3.2 List of new studies on vertebrate animals

References of studies on vertebrate animals are given for the active substance pyraclostrobin (BAS 500 F), its metabolites and the representative formulations BAS 500 06 F and BAS 516 07 F.

3.2.1 Active substance pyraclostrobin (BAS 500 F)

Section 5: Toxicology and metabolism studies - active substance and its metabolites

Data point	Author(s)	Year	Title Company Report No. Source (where different from company) GLP or GEP status Published or not	Justification for submission of study	Data protection claimed Y/N	Owner
KCA 5.2.3/1	[redacted]	2001 a	BAS 500 F 40% in Solvesso (technical active ingredient) - Acute inhalation toxicity study in Wistar rats - 4-hour liquid aerosol exposure 2001/1010625 [redacted] Yes Unpublished	New data (submitted to US-EPA)	Yes	BASF
KCA 5.2.3/2	[redacted]	2002 a	BAS 500 F - Acute inhalation toxicity study in Wistar rats - 4-hour liquid aerosol exposure 2002/1012053 [redacted] Yes Unpublished	New data	Yes	BASF
KCA 5.2.3/3	[redacted]	2003 a	Amendment No. 1 to the report: BAS 500 F - Acute inhalation toxicity study in Wistar rats - 4-hour liquid aerosol exposure 2003/1009200 [redacted] Yes Unpublished	New data	Yes	BASF
KCA 5.2.3/4	[redacted]	2003 b	Amendment No. 2 to the report: BAS 500 F - Acute inhalation toxicity study in Wistar rats - 4-hour liquid aerosol exposure 2003/1009427 [redacted] Yes Unpublished	New data	Yes	BASF
KCA 5.3.2/1	[redacted]	1999 a	BAS 500 F - Subchronic oral toxicity study in Wistar rats. Administration in the diet for 3 months - Volume I of III 1999/10195 [redacted] Yes Unpublished	Previously evaluated study submitted for completeness (basis for the assessment of the amendments listed below)	No	BASF

Data point	Author(s)	Year	Title Company Report No. Source (where different from company) GLP or GEP status Published or not	Justification for submission of study	Data protection claimed Y/N	Owner
KCA 5.3.2/2	[redacted]	1999 b	Amendment No. 1 to the report: BAS 500 F - Subchronic oral toxicity study in Wistar rats. Administration in the diet for 3 months 1999/11899 [redacted] Yes Unpublished	Correction of clerical errors (see page 29)	No	BASF
KCA 5.3.2/3	[redacted]	2000 a	Amendment No. 2 to the report: BAS 500 F - Subchronic oral toxicity study in Wistar rats administration in the diet for 3 months 2000/1012360 [redacted] Yes Unpublished	Correction of clerical errors	No	BASF
KCA 5.3.2/4	[redacted]	2003 a	Amendment No. 3 to the report: BAS 500 F - Subchronic oral toxicity study in Wistar rats - Administration in the diet for 3 months 2003/1013399 [redacted] Yes Unpublished	Additional histopatho-logical evaluation	No	BASF
KCA 5.3.2/5	[redacted]	2004 a	Amendment to the report for Japanese registration: BAS 500 F - Subchronic oral toxicity study in Wistar rats - Administration in the diet for 3 months 2004/1027673 [redacted] Yes Unpublished	Description of duodenum trimming procedure (requested by Japanese authorities)	No	BASF
KCA 5.3.2/6	[redacted]	1998 a	BAS 500 F - Subchronic oral toxicity study in B6C3F1 Crl BR mice. Administration in the diet for 3 months 1998/11345 [redacted] Yes Unpublished	Previously evaluated study submitted for completeness (basis for the assessment of the amendments listed below)	No	BASF
KCA 5.3.2/7	[redacted]	1999 c	Amendment No. 1 to the report: BAS 500 F - Subchronic oral toxicity study in B6C3F1 Crl mice. Administration in the diet for 3 months 1999/11900 [redacted] Yes Unpublished	Correction of clerical errors and addition of new data	No	BASF
KCA 5.3.2/8	[redacted]	2003 b	Amendment No. 2 to the report: BAS 500 F - Subchronic oral toxicity study in B6C3F1 Crl mice - Administration in the diet for 3 months 2003/1013400 [redacted] Yes Unpublished	Additional histopatho-logical evaluation	No	BASF

Data point	Author(s)	Year	Title Company Report No. Source (where different from company) GLP or GEP status Published or not	Justification for submission of study	Data protection claimed Y/N	Owner
KCA 5.3.3/1	[redacted]	2005 a	BAS 500 F - Subacute inhalation study in Wistar rats - 20 aerosol exposures during 4 weeks 2005/1013950 [redacted] Yes Unpublished	New data (request of US-EPA)	Yes	BASF
KCA 5.3.3/2	[redacted]	2014	Supplementary subacute inhalation study in Wistar rats 2014/1003946 [redacted] Yes Unpublished	Additional concentrations needed for risk assessment	Yes	BASF
KCA 5.5/1	[redacted]	1999 d	BAS 500 F - Chronic toxicity study in Wistar rats. Administration in the diet for 24 months 1999/11672 [redacted] Yes Unpublished	Previously evaluated study submitted for completeness (basis for the assessment of the amendment listed below)	No	BASF
KCA 5.5/2	[redacted]	2002 a	Amendment No. 1 to the report: BAS 500 F - Chronic toxicity study in Wistar rats. Administration in the diet for 24 months 2002/1005113 [redacted] Yes Unpublished	Additional histopatho-logical evaluation of intermediate dose group males (requested by US-EPA)	No	BASF
KCA 5.5/3	[redacted]	1999 e	BAS 500 F - Carcinogenicity study in Wistar rats. Administration in the diet for 24 months 1999/11868 [redacted] Yes Unpublished	Previously evaluated study submitted for completeness (basis for the assessment of the amendment listed below)	No	BASF
KCA 5.5/4	[redacted]	2002 b	Amendment No. 1 to the report: BAS 500 F - Carcinogenicity study in Wistar rats. Administration in the diet for 24 months 2002/1005114 [redacted] Yes Unpublished	Additional histopatho-logical evaluation of intermediate dose group males (requested by US-EPA)	No	BASF
KCA 5.5/6	[redacted]	2002 c	BAS 500 F - First supplementary chronic toxicity study in Wistar rats - Administration in the diet for 24 months 2002/1004125 [redacted] Yes Unpublished	New data (submitted to US-EPA)	Yes	BASF

Data point	Author(s)	Year	Title Company Report No. Source (where different from company) GLP or GEP status Published or not	Justification for submission of study	Data protection claimed Y/N	Owner
KCA 5.5/7	[redacted]	2002 d	BAS 500 F - Second supplementary chronic toxicity study in female Wistar rats - Administration in the diet for 24 months 2002/1004126 [redacted] Yes Unpublished	New data (submitted to US-EPA)	Yes	BASF
KCA 5.5/8	[redacted]	2002 e	BAS 500 F - First supplementary carcinogenicity study in Wistar rats - Administration in the diet for 24 months 2002/1004123 [redacted] Yes Unpublished	New data (submitted to US-EPA)	Yes	BASF
KCA 5.5/9	[redacted]	2002 f	BAS 500 F - Second supplementary carcinogenicity study in female Wistar rats - Administration in the diet for 24 months 2002/1004124 [redacted] Yes Unpublished	New data (submitted to US-EPA)	Yes	BASF
KCA 5.5/10	[redacted]	2005 a	BAS 500 F: Terminated carcinogenicity study in female B6C3F1 mice; administration in the diet for 7 months 2005/1026477 [redacted] Yes Unpublished	New data (submitted to US-EPA)	Yes	BASF
KCA 5.5/11	[redacted]	2002 a	Chronic and oncogenicity study with BAS 500 F: Further evaluations of body weight, food consumption and food efficiency 2002/5002875 [redacted] No Unpublished	New evaluation of BW, FC and Food eff. data from the rat and mouse long-term studies (evaluation submitted to US-EPA)	No	BASF
KCA 5.8.1/4	[redacted]	1997 a	Study on the acute oral toxicity of Pyrazolon in rats 1997/10963 [redacted] Yes Unpublished	New data for the risk assessment of metabolites	Yes	BASF
KCA 5.8.1/5	[redacted]	1997 b	Study on the acute dermal irritation/corrosion of Pyrazolon in the rabbit 1997/10964 [redacted] Yes Unpublished	New data for the risk assessment of metabolites	Yes	BASF

