from the 0.5x, 1.5x and depuration groups were not further analyzed.

Ruminants

A residue transfer study with BAS 500 F was conducted in cows. The animals were dosed with 7, 21 and 70 mg/kg feed (dry matter) equal to 140, 420 and 1400 mg/animal and day for a period of 28 days. The samples were analyzed with two methods.

- The analysis according to the single analyte method covering exclusively pyraclostrobin (as proposed for enforcement purposes), did not result in any detectable residue even at the 10 x dose.
- Analysis was also performed according to the common moiety approach, which corresponds to the proposed residue definition for risk assessment. In the dose group relevant under normal agricultural conditions (7 mg/kg feed), no residues could be detected in milk, meat, fat and kidney. Low residues of BAS 500 F metabolites may occur in liver. In the 10 x group (70 mg/kg feed) residues could be detected; the highest levels occurred in liver. The hydroxylated metabolites (pyrazole ring system) formed the major part of residues.

Pig

In case of pyraclostrobin, the metabolism in rats and ruminants are similar. Therefore, no pig feeding study is required.

Fish

According to the Commission Regulations (EU) No 283/2013 (active substances) and 284/2013 (plant protection products) as of 1 March 2013, metabolism studies on fish and fish feeding studies might be required in future (latest by 31 Dec 2015), if residues occur in crops that are intended as feed items for fish. As pyraclostrobin is intended to be used in several crops being fed to fish, a fish metabolism study was performed. The study is reported in section M-CA 6.2. It is considered as suitable for deriving a MRL proposal, despite MRLs will not be set in close future for fish matrices. Due to this fact, but also driven by the lack of any suitable EU guideline / guidance document for the conduct of fish feeding studies, the study is not required.

7.6 Summary of effects of processing

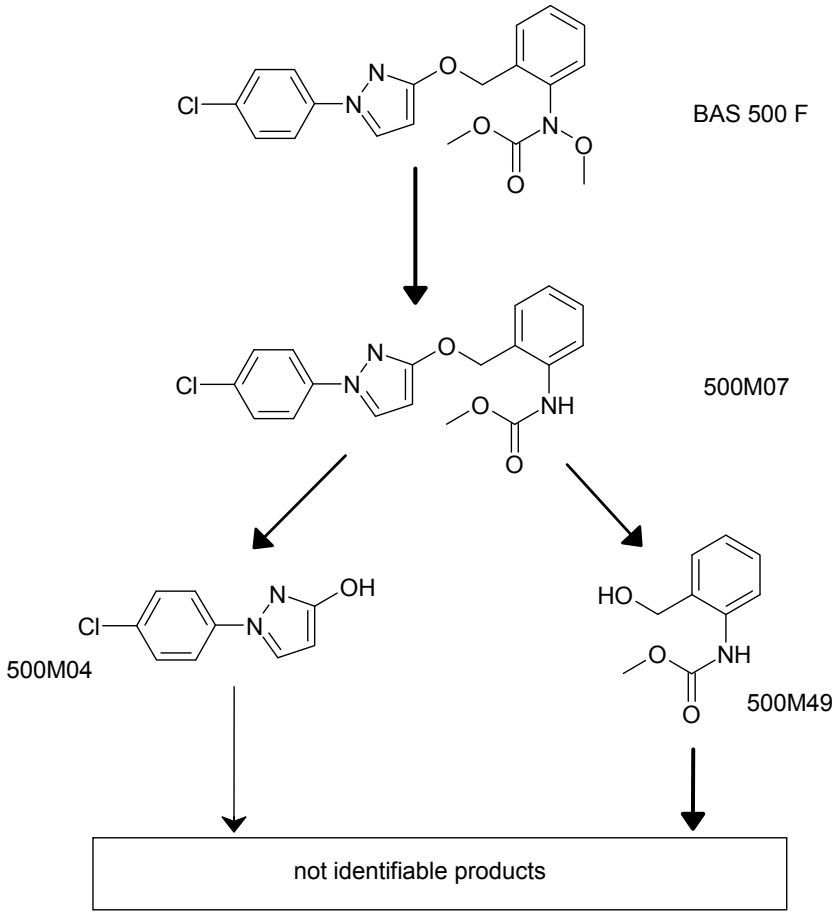
7.6.1 Nature of residues

During the registration according to Directive 91/414/EEC, a study was conducted simulating representative hydrolytic conditions for pasteurization (20 minutes at 90°C, pH 4), boiling/brewing/baking (60 minutes at 100°C, pH 5) and sterilization (20 minutes at 120°C, pH 6). This study, which was evaluated during the previous Annex I inclusion process, demonstrates that food processes such as brewing, cooking, sterilization or pasteurization, will not impact the nature of pyraclostrobin residues. Pyraclostrobin was found to be stable under the test conditions applied.

Upon request of Italy, a ^{14}C study was performed simulating processing conditions of oil purification (deodorization step from raw to refined oil). The hydrolytic degradation of pyraclostrobin was investigated at high temperatures in an olive oil / water mixture to simulate the process of olive oil raffination (deodorization step from raw oil to refined oil). The study was performed with ^{14}C-pyraclostrobin labeled at the chlorophenyl and at the tolyl ring. The test substance was applied into a mixture of olive oil and aqueous sodium chloride solution (in a ratio of 2:1) at a rate of 1 mg/mL and heated up to 190°C ± 5°C and 240°C ± 5°C for 30 minutes. After the incubation, the mixture was analyzed for the parent compound and possible transformation products. Phases and extracts of them were analyzed by LSC, HPLC-MS/MS and radio TLC.

In the study, an extensive degradation of the test item was observed at both temperatures. In almost all samples the same metabolites were found in different compositions. Hydrolytic degradation of the parent compound at 190°C resulted in the formation of the metabolite 500M07, which was then degraded to 500M49 and 500M04. At 240°C further degradation occurred. Parent and the metabolite 500M07 were only found in minor amounts. While for the chlorophenyl label the metabolite 500M04 was the major component, for the tolyl label most of the radioactivity present could be only characterized. Intensive characterization attempts were undertaken using different enzymes (lipase, pepsin, pancreatin), but also chromatographic techniques. They did not indicate the presence of any individual or distinct metabolite. The metabolite 500M07 was still the most abundant peak, which could be identified, followed by metabolite 500M49.

Figure 7.6.1-1: Proposed metabolic pathway of pyraclostrobin during oil processing



The results of this study were considered for proposing suitable residue definitions in plant matrices.

7.6.2 Magnitude of residues

During the past 15 years, multiple processing studies have been performed with pyraclostrobin containing products covering industrial production, but also household preparations. For the crops below, processing studies exist. The information on the processing steps covered is limited to those steps being considered as relevant for human consumption.

Table 7.6.2-1: Overview on available processing studies supporting registered use of pyraclostrobin containing formulations

EU Crop Group	Crops	Processing steps covered
Citrus fruits	Oranges	Peeling, canning, juice and marmalade production
Pome fruits	Apples	Washing, juice and sauce production
Stone fruits	Cherries	Washing, canning, juice and fruit syrup production
	Plums	Washing, puree and prune production
Berries and small fruits	Grapes	Wine, juice, raisins
	Strawberries	Washing, canning, jam, fruit syrup and distillate production
	Currants	Washing, canning, juice, jam and jelly production
Root and tuber vegetables	Carrots	Washing, peeling, cooking, juice production, canning
Fruiting vegetables	Tomatoes	Washing, canning, juice, puree and paste production
	Melons	Peeling
Brassica vegetables	Cabbage	Washing, cooking, Sauerkraut production, juice production
Leaf vegetables and fresh herbs	Lettuce, spinach	Washing, blanching, cooking
Legume vegetables	Peas	Washing, canning
Oilseeds and oilfruits	Soybean, oilseed rape, cotton, sunflower	Oil production (raw, refined)
Cereals	Barley	Pot barley, beer production
	Wheat	Flour, bran and germ production
Tea, coffee, herbal infusions and cocoa	Coffee	Roasting, brewing of coffee
Hops	Hops	Beer production
Sugar plants	Sugar cane	Sugar production (brown, refined)

Some of the studies were conducted according to the EU guidance document whereas the investigations performed in the USA are following US EPA OPPTS guidelines. The more recent studies are fulfilling the relevant OECD GD and GL.

The majority of processing factors is included in the data bases of the German BfR and Dutch RIVM (BfR webpage: BfR compilation of processing factors for pesticide residues (October 2011), http://chemkap.rivm.nl/groente-fruit/processing-factors/). In almost all studies, pyraclostrobin residues did not show any accumulation in food destined for human consumption. Exceptions are prunes and raisins, which can be explained by loss of water.

New processing studies are submitted in this dossier covering the intended uses in wheat, oats and maize. The results of these studies confirmed the previous findings with no or low indication for accumulation of residues in food destined for human consumption.

Wheat:
Pyraclostrobin was concentrated in wilted silage, bran, middlings, shorts and gluten, whereas the metabolite 500M07 (BF 500-3) was concentrated in wet silage, wilted silage, bran, germ, middlings, shorts, gluten and whole meal flour. The concentration is most likely based on the weight ratio and different water contents between RAC and processing fractions. In all further matrices the residues declined during processing.

Oats:
In husks and dust, the residue levels of pyraclostrobin and its metabolite 500M07 (BF 500-3) indicated concentration (pyraclostrobin: TF 2.34 and 5.23, 500M07: TF 2.42 and 5.45), whereas in all further matrices the residues declined during processing.

Maize:
The concentration factors for residues of pyraclostrobin and its metabolite 500M07 (BF 500-3) from maize grain to its processed fractions were 1, indicating that residues did not concentrate. Residues in the RAC grain samples were ≤ LOQ.

7.7 Summary of residues in rotational crops

7.7.1 Nature of residues in rotational crops

A confined rotational crop study was evaluated during the previous Annex I inclusion process. The metabolism of pyraclostrobin in rotational crops was studied in lettuce, radish and wheat after application of [tolyl-U-14C]-pyraclostrobin and [chlorophenyl-U-14C]-pyraclostrobin. The radiolabelled active substance was applied once to bare soil at an application rate of 0.9 kg a.s./ha; the respective crops were sown or planted at 30, 120 and 365 DAT.
Based on the results of the study, no accumulation of pyraclostrobin or its degradation products in the parts of plants used for human or animal consumption was observed. For succeeding crops, the proposed metabolic pathway involves desmethoxylation, a further degradation to various medium polar and polar metabolites and afterwards, most likely, conjugation reactions and final incorporation and/ or association into natural products, such as starch, cellulose and/ or lignins. The metabolic pathway of pyraclostrobin in rotational crops is similar to that in primary crops, and no formation of any other metabolite was observed.

In order to prove that no metabolite consisting solely of the pyrazole moiety is formed in soil (see also M-CA 7) and taken up by plants, preliminary investigations with the ^{14}C-pyrazole labelled pyraclostrobin were performed. ^{14}C-pyrazole labelled pyraclostrobin was applied at the maximum seasonal rate of 500 g as/ha to bare soil; crops were planted / sown after an aging period of 30 DAT. The use rate of 500 g as/ha corresponds to a realistic worst case GAP for Europe (2 x 250 g as/ha in cereal crops).

In all rotational crop matrices (radish, wheat, lettuce) low levels of radioactive residues were determined. The calculated Total Radioactive Residues (TRR) in radish leaf accounted for 0.010 mg/kg, for radish root 0.003 mg/kg, for wheat forage 0.014 mg/kg and for lettuce plant 0.016 mg/kg. Despite the low levels confirming the previous findings of the full guideline study, further investigations (extraction, partition, chromatographic analysis) were performed.
HPLC analysis of the concentrated water phases of the methanol extracts of radish leaf, wheat forage and lettuce plant resulted in a metabolite pattern of one polar peak at a retention time of approximately 4.3 min and three peaks with medium polarity (at approximately 20.2 min, 21.7 min and 22.8 min). An assignment of the peaks to structures was not possible due to the low levels of radioactive residues. All peaks were below 0.01 mg/kg. The Residual Radioactive Residues (RRR) were also low with values ranging from 0.002 to 0.006 mg/kg.

The results of both studies indicate that there was no significant translocation of pyraclostrobin and/or its degradation products from soil.

7.7.2 Magnitude of residues in rotational crops

According to Reg. 283/2013, studies on the magnitude of residues in rotational crop are required under the following circumstances:

If the metabolism studies indicate that residues of the active substance or of relevant metabolites or breakdown products either from plant or soil metabolism may occur (> 0.01 mg/kg), limited field studies and, if necessary, field trials shall be carried out.

Studies shall not be required in the following cases:
- no metabolism studies on rotational crops are to be performed, or
- metabolism studies on rotational crops show that no residues of concern are to be expected in rotational crops

Due to the favorable residue behavior of pyraclostrobin in succeeding crops, which has been demonstrated in two studies with different ring labels and under worst case conditions (bare soil application with partly exaggerated rates), no residues are expected. Consequently, no higher tier study is required.

7.8 Summary of other studies

Not relevant as no supplemental studies are provided for pyraclostrobin and its intended uses in potatoes, cereals and maize.

7.9 Estimation of the potential and actual exposure through diet and other sources

Chronic and acute assessments were conducted for parent pyraclostrobin and the metabolites of concern.

7.9.1 Chronic exposure

7.9.1.1 Pyraclostrobin (parent)

With the current EFSA model the chronic risk assessment ranges from 10 to 77% of ADI. The diet with the highest TMDI is "DE child" with 77% of ADI. For this diet, the highest contributors are oranges with 25.4% of ADI. The diet with the second highest TMDI is “NL child” with 60.1% of ADI, in which also oranges are the major contributor with 20.8% of ADI.

In order to check the contribution of fish, a dietary exposure assessment was performed using the German consumption data as published in 2012. Besides the child, the revised spreadsheet contains two additional consumer groups (total population: age group 14 – 80 years, females in child bearing age: 14 – 50 years).

Three assessments are performed. In accordance with the EFSA PRIMo model, the % ADI utilizations are based on mean body weights.

- In the first assessment, the same input values as for PRIMo were entered into the calculation.
- In the second assessment, the contribution of fish (at 0.05 mg/kg) was investigated.
- In the third assessment, the overall assessment was performed.

The NEDI calculation showed the low contribution of fish commodities to the chronic dietary risk for pyraclostrobin. The data clearly demonstrates that the presence of pyraclostrobin in fish does not result in any consumer risk. Compared to all other commodities, the contribution of fish to the chronic exposure is even under worst case assumptions rather small.

Table 7.9.1.1-1: NEDI calculations using the German model (NVS2_V_0-9_DE1)

Subpopulation group	% ADI utilization based on current MRLs	% ADI utilization fish commodities	% ADI utilization (total)
German child (VELS)	77	0.1	77.1
General population	36.8	0.1	36.9
Women in child bearing age	39.2	0.1	39.3

7.9.1.2 Metabolites

Metabolites identified in crop and livestock metabolism studies

For performing indicative assessments, the metabolites were grouped according to sub-structures (see M-CA 6.9). In a second step, the exposure was estimated based on all available data (combination of metabolism information and data from residue field trials / feeding studies). Subsequently, chronic dietary exposure assessments were performed for identifying the contributions of the metabolites to the total dietary risk.

Desmethoxy metabolite 500M07:
With the current EFSA model the chronic risk assessment ranges from 0.3 to 1.7% of ADI. The diet with the highest TMDI is "WHO Cluster Diet B" with 1.7% of ADI. For this diet, the highest contributor is wheat with 0.6% of ADI. The diet with the second highest TMDI is “DE child” with 1.7% of ADI, in which pome fruits are the major contributor with 0.8% of ADI.

Chlorophenyl pyrazole derivatives (500M04 and conjugates, 500M85):
With the current EFSA model the chronic risk leads to no values above 0.0% of ADI.

Anthranilic acid derivative 500M24:
With the current EFSA model the chronic risk assessment ranges from 0 to 8.9% of ADI. The diet with the highest TMDI is "IE Adult" with 8.9% of ADI. For this diet, the highest contributor is barley with 8.3% of ADI. The diet with the second highest TMDI is “WHO Cluster Diet E” with 6.3% of ADI, in which also barley is the major contributor with 5.4% of ADI.

Anthranilic acid derivative 500M49:
With the current EFSA model the chronic risk assessment ranges from 0.0 to 0.1% of ADI. The diet with the highest TMDI is "WHO Cluster Diet E" with 0.1% of ADI. For this diet, the highest contributor is rape seed with 0.1% of ADI. The diet with the second highest TMDI is “WHO Cluster Diet B” with 0.1% of ADI, in which sunflower seed is the major contributor with 0.1% of ADI.

Anthranilic acid derivative 500M51:
The estimation of the metabolite in food of animal origin resulted in median residue levels far below 0.001 mg/kg. Due to negligible exposure, no chronic exposure assessment was performed.

Hydroxylated metabolites (chlorphenyl pyrazole moiety):
With the current EFSA model the chronic risk assessment ranges from 0.1 to 0.6% of ADI. The diet with the highest TMDI is "DE child" with 0.6% of ADI. For this diet, the highest contributors are pome fruits with 0.3% of ADI. The diet with the second highest TMDI is “NL child” with 0.5% of ADI, in which also pome fruits are the major contributor with 0.2% of ADI.