Data point	Author(s)	Year	Title Company Report No. Source (where different from company) GLP or GEP status Published or not	Justification for submission of study	Data protection claimed Y/N	Owner

Table of Contents

1 BACKGROUND

Pyraclostrobin is a broad spectrum fungicide, which is active against fungal development stages both on the plant surface and within the tissues. It has a protective as well as an eradicative/curative action. Pyraclostrobin belongs to the group of active substances which is collectively known as strobilurins. The biochemical mode of action of the strobilurins is the inhibition of mitochondrial respiration.
In addition to the fungicidal effects plant physiology is also affected by the application of pyraclostrobin. Among these effects higher yield and better product quality in absence of diseases, improvement of the assimilation rate and delayed senescence have been reported. Furthermore, some studies showed better stress tolerance to abiotic stresses (e.g. drought or frost).
Pyraclostrobin is used world-wide in a large variety of crops including cereals, oilseeds, legumes, fruits and vegetables.

BASF submitted a dossier to include pyraclostrobin in Annex I on 28 February 2000. The Rapporteur Member State (RMS) was Germany.

5th Addendum
C.1 Addendum Confidential information, 12 February 2004, 5 pages, no reference list

Pyraclostrobin was included in Annex I of Directive 91/414/EEC on 1 June 2004 (entry into force) under Inclusion Directive 2004/30/EC for the use as fungicide. This use was amended on 22 April 2009 (entry into force) by Inclusion Directive 2009/25/EC to the use as fungicide or plant growth regulator. Both Annex I inclusion decisions were based on the same endpoints and provisions.

The Review Report (Pyraclostrobin - SANCO/1420/2001-Final) is dated 08 September 2004 and provides endpoints agreed during first inclusion evaluation (Appendix II to the Review Report).

Member States were required to pay particular attention to the following areas:
- should pay particular attention to the protection of aquatic organisms, especially fish,
- should pay particular attention to the protection of terrestrial arthropods and earthworms

Due to the improvement of physical and chemical properties, the representative formulation will be changed to a 200 g/L EC solo formulation (coded BAS 500 06 F) representing the use in important and widely grown “row crops” (cereals and maize). In addition a second (new) representative formulation (coded BAS 516 07 F and containing boscalid as second active substance) has been chosen to represent the many uses in “specialty crops” were typically lower application rates are used.

The intended use patterns (GAPs) of the representative crops for which data and risk assessments will be provided in the supplemental dossier are already registered in several EU Member States for BAS 500 06 F and BAS 516 07 F. Details of the use patterns are shown in the Appendix of this document.

List of endpoints agreed at approval (Annex I inclusion) and proposed changes, by scientific area:

Toxicology and metabolism

The endpoints as given in the EU Review Report of pyraclostrobin in 2004 are listed in the tables below. In case new information on certain endpoints is available, a comment is made in the additional right table column. Further explanations are given in the text below the table.

Absorption, distribution, excretion and metabolism in mammals

Rate and extent of absorption:	About rapid absorption: Tmax ~ 1 hour: 50% (based on urinary and biliary excretion within 48 hours)	
Distribution:	Widely, highest concentrations in the liver	
Potential for accumulation:	None	
Rate and extent of excretion:	Complete within 5 d; mainly via faeces (80-90%, biliary excretion amounting to 35%), via urine 11-15%	
Toxicologically significant compounds:	Parent compound and metabolites	
Metabolism in animals:	Extensive (>95%) with nearly 50 metabolites occurring Main metabolic pathways included N-demethoxylation, hydroxylation, cleavage of ester bond and further oxidation of the resulting molecule parts, conjugation with glucoronic acid or sulphate	

Acute toxicity

Rat LD_{50} oral:	> 5000 mg/kg bw (Mouse: mortality at ≥ 300 mg/kg bw)	
Rat LD_{50} dermal:	> 2000 mg/kg bw	
Rat LC_{50} inhalation:	0.69 mg/L	0.58 mg/L (see comment below)
Skin irritation:	Irritating	
Eye irritation:	Not irritating	
Skin sensitisation (test method used and result):	Not sensitising (M&K maximisation test)	

Short term toxicity

Target / critical effect:	Reduced body weight, gastrointestinal tract, red blood cells, diarrhoea (dog), hepatocellular hypertrophy (rat), white blood cells and lymphatic organs (mouse)	
Lowest relevant oral NOAEL / NOEL:	90-day mouse[3]: 30 ppm (4 mg/kg bw/d)	
Lowest relevant dermal NOAEL / NOEL:	28-day rat: > 250 mg/kg bw/d (systemic)	
Lowest relevant inhalation NOAEL / NOEL:	No data - not required (because of physical and chemical properties)	New data available, respectively in the process of generation (see below)

[3] based on effects on body weight after 90 days in the carcinogenicity study in male mice

Genotoxicity

No genotoxic potential	

Long term toxicity and carcinogenicity

Target / critical effect:	Reduced body weight (rat & mouse); liver cell necrosis (rat)	
Lowest relevant NOAEL:	Chronic rat (75 ppm) 3 mg/kg bw/d	
Carcinogenicity:	No carcinogenic potential	

Reproductive toxicity

Target / critical effect - Reproduction:	Reduced pup body weight gain in the presence of parental toxicity	
Lowest relevant reproductive NOAEL / NOEL:	75 ppm (8.2 mg/kg bw/d)	
Target / critical effect - Developmental toxicity:	Developmental effects in rats and embryotoxicity (including malformations) in rabbits at maternally toxic doses	
Lowest relevant developmental NOAEL / NOEL:	5 mg/kg bw/d (rabbit)	
Lowest relevant maternal NOAEL / NOEL:	3 mg/kg bw/d (rabbit)	

Delayed neurotoxicity

No neurotoxic potential (rat, acute and 13wk studies)	

Other toxicological studies

Three water metabolites (BF 500-11, BF 500-13, BF 500-14) proved negative in the Ames test	New data available (see below)

Medical data

Limited data (new compound); no human health problems identified	After around 10 years of production, literature and company surveys did not identify human health problems.

Summary

	Value	Study	Safety factor	
ADI:	0.03 mg/kg bw	Chronic rat study	100	
AOEL systemic:	0.015 mg/kg bw	Rabbit, developmental toxicity study (maternal toxicity); 50 % oral absorption	100	
ARfD (acute reference dose):	0.03 mg/kg bw	Rabbit, developmental toxicity study (maternal toxicity)	100	

Dermal absorption

EC formulation: 2.6% (rat, in vivo); in vitro data suggest much lower permeability of human skin; 1% used for calculation based on in vitro/in vivo data	new representative formulations, studies ongoing (see below)

Toxicology and metabolism – comments to endpoints

Acute inhalation toxicity
A new acute inhalation toxicity study with pyraclostrobin dissolved in acetone was conducted for a more accurate determination of the LC_{50}. This study was performed at actual concentrations of 0.52, 0.65 and 0.85 mg/L. This study revealed a LC_{50} of 0.58 mg/L.

Subchronic inhalation toxicity
A 28-day inhalation toxicity study was performend upon request of US EPA at concentrations of 0, 1, 30 and 300 mg/m³. A 28-day inhalation study with intermediate dose levels (3 and 10 mg/m³) is currently conducted.

Other toxicological studies
Additional in-vitro and in-vivo mutagenicity studies were performed for the water metabolites BF 500-11, BF500-13 and BF 500-14. Furthermore, in-vivo and/or in-vitro mutagenicity studies were conducted for the metabolites BF 500-5 (synonym: 500M04), 500M24, 500M49 and 500M51. For all mentioned metabolites the weight of evidence showed the absence of a mutagenic potential.
For the metabolite BF 500-5 (500M04) a set of acute toxicity studies as well as a subchronic 90-day study in rats is available. All studies indicate that the metabolite has a lower toxicological potential than pyraclostrobin.

Dermal absorption
While the dermal penetration values were derived from studies with the former representative formulation BAS 500 00 F, new in-vitro dermal penetration studies with human skin are currently conducted. The studies will be evaluated according to the latest EFSA Guidance Document on dermal penetration.

Fate and behaviour in the environment

The endpoints as given in the EU Review Report of pyraclostrobin in 2004 are listed in the tables below. Endpoints for risk assessments which were used up to now and which differed from the EU Review Report are presented below in the third table column. Since the endpoints which will be derived from the new studies are not finally known yet, an indication on possible changes for soil, water, and air assessments is given in the text below the respective table sections.

Fate and behaviour in soil

Route of degradation

Aerobic

Mineralization after 100 days:	4% after 87 d (tolyl-label, route study) 5% after 91 d (chlorophenyl-label, route study)	
Non-extractable residues after 100 days:	54.3% after 87 d (tolyl-label, route study) 56.1% after 91 d (chlorophenyl-label, route study)	
Major metabolites above 10 % of applied active substance: name and/or code % of applied rate (range and maximum)	BF 500-6, max. 31% after 120 days (rate studies) BF 500-7, max. 13% after 62 days (rate studies)	

Supplemental studies

Anaerobic:	no residues of the parent after 120 days, bound residues: 61% (tolyl-label), 37% (chlorophenyl-label). Major metabolite BF 500-3: max 95.8% after 14 d (tolyl-label), 80% after 14 d (chlorophenyl-label)	
Soil photolysis:	after 15 days: 64-74% parent, 12% bound residues, 2% CO_2, no major metabolites (>10%)	
Remarks:	degradation in soil is mainly depending on microbial activity	

Rate of degradation

Laboratory studies

DT_{50lab} (20 °C, aerobic):	DT_{50lab} **as** (20°C, aerobic): 12-101 days (5 soils) DT_{50lab} BF 500-6 (tolyl-label, route study): 129 d DT_{50lab} BF 500-6 (chlorphenyl-label, route study): 166 d DT_{50lab} BF 500-7 (tolyl-label, route study): 112 d DT_{50lab} BF 500-7 (chlorphenyl-label, route study): 159 d	
DT_{90lab} (20 °C, aerobic):	DT_{90lab} **as** (20°C, aerobic): 143-163 days (5 soils) DT_{90lab} BF 500-6 (tolyl-label, route study): 428 d DT_{90lab} BF 500-6 (chlorphenyl-label, route study): 552 d DT_{90lab} BF 500-7 (tolyl-label, route study): 372 d DT_{90lab} BF 500-7 (chlorphenyl-label, route study): 529 d	
DT_{50lab} (10 °C, aerobic):	DT_{50lab} (5°C, aerobic): > 120 days	
DT_{50lab} (20 °C, anaerobic):	DT_{50lab} (20°C, anaerobic): 3 days	

Field studies (country or region)

DT_{50f} from soil dissipation studies:	DT_{50f}: 8 – 55 days, 6 locations (3 Germany, 2 Spain, 1 Sweden)	error in Review Report; highest observed DT_{50} in peer reviewed field diss. studies = 37 days
DT_{90f} from soil dissipation studies:	DT_{90f} : 83-230 days	
Soil accumulation studies:	not required	
Soil residue studies:	not required	

Remarks

e.g. effect of soil pH on degradation rate	no pH-effect, degradation in soil mainly depending on microbial activity, metabolites BF 500-6 and BF 500-7 were not found in field studies	

Adsorption/desorption

	Soils: 3 German, 2 US, 1 Canadian		
K_f / K_{oc}:	K_{oc}	Active substance (^{14}C-Chlorphenol-ring) 6000 – 16000 (no average value calculated because of high variance)	
K_d	K_d	30 – 368	
	1/n	0.861 – 1.025	
pH dependence:	none		

BF 500-6	K_{oc}	3160 – 71300	
	K_d	79 – 610	
	1/n	not available. Due to low water solubility only one concentration considered.	

BF 500-7	K_{oc}	3920 – 147600	
	K_d	98 – 738	
	1/n	not available. Due to low water solubility only one concentration considered.	

Mobility

Laboratory studies

Column leaching:	0% in leachate, all radioactivity in top soil layer	
Aged residue leaching:	0% in leachate, all radioactivity in top soil layer	

Field studies

Lysimeter/Field leaching studies:	based on K_{oc} and DT_{50} values, no leaching expected Studies are not required.	

Remarks

None	

Fate and behaviour in soil – comments to endpoints

Concerning route of degradation in soil, an aerobic soil metabolism study as well as a soil photolysis study was performed with the up to now not investigated ^{14}C-pyrazole-label of pyraclostrobin. This was done to confirm that no additional metabolite consisting solely of the pyrazole- moiety is formed during soil degradation although the chlorophenyl-label and tolyl-label produced high amounts of bound residues and also showed mineralization. No new metabolites occured with the pyrazole-label and thus the route of degradation as proposed in the original dossier is confirmed.

New DT_{50} endpoints in aerobic soil under laboratory conditions are being generated for parent, for the minor metabolite BF 500-3, and for the major soil metabolites BF 500-6 and BF 500-7. New DT_{50} endpoints in soil will be also produced for metabolites BF 500-4 and BF 500-5 which appear in measurable amounts only under strict anaerobic soil conditions, but which need now to be considered for risk assessment under Regulation 1107/2009.

A new field dissipation study addresses the degradation behaviour of pyraclostrobin in soil according to the new requirements of 1107/2009, i.e. dissipation processes like photolysis are excluded. New endpoints are expected.

New adsorption values will be generated for metabolites BF 500-6 and BF 500-7 as well as for BF 500-4 and BF 500-5.

Fate and behaviour in water

Abiotic degradation

Hydrolytic degradation:	pH 5 – 9, 25°C: stable	
Major metabolites:		
Photolytic degradation:	DT_{50}: 1 – 2 days	
Major metabolites:	not determined	

Biological degradation

Readily biodegradable:	not readily biodegradable	
Water/sediment study: DT_{50} water: DT_{90} water: DT_{50} whole system: DT_{90} whole system: DT_{50} water: DT_{50} whole system: DT_{50} sediment: DT_{90} sediment:	best fit pond: 3 days; river: 1 day pond: 41 days; river: 9 days pond: 27 days; river: 29 days** pond: 89 days; river: 96 days** ** = low r^2 value (0.5593) 1st-order pond: 8.7 days; river: 1 day pond: 29 days; river: not extrap. pond: 33 days; river: 9 days pond: 105 days; river: no calc. possible	
Distribution in water / sediment systems (active substance)	pond system: sediment max. 53% after 14 days, decreasing to 7% after 100 days river system: sediment max. 62% after 2 days, decreasing to 10% after 100 days	
(metabolites)	BF 500-3: in water: max. 2% in sediment: max. 12% after 100 days (pond); max. 66% after 14 days (river), decreasing to 29% after 100 days BF 500-6: (only in pond system) in sediment max. 7% after 61 days BF 500-7: (only in pond system) in sediment max. 6% after 61 days	
Mineralisation	0.7 – 7.5 % in 100 days	
Bound residues	51 – 66.2 % in 100 days	
Accumulation in water and/or sediment:	not expected, only bound residues	
Metabolites from additional water/sediment study with irradiation:	BF 500-11: max. 11% after 21 days BF 500-13: max. 16% after 62 days BF 500-14: max. 11% after 10 days	

Degradation in the saturated zone

not relevant	

Remarks

results from water/sediment study with irradiation only useful as additional information concerning possible metabolites, not accepted as higher tier study for the determination of degradation rates	

Fate and behaviour in water – comments to endpoints

Since irradiation is an important degradation/dissipation route for pyraclostrobin in water, a new irradiated water/sediment study including full material balance was performed. The route of degradation in surface waters was confirmed. In addition, an aerobic mineralization study according to guideline OECD 309, Aerobic Mineralization in Surface Water, was performed due to the new data requirement in regulation 1107/2009. The only metabolite formed was the BF 500-5 (max. 7-8%), a hydrolytic cleavage product, which will be considered for aquatic risk assessment.