Hydroxylated metabolites (tolyl moiety):
With the current EFSA model the chronic risk assessment ranges from 0.1 to 0.6% of ADI. The diet with the highest TMDI is "DE child" with 0.6% of ADI. For this diet, the highest contributors are pome fruits with 0.3% of ADI. The diet with the second highest TMDI is “WHO Cluster Diet B” with 0.4% of ADI, in which wine grapes are the major contributor with 0.2% of ADI.

Photo metabolite 500M76:
With the current EFSA model the chronic risk assessment ranges from 0 to 0.2% of ADI. The diet with the highest TMDI is "WHO Cluster Diet B" with 0.2% of ADI. For this diet, the highest contributor is lettuce with 0.1% of ADI. The diet with the second highest TMDI is “FR toddler” with 0.2% of ADI, in which leek is the major contributor with 0.1% of ADI.

The exposure estimates for metabolites applying worst case assumptions (for vegetables: no consideration of processing) did not indicate any dietary concern. The calculation of the % ADI utilizations resulted in values far below 100% and – even more important - clearly below the ones of the parent molecule. No significant contribution to the chronic exposure can be expected from any plant or livestock metabolite.

Metabolites identified in the *in-vitro* comparison study

Based on the study results of an *in-vitro* comparison study with cell cultures from different species, it cannot be excluded that humans might be exposed to metabolites 500M02, 500M106 and 500M107 (glucuronic acid conjugate of 500M106) after consumption of food containing pyraclostrobin residues. For the time being no guidance document exists how to perform a dietary risk assessment for such metabolites. However, as the metabolite 500M106 showed a considerable lower toxicity in the 28-day rat study compared to parent, no separate dietary risk assessment should be needed. The assessment is covered by the chronic exposure estimate provided for the parent molecule.

7.9.2 Acute exposure

7.9.2.1 Pyraclostrobin (parent)

The evaluation resulted in ARfD utilizations well below 100% for all representative crops. The highest utilization using default variability factors was calculated for sweet corn (17.1 %).
In the context of this dossier, MRLs for fish are proposed for the first time. In order to check the contribution of fish to acute exposure, an indicative assessment has been performed. The proposed MRL of 0.05 mg/kg was entered into the German model as it includes the relevant consumption data. The maximum % ARfD utilizations are comparable for all subpopulation groups (child, total population, women in child bearing age); maximum ARfD utilizations of about 4.5% are reached for shell fish and freshwater fish, respectively.

7.9.2.2 Metabolites

Metabolites identified in crop and livestock metabolism studies

The acute dietary exposure was also assessed for the metabolites following the same grouping principles.

Desmethoxy metabolite 500M07:
For the assessment, an ARfD of 0.03 mg/kg bw/day was used. The calculation was done with default variability factors, except of pome fruits and table grapes in the IESTI2 calculation, for which a variability factor of 3 was applied (already accepted by EFSA, see EFSA Journal 2011;9(8):2344). The evaluation resulted in ARfD utilizations well below 100% for all commodities. Highest ARfD utilization was observed for celery (29.1%), followed by onions (18.1%) and cucumbers (17.5%).

Anthranilic acid derivative 500M49:
For the assessment, an ARfD of 0.005 mg/kg bw/day was used. The calculation was done with default variability factors. As a result, no ARfD utilization above 0.0% was determined.

Anthranilic acid derivative 500M51:
For the assessment, an ARfD of 0.005 mg/kg bw/day was used. The calculation was done with the default variability factors. The evaluation resulted in ARfD utilizations well below 100% for all commodities. Highest ARfD utilization was observed for bovine kidney (0.2%), followed by swine kidney (0.1%).

Hydroxylated metabolites (chlorphenyl pyrazole moiety):
For the assessment, an ARfD of 0.03 mg/kg bw/day was used. The calculation was done with default variability factors, except of pome fruits and table grapes in the IESTI2 calculation, for which a variability factor of 3 was applied (already accepted by EFSA, see EFSA Journal 2011;9(8):2344). The evaluation resulted in ARfD utilizations well below 100% for all commodities. Highest ARfD utilization (IESTI2) was observed for melons (8.1%), followed by watermelons (6.5%) and table grapes (5.2%).

Hydroxylated metabolites (tolyl moiety):
For the assessment, an ARfD of 0.03 mg/kg bw/day was used. The calculation was done with default variability factors, except of pome fruits and table grapes in the IESTI2 calculation, for which a variability factor of 3 was applied (already accepted by EFSA, see EFSA Journal 2011;9(8):2344). The evaluation resulted in ARfD utilizations well below 100% for all commodities. Highest ARfD utilization (IESTI2) was observed for melons (8.1%), followed by kale (7.9%) and watermelons (6.5%).

Photo metabolite 500M76:
For the assessment, an ARfD of 0.005 mg/kg bw/day was used. The calculation was done with default variability factors. The evaluation resulted in ARfD utilizations well below 100% for all commodities. Highest ARfD utilization (IESTI2) was observed for kale (10.6%), followed by Chinese cabbage (8.2%) and globe artichokes (6.3%).

The exposure estimates for metabolites applying worst case assumptions (for vegetables: no consideration of processing) did not indicate any dietary concern. The calculation of the % ARfD utilizations resulted in values far below 100% and – even more important - clearly below the ones of the parent molecule. No significant contribution to the acute exposure can be expected from any plant or livestock metabolite.

Metabolites identified in the *in-vitro* comparison study

Based on the study results from an *in-vitro* comparison study with cell cultures from different species, it cannot be excluded that humans might be exposed to the metabolites 500M02, 500M106 and 500M107 (glucuronic acid conjugate of 500M106) after consumption of food containing pyraclostrobin residues. As metabolite 500M106 showed a considerable lower acute toxicity compared to parent, no separate dietary risk assessment should be needed. The assessment is covered by the exposure estimates provided for the parent molecule.

7.10 Proposed MRLs and compliance with existing MRLs

7.10.1 Plant matrices

In the context of this dossier, the residue data summarized in M-CA 6.3 were compared with those being already evaluated by EFSA within previous submissions (EU MRL Regulation 396/2005, Art. 6-10 or Art. 12).

Potatoes
In none of the trials any detectable residue above the limit of quantitation (LOQ) was found.
As all residue levels in potato tubers were below the LOQ of 0.02 mg/kg, it is not needed to perform any statistical calculation to derive an MRL. Based on the findings of the residue trials it is proposed **to keep the established EU MRL** for potato tubers at the limit of quantitation of the enforcement method, which corresponds to 0.02 mg/kg.

Code number 0211000 (potatoes): 0.02 mg/kg (default MRL)

Barley
The data show, that the calculated MRL for pyraclostrobin in barley grain is **covered** by the current MRL of 1.0 mg/kg. And therefore BASF proposes **to keep the current EU MRL** of pyraclostrobin at 1.0 mg/kg for barley grain.

Code number 0500010 (barley): 1.0 mg/kg

Based on the extrapolation rules of the EU guidance document "Guidelines on comparability, extrapolation, group tolerances and data requirements for setting MRLs" (SANCO 7525/VI/95 rev. 9, March 2011), **the same MRL should apply** for oat grain:

Code number 0500050 (oats): 1.0 mg/kg

Barley straw (feed item)
The data show, that the calculated MRL for pyraclostrobin in barley straw is covered by the current *"pseudo MRL"* of 15 mg/kg (see MRL review for pyraclostrobin according to Article 12, EFSA Journal 2011;9(8):2344). Therefore, BASF proposes **to keep the current value** of pyraclostrobin at 15 mg/kg for barley and oat straw.

Sweet corn [extrapolation from maize "cobs without husks"]
The data show, that the calculated MRL for pyraclostrobin in sweet corn after application of formulation BAS 500 06 F is not covered by the current MRL of 0.02 mg/kg (default MRL). Therefore, BASF **proposes to establish an EU MRL** of pyraclostrobin at 0.07 mg/kg for sweet corn.

Code number 0234000 (sweet corn): 0.07 mg/kg

Maize
In none of the trials any detectable residue above the limit of quantitation (LOQ) was found.
As all residue levels in maize grain were below the LOQ of 0.01 mg/kg, it is not needed to perform any statistical calculation to derive an MRL.

Based on the findings of the residue trials **it is proposed to keep** the MRL for maize grain at the limit of quantitation of the enforcement method, which corresponds to 0.02 mg/kg. This MRL also covers potential imports of maize grain from the NAFTA region.

Code number 0500030 (maize): 0.02 mg/kg (default MRL)

Maize (feed item)
As a conclusion it is proposed **to keep the established pseudo MRL** for pyraclostrobin of 1.5 mg/kg in maize -feed items (silage), see EFSA Journal 2012;10(3):2606. The residue situation is very comparable in the Northern and in the Southern EU.

Wheat
The data show, that the calculated MRL for pyraclostrobin in wheat grain is covered by the current MRL of 0.2 mg/kg. Therefore, BASF proposes **to keep the current EU MRL** of pyraclostrobin at 0.2 mg/kg for wheat grain.

Code number 0500090 (wheat): 0.2 mg/kg

Based on the extrapolation rules of the EU guidance document "Guidelines on comparability, extrapolation, group tolerances and data requirements for setting MRLs" (SANCO 7525/VI/95 rev. 9, March 2011), **the same MRL should apply** for rye grain:

Code number 0500070 (rye): 0.2 mg/kg

Wheat straw (feed item)
The data show, that the calculated MRL for pyraclostrobin in wheat straw is covered by the current *"pseudo MRL"* of 10 mg/kg (see MRL review for pyraclostrobin according to Article 12, EFSA Journal 2011;9(8):2344). Therefore, BASF proposes **to keep the current value** of pyraclostrobin at 10 mg/kg for wheat and rye straw.

7.10.2 Animal matrices

In the context of this dossier, revised dietary feed burden calculations were conducted (see M-CA 6.7.2) using the EU and the OECD agreed methodology and the input values derived in this dossier. The following maximum feed burdens were derived for dairy ruminants, meat ruminants, poultry and pigs using the agreed EU methodology. As supplemental information the main contributor is also provided below.

Table 7.10.2-1: Summarised results of the livestock dietary burden calculations for dairy ruminants

Dietary burden of dairy ruminants	
Maximum dietary burden (mg/kg bw/d):	0.145683
Maximum dietary burden (mg/kg feed DM):	4.006279
Highest contributing commodity:	Barley straw

Table 7.10.2-2: Summarised results of the livestock dietary burden calculations for meat ruminants

Dietary burden of meat ruminants	
Maximum dietary burden (mg/kg bw/d):	0.296061
Maximum dietary burden (mg/kg feed DM):	6.908081
Highest contributing commodity:	Barley straw

Table 7.10.2-3: Summarised results of the livestock dietary burden calculations for poultry

Dietary burden of poultry	
Maximum dietary burden (mg/kg bw/d):	0.041119
Maximum dietary burden (mg/kg feed DM):	0.651047
Highest contributing commodity:	Barley grain

Table 7.10.2-4: Summarised results of the livestock dietary burden calculations for pigs

Dietary burden of pigs	
Maximum dietary burden (mg/kg bw/d):	0.047270
Maximum dietary burden (mg/kg feed DM):	1.181744
Highest contributing commodity:	Kale

The following results in the context of the feed burden calculations were derived for cattle, sheep, swine and poultry using the OECD methodology. For the time being, the calculation according to OECD is considered as supplemental information. In general, the results are in good accordance with the feed burden calculations according to EU.

Table 7.10.2-5: Summary of the results for RWCFL (EU)

	Cattle Beef	Cattle Dairy	Sheep Ram/Ewe	Sheep Lamb	Swine Breeding	Swine Finishing	Poultry Broiler	Poultry Layer	Poultry Turkey
Regions	EU	EU	EU	EU	EU	EU	EU	EU	EU
Body weight (kg)	500	650	75	40	260	100	1.7	1.9	7
Daily intake (kg DM)	12	25	2.5	1.7	6	3	0.12	0.13	0.5
Dietary burden (mg/kg bw)	**0.083**	**0.134**	**0.212**	**0.271**	**0.028**	**0.024**	**0.036**	**0.079**	**0.031**
Feed burden (mg/kg DM)	**3.461**	**3.483**	**6.365**	**6.365**	**1.225**	**0.798**	**0.515**	**1.149**	**0.435**

Based on these feed burden calculations, the livestock metabolism and feeding studies were carefully re-evaluated.

The established EU MRLs were reconfirmed.

0.05 mg/kg for all animal matrices (except milk)
0.01 mg/kg for milk

For fish, a preliminary proposal for a future EU MRL was derived based on the estimated feed burden and the results of the fish metabolism study (after oral dosing):

0.05 mg/kg for all fish commodities

The established and proposed MRLs for commodities being relevant in context of this dossier are summarized in the following table:

Table 7.10.2-6: Maximum residue levels for pyraclostrobin in the EU and changes proposed by BASF

Plant/animal commodity (Code number)	**Established EU MRL [mg/kg]**	**Proposed EU MRL [mg/kg]**
Potatoes (0211000)	0.02*	0.02*
Sweet corn (0234000)	0.02*	**0.07**
Barley (0500010)	1.0	1.0
Maize (0500030)	0.02*	0.02*
Oats (0500050)	1.0	1.0
Rye (0500070)	0.2	0.2
Wheat (0500090)	0.2	0.2
Products of animal origin-terrestrial animals, except milk (1000000)	0.05*	0.05*
Milk (1020000)	0.01*	0.01*
Fish, fish products, shell fish, molluscs and other marine and freshwater food products (1100000)	n.a.	**0.05**

* default MRL
n.a. not applicable
proposed MRL changes are highlighted in **bold**

7.11 Proposed import tolerances and compliance with existing import tolerances

The MRLs listed in M-CA 6.7.2 include domestic uses, but also values for imported crops. Prior to final approval, the import tolerances have been evaluated by Germany (RMS) and EFSA. Parts of them are resulting from the adoption of CODEX MRLs. In the meantime, pyraclostrobin and its crops have been assessed three times by JMPR.

8 FATE AND BEHAVIOUR IN THE ENVIRONMENT

8.1 Summary of fate and behaviour in soil

Laboratory soil degradation studies

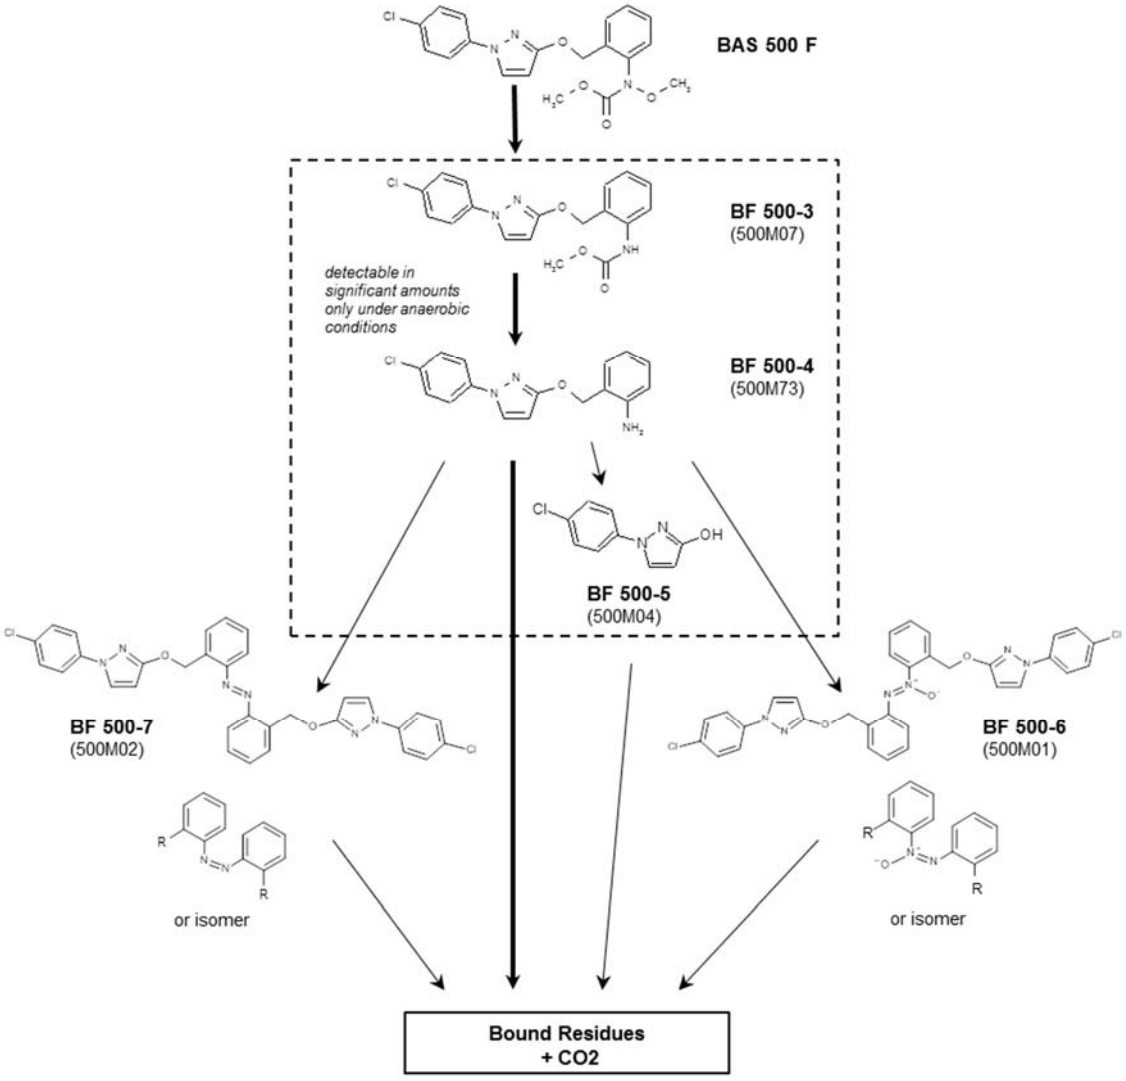
Route of degradation

The aerobic soil degradation of pyraclostrobin was evaluated in GLP laboratory studies conducted with either tolyl-, chlorophenyl-, or pyrazole-labelled test item. The degradation of pyraclostrobin occurs by stepwise degradation of the carbamate group via des-methoxylation (BF 500-3) to an anilinic intermediate (BF 500-4), which then reacts rather fast with organic (humic) substances in soil (major pathway) forming non-extractable residues up to ~56% TAR (total applied radioactivity) after 100 days. The anilinic intermediate can also react with each other (minor pathway) forming the dimeric metabolites BF 500-6 (max. 31% TAR) and BF 500-7 (max. 13% TAR). Cleavage of the pyraclostrobin molecule by formation of metabolite BF 500-5 is also observed, however, only to a very minor extent (~2.8% TAR). Mineralization is obtained with all three ^{14}C-ring labels (tolyl-label up to 7% TAR, chlorophenyl-label ~5% TAR, pyrazole-label ~2.2% TAR), indicating that the pyraclostrobin molecule is finally attacked at each ring system leading to degradation to CO_2.