Fate and behaviour in air

Volatility

Vapour pressure:	2.6 x 10^{-8} Pa, 20°C	
Henry's law constant:	5.307 x 10^{-6} Pa m^3 mol^{-1}	

Photolytic degradation

Direct photolysis in air:	see photochemical oxidative degradation	
Photochemical oxidative degradation in air DT_{50}:	< 2 hours (24- hours day, according to Atkinson, AOP)	
Volatilisation:	from plant surfaces: about 3% in 24 hours	

Remarks

no short or long range transport in air expected	

Fate and behaviour in air – comments to endpoints

No new experimental data will be generated. A new Atkinson calculation will be performed according to the newest calculation procedure.

Ecotoxicology

A significant number of new studies was performed following Annex I inclusion. These studies were conducted
a) to support registrations outside the EU,
b) to fulfill new data requirements,
c) to cover further metabolites identified as potentially relevant in additional e-fate investigations,
d) to address the risk assessment for the new representative formulations.

The endpoints given in the Review Report from 2004 are shown in the tables below. Comments are made in the last column as appropriate. All additional study endpoints not previously evaluated during the Annex I inclusion process are presented in the tables as well (endpoint values are given in the last column). Further comments on possible changes for endpoints and risk assessments are given below the tables if appropriate.

The test substance is coded "as" for pyraclostrobin, "BAS … F" for the representative formulations and "BF 500 -.." for the metabolites.

Terrestrial vertebrates

Acute toxicity to mammals:	LD_{50} > 5000 mg/kg bw (rat)	
Acute toxicity to birds:	LD_{50} > 2000 mg/kg bw (bobwhite quail)	
	LD_{50} (canary)	Study ongoing
Dietary toxicity to birds:	LC_{50} > 5000 ppm (bobwhite quail and mallard duck) LC_{50} > 1176 mg/kg bw/d (bobwhite quail) LC_{50} > 1320 mg/kg bw/d (mallard duck)	No longer part of the core data package
Reproductive toxicity to birds:	NOEL 1000 ppm (bobwhite quail and mallard duck) NOEL 105 mg/kg bw/d (bobwhite quail) NOEL 128 mg/kg bw/d (mallard duck)	
Reproductive toxicity to mammals:		Tier 1: NOEL = 3 mg as/kg bw/d (rabbit, developmental toxicity) Higher tier: NOEL = 8.2 mg as/kg bw/d (rat, two-generation study)

Aquatic organisms

	Group	Test substance	Timescale	Endpoint	Toxicity (mg/L)	New Information / comments
Acute toxicity fish:	*Oncorhyn-chus mykiss*	as	96 h, static	LC_{50}	0.006	0.00616 is the correct value, which was rounded in the Review Report to 0.006
	O. mykiss	as	96 h, flow-through	LC_{50}		0.0062 (study performed as flow-through test for US registration)
	Lepomis macrochirus	as	96 h, flow-through	LC_{50}		0.0114 (study performed as flow-through test for US registration)
	Cyprinodon variegatus	as	96 h, flow-through	LC_{50}		0.0769 (study for US salt water/ estuarine risk assessment, not required in the EU)
	O. mykiss	BAS 500 00 F	96 h, static	LC_{50}	0.017	old representative formulation (given for completeness)
	O. mykiss	BAS 500 06 F	96 h, static	LC_{50}		0.046 new representative formulation
	Cyprinus carpio	BAS 500 06 F	96 h, static	LC_{50}		0.098 new representative formulation (study for registration in Japan)
	O. mykiss	BAS 516 07 F *	96 h, static	LC_{50}		0.088 new representative formulation
	O. mykiss	BF 500-13	96 h, static	LC_{50}	> 50 - < 100	
	O. mykiss	BF 500-14	96 h, static	LC_{50}	> 39 - < 83	
	O. mykiss	BF 500-11	96 h, static	LC_{50}	> 100	
	O. mykiss	BF 500-3	96 h, static	LC_{50}		> 0.095 soil/sediment metabolite (study for registration in Canada)
	O. mykiss	BF 500-5	96 h, static	LC_{50}		study ongoing (to address an additional aquatic metabolite)

Long term toxicity fish:	*O. mykiss*	as	28 d, flow-through	NOEC	0.005	
	O. mykiss	as	98 d, ELS flow-through	NOEC	0.002	0.002349 is the correct value, which was rounded to 0.0023 (study summary and DAR) and 0.002 (Review Report)
	Pimephales promelas	as	36 d, ELS flow-through	NOEC		0.00414 (study for US registration)
	Cyprinodon variegatus	as	36 d, ELS flow-through	NOEC		0.0108 (study for US salt water/ estuarine risk assessment, not required in the EU)
Bioaccumulation fish:	675 (whole fish, chlorophenyl label) 736 (whole fish, tolyl label)					
Acute toxicity invertebrate:	*Daphnia magna*	as	48 h, static	EC_{50}	0.016	
	Americamysis bahia	as	96 h, flow-through	LC_{50}		0.00416 (study for US salt water/ estuarine risk assessment, not required in the EU)
	Crassostrea virginica	as	96 h, flow-through	LC_{50}		0.0125 (study for US salt water/ estuarine risk assessment, not required in the EU)
	D. magna	BAS 500 00 F	48 h, static	EC_{50}	0.065	old representative formulation (given for completeness)
	D. magna	BAS 500 06 F	48 h, static	EC_{50}		0.065 new representative formulation
	D. magna	BAS 516 07 F	48 h, static	EC_{50}		0.210 new representative formulation
	D. magna	BF 500-13	48 h, static	EC_{50}	> 100	
	D. magna	BF 500-14	48 h, static	EC_{50}	61	
	D. magna	BF 500-11	48 h, static	EC_{50}	> 100	
	D. magna	BF 500-3	48 h, static	EC_{50}		> 0.100 soil/sediment metabolite (study for registration in Canada)
	D. magna	BF 500-5	48 h, static	EC_{50}		study ongoing (to address an additional aquatic metabolite)

Chronic toxicity invertebrate:	*D. magna*	as	21 d, semi-static	NOEC	0.004	
	A. bahia	as	31 d, flow-through	NOEC		0.00128 (study for US salt water/ estuarine risk assessment, not required in the EU)
Acute toxicity algae:	*Pseudokirch-neriella subcapitata*	as	72 h, static	E_rC_{50} E_bC_{50}	> 0.843 0.152	E_bC_{50} = 0.148 (based on recalculation of endpoints)

Mesocosm: #	ecosystem	BAS 500 00 F	c. 6 month, multiple applica-tions	NOEC		8 Study evaluated by RMS, but not included in the Review Report

* Study was conducted with the minor change formulation BAS 516 00 F.

\# A mesocosm study was conducted with the formulated product BAS 500 00 F and was evaluated according to current requirements. Four concentration levels ranging from 0.9 µg as/L to 24 µg as/L simulating a vineyard situation with 8 applications in 14 d intervals were investigated. Approximately 260 different taxa of aquatic invertebrates were determined in the study. In most cases only insignifcant transient effects were observed at the highest concentrations and affected populations usually recovered until the end of the study. The NOEAEC (No Observed Ecologically Adverse Effect Concentration) was determined to be > 8 < 24 µg as/L and the NOEC was 8 µg as/L.

Aquatic organisms – comments to endpoints

A significant number of new studies has been generated. However, the new data are largely in line with previous results and will not significantly change the overall aquatic risk assessment. This is also true regarding the new endpoints for the new representative formulations. The new endpoints for additional metabolites tested confirm the low risk of these metabolites, too. There are several new endpoints for marine organisms, which are partly lower (e.g. for mysids) than available data or which are higher or in line (e.g. fish data) with previous endpoints. However, the extensive information available for fresh water organisms including a mesocosm study with a wide range of taxa and more realistic exposure conditions provide the relevant information for the risk assessment of edge of field freshwater ecosystems.

Honeybees

Acute oral toxicity:	LD_{50} > 73.1 µg as/bee	LD_{50} > 110.0 µg as/bee [1)] New representative formulations: BAS 500 06 F: LD_{50} = 381.8 µg/bee BAS 516 07 F: LD_{50} > 258.7 µg/bee

[1)] endpoint corrected to account for $logP_{ow}$ > 2 and high peat content (10%) in test soil

Soil macro-organisms other than earthworms

No endpoints are given in the EU Review Report. Available information on reproductive toxicity is shown in the table below.

Metabolite BF 500-6 (*Folsomia candida*):	NOEC ≥ 1000 mg/kg dry soil
Metabolite BF 500-7 (*Folsomia candida*):	NOEC ≥ 800 mg/kg dry soil
BAS 500 06 F (*Folsomia candida*):	NOEC = 125 mg/kg dry soil (23.9 mg as/kg dry soil)
BAS 516 07 F (*Folsomia candida*):	NOEC = 250 mg/kg dry soil
BAS 500 06 F (*Hypoaspis aculeifer*):	NOEC ≥ 90 mg/kg dry soil (17.3 mg as/kg dry soil)
BAS 516 07 F (*Hypoaspis aculeifer*):	Study in preparation

Furthermore, an organic matter decomposition study was conducted with BAS 500 06 F resulting in a NOEC of 1.25 L/ha.

Soil micro-organisms

Nitrogen mineralization:	No effects up to 10 L product/ha (2.5 kg as/ha) BF 500-6: No effect up to 750 g/ha BF 500-7: No effect up to 375 g/ha	New representative formulations: BAS 500 06 F: No unacceptable effects up to 12.5 L/ha (3.33 mg as/kg dry soil). BAS 516 07 F: No unacceptable effects up to 24 kg/ha
Carbon mineralization:	No effects up to 10 L product/ha (2.5 kg as/ha) BF 500-6: No effect up to 750 g/ha BF 500-7: No effect up to 375 g/ha	New representative formulations: BAS 500 06 F: No requirement anymore, thus no additional study conducted BAS 516 07 F: No unacceptable effects up to 24 kg/ha

Non-target plants

No endpoints are given in the EU Review Report. The following information is available for the new representative formulations:

BAS 500 06 F: ER_{50} (seedling emergence) > 1.25 L/ha, ER_{50} (vegetative vigor) > 1.25 L/ha

BAS 516 07 F: ER_{50} (vegetative vigor) > 5.4 kg/ha

Further studies will be conducted with BAS 516 07 F.

2 THE ACTIVE SUBSTANCE AND THE PLANT PROTECTION PRODUCT

Active substance

The actice substance pyraclostrobin was approved by the EU with the reference specification referred to in EU Directive 2004/30/EC. The minimum purity of the active substance specified in the Inclusion Directive is 975 g/kg. The manufacturing impurity dimethylsulfate (DMS) was considered to be of toxicological concern and must not exceed a concentration of 0.0001 % (1 ppm w/w) in the technical product.

The equivalency of the current technical pyraclostrobin to the reference specification and the impurity profile of all active substance batches used for (old and new) toxicological and ecotoxicological studies will be shown in the supplemental dossier. Due to continuous optimisation of the commercial production process the current active substance content is higher and the current concentration of technical impurities is lower compared to the reference specification. Further important information on the identity of the active substance is given in chapter 3.1.

Plant protection product

The representative formulations chosen for renewal of approval are BAS 500 06 F and BAS 516 07 F.

BAS 500 06 F (200 g/L pyraclostrobin, EC) is the result of further optimising the previous representative formulation BAS 500 00 F (250 g/L pyraclostrobin, EC).

BAS 516 07 F (26.7 % w/w boscalid, 6.7 % w/w pyraclostrobin, WG) was not involved in the Annex I evaluation process of either pyraclostrobin or boscalid.

For both formulations a complete set of studies and other documents will be provided in the supplemental dossier.

3 SPECIFIC CONCLUSIONS BASED ON PREVIOUS EVALUATION

3.1 Identity, physical/chemical/technical properties and methods of analysis

Identity
During the Annex I inclusion process two five batch analysis reports were submitted and evaluated. The first one was based on lab / pilot plant samples (tox-batches), while for the second one representative samples of the commercial production plant were used. The current reference specification is based on the analysed production plant samples. However, in the EU Review Report (SANCO/1420/2001-Final) a remark was made that the reference specification was based on pilot plant data.
According to current requirements a new five batch analysis will be submitted in the supplemental dossier based on the commercially produced technical material.

Phys.-chem. properties
Purified pyraclostrobin is a white to light beige crystalline solid, while the commercially produced technical material is an amber-coloured glass-like solid.
Pyraclostrobin is neither flammable, nor explosive, nor corrosive, nor oxidizing. The pure active ingredient (PAI) has a vapour pressure of 2.6×10^{-8} Pa at 20°C. It is slightly soluble in pure water (1.9 mg/L at 20°C and pH 5.8). Its n-octanol/water partition coefficient (log P_{ow}) is 3.99. Due to the lack of acidic protons pyraclostrobin does not dissociate. The active substance absorbs light in the UV area (absorption bands around at 205 and 275 nm), showing sensitivity to photolysis (measured with PAI).

Analytical methods

Product chemistry
Analytical methods to determine significant impurities and the relevant impurity dimethyl sulfate in the technical material were evaluated during the Annex I inclusion process. Updated analytical methods will be submitted as appropriate. In addition, the new CIPAC method for the determination of the active substance will be contained in the supplemental dossier.
Validated analytical methods for the determination of the active substance and of dimethyl sulfate in the new representative formulations will be submitted in the AIR 3 dossier.

Consumer safety
New methods for data generation and monitoring purposes were developed for plant matrices and animal tissues (including blood as body fluid). The methods cover the new guideline requirements (OECD, SANCO 825) and the metabolites identified during metabolism studies. The methods are fully validated. For proving the validity of the cow feeding study, the common moiety method used as data generation method will be validated for the main metabolites (especially 500M04 in milk). In order to support the poultry feeding study, the common residue analytical method used for sample analysis will be provided as supplemental information. Independent lab validation studies will be submitted for plants (additional commodities) and for livestock.

Environmental fate

New methods for monitoring purposes and generation of residue data were developed for soil, surface and ground water and air. The methods cover the new guideline requirements and the metabolites identified during metabolism studies. The methods were also fully validated. An independent lab validation will be provided for surface and ground water.

3.2 Mammalian toxicology

3.2.1 Absorption, distribution, metabolism and excretion in mammals

With the exception of the below described study all relevant data were already reviewed in the Annex I inclusion process.

The comparison of in-vitro-metabolism in humans with species used in toxicological pivotal studies is a new data requirement according to Regulation 1107/2009. It will be addressed by a study with hepatocytes from humans, rat and rabbit (pools of females and males), which is currently ongoing and will be submitted with the supplemental dossier. Two different concentrations of pyraclostrobin will be incubated with hepatocytes from the different species and metabolite patterns will be compared via retention times on radio-HPLC and mass.

3.2.2 Acute toxicity

Pyraclostrobin has low acute toxicity via the oral and dermal route.