Under anaerobic conditions, the degradation follows in principle the same pathway. Since oxygen demanding reactions are slowed down considerably, the des-methoxy metabolite BF 500-3 as well as the anilinic metabolite BF 500-4 are formed in higher amounts than under aerobic conditions. BF 500-3 reaches up to 96% TAR and BF 500-4 up to 11% TAR under water-logged and nitrogen-flooded conditions. BF 500-4, which is never detected in aerobic soil, showed some isomerization (500M74 max. 11.4 and 500M75 max. 7.3% TAR, respectively) in the anoxic water phase, which is however considered unlikely to occur under agricultural field conditions. Pyraclostrobin will not be sprayed on water-logged soils, and even in water-logged soil after heavy rain at least some oxygen is supposed to be present, which immediately would lead to BF 500-4 degradation.

Under photolytic conditions, the same metabolites are detected as under dark conditions. No special photo-degradates are formed.

Figure 8.1-1: Proposed route of pyraclostrobin degradation in soil



Rate of degradation

Using the data from both older and new studies, the laboratory $DegT_{50}$ values for pyraclostrobin and its metabolites were (re-)calculated according to the current guidance of the FOCUS workgroup on degradation kinetics (FOCUS 2006).

Pyraclostrobin non-normalized half-lives under laboratory conditions (i.e. persistence endpoints) ranged from 11 to 98 days in soils (n=10) incubated at 20ºC in the dark with soil moistures maintained at ~40-50% maximum water holding capacity.

The kinetic endpoints for metabolites BF 500-4, BF 500-5, BF 500-6 and BF 500-7 were derived either from the laboratory soil degradation studies with pyraclostrobin or from studies performed with the metabolites as test substance. The non-normalized laboratory $DegT_{50}$ values (i.e. persistence endpoints) were calculated to be 0.2 to 1.8 days for BF 500-4, 0.1 to 0.2 days for BF 500-5, 96 to 971 days for BF 500-6, and 81 to > 1000 days for BF 500-7. The transient metabolite BF 500-3 was also included in the kinetic evaluation of soil degradation studies with pyraclostrobin, however, reliable endpoints could not be derived.

Under anaerobic conditions, the $DegT_{50}$ values were calculated to be 1.5 - 2.3 days for pyraclostrobin, 57 - 70 days for BF 500-3, 8 - 11 days for BF 500-4, 37 - 65 days for isomer 500M74, 15 - 24 days for isomer 500M75 and 32 days for BF 500-5.

Field studies

Field soil dissipation

In the previous DAR considering studies conducted prior to 2000, dissipation of pyraclostrobin in soil under field conditions was shown to be rapid with non-normalized DT_{50} values from 6 trials ranging from 2 to 37 days. The 6 trials were distributed in Germany (3), Spain (2), and Sweden (1). Applications were made in spring at 250 g a.s. ha^{-1} on bare soil. Metabolites BF 500-3, BF 500-6 and BF 500-7 were, if at all, only sporadically observed close to the LOQ of 0.01 mg/kg.

A kinetic re-evaluation of the original 6 field dissipation datasets was conducted according to current FOCUS (2006) kinetics guidance to determine persistence (trigger) endpoints. The pyraclostrobin best-fit $DisT_{50}$ values ranged from 5 to 56 days and the corresponding $DisT_{90}$ ranged from 80 – 348 days. There was no dependence of pyraclostrobin dissipation on soil pH. No endpoints could kinetically be derived for the metabolites due to the low frequent occurrence. These results support that pyraclostrobin and its metabolites are not persistent under field conditions.

Field soil degradation

The old field soil dissipation study was analyzed following EFSA (2010) [*Guidance for evaluating laboratory and field dissipation studies to obtain DegT50 values of plant protection products in soil.* EFSA Journal 2010; 8(12):1936] in conjunction with FOCUS (2006) to obtain degradation rates in the soil matrix. A total of four sites could be analyzed with normalized $DegT_{50}$ values (20°C and pF2) that range from 15.5 – 32.2 days.

A new field soil degradation study was conducted in 2011-2012 following the EFSA (2010) opinion by excluding soil surface processes (e.g. volatilization, photolysis) by covering the soil with a 4 – 10 mm sand layer. The four trials were located in Denmark, Germany, Italy and France. The nominal application rate at each site was 250 g a.s. ha^{-1} on bare soil. Soil samples were analyzed for pyraclostrobin and the metabolites BF 500-3, BF 500-6 and BF 500-7. Pyraclostrobin residues were almost exclusively found in the top 0-10 cm soil layer (residues $\leq$ 0.004 mg kg^{-1}) and only sporadically detected in the 10-20 cm layer. Below 20 cm no residues above LOQ (0.001 mg kg^{-1}) were found. The metabolites BF 500-3, BF 500-6 and BF 500-7 and were detected at all sites. They were found above LOQ only in the top 0-20 cm soil layer.

Data were normalized to 20°C and pF2 moisture and evaluated according to FOCUS (2006) kinetics guidance. The $DegT_{50}$ values for pyraclostrobin ranged from 15 to 181 days. For the metabolites $DegT_{50}$ values ranged from 163 – 361 days for BF 500-6 and from 184 - 460 days for BF 500-7. No endpoints could be derived for metabolite BF 500-3.

Mobility in soil

Pyraclostrobin mobility in soil was evaluated using data from studies considered in the previous EU evaluation ($K_{f,oc}$, column leaching, aged soil column leaching). The $K_{f,oc}$ values determined in 3 EU, 2 US and 1 Canadian soil ranged from 6000 to 16000 mL g^{-1} (n = 6) with an arithmetic mean of 9304 mL g^{-1}. No radioactivity could be found in the leachates of the column and aged soil column leaching studies. Pyraclostrobin can thus be considered to be immobile in soil.

Adsorption isotherms were determined for metabolite BF 500-3 in 3 EU, 2 US and 1 Canadian soil during the previous EU evaluation. The $K_{f,oc}$ values ranged from 4240 - 12000 mL g^{-1} with an arithmetic mean of 9315 mL g^{-1}.

Adsorption values were determined for metabolite BF 500-6 in 3 EU, 2 US and 1 Canadian soil during the previous EU evaluation. Due to the extremely low water solubility, the adsorption could be determined for one concentration only. The K_{oc} values ranged from 3360 - 126800 mL g^{-1}. Since the reported recoveries of the test substance were partly very low, a new study was performed with 4 German soils and 1 Spanish soil. The K_{oc} values of this new study, providing an acceptable substance recovery, ranged from 107301 to 311704 mL g^{-1}. Since the second study confirmed the high values of the first, both data sets were combined resulting in a median K_{oc} of 107301 mL g^{-1}.

Adsorption values were determined for metabolite BF 500-7 in 3 EU, 2 US and 1 Canadian soil during the previous EU evaluation. Due to the extremely low water solubility, the adsorption could be determined for one concentration only. The K_{oc} values of ranged from 4020 - 149900 mL g^{-1}. Since the reported recoveries of the test substance were partly very low, a new study was performed with 4 German soils and 1 Spanish soil. The K_{oc} values of this study, providing an acceptable substance recovery, ranged from 242564 to 801927 mL g^{-1}. Since the second study confirmed the high values of the first, both data sets were combined resulting in a median K_{oc} of 149900 mL g^{-1}.

Adsorption values were determined for metabolite BF 500-4 in 4 German soils and 1 Spanish soil. Due to the extremely low water solubility, the adsorption could be determined for one concentration only. The K_{oc} values ranged from 6871 - 15748 mL g^{-1} with an arithmetic mean (n=5) of 9819 mL g^{-1}.

Adsorption isotherms were determined for metabolite BF 500-5 in 4 German soils and 1 Spanish soil. The K_{foc} values ranged from 400 - 831 mL g^{-1} with an arithmetic mean (n=5) of 705 mL g^{-1}.

The groundwater risk assessment, which considers conservative assumptions on sorption and degradation, supports that pyraclostrobin and its metabolites are unlikely to enter groundwater.

8.2 Summary of fate and behaviour in water and sediment

Pyraclostrobin was hydrolytically stable at pH 5 and 7. Only with pH 9, a very slight degradation could be observed.

In the aqueous photolysis study, pyraclostrobin degraded quickly to numerous breakdown and rearrangement products (in total 38 compounds identified or at least characterized by mass). The half-life of pyraclostrobin was calculated to be 0.06 days (when considering continuous irradiation).

According to a Manometric Respiratory Test (OECD 301), pyraclostrobin has to be considered as not readily biodegradable.

In a water/sediment study under dark conditions, no metabolites were formed in water, but a very fast binding to the sediment occurred. In sediment, the metabolite BF 500-3 was detected in amounts > 10% TAR and BF 500-6 and BF 500-7 were detected in amounts > 5% TAR. The degradation rates of pyraclostrobin were re-evaluated according to FOCUS (2006). The evaluation at P-I level resulted in $DisT_{50}$ values for the water of 0.4 - 2.3 days (2 labels, 2 systems). Reliable $DegT_{50}$ values for the total system could be obtained only from one w/s system and were calculated to be 23 - 27 days.

Since under outdoor conditions, photolysis as well as sediment adsorption are simultaneously influencing the degradation/dissipation of pyraclostrobin in water, already for the previous EU evaluation a higher tier study was performed simulating the light and temperature regime of the major application period for the active substance (May-July).

This study showed that besides about 15 minor degradation products, 3 photo-metabolites were formed in the water in amounts >10% TAR (BF 500-11, BF 500-13, and BF 500-14). In the sediment, only metabolite BF 500-3 was detected (max. 16.9% TAR). This study was performed without volatile collection and no material balance could be provided. Therefore, a new irradiated water/sediment study was initiated with an adapted test design (very similar to the OECD 308 guideline, but with irradiation), and with collection of volatiles to enable a full material balance.

The overall route of degradation in water/sediment under realistic outdoor conditions was confirmed by this new study. The metabolites BF 500-11, BF 500-13 and BF 500-14 were again detected, however, in much lower amounts than in the previous study (all < 6% TAR). In sediment, besides high amounts of non-extractable residues (max. 63 - 66% TAR after 42 days), the metabolites BF 500-3, BF 500-6 and BF 500-7 were formed in max. amounts of 6, 4 and 2% TAR, respectively. Mineralization to CO_2 amounted to 3 - 4% TAR after 42 days.

Reliable dissipation and degradation rates for pyraclostrobin were re-calculated according to FOCUS 2006. The SFO kinetic model (P-I level) revealed $DisT_{50}$ values of 4.5 and 5.9 days for water and sediment, respectively, and a $DegT_{50}$ of 7.2 days for the total system. Calculations at the P-II level resulted in $DegT_{50}$ values of 7.5 and 6.5 days for the water and the sediment compartment, respectively. Total system $DisT_{50}$ values could be calculated for metabolites BF 500-3, BF 500-11 and BF 500-14 reaching 93, 23 and 17 days, respectively.

All these results show that in case pyraclostrobin reaches the water, it quickly disappears from the water phase by fast photolytic reactions and by precipitation to the sediment and further binding to the organic matrix.

Aerobic mineralization of pyraclostrobin in surface water was tested with and without suspended sediment. Without suspended sediment, the degradation of pyraclostrobin was characterized by a low mineralization rate irrespective of test concentration or label position (< 1% TAR). With suspended sediment, the mineralization reached 2.8 - 4.6% TAR (2 labels, 2 test concentrations).

In the pelagic test without suspended sediment, pyraclostrobin degraded only very slowly. More than 78 - 97% TAR unchanged parent were still detectable in the water phase after 63 days. Only the des-methoxy metabolite BF 500-3 (max. 6.7% TAR) and the cleavage product BF 500-5 (max. 5.9 - 10.9% TAR) appeared in significant amounts. The $DegT_{50}$ of pyraclostrobin were 410 and 458 days (high and low test conc.) and 11 - 29 days for BF 500-3.

In the suspended sediment test, the behavior of pyraclostrobin was very similar to the dark water/sediment study. Pyraclostrobin quickly disappeared from the water phase with $DisT_{50}$ values of 1.7 - 2.3 days. Although the amount of sediment was only 1 g L^{-1}, 73 - 80% of the applied radioactivity was associated with the solid particles after 63 days and 47 - 58% could not be extracted with solvents. The $DegT_{50}$ (total system) was calculated with SFO kinetic to be 26 - 28 days.

8.3 Summary of fate and behaviour in air

Pyraclostrobin is characterized by a low vapor pressure (2.6 x 10^{-8} Pa at 20°C) and a low volatilization from soil and plant surfaces (< 3% in 24h). The photochemical oxidative degradation in air (Atkinson) was calculated to be 0.62 hours, indicating that pyraclostrobin is rapidly degraded in air. Consequently, there is no risk of long-range transport of pyraclostrobin.

8.4 Summary of monitoring data concerning fate and behaviour of the active substance, metabolites, degradation and reaction products

No relevant monitoring data are available.

8.5 Definition of the residues in the environment requiring further assessment

According to the results presented in M-CA 7.1 – 7.3 the following compounds have to be considered for the environmental risk assessment:

Soil:	pyraclostrobin, BF 500-6, BF 500-7
Ground Water:	pyraclostrobin, BF 500-3, BF 500-4, BF 500-5, BF 500-6, BF 500-7
Surface Water:	pyraclostrobin, BF 500-5, BF 500-11, BF 500-13, BF 500-14
Sediment:	pyraclostrobin, BF 500-3, BF 500-6, BF 500-7
Air:	pyraclostrobin

For monitoring purposes, the residue definition is parent only.

8.6 Summary of exposure calculations and product assessment

Soil:

PEC_{soil} following application of BAS 500 06 F (to cereals and maize) and BAS 516 07 F (to potatoes) were calculated for worst-case application scenarios. The calculations were carried out according to the recommendations of the FOCUS working group on degradation kinetics, assuming a soil bulk density of 1.5 g cm^{-3} and a soil layer depth of 5 cm. Maximum, actual and time-weighted average concentrations in soil ($PEC_{soil,max}$, $PEC_{soil,act}$, $PEC_{soil,twa}$) were calculated for pyraclostrobin and its soil metabolites BF 500-6 and BF 500-7. Additionally, the plateau concentration of BF 500-6 and BF 500-7 in soil at steady state ($PEC_{soil,plateau}$) and the overall accumulation PEC in soil ($PEC_{soil,accu}$) after application of the parent pyraclostrobin over many years, was calculated.

Results can be found in CP 9.1.3/2.

Groundwater:

Predicted environmental concentrations in groundwater (PEC_{gw}) of pyraclostrobin, its aerobic soil metabolites BF 500-6 and BF 500-7 and its anaerobic soil metabolites BF 500-3, BF 500-4 and BF 500-5 following application of BAS 500 06 F (to cereals and maize) and BAS 516 07 F (to potatoes) were calculated in accordance with the guidance of the FOCUS groundwater scenarios work group.

PEC_{gw} of pyraclostrobin and its aerobic and anaerobic soil metabolites were calculated with the model FOCUS-PEARL 4.4.4 and FOCUS-PELMO 5.5.3 for all available FOCUS scenarios for all crops with an annual application pattern (continuous cropping over a period of 26 years).

The maximum PEC_{gw} for all compounds was < 0.001 µg L^{-1} and thus clearly below the 0.1 µg L^{-1} threshold value.

Based on the exposure assessment, no risk mitigation measures are needed.

Surface water and sediment:

Predicted environmental concentrations (PEC) in surface water and sediment were calculated for pyraclostrobin, its water metabolites BF 500-5, BF 500-11, BF 500-13, BF 500-14 and its sediment metabolites BF 500-3, BF 500-6 and BF 500-7 after a spray application of pyraclostrobin to cereals (single and twofold application), maize (single application) and potatoes (single and fourfold application). Calculations were performed according to the recommendations of the FOCUS working group on surface water scenarios in a stepwise approach considering the pathways spray drift, drainage and runoff.

PEC_{sw} and PEC_{sed} of pyraclostrobin were calculated with all available scenarios for all use patterns. The calculations were performed for the FOCUS Steps 1 – 4 using the software packages STEPS1-2 for Step 1 and Step 2, SWASH 3.1, FOCUS-PRZM 3.1.1, FOCUS-MACRO 4.4.2 and TOXSWA 3.3.1 for Step 3. Moreover, the pre- and post-processing tool PECRobot v1.4 was used for setting up the Step 4 calculations, which were finally simulated using TOXSWA 3.3.1. Step 4 calculations were performed using no-spray buffer zones (up to 20 m for cereals and 10 m for maize) and/or drift reducing nozzles for drift mitigation. Moreover, vegetated filter strips for runoff and erosion were applied (up to 20 m for cereals and 10 m for maize). For the use in potatoes no additional mitigation measures were required beyond edge-of-field (Step 3). PEC_{sw} and PEC_{sed} of the metabolites of pyraclostrobin were only calculated at Step 1 and Step 2.

Results can be found in CP 9.2.5/1.

Air:

No exposure assessment required nor performed.

Other routes of exposure:

No other routes of exposure are relevant for the representative uses of pyraclostrobin.

9 EFFECTS ON NON-TARGET SPECIES

9.1 Summary of effects on birds and other terrestrial vertebrates

BAS 500 06 F and BAS 516 07 F are two new representative formulations, which have not been evaluated during a previous Annex I inclusion. For pyraclostrobin, the EU agreed endpoints plus endpoints from new, additional studies as well as revised endpoints from EU agreed studies are used for the risk assessment on birds and mammals. The risk assessment is based on the proposed uses of BAS 500 06 F and BAS 516 07 F. Note that BAS 516 07 F contains pyraclostrobin and boscalid. No separate risk assessment for boscalid is presented, as the active substance in focus of the evaluation is pyraclostrobin. Boscalid is solely addressed in the context of the assessment of combined effects of formulations containing more than one active substance (i.e. dietary risk assessment for a virtual compound and the formulation).

The risk assessment on birds and mammals considers the principles given in the latest guidance document by EFSA (*Anonymous 2009: Guidance Document on risk assessment for Birds & Mammals on request from EFSA. EFSA Journal 2009; 7(12):1438. European Food Safety Authority*), hereafter cited as EFSA/2009/1438.

Effects on Birds:

Dietary risk assessment

Under the conservative assumptions of a tier 1 assessment all TER_A and TER_{LT} values of pyraclostrobin exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects for applications in cereals and maize (both BAS 500 06 F) and potatoes (BAS 516 07 F).

Food chain behaviour (secondary poisoning) and bioaccumulation

Based on the tier 1 assessment, all TER values for the risk assessments for earthworm- and fish-eating birds for pyraclostrobin as contained in BAS 500 06 F and BAS 516 07 F, exceed the trigger of 5 set by Commission regulation (EU) 546/2011 for acceptability of effects for secondary poisoning. The bioaccumulation potential of pyraclostrobin was considered as low in the respective EU reviews and therefore further evaluation on biomagnification is not necessary. It can therefore be concluded that the application of BAS 500 06 F and BAS 516 07 F does not raise concerns regarding food chain behaviour (secondary poisoning) or biomagnification.

Drinking water risk assessment

Following EFSA/2009/1438, the puddle scenario is the one relevant for cereals, maize and potatoes. Since the ratio of the effective application rate to the relevant toxicity endpoints is below the value of 3000 for pyraclostrobin, conducting a quantitative risk assessment for the proposed use pattern of BAS 500 06 F and BAS 516 07 F is not necessary. In conclusion the proposed use pattern of BAS 500 06 F in cereals and maize and BAS 516 07 F in potatoes does not pose a risk to birds via uptake of contaminated drinking water.

Effects of the formulations

All TER_A values from the tier 1 acute dietary risk assessment of the formulation, calculated for the virtual compound (BAS 516 07 F) as well as for the formulation (BAS 500 06 F and BAS 516 07 F), exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low acute risk for birds from the use of BAS 500 06 F in cereals and maize and BAS 516 07 F in potatoes according to the recommended use pattern.

Overall conclusion

It can be concluded that the application of BAS 500 06 F in cereals and maize and BAS 516 07 F in potatoes according to good agricultural practice will not adversely affect birds under natural conditions.

Effects on Terrestrial Vertebrates Other Than Birds

Dietary risk assessment

Under the conservative assumptions of a tier 1 assessment all TER_A values of pyraclostrobin exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects for applications in cereals and maize (both BAS 500 06 F) and potatoes (BAS 516 07 F).

All TER_{LT} values for potatoes (BAS 516 07 F) and the TER_{LT} values of BAS 500 06 F for two scenarios in cereals (small insectivorous mammal "shrew" at BBCH ≥ 20 and small omnivorous mammal “mouse” at BBCH ≥ 40) and three scenarios in maize (small insectivorous mammal “shrew” at BBCH ≥ 20 and small omnivorous mammal “mouse” at BBCH 30 - 39 and BBCH ≥ 40) are above the relevant trigger.

For the scenarios large herbivorous mammal “lagomorph” (cereals), small omnivorous mammal “mouse” (cereals at BBCH 10-29) and small herbivorous mammal “vole” (cereals at BBCH ≥ 40 and maize at BBCH 30 - 39 and BBCH ≥ 40) the TER_{LT} values for pyraclostrobin are below the trigger and need to be refined. Based on a thorough analysis of existing data for several vole species, BASF believes that the "vole" scenario is not really relevant for higher tier reproductive risk assessments in arable crops like cereals and maize. Nevertheless, as the relevance of the “vole” scenario has been controversially discussed by the European Member States and a harmonized approach is currently lacking, quantitative higher tier risk assessments for the vole in cereals and maize have been added.

The refined reproductive risk assessment for the scenarios large herbivorous mammal “lagomorph”, small omnivorous mammal “mouse” and small herbivorous mammal “vole” considers the following refinement parameters:

- Ecologically relevant reproductive toxicity endpoint for pyraclostrobin
- Residue decline of pyraclostrobin in plants for refinement of MAF x twa
- Identification of representative mammal species including ecological data (PT and PD values and FIR)
- Interception by cereal and maize plants

Taking these refinement steps into account, all relevant TER_{LT} values exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects indicating a low and acceptable risk to mammals from the use of BAS 500 06 F in cereals and maize and BAS 516 07 F in potatoes. A low long-term risk to mammals from applications of BAS 500 06 F is further confirmed by two field effect studies with BAS 500 06 F.

Food chain behaviour (secondary poisoning) and bioaccumulation

Based on the tier 1 assessment all TER values for the risk assessments for earthworm- and fish-eating mammals, for pyraclostrobin as contained in BAS 500 06 F and BAS 516 07 F, exceed the trigger of 5 set by Commission regulation (EU) 546/2011 for acceptability of effects for secondary poisoning. The bioaccumulation potential of pyraclostrobin was considered as low in the respective EU reviews and therefore further evaluation on biomagnification is not necessary. It can therefore be concluded that the application of BAS 500 06 F and BAS 516 07 F does not raise concerns regarding food chain behaviour (secondary poisoning) or biomagnification.

Drinking water risk assessment

Following EFSA/2009/1438, the puddle scenario is the one relevant for mammals. Since the ratio of the effective application rate to the relevant toxicity endpoints is below the value of 3000 for pyraclostrobin, conducting a quantitative risk assessment for the proposed use pattern of BAS 500 06 F and BAS 516 07 F is not necessary. In conclusion the proposed use pattern of BAS 500 06 F in cereals and maize and BAS 516 07 F in potatoes does not pose a risk to birds via uptake of contaminated drinking water.

Effects of the formulation

All TER_A values from the tier 1 acute dietary risk assessment of the formulation BAS 516 07 F, calculated for the virtual compound as well as for the formulation, exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects.

For BAS 500 06 F, the TER_A from the tier 1 acute dietary risk of the formulation was below the trigger for the large herbivorous mammal scenario “lagomorph” (cereals) and the small herbivorous mammal scenario “vole” (cereals at BBCH ≥ 40 and maize at BBCH 30 - 39) and required refinement.

For the refined acute risk assessment the following parameters are considered:

- Residue decline of pyraclostrobin in plants for refinement of MAF_{90}
- Identification of representative mammal species including ecological data (PD values and FIR)

Taking these refinement steps into account, the refined TER_A value for the large herbivorous mammal scenario "lagomorph" and the small herbivorous mammal scenario "vole" in cereals exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. The conservatively refined TER_A value for the small herbivorous mammal scenario "vole" was slightly below the trigger for ~~cereals and~~ maize.

A further higher tier assessment of the small herbivorous mammal scenario based on three lines of evidence (i.e. results from a body burden modelling approach in small mammals, dietary toxicity studies under field-relevant exposure conditions, and results from two field effect studies with BAS 500 06 F) indicates a low and acceptable risk to mammals from the use of BAS 500 06 F in cereals and maize.

Overall conclusion

It can be concluded that the application of BAS 500 06 F in cereals and maize and BAS 516 07 F in potatoes according to good agricultural practice will not adversely affect mammals under natural conditions.

Effects on other terrestrial vertebrate wildlife (reptiles and amphibians)

Pyraclostrobin shows inherent toxicity to amphibians and can cause mortality to young and sensitive amphibian metamorphs under worst-case laboratory conditions at and below maximum field rates. However, this is only true if those sensitive metamorphs are exposed to direct overspraying. An additional soil residue study exposing animals on treated soil demonstrate strongly reduced toxicity already shortly after spraying and no toxicity was seen if introduced 4 hours after spraying. Furthermore, two semi-field studies with BAS 500 06 F performed with young metamorphs under realistic worst-case conditions in cereals at BBCH 25-30 using the full field rate of 250 g a.s./ha and higher rates (+25% in the 1st study with frogs and +50% in the 2nd study with toads), showed no mortality and no significant sublethal effects to frogs and no effects on toads were observed (at field rates up to 375 g a.s./ha). The semi-field studies cover on the one side all relevant exposure routes including direct spray, uptake from contaminated surfaces and potential oral uptake of potentially contaminated feed items. On the other side it also includes more realistic exposure considering plant interception and above all amphibian behavioral aspects leading to reduced exposure (such as hiding).
Data from literature indicate that certain formulations produce higher toxicity while others show a reduced toxicity. Particularly formulations with high organic solvent content maximizing immediate and full bioavailability of the active substance (and which may themselves have certain direct toxicity to amphibians) show higher toxicity. The semi-field study was performed with the EC formulated product BAS 500 06 F, having a high content of organic solvents, and thus constituting a respective worst-case formulation.
BAS 516 07 F is applied at much lower rates of pyraclostrobin (17 g a.s./ha). This is about three times below the rate at which even under worst-case laboratory conditions no effects are observed. Furthermore, BAS 516 07 F is a WG-formulated product, which does not contain organic solvents and which is expected to have a reduced toxicity.

There is no indication that reptiles might be particularly at risk from applications of this fungicide. It is considered that the risks to reptiles are fully covered by the risk assessment to other vertebrates (birds, mammals, amphibians) shown above.

Overall Conclusion

Pyraclostrobin and certain pyraclostrobin containing products show inherent toxicity to sensitive amphibian live stages. However, a refined risk assessment and a higher tier semi-field study performed under realistic worst-case conditions showed low risk of BAS 500 06 F applications in cereals under realistic conditions. BAS 516 07 F is applied at much lower rates ensuring low risk to amphibians for applications of this product in potatoes.

9.2 Summary of effects on aquatic organisms

BAS 500 06 F and BAS 516 07 F are two new representative formulations, which have not been evaluated during a previous Annex I inclusion. For pyraclostrobin and its major metabolites, the EU agreed endpoints plus endpoints from new, supplementary studies as well as revised endpoints from EU agreed studies are used for the risk assessment on aquatic organisms. The risk assessment is based on the already registered uses of BAS 500 06 F and BAS 516 07 F.
BAS 500 06 F: 2 x 1.25 L product/ha equivalent to 250 g a.s./ha in cereals and 1x 1.0 L product/ha (equivalent to 200 g a.s./ha) in maize
BAS 516 07 F: 4 x 0.25 kg product/ha; equivalent to 17 pyraclostrobin/ha in potato

The TER values for all metabolites of pyraclostrobin are significantly above the respective trigger values based on worst-case standard assumptions; they are thus considered not to be of ecotoxicological relevance.

The acute and long-term TER values for aquatic insects, aquatic crustaceans, algae and the aquatic plant *Lemna gibba* exposed to pyraclostrobin exceed the required trigger values, indicating low risk to these groups of aquatic organisms. TER values for fish and daphnids, however, do not meet the required trigger value for applications close to sensitive surface water bodies according to standard worst-case assumptions. However, higher tier studies (such as a mesocosm study covering the risk to aquatic invertebrates including *Daphnia* and a SSD for fish) demonstrate the lack of an unacceptable risk from the use of this substance in winter and spring cereals according to good agricultural practice if no-spray buffer zones of 5 m or 50% drift reducing nozzles are considered. Application in potato and maize according to the proposed GAP and good agricultural practice is of low risk to aquatic ecosystems with no need for any additional mitigation measures.

The studies performed with the formulated products BAS 500 06 F and BAS 516 07 F reflect the toxicity of the active substance pyraclostrobin and there is no indication of any higher (or unexpected) toxicity of the products. Therefore, the risk assessment presented based on the data of the active substance also covers the risk to aquatic organisms following the proposed uses of BAS 500 06 F and BAS 516 07 F.

Overall Conclusion
The active substance pyraclostrobin is toxic to aquatic organisms, in particular to fish and contamination of water must be avoided. However, a refined risk assessment has been performed based on a number of additional and higher tier studies. According to the refined risk assessment it can be concluded that applications according to GAP and good agricultural practice will be of low risk to aquatic ecosystems for application of BAS 500 06 F in winter and spring cereals if no-spray buffer zones of 5 m or the use of 50% drift reducing nozzles are considered. For the proposed uses of BAS 500 06 F in maize and BAS 516 07 F in potato, low risk to aquatic organisms can be shown with no need for additional mitigation measures.

9.3 Summary of effects on arthropods

Bees

The calculated HQs for acute oral and acute contact exposure of honeybees to pyraclostrobin and the formulated products BAS 516 07 F and BAS 500 06 F are below the Commission Regulation (EU) 546/2011 trigger value of 50.

Additionally, no unacceptable effects in queen development, queen survival and adult worker bee health at 400 ppm Pristine treated pollen (which is based on analysis equivalent to 22 ppm pyraclostrobin treated pollen) were observed. Furthermore, the potential acute toxicity (oral and contact) of pyraclostrobin to adult bumblebees was addressed in a laboratory study. As currently no risk assessment scheme exists, these results are presented as additional information.

Furthermore, no unacceptable effects were observed in a semi-field tunnel study conducted with BAS 500 06 F on honeybee colonies in flowering *Phacelia tanacetifolia* with focus on bee brood at a rate of 1.25 L/ha. The study was carried out according to EPPO Guideline 170 (4) and the OECD Guidance Document. The test item caused no unacceptable effects on honeybee survival, colony development and colony strength when applied at a rate of 1.25 L/ha under semi-field conditions (tunnel) to *P. tanacetifolia* during active foraging conditions. The brood termination rates, the brood indices as well as the brood compensation indices indicate no test item related effect on the brood development following the labelling of the eggs.

Overall conclusion:
The recommended representative uses of BAS 516 07 F and BAS 500 06 F according to good agricultural practice present a low risk to honeybees and will not adversely affect honeybees or honeybee colonies.

Non-target arthropods other than bees

In the case of the formulated product BAS 516 07 F, the calculated hazard quotient of the first tier risk assessment indicated no in-field and no off-field risk for both tested species. However, in order to have additional information for the risk assessment, Tier II tests were carried out with *C. carnea*, *A. bilineata*, *P. cupreus* and *Pardosa* spec. For these species the Tier II risk assessment indicated no in-field and no off-field risk, too. Additionally, three field studies were carried out to observe effects on natural occurring populations of predatory mites. No unacceptable effects on population development of predatory mites were observed up to 5 x 0.75 kg/ha. Therefore, a potential in-field and off-field risk can be excluded for BAS 516 07 F at the proposed use pattern of 4 x 0.25 kg/ha.