As the physical form of technical pyraclostrobin is a solidified melt it can not be inhaled. Dissolved in acetone it was toxic to rats when inhaled as an aerosol for 4 hours. A study performed 1997 revealed an acute toxicity value of 0.31 mg/L < LC_{50} < 1.07 mg/L with no and 100% mortality at 0.31 and 1.07 mg/L, respectively. The derived LC_{50} in the List of Endpoints was 0.69 mg/L. A new study performed in 2002 at concentrations of 0.52, 0.65 and 0.85 mg/L, using also acetone as solvent, revealed an LC_{50} of 0.58 mg/L. A substantially different result was obtained in a second new acute inhalation study performed in 2001, using Solvesso 200 as a solvent, revealing an acute inhalation toxicity value of 4.07 < LC_{50} < 7.3. Thus, the solvent used affects – together with the particle size distribution of the generated aerosol – the acute inhalation toxicity of pyraclostrobin.

With regard to local effects pyraclostrobin is irritant to the skin and non-irritant to the eye. In a maximization assay no sensitizing effects were observed.

No phototoxic potential was seen with pyraclostrobin in a 3T3 NRU cell phototoxicity test according to OECD 432. Thus no impact on human health risk is expected by exposure to UV light.

3.2.3 Short-term toxicity

With the exception of a new 28-day inhalation toxicity study all relevant data were already reviewed in the Annex I inclusion process.

Subchronic oral toxicity studies were performed in rats, mice and dogs. Mice proved to be the most sensitive species. According to the former EU review the lowest dose tested (50 ppm) was still an effect level based on effects on body weight gain and serum urea levels in males. A NOAEL was set at 30 ppm (~ 4 mg/kg) based on body weight data after 91 days of treatment in the mouse carcinogenicity study (0, 10, 30, 120 ppm). The 90-day respectively 1-year NOAELs in rats and dogs were 500 and 200 ppm, respectively.
Common effects in all three species were effects on body weight, hypertrophy of the duodenal mucosa and effects on red and white blood cell parameters. Mainly in female rats an increased incidence of extramedullary hematopoiesis was observed. Apart from the correction of clerical errors the newly submitted report amendments to the rat and mouse 90-day studies indicate no treatment-related effects on hemosiderin deposition in the spleen.
Whereas in female rats and male dogs (12-months study) increased white blood cell counts were recorded, a (partially substantial) decrease of white blood cell counts was observed in mice. This was mainly due to an absolute decrease of lymphocyte counts down to 25% of the control value. The effects on lymphocyte counts in mice were accompanied by effects on lymphoid organs.
Effects on the liver were mainly observed in rats with males being the more susceptible sex. The effects on the liver consisted of hepatocellular hypertrophy. Secondary to the markedly reduced body weights, absolute liver weights were decreased in males whereas relative liver weights were unchanged. In females effects on body weight were much less pronounced, resulting in a statistical significant increase of absolute and or relative liver weight at dose levels > 500 ppm. The decreased absolute and increased relative liver weights in mice were secondary to the reduced terminal body weight. Histopathologically a reduced incidence or severity of diffuse fatty infiltration was noted, which likewise was considered secondary to the observed body weight effects.

The 28-day dermal toxicity study in rats did not reveal signs of systemic toxicity up to the highest dose tested (250 mg/kg). In contrast, local dermal toxicity was observed based on the irritant properties of pyraclostrobin.

Upon request of US-EPA a 28-day inhalation toxicity study was performed in 2005 at concentrations of 1, 30, and 300 mg/m³ (0.001, 0.03 and 0.3 mg/L) using acetone as solvent to generate an inhalable aerosol. The high concentration was about half of the acute inhalation LC_{50} of 0.58 mg/L (see chapter “Acute toxicity” above). The 4 and 3 cases of mortality in male and female high concentration rats between study days 7 and 24 were the consequence of this high dose. Adverse effects on body weight development were noted at 300 mg/m³, whereas no treatment-related clinical biochemistry differences were noted between vehicle (acetone) and treated groups. The only exception was a slight increase of white blood cell counts, which at the differential blood count correlated to an increase of polymorphonuclear neutrophils. This was indicative of a mild inflammatory process probably in the respiratory tract. Histopathology identified the nasal cavity, the larynx, the lung and the duodenum as target organs. The NOAEC in this study was 1 mg/m³. An additional 28-day inhalation study with intermediate dose levels (3 and 10 mg/m³) is currently conducted in order to support the risk assessment.

3.2.4 Genotoxicity

All relevant data were already reviewed in the Annex I inclusion process. The mutagenic potential of pyraclostrobin was studied in a number of in-vitro and in-vivo test systems. None of the test systems revealed any evidence of a mutagenic potential of pyraclostrobin.

3.2.5 Long-term toxicity

The main and most relevant data were reviewed in the Annex I inclusion process. New data to be submitted pertain additional histopathological and statistical evaluations of the already submitted long-term studies in rats and mice, data on additional dose groups performed in parallel to the rat long-term studies as well as data on an additional carcinogenicity study in female mice at a higher dose than that used in the already submitted study. All these data were generated for and/or submitted to US-EPA. The additional animal studies were all terminated latest after 13 months of treatment as the MTD was either reached in the main studies or exceeded in the additional studies. No gross or histopathological examination of the animals was performed.

The 24-months chronic toxicity study in Wistar rats performed at dose levels of 0, 25, 75 and 200 ppm revealed slight body weight effects and marginal effects on a few clinical chemistry parameters. No treatment-related findings were noted in ophthalmology, hematology and urinalysis. Likewise, no adverse histopathological effects including neoplastic lesions were noted.
The newly submitted supplementary chronic toxicity studies were performed at dose levels of 400 ppm in males and females and 600 ppm in females. A consistent and often statistically significant decrease of food consumption and body weight/body weight gain was observed in treated groups. Dose dependent effects on clinical pathology parameters consistent to those observed in the regular 90-day subchronic and 24-months chronic toxicity study were noted in both sexes.

The 24-months carcinogenicity study in Wistar rats was likewise performed at dose levels of 0, 25, 75 and 200 ppm. No treatment-related mortality or clinical signs were noted. Impaired body weight development was observed in both sexes at 200 ppm. Additionally, a decrease of food consumption was noted in high dose males during the first 3 months of treatment. No treatment-related neoplastic findings were noted. The only treatment-related histopathological finding was an increased incidence of liver cell necrosis in males at the high dose level. The NOAEL for systemic toxicity was 75 ppm, whereas the NOAEL for carcinogenicity was at least 200 ppm.
The newly submitted supplementary carcinogenicity studies in rats were performed at dose levels of 400 ppm in males and females and 600 ppm in females. No treatment-related clinical signs or mortality was recorded. Food consumption and body weight development was impaired at all dose levels.

Based on a request from EPA an extended histopathological evaluation on the low and mid dose males of the rat long-term studies was performed with specific attention to the incidence of histiocytic sarcoma. These data were reported in report amendments to the respective studies. Neither in the chronic nor in the carcinogenicity study the additional neoplastic, pre-neoplastic and non-neoplastic findings did alter the conclusions in the original reports.

Pyraclostrobin was administered to groups of 50 male and 50 female B6C3F1 mice at dietary concentrations of 0, 10, 30 and 120 ppm and additionally 180 ppm (females only) for 18 months. No treatment related mortality, clinical signs, effects on food consumption, hematology (blood smears) or histopathology were observed. The only treatment-related findings consisted of impaired body weight development in high dose males (120 ppm) and high dose females (180 ppm). Based on the observed body weight effects the NOAEL for systemic toxicity was 30 ppm (4.1 mg/kg) in males and 120 ppm (20.5 mg/kg) in females.

Upon request of US-EPA a supplemental mouse carcinogenicity study was performed in female mice at a dietary dose of 360 ppm. As the absolute body weight and the body weight gain was markedly decreased, the study was terminated after 7 months in agreement with US-EPA. Besides slightly increased food consumption, decreased absolute and increased relative organ weights, no other findings were noted. No histopathological examinations were performed.