Considering the formulated product BAS 500 06 F, a potential in-field risk to non-target arthropods cannot be excluded (HQ > 2) based on the calculated $HQ_{in\text{-}field}$ of *T. pyri* and *A. rhopalosiphi*. Therefore, higher Tier 2 tests were carried out with *T. pyri* and *A. rhopalosiphi* and additionally with the foliage-dweller *Chrysoperla carnea* and the soil-dweller *Aleochara bilineata*. For *T. pyri*, *A. rhopalosiphi* and *A. bilineata* no risk was indicated for in- and off-field habitats. Based on the results of an extended laboratory study with *C. carnea*, a potential risk for in-field habitats cannot be excluded. Therefore, an aged residue study with *C. carnea* was carried out under more realistic conditions, which resulted in no unacceptable effects on survival and reproduction at DAT 0 up to 1.25 L/ha and DAT 7 up to 2.5 L/ha. Based on the results of the aged residue study, no in-field and off-field risk for *C. carnea* is indicated.

Overall conclusion:

Taking into account all available data, it can be concluded that low risk for non-target arthropods is expected from the use of the representative formulations BAS 516 07 F and BAS 500 06 F at application rates of up to 4 x 0.25 kg/ha and 2 x 1.25 L/ha, respectively. No unacceptable effects on non-target arthropods are expected in in-field and off-field habitats.

9.4 Summary of effects on non-target soil meso- and macrofauna

Acute studies on earthworms were performed with pyraclostrobin, its metabolites (BF 500-6 and BF 500-7) and with the representative formulations (BAS 516 07 F and BAS 500 06 F). The results of the acute studies conducted both products are presented as additional information (please refer to M- CP 10.7). Chronic studies with earthworms and collembolans were carried out with pyraclostrobin (earthworm only), the metabolites BF 500-6 and BF 500-7 as well as with the two formulations. Moreover, chronic studies on soil mites and field studies on earthworms have been conducted with both products.

In the risk assessment, all TER values exceeded the trigger value of 5 for chronic exposure.

A study with BAS 500 06 F on organic matter breakdown is presented as additional information in M-CP 10.7.

Overall conclusion:
It is concluded that the recommended representative uses of BAS 516 07 F and BAS 500 06 F will not pose any unacceptable risks to populations of earthworms or other soil macro-organisms.

9.5 Summary of effects on soil nitrogen transformation

BAS 516 07 F (tested as minor change formulation BAS 516 00 F) had no significant effect on soil micro-organisms at 24 mg BAS 516 07 F/kg dry soil, corresponding to 1.6 mg pyraclostrobin/kg dry soil and 8.0 mg total a.s./kg dry soil. These concentrations are approximately 107 higher than the maximum $PEC_{soil, max}$ of 0.015 mg pyraclostrobin/kg dry soil - and approximately 31-times higher than the sum of the highest PEC-values for both a.s., i.e. 0.260 mg total a.s./kg dry soil. This supports the conclusion that under field conditions, the use of BAS 516 07 F at the proposed rates poses no unacceptable risk to non-target soil micro-organisms.

BAS 500 06 F had no significant effect on soil micro-organisms at 17.3 mg BAS 500 06 F/kg dry soil, corresponding to 3.33 mg pyraclostrobin/kg dry soil. This is approximately 15 times higher than the maximum $PEC_{soil, max}$ of 0.228 mg pyraclostrobin/kg dry soil. This supports the conclusion that under field conditions, the use of BAS 500 06 F at the proposed rates poses no unacceptable risk to non-target soil micro-organisms.

The NOEC values of the pyraclostrobin metabolites BF 500-6 and BF 500-7 are higher than the respective worst-case PEC values.

Overall conclusion:
It is concluded that the recommended representative uses of BAS 516 07 F and BAS 500 06 F will not pose an unacceptable risk to non-target soil micro-organisms, if applied according to the recommended use pattern.

9.6 Summary of effects on terrestrial non-target higher plants

Based on the risk assessments it can be concluded that the use of BAS 516 07 F and BAS 500 06 F poses no unacceptable risk to non-target plants. Particular precautions to reduce the environmental concentrations resulting from BAS 516 07 F and BAS 500 06 F applications are not required for the protection of terrestrial non-target plants.

Overall conclusion:
It is concluded that the uses of BAS 516 07 F and **BAS 500 06 F according to the recommended use pattern will not pose an unacceptable risk to non-target plants.**

9.7 Summary of effects on other terrestrial organisms (flora and fauna)

A study on carbon transformation (BAS 516 07 F tested as BAS 516 00 F), studies on acute earthworm toxicity (both products) and a study with BAS 500 06 F on organic matter breakdown has been carried out. The results are presented as additional information.

9.8 Summary of effects on biological methods for sewage treatment

Disturbances in the bio-degradation process of activated sludge are not to be expected if the test item is correctly introduced into adapted wastewater treatment plants at low concentrations.

9.9 Summary of product exposure and risk assessment

Applications of the formulated products BAS 500 06 F and BAS 516 07 F according to good agricultural practice will not adversely affect birds and mammals and other vertebrates (amphibians) under natural conditions.

The formulated products are toxic to aquatic organisms and contamination of aquatic ecosystems must be prevented. However, according to the risk evaluation presented, low risk to aquatic organisms can be demonstrated. For the proposed uses of BAS 500 06 F, low risk to aquatic organisms can be shown if no-spray buffer zones of 5 m or the use of 50% drift reducing nozzles for winter and spring cereals are considered. For the proposed uses of BAS 500 06 F in maize and BAS 516 07 F in potatoes, low risk to aquatic organisms can be demonstrated with no need for any additional mitigation measures.

Following application of both representative formulations no risk or unacceptable effects are expected for honeybees, non-target arthropods others than bees, non-target meso- and macrofauna, soil nitrogen transformation processes and non-target higher plants. Particular precautions to reduce the environmental concentrations resulting from BAS 500 06 F and BAS 516 07 F applications are not required for the protection of terrestrial non-target organisms.

Comprehensive risk assessments for aquatic organisms and terrestrial vertebrates are presented in M-CP 10.1 and 10.2. For risk assessments of arthropods, soil meso- and macrofauna, soil micro-organisms and non-target terrestrial plants please refer to M-CP 10.3 – 10.6.

10 CLASSIFICATION AND LABELLING

10.1 Classification and labelling of the active ingredient

The following harmonized classification and labelling was adopted for pyraclostrobin:

Legislation	**Classification**	**Labelling**	**Concentration limits**
Directive 67/548/EEC	T, N R: 23-38-50-53	T, N R: 23-38-50/53 S: 1/2-45-60-61-63	None
Regulation (EC) No 1272/2008	Hazard class and category code: Acute Tox. 3 Skin Irrit. 2 Aquatic Acute 1 Aquatic Chronic 1 Hazard statement code: H331, H315, H400, H410	Pictogram signal word code: GHS06 GHS09 Danger Hazard statement code: H331, H315, H410	M-factor = 100

Single accidental exposure of humans to spray mist of pyraclostrobin containing formulations resulted in symptoms of respiratory irritation (see M-CA 5.9.3). Based on this direct observation in humans and supportive evidence for respiratory irritation observed in subchronic inhalation studies in rats (see CA 5.3.3/1 and 5.3.3/2), BASF self-classified pyraclostrobin with STOT SE Category 3 (H335, May cause respiratory irritation). Consequently, BASF proposes for pyraclostrobin the classification and labelling as shown below.

Legislation	**Classification**	**Labelling**	**Concentration limits**
Directive 67/548/EEC	T, N R: 23-37-38-50-53	T, N R: 23-37/38-50/53 S: 1/2-45-60-61-63	None
Regulation (EC) No 1272/2008	Hazard class and category code: Acute Tox. 3 Skin Irrit. 2 Aquatic Acute 1 Aquatic Chronic 1 STOT SE 3 Hazard statement code: H331, H315, H400, H410, H335	Pictogram signal word code: GHS06 GHS09 Danger Hazard statement code: H331, H315, H410, H335	M-factor = 100

10.2 Classification and labelling

Formulation BAS 500 06 F:

Proposed classification according to Regulation (EC) No 1272/2008 on the classification, labelling and packaging of substances and mixtures:

Labelling:	Signal word:	Danger
	Hazard statements:	H319, H315, H332, H302, H317, H304, H400, H410, EUH401
	Precautionary statements:	please refer to document CP12

Proposed classification according to Dangerous Substances Directive (Directive 67/548/EEC):

Labelling:	Indication of danger:	Harmful, Dangerous for the environment
	R-phrases:	R20/22, 38, 43, 50/53
	S-phrases:	please refer to document CP12

Formulation BAS 516 07 F:

Proposed classification according to Regulation (EC) No 1272/2008 on the classification, labelling and packaging of substances and mixtures:

Labelling:	Signal word:	Warning
	Hazard statements:	H400, H410, EUH401
	Precautionary statements:	please refer to document CP12

Proposed classification according to Dangerous Substances Directive (Directive 67/548/EEC):

Labelling:	Indication of danger:	Dangerous for the environment
	R-phrases:	R50/53
	S-phrases:	please refer to document CP12

11 RELEVANCE OF METABOLITES IN GROUNDWATER

11.1 Summary

None of the pyraclostrobin metabolites poses any risk for groundwater contamination.

11.2 Conclusion

A relevance assessment is not considered necessary.

12 CONSIDERATION OF ISOMERIC COMPOSITION IN THE RISK ASSESSMENT

Pyraclostrobin does not consist of any isomers.

FURTHER INFORMATION TO BE SUBMITTED

None

Appendix 1: Metabolites formed from Active Substance and their occurrence

Version history[1]

Date	Data points containing amendments or additions and brief description	Document identifier and version number
18-Jul-2014		BASF DocID 2014/1165142 (version 1)
27-Feb-2017	Chapter 3: The results of a rat metabolism study with metabolite 500M106 and new endpoints derived from toxicity studies with metabolites 500M02 and 500M106 were included. In addition update of information on 500M62. Chapter 4: A new residue trial in potatoes was added. Chapter 6: Update of the mammal risk assessment and consideration of two new amphibia studies as well as a new bumble bee study. New or changed text is marked in yellow.	BASF DocID 2017/1032928 (version 2)

[1] It is suggested that applicants adopt a similar approach to showing revisions and version history as outlined in SANCO/10180/2013 Chapter 4 How to revise an Assessment Report

LISTING OF END POINTS FOR *ACTIVE SUBSTANCE*

Chapter 1: Identity, Physical and Chemical Properties, Details of Uses and Further Information, and Proposed Classification and Labelling

Active substance (ISO Common Name)	Pyraclostrobin
Function (*eg.* fungicide)	Fungicide
Rapporteur Member State	Germany

Identity (SANCO/11802 data point 1)

Chemical name (IUPAC)	methyl N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxymethyl}phenyl) N-methoxy carbamate
Chemical name (CA)	carbamic acid, [2-[[[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxy]methyl]phenyl]methoxy-, methyl ester
CIPAC No	657
CAS No	175013-18-0
EC No (EINECS or ELINCS)	not assigned
FAO Specification (including year of publication)	not assigned
Minimum purity of the active substance as manufactured (g/kg)	975 g/kg
Identity of relevant impurities (of toxicological, environmental and/or other significance) in the active substance as manufactured (g/kg)	Dimethyl sulfate (max. 1 mg/kg)
Molecular formula	$C_{19}H_{18}ClN_3O_4$
Molecular mass	387.8 g/mol
Structural formula	
Physical-chemical properties (SANCO/11802 data point 2)

Melting point and boiling point (state purity)	Melting point: 63.7 - 65.2°C (99.8%) Boiling point: no boiling point up to decomposition at 200°C (99.8%)
Vapour pressure, volatility (in Pa, state temperature and purity)	Vapour pressure: 2.6 x 10^{-8} Pa, 20°C (99.8%) Henry's law constant: 5.307 x 10^{-6} Pa m^3 mol^{-1}
Appearance (physical state, colour)	PAI (99.8%): white to light beige crystalline solid TGAI (amorphous, 96.8%): solid, amber, glass like material TGAI (crystalline, 99.4%): solid, light yellow, odourless, fine crystalline powder
Spectra (UV/VIS, IR, NMR, MS), molar extinction at relevant wavelengths, optical purity	UV-Vis absorption (22°C, 99.8%): 2.5 x 10^4 L mol^{-1} cm^{-1} at 205 nm 2.4 x 10^4 L mol^{-1} cm^{-1} at 275 nm
Solubility in water (in g/l or mg/l, state temperature and purity)	1.9 ± 0.17 mg/L at 20°C (99.8%) in deionised water (pH of 5.8) There is no dissociation in water, therefore pH dependence on solubility is not applicable.
Solubility in organic solvents (in g/l or mg/l, state temperature and purity)	All data at 20°C (purity: 99.8%) n-heptane 3.7 g/L solution 2-propanol 30.0 g/L solution octanol 24.2 g/L solution olive oil 28.0 g/L solution methanol 100.8 g/L solution acetone >500 g/L solution ethyl acetate >500 g/L solution acetonitrile >500 g/L solution dichloromethane >500 g/L solution toluene >500 g/L solution
Partition coefficient n-octanol/water (log POW) (state pH and temperature)	3.99 (20°C, 99.8%)
Dissociation in water (state purity)	not applicable (no indication of dissociation in water)
Flammability and self-heating (state purity)	not highly flammable, not self-heating (99.0 and 99.9%)
Flash point (state purity)	not applicable (test material has a melting point >40°C)
Explosive properties (state purity)	not explosive (99.0 and 99.9%)
Surface tension (state concentration and temperature, state purity)	71.8 mN/m at 0.5 % (w/w) (20°C, 98.5%) 71.5 mN/m at 2.0 % (w/w) (20°C, 98.5%)
Oxidising properties (state purity)	not oxidising (99.0 and 99.9%)

Chapter 2: Methods of Analysis

Analytical methods for the active substance (SANCO/11802 data point 4.1)

Technical as (principle of method)	Reverse phase HPLC with UV detection and external calibration
Impurities in technical as (principle of method)	Significant impurities: see Document J Dimethyl sulfate: Solid-phase microextraction (SPME) coupled to GC/MS and external calibration
Plant protection product (principle of method)	Active substance in BAS 500 06 F and BAS 516 07 F: Reverse phase HPLC with UV detection and external standard Dimethyl sulfate in both formulations: Head space GC-MS with internal standard

Analytical methods for residues (SANCO/11802 data point 4.1 to 4.2)

Residue definitions for monitoring purposes

Food/feed of plant origin	Pyraclostrobin (parent)
Food/feed of animal origin	Pyraclostrobin (parent)
Soil	Pyraclostrobin (parent)
Water surface drinking/ground	Pyraclostrobin (parent) Pyraclostrobin (parent)
Air	Pyraclostrobin (parent)
Body fluids and tissues	Pyraclostrobin (parent)

Monitoring/Enforcement methods

Food/feed of plant origin (principle of method and LOQ for methods for monitoring purposes)	BASF Method 421/0: LC/MS-MS: LOQ 0.02 mg/kg QuEChERS method: LC/MS-MS: LOQ: 0.01 mg/kg
Food/feed of animal origin (principle of method and LOQ for methods for monitoring purposes)	BASF method L0151/01: LC/MS-MS: LOQ: 0.01 mg/kg
Soil (principle of method and LOQ)	BASF method L0166/01: LC/MS-MS: LOQ: 0.001 mg/kg or BASF method L0161/01: LC/MS-MS: LOQ: 0.001 mg/kg
Water (principle of method and LOQ)	BASF method L0182/02: LC/MS-MS: LOQ: 0.003 µg/L
Air (principle of method and LOQ)	BASF method L0197/01: LC/MS-MS: LOQ: 4.44 ng/L
Body fluids and tissues (principle of method and LOQ)	BASF method L0151/01: LC/MS-MS: LOQ: 0.01 mg/kg

Classification and proposed labelling (SANCO/11802 data point 10 and SANCO/11803 data point 12) according to Regulation (EC) No 1272/2008

Active substance

Pictogram:		
Signal words:	Danger	
Hazard statements:	H315	Causes skin irritation.
	H331	Toxic if inhaled.
	H400	Very toxic to aquatic life.
	H410	Very toxic to aquatic life with long lasting effects.
	H335	May cause respiratory irritation.
Precautionary statements:	P271	Use only outdoors or in a well-ventilated area.
	P273	Avoid release to the environment.
	P280c	Wear protective gloves.
	P260h	Do not breathe mist or vapour.
	P260i	Do not breathe dust/gas/mist/vapours.
	P264	Wash with plenty of water and soap thoroughly after handling.
	P311	Call a POISON CENTER or doctor/physician.
	P304 + P340	IF INHALED: Remove victim to fresh air and keep at rest in a position comfortable for breathing.
	P303 + P352	IF ON SKIN (on hair): Wash with plenty of soap and water.
	P391	Collect spillage.
	P332 + P313	If skin irritation occurs: Get medical advice/attention.
	P362	Take off contaminated clothing and wash before reuse.
	P403 + P233	Store in a well-ventilated place. Keep container tightly closed.
	P405	Store locked up.
	P501	Dispose of contents/container to hazardous or special waste collection point.

Product BAS 500 06 F

Pictogram:	
Signal words:	Danger
Hazard statements:	H319 Causes serious eye irritation. H315 Causes skin irritation. H332 Harmful if inhaled. H302 Harmful if swallowed. H317 May cause an allergic skin reaction. H304 May be fatal if swallowed and enters airways. H400 Very toxic to aquatic life. H410 Very toxic to aquatic life with long lasting effects. EUH401 To avoid risks to human health and the environment, comply with the instructions for use.

Precautionary statements:	**P280**	Wear protective gloves/clothing.
	P261	Avoid breathing vapours.
	P264	Wash contaminated body parts thoroughly after handling.
	P270	Do not eat, drink or smoke when using this product.
	P271	Use only outdoors or in a well-ventilated area.
	P272	Contaminated work clothing should not be allowed out of the workplace.
	P301 + P310	IF SWALLOWED: Immediately call a POISON CENTER or doctor/physician.
	P331	Do NOT induce vomiting.
	P305 + P351 + P338	IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing.
	P302 + P352	IF ON SKIN: Wash with plenty of soap and water.
	P330	Rinse mouth.
	P304 + P340	IF INHALED: Remove victim to fresh air and keep at rest in a position comfortable for breathing.
	P361	Remove/Take off immediately all contaminated clothing.
	P391	Collect spillage.
	P501	Dispose of contents/container to hazardous or special waste collection point.

***** P-statements in **bold** are recommended for product label

Product BAS 516 07 F

Pictogram:		
Signal words:	Warning

Chapter 3: Impact on Human and Animal Health

Absorption, distribution, excretion and metabolism in mammals (SANCO/11802 data point 5.1)

Rate and extent of absorption:	Parent: Rapid absorption: Tmax ~ 1 hour: 50% (based on urinary and biliary excretion within 48 hours)
Distribution:	Parent: Widely, highest concentrations in the liver
Potential for accumulation:	None
Rate and extent of excretion:	Parent: Complete within 5 d, mainly via feces (80-90%, biliary excretion amounting to 35%), via urine 11-15% Metabolite 500M106: Complete within 5 d, mainly via feces (85-90%), via urine 16-18%
Metabolism in animals	Parent: Extensive (>95%) with more than 50 metabolites Main metabolic pathways included N-desmethoxylation, hydroxylation, cleavage of ether bond and further oxidation of the resulting molecule parts, conjugation with glucuronic acid or sulphate Metabolite 500M106: Extensive with more than 10 metabolites Main metabolic pathways included cleavage of the NO bond followed by dimerization, hydroxylation, cleavage of ether bond, conjugation with glucuronic acid or sulphate
Toxicologically significant compounds (animals and plants)	Parent and metabolites
Toxicologically significant compounds (environment)	Parent

Acute toxicity (SANCO/11802 data point 5.2)

Rat LD_{50} oral	LD_{50} > 5000 mg/kg bw
Rat LD_{50} dermal	LD_{50} > 2000 mg/kg bw
Rat LC_{50} inhalation	LC_{50} = 0.58 mg/L
Skin irritation	Irritating
Eye irritation	Not irritating
Skin sensitization (test method used and result)	Not sensitising (M & K maximisation test)
Phototoxicity	Not phototoxic

Short term toxicity (SANCO/11802 data point 5.3)

Target / critical effect	Reduced body weight, gastrointestinal tract, red blood cells, diarrhoea (dog), hepatocellular hypertrophy (rat), white blood cells and lymphatic organs (mouse), local irritation of the upper respiratory tract (rat inhalation)
Lowest relevant oral NOAEL / NOEL	90-day mouse[#]: 30 ppm (4 mg/kg bw/d)
Lowest relevant dermal NOAEL / NOEL	28-day rat: > 250 mg/kg bw/d (systemic toxicity)
Lowest relevant inhalation NOAEL / NOEL	0.01 mg/L (local toxicity) 0.3 mg/L (systemic toxicity)

[#] based on effects on body weight after 90 days in the carcinogenicity study in male mice

Genotoxicity (SANCO/11802 data point 5.4)

In vitro studies	Weight of evidence suggests no genotoxic concern
In vivo studies in somatic cells	Not genotoxic
In vivo studies in germ cells	No data, not required

Long term toxicity and carcinogenicity (SANCO/11802 data point 5.5)

Target/critical effect	Reduced body weight (rat & mouse); liver cell necrosis (rats)
Lowest relevant NOAEL / NOEL	24-months, rat/mouse: 75/30 ppm (4 mg/kg bw/d)
Carcinogenicity	No evidence of carcinogenicity

Reproductive toxicity (SANCO/11802 data point 5.6)

Reproduction target / critical effect	Reduced pup body weight gain in the presence of parental toxicity
Lowest relevant reproductive NOAEL / NOEL	Rat: 75 ppm (8.2 mg/kg bw/d)
Developmental target / critical effect	Developmental effects in rats and embryotoxicity (including malformations) in rabbits at maternally toxic doses
Lowest relevant developmental NOAEL / NOEL	Rabbit: 5 mg/kg bw/d
Lowest relevant maternal NOAEL / NOEL	Rabbit: 3 mg/kg bw/d

Neurotoxicity / Delayed neurotoxicity (SANCO/11802 data point 5.7)

Acute neurotoxicity	Not neurotoxic; NOAEL > 1000 mg/kg bw
Subchronic neurotoxicity	Not neurotoxic; NOAEL > 50 mg/kg bw/d in males and > 112 mg/kg bw/d in females (highest doses tested)

Other toxicological studies (SANCO/11802 data point 5.8)

Toxicity studies of metabolites	**Plant and livestock metabolites** **Group 2** **500M04** - LD50 oral > 2000 mg/kg bw - not irritating to skin and eye, not a skin sensitizer - 90-day dietary rat study: NOAEL 102 mg/kg bw/day (males), 316 mg/kg bw/day (females), target organs: red-blood cell system, kidney - no evidence for genotoxicity in vitro and in vivo - ADI: 0.52 mg/kg bw/day (200 SF, 90-day rat study) **Conclusion: not toxicologically relevant** **Group 3** **500M24** - no evidence for genotoxicity in vitro and in vivo - ADI: 0.0015 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) - ARfD: 0.005 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) **Conclusion: not toxicologically relevant** **500M49** - no evidence for genotoxicity in vitro - ADI: 0.0015 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) - ARfD: 0.005 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) **Conclusion: not toxicologically relevant** **500M51** - no evidence for genotoxicity in vitro - ADI: 0.0015 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) - ARfD: 0.005 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) **Conclusion: not toxicologically relevant** **Group 6** **500M76** - no evidence for genotoxicity in vitro and in vivo - ADI: 0.0015 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) - ARfD: 0.005 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) **Conclusion: not toxicologically relevant** **Metabolites identified in new metabolism studies** **500M02** no evidence for genotoxicity in vitro - ADI: 0.5 mg/kg bw/day (600 SF, extended 28-day rat study with metabolite 500M106) - ARfD: not needed **Conclusion: not toxicologically relevant** **500M106** - 28-day oral gavage rat study: NOAEL 300 mg/kg bw/day (both sexes), target organs: duodenum, liver, spleen and the hematological system - no evidence for genotoxicity in vitro and in vivo - ADI: 0.5 mg/kg bw/day (600 SF, extended 28-day rat study) - ARfD: not needed **Conclusion: not toxicologically relevant**

Water photolysis metabolites **500M60** - no evidence for genotoxicity in vitro and in vivo **Conclusion: not toxicologically relevant** **500M62** - by weight of evidence no conclusive alert for genotoxicity - high weight of evidence being not genotoxic based on comparison to 8 already tested metabolites and due to metabolic considerations - not genotoxic in the Ames test **Conclusion: not toxicologically relevant**

Medical data (SANCO/11802 data point 5.9)

.....	Exposure to humans may result in irritation of skin and eyes. Accidental inhalation of pyraclostrobin containing products was reported to result in symptoms of respiratory irritation

Summary	Value	Study	Safety factor
ADI	0.03 mg/kg bw/day	2-year study in rats	100
AOEL	0.015 mg/kg bw/day	Developmental toxicity, rabbit (maternal effects); 50% oral absorption	100
ARfD (acute reference dose)	0.03 mg/kg bw/day	Developmental toxicity, rabbit (maternal effects)	100

Dermal absorption (SANCO/11803 data point 7.3)

.....	**BAS 500 06 F (EC):** Concentrate: 3% Spray dilute: 7% **BAS 516 07 F (WG):** Concentrate: 0.2% Spray dilute 5%

Acceptable exposure scenarios (including method of calculation)

BAS 500 06 F (EC formulation) in cereal crops and maize

Operator	BBA-model with PPE: 6% of AOEL UK-POEM with PPE: 165% of AOEL Refined risk assessment based on field exposure data, with PPE: 0.3% of AOEL

Chapter 4: Residues

Metabolism in plants (SANCO/11802 data point 6.2.1 and 6.7)

Plant groups covered	Fruits (grapes), root and tuber vegetables (potatoes), leafy vegetables (Chinese cabbage), cereals (wheat, rice)
Rotational crops	Root crop (radish), leafy vegetables (lettuce), cereals (wheat)
Metabolism in rotational crops similar to metabolism in primary crops?	Yes
Processed commodities	Stable under hydrolysis conditions according to OECD 507, degradation to 500M07, 500M04 and 500M49 under conditions of oil processing (deodorization step, 190°C and 240°C)
Residue pattern in processed commodities similar to residue pattern in raw commodities	Yes
Plant residue definition for monitoring	Pyraclostrobin (parent)
Plant residue definition for risk assessment	Pyraclostrobin (parent)
Conversion factor (monitoring to risk assessment)	None

Metabolism in livestock (SANCO/11802 data points 6.2.2 to 6.2.5 and 6.7)

Animals covered	Ruminant (goat), poultry (hen), fish (rainbow trout)
Time needed to reach a plateau concentration in milk and eggs	Goat - milk: about 3 days Poultry - eggs: not reached after 7 days of dosing
Animal residue definition for monitoring	Pyraclostrobin (parent)
Animal residue definition for risk assessment	Pyraclostrobin and its metabolites analysed as the hydroxypyrazoles BF 500-5 (synonym 500M04) and BF 500-8 (synonym 500M85), sum expressed as pyraclostrobin
Conversion factor (monitoring to risk assessment)	Liver (w/o poultry): 4 All other: 1
Metabolism in rat and ruminant similar (yes/no)	Yes
Fat soluble residue: (yes/no)	Yes

Residues in succeeding crops (SANCO/11802 data point 6.6)

30, 120, 365 days plant back interval after application of 0.9 kg as/ha: TRR in the edible parts for human consumption are very low (radish roots, lettuce: < 0.040 mg/kg; wheat grain: < 0.089 mg/kg). No accumulation of pyraclostrobin or its degradation products (radish, lettuce: < 0.0106 mg/kg; wheat straw: < 0.0147 mg/kg; wheat grain: not detectable)

Stability of residues (SANCO/11802 data point 6.1)

Food of plant origin (peanut nutmeat, peanut oil, wheat grain, wheat straw, sugar beet tops, sugar beet roots, tomatoes, grape juice): Pyraclostrobin and metabolite BF 500-3 stable for 18 months (peanut) or 25 months (all other matrices) Food of animal origin: Pyraclostrobin stable for 8 month, metabolite BF 500-10 (model compound) with slow degradation, but sufficiently stable to evaluate the submitted feeding study (analysed within 6 month)

Residues from livestock feeding studies (SANCO/11802 data point 6.4)

Intakes by livestock ≥ 0.1 mg/kg diet (dry weight basis) (yes/no – if yes, specify the level):	Ruminant: Yes 4.0 mg/kg (dairy) 6.9 mg/kg (beef)	Poultry: Yes 0.65 mg/kg	Pig: Yes 1.2 mg/kg
Potential for accumulation (yes/no):	Yes	Yes	Yes
Metabolism studies indicate potential level of residue ≥ LOQ in edible tissue	Yes	No	Yes
Muscle	< 0.05* / < 0.1**		< 0.05*
Liver	< 0.05* / 0.2**		< 0.05*
Kidney	< 0.05* / < 0.1**		< 0.05*
Fat	< 0.05* / < 0.1**		< 0.05*
Milk	< 0.01* / < 0.02**		n.a.
Eggs	n.a.		n.a.

* Residue levels according to the enforcement method used during the cow feeding study
** Residue levels according to the data generation method used during the cow feeding study

Summary of critical residue data (SANCO/11802 data point 6.3)

Crop	Northern/ Southern field or glasshouse	Trial results relevant to the critical GAP (a)	Recommendation/comments	MRL	HR (b)	STMR (c)

Rye (straw)	Northern EU	0.30, 0.37, 0.41, 0.51, 1.1, 1.3 (2x), 1.74, 1.9, 1.98, 3.01, 5.43, 5.5, 5.76 mg/kg		*(10)*	5.76	1.52
Rye (straw)	Southern EU	0.45, 0.46, 0.85, 0.95 (2x), 1.5, 1.55, 1.6, 2.26, 4.08, 4.17, 4.18, 4.40, 6.96 mg/kg		*(10)*	6.96	1.575
Maize (grain)	Northern EU	13x <0.01 mg/kg		0.02	<0.01	<0.01
Maize (grain)	Southern EU	12x <0.01 mg/kg		0.02	<0.01	<0.01
Maize (green plant)	Northern EU	0.11, 0.21, 0.22, 0.25 (2x), 0.28, 0.30, 0.33, 0.36, 0.42, 0.43, 0.44, 0.66, 0.71, 0.84 mg/kg		*(1.5)*	0.84	0.33
Maize (green plant)	Southern EU	0.15, 0.18, 0.21 (2x), 0.26, 0.27, 0.29, 0.34, 0.50, 0.57, 0.60, 0.74, 0.76, 0.89 mg/kg		*(1.5)*	0.89	0.315
Sweet corn	Northern EU	<0.01 (3x), 0.011, 0.015, 0.039 mg/kg		0.07	0.039	0.011
Sweet corn	Southern EU	<0.01 (4x) mg/kg		0.07	<0.01	<0.01

(a) Number of trials in which particular residue levels were reported e.g. "<0.01 (3x), 0.01" means in 3 trials residue levels of <0.01 mg/kg and in 1 trial a residue level of 0.01mg/kg were found

(b) Highest Residue

(c) Supervised Trials Median Residue i.e. the median residue level estimated on the basis of supervised trials relating to the critical GAP

Consumer risk assessment (SANCO/11802 data point 6.9)

ADI	0.03 mg/kg bw/day
TMDI (% ADI) according to EFSA PRIMo model rev 2	77% (German child)
NEDI (% ADI)	Not applicable
Factors included in IEDI and NEDI	MRLs established for food of plant and animal origin (except liver)
ARfD	0.03 mg/kg bw/day
IESTI (% ARfD)	17% (sweet corn), 10% (potatoes, wheat grain), 6% (barley grain)
NESTI (% ARfD) according to national large portion consumption data	Not applicable
Factors included in IESTI and NESTI	Indicative assessment using MRLs

Processing factors (SANCO/11802 data point 6.5), based on BAS 500 F residues

Crop / processed crop	Number of studies	Transfer factor	% Transference*
Barley grain / brewing malt	4	1.2	
Barley grain / beer	4	0.7	
Barley grain / pot barley	1	0.7	
Wheat grain / bran	4	2.72	
Wheat grain / flour	4	<0.30	
Wheat grain / germ	4	0.68	
Wheat grain / middlings	4	1.82	
Wheat grain / shorts	4	2.78	
Wheat grain / gluten	4	1.61	
Wheat grain / gluten feed meal	4	0.64	
Wheat grain / starch	4	0.27	
Wheat grain / whole meal flour	4	0.83	
Wheat grain / whole grain bread	4	0.30	
Oat grain / flour	4	0.12	
Oat grain / groats / rolled oats	4	0.06	
Oat grain / husks	4	2.34	
Oat grain / dust	4	5.23	
Oat grain / bran	4	0.30	

Crop / processed crop	Number of studies	Transfer factor	% Transference*
Maize whole plant / chopped fodder	4	1.22	
Maize whole plant / silage	4	1.38	
Maize grain / refined oil	4	1	
Maize grain / flour	4	1.25	
Maize grain / meal	4	1.5	
Maize grain / starch	4	1	
Maize grain / bran	4	1	
Maize grain / middlings	4	1	
Maize grain / gluten	4	1	
Maize grain / gluten feed meal	4	1	
Maize grain / steep water	4	1	
Maize grain / germs	4	1	
Maize grain / press cake	4	1	

* Calculated on the basis of distribution in the different portions, parts, or products as determined through balance studies

Proposed MRLs (mg/kg) (SANCO/11802 data point 6.7) – for intended uses; for all others see Document E1

Potatoes:	0.02
Sweet corn:	0.07
Barley and oat grain:	1
Maize grain:	0.02
Wheat and rye grain:	0.2
Food of animal origin (including fish, except milk):	0.05
Food of animal origin – milk:	0.01

Chapter 5: Fate and Behaviour in the Environment

Route of degradation (aerobic) in soil (SANCO/11802 data point 7.1.1.1)

Mineralization after 100 days	4-7% (tolyl label) 5% (chlorophenyl label) 2.2% (pyrazole label)
Non-extractable residues after 100 days	37-55% (tolyl label) 56% (chlorophenyl label) 53% (pyrazole label)
Metabolites requiring further consideration - name and/or code, % of applied (range and maximum)	BF 500-6, max. 31% after 120 days BF 500-7, max. 13% after 62 days

Route of degradation in soil (anaerobic and photolysis) (SANCO/11802 data points 7.1.1.2 and 7.1.1.3)

Anaerobic degradation

Mineralization after 100 days	~2% (tolyl label) 0% (chlorophenyl label)
Non-extractable residues after 100 days	61% (tolyl label) 37% (chlorophenyl label)
Metabolites requiring further consideration - name and/or code, % of applied (range and maximum)	BF 500-3, max. 96% after 7 days BF 500-4 + 2 isomers, max. 11.1, 7.3 and 11.4% BF 500-5, max. 7.7%

Soil photolysis

Metabolites requiring further consideration - name and/or code, % of applied (range and maximum)	after 15 days: 64-74% parent, 12% bound residues, 2% CO_2 no photodegradates for further consideration

Rate of degradation in soil (SANCO/11802 data point 7.1.2 and SANCO/11803 data point 9.1.1)

Method of calculation	FOCUS Kinetics (2006)
Laboratory studies (range or median, with n value, with r^2 value) - DT_{50}	Pyraclostrobin DT_{50lab} (aerobic, non-normalised trigger endpoints): 11.2 – 97.9 d (n=10) DT_{50lab} (20°C, pF2, aerobic, normalised modelling endpoints): 15.6 – 95.4 d (n=10) BF 500-3 Transient metabolite, no reliable endpoints could be derived.