The supplementary studies described above as well as an additionally submitted statistical evaluation of body weight and food consumption data of the rat and mouse long-term studies indicate that these studies were performed at adequate dose levels.

3.2.6 Reproductive studies

All relevant data were reviewed in the Annex I inclusion process.

A 2-generation reproduction study performed at dose levels of 0, 25, 75 and 300 ppm revealed parental toxicity at the high dose as indicated by reduced food consumption and impaired body weight development. No adverse effects on reproductive performance including sperm and ovarian parameters as well as estrus cycle were observed. Pup survival and birth weights were not affected by treatment, while pup body weight development was impaired in both generations at the high dose level. Secondary to the impaired body weight development of pups a slight delay in vaginal opening was observed. The mean value for the day of vaginal opening was still within the historical control range. Lower thymus, spleen and brain pup weights at weaning as well as increased relative liver weights were likewise secondary to the impaired body weight development of pups. Based on the effects described above the parental and developmental NOAEL was determined at 75 ppm (~ 8.2 mg/kg bw/day), whereas the reproductive NOAEL was at least 300 ppm (~ 32.6 mg/kg bw/day).

Oral administration of pyraclostrobin to pregnant Wistar rats at dose levels of 0, 10, 25 and 50 mg/kg bw/day elicited overt maternal toxicity at 50 mg/kg bw/d and was still toxic to the dams at ≥ 25 mg/kg bw/d as indicated by impaired body weight development and/or reduced food consumption and corrected body weight gain. There was no evidence of an increase in the incidence of malformations up to the highest dose tested. A statistically significant increase of skeletal variations was observed at the high dose. However, all incidences were within the historical control range. Nonetheless, in the EU review these variations were considered as potentially treatment-related. Consequently, the NOAEL for developmental toxicity was set at 25 mg/kg bw/day whereas the NOAEL for maternal toxicity was 10 mg/kg bw/day.

The developmental toxicity study in Himalayan rabbits performed at dose levels of 0, 5, 10 and 20 mg/kg bw/day revealed maternal toxicity down to the low dose level as indicated by dose dependent reduction of mean food consumption (up to 90%) and mean body weight loss during the initial phase of treatment. The high maternal toxicity at the high dose resulted in embryotoxicity (increased early post-implantation loss) and reduced litter sizes. The incidence of external or soft tissue malformations or variations of any type was not affected by treatment, but there was an apparent increase in the occurrence of skeletal malformations. However, the incidences were within the historical control range and were thus considered incidental (see Addendum 4 to the DAR). Based on the increased embryotoxicity at ≥ 10 mg/kg bw/day the developmental NOAEL was set at 5 mg/kg bw/day, whereas the maternal NOAEL was considered < 5 mg/kg bw/day. A maternal NOAEL of 3 mg/kg bw/day was determined in a supplemental study employing dose levels of 0, 3 and 5 mg/kg bw/day.

3.2.7 Neurotoxicity studies

All relevant data were reviewed in the Annex I inclusion process.

Pyraclostrobin was tested in an acute and in a short-term (90-day) neurotoxicity study in rats. These studies included extensive functional observation batteries as well as neurohistopathological investigations. No indications of a specific neurotoxic potential of pyraclostrobin were observed confirming the lack of toxic properties of this kind as suggested by the other toxicological studies.

3.2.8 Other toxicological studies

3.2.8.1 Toxicity studies on metabolites

A number of environmental and plant/lifestock metabolites were investigated mainly in genotoxicity studies. One exception is Reg.No. 298327 which is – apart from its occurrence in the environment - a major plant and lifestock metabolite, for which a more extended testing program was performed. In the following the metabolites are sorted according to their BASF internal Reg. No. (registration number). If other denominators are available these are indicated as well. With the exception of 3 Ames tests performed with water metabolites all studies were not yet submitted/reviewed in the EU.

Reg.No. 78810 (500M51) – Plant metabolite
A set of 3 in-vitro studies (Ames (OECD 471), mouse lymphoma L5178Y$^{TK+/-}$ (OECD 476) and in-vitro micronucleus assay (OECD 487)) was performed. All studies were negative, i.e. did not indicate a genotoxic potential.

Reg.No. 298327 (500M04, BF 500-5) – Plant, lifestock and environmental metabolite
Reg.No. 298327 is of low acute toxicity (LD_{50} > 2000 mg/kg), is not irritant to the skin and eye and is not a skin sensitizer (Maximization assay).
In a 90-day subchronic toxicity study in rats the metabolite proved to be considerably less toxic than pyraclostrobin. No effects on food consumption and body weight development were observed up to the limit dose of 1000 mg/kg bw/day. Hematology effects were restricted to the high dose and consisted of altered red blood cell parameters. No hematological effects were observed in females. Likewise, clinical chemistry effects were noted in high dose males only. Urinalysis revealed in both sexes at the high dose increased urine volumes accompanied by a lower specific gravity of the urine. In males at ≥ 300 mg/kg bw/day an increased incidence of crystals of unknown origin was noted in the sediment. Consistent to the hematological effects in high dose males an increased severity of extramedullary hematopoiesis was noted in the spleen. The findings in the urine were accompanied by a number of histopathological findings in the kidneys and the ureter in males at ≥ 300 mg/kg bw/day and females at 1000 mg/kg bw/day. Thus the NOAEL in this study was 100 mg/kg bw/day, i.e. roughly 30 fold higher than that in the corresponding pyraclostrobin study. Furthermore, the toxicological profile was considerably different to the parent as indicated by the absence of effects on the liver and duodenum, while no effects on the kidney were observed with pyraclostrobin.
In-vitro gene mutation assays in bacteria (Ames) and mammalian cells (HPRT) with Reg.No. 298327 were negative, whereas the in-vitro chromosome aberration test in V79 cells revealed a clastogenic activity in presence of metabolic activation. However, an in-vivo micronucleus assay in mice did not confirm the in-vitro results. In a parallel study with radioactive Reg.No. 298327 it was demonstrated that the bone marrow of mice was exposed to the metabolite. Thus overall the studies showed the absence of a genotoxic potential of this metabolite.

Reg.No. 411847 (500M60, BF 500-11) - Environmental metabolite
A negative Ames test was submitted with the initial EU dossier. Based on a Dutch request additional genotoxicity studies were conducted. While the gene mutation assay in mammalian cells (HPRT) was negative, the in-vitro analysis for chromosomal damage was positive without metabolic activation. However, the higher tier in-vivo study did not reveal any clastogenic activity in mouse erythrocytes. In this study the presence of the metabolite in blood plasma was confirmed, indicating the exposure of the target organ. Thus overall the studies showed the absence of a genotoxic potential of this metabolite.

Reg.No. 413038 (500M76, BF 500-14) – Environmental metabolite
A negative Ames test was submitted with the initial EU dossier. Based on a Dutch request additional genotoxicity studies were conducted. While the gene mutation assay in mammalian cells (HPRT) was negative, the in-vitro analysis for chromosomal damage was positive in presence and absence of a metabolizing system. However, the higher tier in-vivo study did not reveal any clastogenic activity in mouse erythrocytes. In this study the presence of the metabolite in blood plasma was confirmed, indicating the exposure of the target organ. Thus overall the studies showed the absence of a genotoxic potential of this metabolite.

Reg.No. 4916420 (500M49) – Lifestock metabolite
A set of 3 in-vitro studies (Ames, mouse lymphoma $L5178Y^{TK+/-}$ and in-vitro micronucleus assay) was performed. All studies were negative, i.e. did not indicate a genotoxic potential.

Reg.No. 4916421 (500M24) – Plant metabolite
The gene mutation assays in bacteria (Ames) and mammalian cells (mouse lymphoma assay) were negative, whereas the in-vitro micronucleus assay indicated a clastogenic potential. However, the higher tier in-vivo mouse micronucleus assay did not reveal an increased incidence of micronucleated polychromatic erythrocytes. An analysis of blood plasma levels of Reg.No. 4916421 is currently ongoing to demonstrate the exposure of the target organ. Thus overall the studies showed the absence of a genotoxic potential of this metabolite.