Rate of degradation in soil (SANCO/11802 data point 7.1.2 and SANCO/11803 data point 9.1.1)

	BF 500-4 DT_{50lab} (aerobic, non-normalised trigger endpoints): 0.2 – 1.8 d (n=3) DT_{50lab} (20°C, pF2, aerobic, normalised modelling endpoints): 1.6 – 6.1 d (n=3) BF 500-5 DT_{50lab} (aerobic, non-normalised trigger endpoints): 0.09 – 0.24 d (n=3) DT_{50lab} (20°C, pF2, aerobic, normalised modelling endpoints): 0.4 – 0.7 d (n=3) BF 500-6 DT_{50lab} (aerobic, non-normalised trigger endpoints): 95.9 – >1000 d (n=6) DT_{50lab} (20°C, pF2, aerobic, normalised modelling endpoints): 59.2 – 903.2 d (n=8) BF 500-7 DT_{50lab} (aerobic, non-normalised trigger endpoints): 81.5 - >1000 d (n=7) DT_{50lab} (20°C, pF2, aerobic, normalised modelling endpoints): 51.3 - 729 d (n=6)
Laboratory studies (range or median, with n value, with r^2 value) - DT_{90}	Pyraclostrobin DT_{90lab} (aerobic, non-normalised trigger endpoints): 87.7 – >1000 d (n=6) BF 500-3 Transient metabolite, no reliable endpoints could be derived. BF 500-4 DT_{90lab} (aerobic, non-normalised trigger endpoints): 3.9 – 13.5 d (n=3) BF 500-5 DT_{90lab} (aerobic, non-normalised trigger endpoints): 1.77 – 2.95 d (n=3) BF 500-6 DT_{90lab} (aerobic, non-normalised trigger endpoints): 318.7 – >1000 d (n=6) BF 500-7 DT_{90lab} (aerobic, non-normalised trigger endpoints): 270.7 – >1000 d (n=7)

Rate of degradation in soil (SANCO/11802 data point 7.1.2 and SANCO/11803 data point 9.1.1)

Laboratory studies - 10°C	DT_{50lab} (10°C, aerobic, calculated from normalised modeling endpoints at 20°C): 40.3 – 246.1 d (n=10)
Laboratory studies - anaerobic	Pyraclostrobin DT_{50lab} (20°C): 1.5 – 2.3 d (1 soil, 2 labels) BF 500-3 DT_{50lab} (20°C): 56.9 – 70.1 d (1 soil, 2 labels) BF 500-4 DT_{50lab} (20°C): 7.8 – 11.3 d (1 soil, 2 labels) BF 500-5 DT_{50lab} (20°C): 32.2 d (1 soil, 1 label)
Degradation in saturated zone	not relevant
Field studies (state location, range or median with n value)	**Best-fit trigger endpoints** Data from field dissipation study without soil coverage Pyraclostrobin DT_{50f}: 5.2 – 55.8 d 6 locations (3 Germany, 2 Spain, 1 Sweden) **Normalized modelling endpoints (20°C, pF2)** Data from both field studies (with and without sand cover to prevent surface processes) Pyraclostrobin DT_{50f}: 15.5 – 181.2 d 8 locations: uncovered: 3 Germany, 1 Sweden covered: 1 Denmark, 1 Germany, 1 Southern France, 1 Italy BF 500-6 DT_{50f}: 163.5 – 361.4 d 3 locations covered: 1 Denmark, 1 Germany, 1 Southern France BF 500-7 DT_{50f}: 183.7 – 460.1 d 3 locations covered: 1 Denmark, 1 Germany, 1 Southern France

Rate of degradation in soil (SANCO/11802 data point 7.1.2 and SANCO/11803 data point 9.1.1)

	Non-normalized trigger endpoints Data from field dissipation study without soil coverage DT_{90f} : 80.3 – 347.8 d 6 locations (3 Germany, 2 Spain, 1 Sweden)
Soil accumulation and plateau concentration	Not required for pyraclostrobin. Accumulation potential for BF 500-6 and BF 500-7 addressed by modelling.

Soil adsorption/desorption (SANCO/11802 data point 7.1.3)

K_{foc} / K_{oc}	Pyraclostrobin $K_{f,oc}$: 6000 – 16000 mL g^{-1} (arithmetic mean 9304 mL g^{-1}, n=10) 1/n: 0.86 – 1.03 (arithmetic mean 0.95, n=6) BF 500-3 $K_{f,oc}$: 4240 – 12000 mL g^{-1} (arithmetic mean 9315 mL g^{-1}, n=6) 1/n: 0.77 – 0.94 (arithmetic mean 0.83, n=6) BF 500-4 K_{oc} : 6871 – 15748 mL g^{-1} (arithmetic mean 9819 mL g^{-1}, n=5) BF 500-5 $K_{f,oc}$: 400 – 831 mL g^{-1} (arithmetic mean 705 mL g^{-1}, n=5) 1/n: 0.80 – 0.88 (arithmetic mean 0.85, n=5) BF 500-6 K_{oc} : 3360 – 311704 mL g^{-1} (median 107301 mL g^{-1}, n=11) BF 500-7 K_{oc} : 4020 – 801927 mL g^{-1} (median 149900 mL g^{-1}, n=11)

Soil adsorption/desorption (SANCO/11802 data point 7.1.3)

K_f / K_d	Pyraclostrobin K_f: 30 – 368 mL g^{-1} (n=6) BF 500-3 K_f: 47 – 354 mL g^{-1} (n=6) BF 500-4 K_d: 64 – 291 mL g^{-1} (n=5) BF 500-5 K_f: 5 – 15 mL g^{-1} (n=5) BF 500-6 K_d: 84 – 1985 mL g^{-1} (n=11) BF 500-7 K_d: 100.5 – 5025 mL g^{-1} (n=11)
pH dependence (yes / no) (if yes type of dependence)	No (for parent and all metabolites)

Mobility in soil (SANCO/11802 data points 7.1.4 and SANCO/11803 data points 9.1.2)

Column leaching	0% in leachate, all radioactivity in top soil layer
Aged residues leaching	0% in leachate, all radioactivity in top soil layer
Lysimeter/field leaching studies	based on K_{oc} and DT_{50} values no leaching expected

PEC (soil) (SANCO/11803 data point 9.1.3)

Parent

Method of calculation	SFO kinetic model after FOCUS Kinetics (2006) Depth of the soil layer: 5 cm Soil bulk density 1.5 g cm^{-3} <u>Substance parameters:</u> $DT_{50,soil}$ (d): 55.8 worst-case of field dissipation studies (n=4, non-normalised)
Application rate	2 x 250 g a.s. ha^{-1} to cereals (BBCH 25), 21 day interval (worst case scenario) Plant interception: 50% (first application), 70% (second application)

BF 500-3

Parameters used in $FOCUS_{SW}$ step 1 and 2	BF 500-3 Molar mass (g mol^{-1}): 357.8 Water solubility (mg L^{-1}): 0.03 (20°C) $K_{f,oc}$ (L kg^{-1}): 9315, arithmetic mean (n=6) $DT_{50,soil}$ (d): 1, worst-case default (transient metabolite) Max. occurrence in soil (%): 0.01, worst-case default (no occurrence in aerobic soil) Endpoints derived from dark w/s study $DT_{50,whole\ system}$ (d): 1000, worst-case default $DT_{50,water}$ (d): 1000, worst-case default $DT_{50,sediment}$ (d): 1000, worst-case default Max. occurrence in water/sediment (%): 67.7 Endpoints derived from irradiated w/s study $DT_{50,whole\ system}$ (d): 92.5, level M-I analysis, two labels $DT_{50,water}$ (d): 92.5, level M-I analysis, two labels $DT_{50,sediment}$ (d): 92.5, level M-I analysis, two labels Max. occurrence in water/sediment (%): 21.9
Application rate	Metabolite is not applied but formed from parent in sediment only according to max. occurrence
Main routes of entry	Spray drift, runoff, drainage (of parent)

BF 500-5

Parameters used in $FOCUS_{SW}$ step 1 and 2	BF 500-5 Molar mass (g mol^{-1}): 194.6 Water solubility (mg L^{-1}): 21.8 (20°C) $K_{f,oc}$ (L kg^{-1}): 705 (arithmetic mean, n=5) $DT_{50,soil}$ (d): 1, worst-case of lab data (n=3, normalized to 20°C, pF2) Max. occurrence in soil (%): 0.01, worst-case default (no occurrence in aerobic soil) $DT_{50,whole\ system}$ (d): 1000, worst-case default $DT_{50,water}$ (d): 1000, worst-case default $DT_{50,sediment}$ (d): 1000, worst-case default Max. occurrence in water/sediment (%): 10.9 (from OECD 309 study)

Application rate	Metabolite is not applied but formed from parent in water only according to max. occurrence
Main routes of entry	Spray drift, runoff, drainage (of parent)

BF 500-6

Parameters used in $FOCUS_{SW}$ step 1 and 2	<u>BF 500-6</u> Molar mass (g mol^{-1}): 305.8 (0.5 of molar mass as metabolite is a dimer) Water solubility (mg L^{-1}): 0.003 (20°C) K_{oc} (L kg^{-1}): 107301, median (n=11) $DT_{50,soil}$ (d): 321, bias-corrected geometric mean of lab and field data (n=11, normalized to 20°C, pF2) Max. occurrence in soil (%): 31 (laboratory data) $DT_{50,whole\ system}$ (d): 1000, worst-case default $DT_{50,water}$ (d): 1000, worst-case default $DT_{50,sediment}$ (d): 1000, worst-case default Max. occurrence in water/sediment (%): 6.5 (from dark w/s study)
Application rate	Metabolite is not applied but formed from parent in soil and in sediment according to max. occurrence
Main routes of entry	Spray drift, runoff, drainage (of parent), runoff, drainage (of metabolite)

BF 500-7

Parameters used in $FOCUS_{SW}$ step 1 and 2	BF 500-7 Molar mass (g mol^{-1}): 297.8 (0.5 of molar mass as metabolite is a dimer) Water solubility (mg L^{-1}): 0.005 (20°C) K_{oc} (L kg^{-1}): 149900, median (n=11) $DT_{50,soil}$ (d): 312, bias-corrected geometric mean of lab and field data (n=9, normalized to 20°C, pF2) Max. occurrence in soil (%): 19 (field soil degradation study) $DT_{50,whole\ system}$ (d): 1000, worst-case default $DT_{50,water}$ (d): 1000, worst-case default $DT_{50,sediment}$ (d): 1000, worst-case default Max. occurrence water/sediment (%): 6.3 (from dark w/s study)
Application rate	Metabolite is not applied but formed from parent in soil and in sediment according to max. occurrence
Main routes of entry	Spray drift, runoff, drainage (of parent), runoff, drainage (of metabolite)

BF 500-11

Parameters used in $FOCUS_{SW}$ step 1 and 2	BF 500-11 Molar mass (g mol^{-1}): 277.3 Water solubility (mg L^{-1}): 1000, worst-case default K_{oc} (L kg^{-1}): $1x10^{-10}$, worst-case default $DT_{50,soil}$ (d): 1, worst-case default Max. occurrence in soil (%): 0.01, worst-case default (no occurrence in soil) $DT_{50,whole\ system}$ (d): 22.6 (level M-I analysis, two labels, irradiated w/s study) $DT_{50,water}$ (d): 22.6 (level M-I analysis, two labels, irradiated w/s study) $DT_{50,sediment}$ (d): 22.6 (level M-I analysis, two labels, irradiated w/s study) Max. occurrence in water/sediment (%): 12 (from irradiated w/s study)
Application rate	Metabolite is not applied but formed from parent in water only according to max. occurrence
Main routes of entry	Spray drift, runoff, drainage (of parent)

BF 500-13

Parameters used in $FOCUS_{SW}$ step 1 and 2	BF 500-13 Molar mass (g mol^{-1}): 247.3 Water solubility (mg L^{-1}): 1000, worst-case default K_{oc} (L kg^{-1}): $1x10^{-10}$, worst-case default Max. occurrence in soil (%): 0.01, worst-case default (no occurrence in soil) $DT_{50,whole\ system}$ (d): 1000, worst-case default $DT_{50,water}$ (d): 61.3 (aqueous photolysis study) $DT_{50,sediment}$ (d): 1000, worst-case default Max. occurrence in water/sediment (%): 17.8 (from irradiated w/s study)
Application rate	Metabolite is not applied but formed from parent in water only according to max. occurrence
Main routes of entry	Spray drift, runoff, drainage (of parent)

BF 500-14

Parameters used in $FOCUS_{SW}$ step 1 and 2	BF 500-14 Molar mass (g mol^{-1}): 387.8 Water solubility (mg L^{-1}): 1000, worst-case default K_{oc} (L kg^{-1}): $1x10^{-10}$, worst-case default Max. occurrence in soil (%): 0.01, worst-case default (no occurrence in soil) $DT_{50,whole\ system}$ (d): 17.3 (level M-I analysis, two labels, irradiated w/s study) $DT_{50,water}$ (d): 17.3 (level M-I analysis, two labels, irradiated w/s study) $DT_{50,sediment}$ (d): 17.3 (level M-I analysis, two labels, irradiated w/s study) Max. occurrence in water/sediment (%): 12.1 (from irradiated w/s study)
Application rate	Metabolite is not applied but formed from parent in water only according to max. occurrence
Main routes of entry	Spray drift, runoff, drainage (of parent)

Metabolites observed in dark water/sediment study: BF 500-3, BF 500-5, BF 500-6, BF 500-7

Air (indicate location and type of study)	none

Chapter 6: Effects on Non-target Species

Effects on terrestrial vertebrates (SANCO/11802 data point 8.1, SANCO/11803 data point 10.1)

The Annex I Renewal of pyraclostrobin is supported by data from two representative formulations, BAS 500 06 F and BAS 516 07 F. BAS 500 06 F is the representative solo formulation for applications in cereals and maize. BAS 516 07 F (for use in potatoes) contains next to pyraclostrobin as second active substance boscalid. No separate risk assessment for boscalid will be presented in the following chapter, as the active substance in focus of the evaluation is pyraclostrobin. Boscalid is solely addressed in the context of the assessment of combined effects of the formulation.

Acute toxicity to birds	Pyraclostrobin *Colinus virginianus*, *Serinus canaria* $LD_{50\ (geometric\ mean)}$ = 1701 mg a.s./kg b.w. BAS 500 06 F *Colinus virginianus* LD_{50} > 2000 mg/kg b.w. BAS 516 07 F *Colinus virginianus* LD_{50} > 3200 mg/kg b.w.
Dietary toxicity to birds	Pyraclostrobin The two available studies were already evaluated during the previous Annex 1 process and are no longer part of the core data package (EFSA/2009/1438).
Reproductive toxicity to birds	Pyraclostrobin *Colinus virginianus* NOEL = 105 mg a.s./kg b.w./d
Acute toxicity to mammals	Pyraclostrobin Rat LD_{50} > 5 000 mg a.s./kg b.w. BAS 500 06 F Rat LD_{50} ~ 500 mg/kg b.w. BAS 516 07 F Rat LD_{50} > 2000 mg /kg b.w.
Reproductive/long term toxicity to mammals	Pyraclostrobin Rat Tier 1: NOEL = 3 mg a.s./kg b.w./d Higher tier: NOAEL = 8.2 mg a.s./kg b.w./d

Toxicity/exposure ratios for terrestrial vertebrates (SANCO/11803 data point 10.1)

Effects on other terrestrial vertebrate wildlife (reptiles and amphibians)

Publications are available in the scientific literature on the effect of pyraclostrobin, respectively of pyraclostrobin containing formulations on amphibia (Belden et al., 2010; Brühl et al., 2013). In addition, BASF has performed GLP studies to address the risk to amphibians. The results are summarized below.

Laboratory studies on metamorph amphibians under worst-case conditions

Study	Test species	Test substance	Applic. rate [g a.s./ha]	Effect (% mortality)
Belden et al. (2010)	*Bufo cognatus*	BAS 500 00 F	22	0
			220	70
			2200	100
Brühl et al. (2013)	*Rana temporaria*	BAS 500 00 F	22	0
			220	100
		BAS 500 18 F	2200	No significant effect
BASF (2013)	*Rana temporaria*	BAS 500 06 F	40	0
			63	0 (sublethal symptoms)
			99	70
BASF (2014)	*Bufo bufo*	BAS 500 06 F	155 / 15 min 219 / 15 min 310 / 15 min 310 / 60 min 310 / 4 h[1)]	0 0 (20% sublethal) 20 (60% sublethal) 20 (40% sublethal) (20)[2)] (0% sublethal)

1) Animals were exposed to the respective rates either immediately (within 15 minutes) or 1 h or 4 h after spraying.
2) The observed toxicity in this case is not considered treatment-related.

The laboratory studies indicate that BAS 500 06 F can be toxic to amphibians at the full field rate under worst case conditions:
LR_0 = 63 g a.s./ha < 250 g a.s./ha (max field rate for BAS 500 06 F applications in cereals)

No toxicity is to be expected from applications of BAS 516 07 F.
LR_0 = 63 g a.s./ha > 17 g a.s./ha (max field rate for BAS 516 07 F applications in potatoes)

For animals exposed to soil residues of BAS 500 06 F the LR_0 was > 155 g a.s./ha if exposed immediately after spraying, while the LR_{50} was > 310 g a.s./ha under these circumstances. No significant substance related effects occurred at the highest rate, if animals were introduced 4 hours after spraying, simulating spraying during the day and the nocturnal amphibian activity (NOEL ≥ 310 g a.s./ha).

In order to address the risk of BAS 500 06 F to amphibians under more realistic conditions, two semi-field studies have been conducted with *R. temporaria* and *Bufo bufo* under realistic worst case conditions in cereals at BBCH 25-30 with application rates of 0.94 L/ha, 1.25 L/ha and 1.56 L/ha (according to 188, 250 and 313 g a.s./ha) for R. temporaria and application rates of 1.25 L/ha, 1.5 L/ha and 12.5 L/ha (according to 250 g a.s./ha, 375 g a.s./ha and 2 500 g a.s./ha).

Higher tier semi-field study with juvenile Rana temporaria under realistic worst-case conditions

Test item	Application rate	Effect
BAS 500 06 F	0.75 x max field rate (0.94 L/ha)	0%
	1.0 x max field rate (1.25 L/ha)	0%
	1.25 x max field rate (1.56 L/ha)	0% [#]

[#] One single individual (out of 16) showed a short term, transient behavioural impact

Higher tier semi-field study with juvenile Bufo bufo under realistic worst-case conditions

Test item	Application rate	Effect
BAS 500 06 F	1.0 x max field rate (1.25 L/ha)	0%
	1.5 x max field rate (1.875 L/ha)	0%
	10 x max field rate (12.5 L/ha)	50 (75)% [#]

[#] One animal was moribund (if counted as dead mortality results in 75%)

The semi-field studies demonstrate that there is low risk of BAS 500 06 F use in cereals to cause unacceptable impact to amphibians; NOER > 1.25 L BAS 500 06 F/ha (max field rate)

Toxicity data for aquatic species (most sensitive species of each group) (SANCO data point IIA 8.2 and SANCO/11803 data point IIIA 10.2)

***** Study was conducted with the minor change formulation BAS 516 00 F (reference is made to Document JCP, CP 1.4.1 of this dossier).

1) Study was not submitted during the Annex I inclusion process of pyraclostrobin.

2) Marine / saltwater species

3) Study was performed with a previous representative solo-formulation BAS 500 00 F; however, results are given in mg a.s./L

4) In accordance to recent guidelines (EFSA, 2013; OECD, 2011), the 72 h endpoints of the EU agreed study on the green alga have been (re-)calculated from original data. The re-calculated values are presented here and are used in the aquatic risk assessment; for details on these calculations please refer to the supplement. A summary of this study and the re-calculations is provided in chapter 8.2 of the MCA dossier part for Annex I renewal.

5) In accordance to recent guidelines (EFSA, 2013; OECD, 2011), the 72 h endpoints obtained in the 96 h / 120 h alga studies are considered as relevant endpoint and are presented here.

6) Endpoint obtained in the 96 hour TTE study after exposure over respective duration, *i.e.* the value in brackets (0.5, 2 or 8 h exposure time).

TER-calculations

For the sake of clarity, it has been abstained from showing the TER-calculations for each individual species that has been tested; instead TER calculations are performed with a representative of each group and with the relevant higher tier endpoint (e.g. only one representative fish species plus the HC_5 for all fishes and only *Daphnia* and *Chironomus* data for water and sediment dwelling aquatic invertebrates plus the higher tier mesocosm).

TERs shown in **bold** fall below the relevant trigger.
D = Drift mitigation using no-spray buffer zones; D + R = Drift and runoff mitigation using no-sprayed vegetated filter strips
SSD = Species Sensitivity Distribution

§ Metabolites were mainly observed in irradiated water/sediment studies; accordingly only PEC values derived from irradiated water/sediment studies are reported.

* Reduced assessment factor for acute risk assessment based on the HC_5 value from the fish SSD (for details see "Refined Risk Assessment" presented in chapter 10.2 of the MCP dossier part for Annex I renewal).

1) Based on sediment concentration in spiked water study.

2) $PEC_{sed, max}$ [µg/kg dry sediment]

3) Study was performed with the solo-formulation BAS 500 00 F (containing 250 g pyraclostrobin/L, nominally)

Bioconcentration

Log Pow	3.99
Bioconcentration factor (BCF)	379 – 507 (whole fish) 178 - 191 (edibles)
Risk assessment trigger for the bioconcentration factor	100 BAS 500 F is not stable in water and is rapidly metabolised and excreted by fish (CT_{50} < 1 day), thus there is low risk for bioaccumulation
Clearance time (CT_{50}) (CT_{90})	CT_{50} < 1 day
Level of residues (%) in organisms after the 14 day depuration phase	Not applicable

Effects on honeybees (SANCO data point 8.3.1 and SANCO/11803 data point 10.3.1)

Acute oral toxicity	LD_{50} (48 h) > 73.1 µg a.s./bee LD_{50} (48 h) > 110.0 µg a.s./bee LD_{50} (96 h) > 97.2 µg a.s./bumblebee LD_{50} (48 h) > 381.84 µg BAS 500 06 F/bee LD_{50} (48 h) > 258.7 µg BAS 516 00 F/bee
Acute contact toxicity	LD_{50} (48 h) > 100.0 µg a.s./bee LD_{50} (48 h) > 100.0 µg a.s./bee LD_{50} (96 h) > 100.0 µg a.s./bumblebee LD_{50} (72 h) > 368.20 µg BAS 500 06 F/bee LD_{50} (48 h) > 299.4 µg BAS 516 00 F/bee

No unacceptable lethal or sublethal effects were found in honeybee colonies exposed to 1.25 L product/ha in a semi-field tunnel test (*Phacelia tanacetifolia*).
Two studies were conducted with pyraclostrobin containing products in sunflower and oilseed rape (OSR) to determine the residues in the bee relevant matrices pollen and nectar. The highest exposure was found in pollen, i.e. 16.6 ppm (sunflower) and 6.7 ppm (OSR).
Additionally, no unacceptable effects in queen development, queen survival and adult worker bee health at 400 ppm Pristine treated pollen (based on analysis equivalent to 22 ppm pyraclostrobin treated pollen) were observed.

Hazard quotients for honey bees (SANCO/11803 data point 10.3.1)

BAS 516 07 F:

Test substance	Use pattern	Exposure route	Endpoint [µg/bee]	Maximum single application rate	Hazard quotient	TER risk assessment trigger
pyraclostrobin	potatoes	acute oral	$LD_{50} > 73.1$	17 g a.s./ha	< 0.23	50
		acute contact	$LD_{50} > 100$		< 0.17	
pyraclostrobin		acute oral	$LD_{50} > 110$	17 g a.s./ha	< 0.15	
		acute contact	$LD_{50} > 100$		< 0.17	
BAS 516 00 F		acute oral	$LD_{50} > 258.7$	250 g/ha	< 0.97	
		acute contact	$LD_{50} > 299.4$		< 0.84	

BAS 500 06 F:

Test substance	Use pattern	Exposure route	Endpoint [µg/bee]	Maximum single application rate	Hazard quotient	TER risk assessment trigger
pyraclostrobin	cereals, maize	acute oral	$LD_{50} > 73.1$	250 g a.s./ha	< 3.4	50
		acute contact	$LD_{50} > 100$		< 2.5	
pyraclostrobin		acute oral	$LD_{50} > 110$	250 g a.s./ha	< 2.3	
		acute contact	$LD_{50} > 100$		< 2.5	
BAS 500 06 F		acute oral	$LD_{50} > 381.84$	1305 g/ha *	< 3.4	
		acute contact	$LD_{50} > 368.20$		< 3.5	

* Taking into account the density of BAS 500 06 F of 1.044 g/cm^3.

Effects on other arthropod species (SANCO data point 8.3.2 and SANCO/11803 data point 10.3.2)

HQ values in **bold** are above the trigger.

1) In the Tier 2 off-field risk assessment, the standard 5-fold uncertainty (correction) factor should be included to the calculation to cover the inter-species variability in sensitivity of off-field non-target arthropod species. However, as additional species are tested, the uncertainty is reduced and no additional safety factor was applied.

2) Endpoint < $PER_{in\text{-}field}$, $PER_{off\text{-}field}$ is covered.

Effects on earthworms (SANCO/11802 data point 8.4.2 and SANCO/11803 data point 10.4.1)

Substances and metabolites; structures, codes, synonyms

The table below is summarizing all metabolites addressed within this dossier. For some of the compounds, structural elucidation is based on mass spectroscopic experiments. MS does typically not allow a clear assignment of e.g. the position of hydroxyl groups in aromatic ring systems. Same applies to information on stereochemistry of e.g. carbohydrate conjugates (glucosides / glucuronic acid conjugates). Hydroxylation followed by subsequent conjugate reactions result in the formation of isomers. The structures shown below are depicted in a way indicating this fact. For such structures no exact IUPAC chemical name can be provided. If not stated otherwise in the "occurrence column", the metabolites indicated for rat and goat have been found in the corresponding *in-vivo* studies.

Table of Contents

1 INTRODUCTION

2 FATE AND BEHAVIOUR IN THE ENVIRONMENT

2.1 Summary of degradation pathway in soil

The degradation of pyraclostrobin in aerobic soil studies is characterized by a rather low mineralization rate (about 5% of applied radioactivity (AR) within 100 days) and a formation of high amounts of bound residues (about 55% AR within 100 days). The two dimeric metabolites, BF 500-6 and BF 500-7, were regularly found in aerobic soil in amounts > 5% AR.

Under anaerobic conditions, a very fast de-methoxylation of pyraclostrobin takes place, forming the metabolite BF 500-3 in high amounts. BF 500-3 is then further degraded to BF 500-4. The cleavage product BF 500-5 can also be formed in soil in low amounts.

2.2 Summary of identification of metabolites in soil

The following metabolites were considered for groundwater risk assessment:
BF 500-3, BF 500-4, BF 500-5, BF 500-6, and BF 500-7

3 RELEVANCE OF METABOLITES IN GROUNDWATER

3.1 Step 1: Exclusion of degradation products of no concern

None of the metabolites can be considered as "product of no concern".

3.2 Step 2: Quantification of potential groundwater contamination

PECgroundwater calculations were performed for five pyraclostrobin metabolites (BF 500-3, BF 500-4, BF 500-5, BF 500-6, and BF 500-7). None of the metabolites showed any risk of leaching into groundwater due to their strong sorption properties and/or their fast degradation rate in soil. All calculated PECgroundwater values were << 0.1 µg/L.

3.3 Step 3: Hazard assessment: identification of relevant metabolites

A further hazard assessment is not considered necessary since none of the metabolites showed any risk for leaching.

3.3.1 Step 3, Stage 1: screening for biological activity

Considered not necessary.

3.3.2 Step 3, Stage 2: screening for genotoxicity

Considered not necessary.

3.3.3 Step 3, Stage 3: screening for toxicity

Considered not necessary.

3.4 Step 4: Exposure assessment – threshold of concern approach

Considered not necessary.

3.5 Step 5: Refined risk assessment for non-relevance of metabolites

Considered not necessary.

3.6 Overall conclusion

Neither pyraclostrobin nor one of its metabolites poses any risk for groundwater.

OCA Evaluation Form Active Substance

for use in checking that all test and study reports required in accordance with SANCO/11802 have been provided

Active Substance: Pyraclostrobin Applicant: BASF SE Date: 18/Jul/2014

This evaluation form comprises the information provided in both, the original dossier and the supplementary dossier. Whenever **new information, tests or studies** are part of the supplementary dossier, "SD yes" is stated in the column "Information, test or study provided". A simple "yes" means that basically all the information, tests and/or studies were already part of the original dossier for Annex I inclusion.

SANCO/ 11802 data point	Information, test or study	Information, test or study provided	Justification provided	Undertaking provided	*Data gap*
1	Identity of the active substance				
1.1	Applicant	yes			☐
1.2	Producer	yes			☐

8.2	Effects on aquatic organisms				
8.2.1	Acute toxicity to fish	SD yes			☐
8.2.2	Long-term and chronic toxicity to fish				
8.2.2.1	Fish early life stage toxicity test	SD yes			☐
8.2.2.2	Fish full life cycle test	yes			☐
8.2.2.3	Bioconcentration in fish	yes			☐
8.2.3	Endocrine disrupting properties	not relevant	M-CA 8.2.3		☐
8.2.4	Acute toxicity to aquatic invertebrates				
8.2.4.1	Acute toxicity to *Daphnia magna*	SD yes			☐
8.2.4.2	Acute toxicity to an additional aquatic invertebrate species	SD yes			☐

SANCO/ 11802 data point	Information, test or study	Information, test or study provided	Justification provided	Undertaking provided	*Data gap*
8.2.5	Long term and chronic toxicity to aquatic invertebrates				
8.2.5.1	Reproductive and development toxicity to *Daphnia magna*	yes			☐
8.2.5.2	Reproductive and development toxicity to an additional aquatic invertebrate species	SD yes			☐
8.2.5.3	Development and emergence in *Chironomus species*	SD yes			☐
8.2.5.4	Sediment dwelling organisms	SD yes			☐
8.2.6	Effects on algal growth				
8.2.6.1	Effects on growth of green algae	SD yes			☐
8.2.6.2	Effects on growth of an additional algal species	SD yes			☐
8.2.7	Effects on aquatic macrophytes	SD yes			☐
8.2.8	Further testing on aquatic organisms	SD yes			☐
8.3	Effects on arthropods				
8.3.1	Effects on bees				
8.3.1.1	Acute toxicity to bees	yes			
8.3.1.1.1	Acute oral toxicity	SD yes			☐
8.3.1.1.2	Acute contact toxicity	SD yes			☐
8.3.1.2	Chronic toxicity to bees	not relevant	M-CA 8.3.1.2		☐
8.3.1.3	Effects on honeybees development and other honeybee life stages	yes	M-CP 10.3.1.5		☐
8.3.1.4	Sub-lethal effects	yes	M-CP 10.3.1.5		☐
8.3.2	Effects on non-target arthropods other than bees	yes	M-CP 10.3.2.1		☐
8.3.2.1	Effects on *Aphidius rhopalosiphi*	yes	M-CP 10.3.2.1		☐
8.3.2.2	Effects on *Typhlodromus pyri*	yes	M-CP 10.3.2.1		☐
8.4	Effects on non-target soil meso- and macrofauna				
8.4.1	Earthworm – sub-lethal effects	SD yes			☐
8.4.2	Effects on non-target soil meso- and macrofauna (other than earthworms)	SD yes			☐
8.4.2.1	Species level testing	not relevant	M-CA 8.4.2.1		☐
8.5	Effects on soil nitrogen transformation	yes			☐
8.6	Effects on terrestrial non-target higher plants				
8.6.1	Summary of screening data	not relevant	M-CA 8.6.1		☐
8.6.2	Testing on non-target plants	SD yes	M-CP 10.6.2		☐
8.7	Effects on other terrestrial organisms (flora and fauna)	not relevant	M-CA 8.7		☐
8.8	Effects on biological methods for sewage treatment	yes			☐
8.9	Monitoring data	SD yes			☐
9	Literature data	SD yes			☐
10	Classification and labelling	SD yes			☐