3.2.8.2 Supplementary studies on the active substance

In a 14-day dietary study, groups of 10 male and 10 female Wistar rats were administered pyraclostrobin at dietary dose levels of 0, 50, 500 and 1500 ppm. Beside the expected effects on food consumption and body weight development at ≥ 500 ppm, a dose and time-dependent decrease of serum iron levels was noted in both sexes at ≥ 500 ppm, with males being more severely affected than females. This study was submitted to US-EPA and will be thus also submitted in the AIR 3 dossier.

Upon a request of US-EPA immunotoxicity studies according to OPPTS 870.7800 were performed. Based on the observation that the effects on immune organs and parameters were more pronounced in mice, the studies were performed in female B6C3F1 mice, i.e. the same strain as used for the subchronic and long-term studies in mice. As the study was performed in the US with mice from a different breeder, an abbreviated range-finding study was performed at dietary dose levels of 0, 500 and 1500 ppm. In contrast to the 90-day study conducted in 1997, the dietary dose of 1500 ppm was not tolerated and the animals had to be killed for animal welfare reasons after 3 days of treatment. At 500 ppm marginal signs of toxicity were noted. These consisted mainly of slightly reduced food consumption and body weight gain in males, lower red blood cell parameters as well as lower thymus weights in female and hyperplasia of the duodenal mucosa.
Two different types of immunotoxicity studies were performed, i.e. a study determining the activity of natural killer (NK) cells and a study to investigate the humoral immunity (T-cell dependent antibody response – TDAR) in sheep red blood cell immunized mice. The latter study was repeated, because the immune response of control animals in the first trial was way out of the historical control range. All three studies were performed in female B6C3F1 mice at dose levels of 0, 50, 200 and 750 ppm with 50 mg/kg bw/day of Cyclophosphamide as positive control for the TDAR studies or anti asialo GM1 for the NK cell study. In all studies impaired body weight development was noted at 750 ppm. At the same dose, spleen and thymus weights were significantly decreased. This was also true for the (absolute) number of spleen cells for high dose females.
The second TDAR study revealed no difference in total spleen TDAR response, however, due to the lower number of splenocytes, the relative TDAR response was at 750 ppm. No differences between control and the 50 and 200 ppm dose were noted. In contrast, no TDAR response was observed with the positive cyclophosphamide.
The activity of NK cells (effector cell) was determined by their cytotoxic action on cultured YAC-1 mouse lymphoma cells (target cell). Cytotoxicity was monitored by the release of ^{51}Cr from preloaded YAC-1 cells. Various effector to target cell ratios were tested (200:1 to 6.25:1).

While NK cells from the positive control animals displayed a significant decrease of lytic activity at effector to target cell ratios of 200:1 to 50:1, no difference between pyraclostrobin and control animal NK cell activity was noted.
Based on the immunotox studies performed, pyraclostrobin treated animals did not show an impaired immune function on humoral and cellular level.

3.2.8.3 Endocrine disrupting properties

There is no indication for an endocrine disruption potential of pyraclostrobin. The organ weight changes of male (testes, epididymis (dogs only)), and female sexual organs (ovaries) and endocrine glands (adrenals, thyroid (dogs only)) observed in subchronic studies at higher dose levels were secondary to the observed decrease of terminal body weights and typically not accompanied by histopathological findings. The decrease of absolute and relative adrenal weights in female mice was accompanied by a decrease of lipid deposition in the x-zone, which is specific to mice and of unknown function. The decreased lipid content is considered secondary to the impaired body weight development. No histopathological effects on the thyroid were observed in rodents and dogs. Likewise, long-term administration of pyraclostrobin did not indicate treatment-related effects on neoplastic or non-neoplastic findings in sexual organs or endocrine tissues.
In the 2-generation study administration of pyraclostrobin had no effect on the estrous cycle, the number, morphology and motility of sperm as well as on male or female fertility. The statistically significant increase of the precoital time in F_1 high dose females (mean of 2.8 days) was considered incidental, as the precoital time was within the historical control range and was identical to the precoital time of F_0 control females. Likewise, the slightly prolonged vaginal opening in high dose F_1 females was within the historical control range and most probably due to a general retardation of development, since the body weights/body weight gains were clearly impaired at the high dose group, especially in females.

3.2.9 Medical data

Literature searches in the past did not reveal relevant information on pyraclostrobin health effects on humans. The BASF internal medical monitoring programme is designed as a general health check-up and includes a general physical examination including neurological status, red and white blood cell counts and liver enzymes. Adverse health effects suspected to be related to pyraclostrobin exposure have not been observed.

Literature and internal data surveys will be updated for the AIR 3 dossier submission.

3.2.10 Acute data for the representative formulation

New representative formulations (BAS 500 06 F and BAS 516 07 F) have been chosen for the renewal of approval. The representative formulation of the initial submission (BAS 500 00 F) will be not a part of the dossier. A set of new acute toxicity studies was/is being conducted for the two representative formulations.

BAS 500 06 F is of moderate acute toxicity by the oral and inhalation route of exposure and of very low toxicity by the dermal route. It is irritant to the skin and – according to CLP criteria – irritant to the eye. Furthermore, the formulation is a sensitizer by the dermal route.

The acute toxicity potential of BAS 516 07 F is determined on the basis of studies performed with BAS 516 07 F and with the very similar formulation BAS 516 00 F, which is considered to be valid for BAS 516 07 F, too. BAS 516 07 F is of low acute toxicity by the oral, dermal and inhalation route of exposure and is not irritant to the skin and eye. The existing Buehler assay does not indicate a sensitizing potential. A mouse local lymph node assay is currently conducted to determine the sensitizing properties of the formulation according to the current requirements.

Moreover, product specific dermal absorption data will be determined for both products. New risk assessments for operators, bystanders, residents and re-entry workers will be provided for both representative formulations.

3.3 Residues

All relevant information on the first Annex I review and the endpoints used in consumer dietary assessments can be found in the monograph of pyraclostrobin and in the SANCO/1420/2001-Final document (EU Review Report). Before Annex I inclusion, EFSA and several Member States have assessed the safety of established and new MRLs covering both, European uses and import tolerances.

For the current renewal of approval under Regulation 1107/2009, a data gap analysis according to new guidelines, new guidance documents and new policies on exposure assessments was performed. New studies / evaluations were initiated where considered necessary.

Furthermore, a literature search is being performed, and scientific publications will be included into the supplemental dossier when considered relevant and being of sufficient high quality. Hence, adequate summaries will be provided in the appropriate dossier chapters.

3.3.1 Metabolism in primary crops

Although there are existing metabolism studies in grapes, potato and wheat (all foliar application), two new crop metabolism studies have been conducted for the new AIR 3 dossier for covering a broader use spectrum. New crop metabolism studies were performed in wheat (seed treatment application) and in paddy rice. Besides these new studies, a cabbage metabolism study will be provided. This study was performed for achieving the Japanese registration. Furthermore, a supplementary document to the grape metabolism study was prepared upon request of Japan. Purpose of the document was to clarify the way of metabolite identification which is based on extracts from grape leaves. The investigations are confirming the results from the previous studies and support the existing residue definition (parent only for MRL setting and risk assessment purposes).

BAS 500 F is intensively metabolised by mainly three key transformation steps:
- N-Desmethoxylation and O-desmethylation of the side chain
- Hydroxylation of the aromatic ring systems
- Cleavage between the ring systems

The contribution of these reactions followed by subsequent conjugation leads to a large number of metabolites. The metabolic pathways in all crops were qualitatively similar. Pyraclostrobin (BAS 500 F) and its desmethoxy metabolite 500M07 (synonym: BF 500-3) formed the major part of the residue followed by the cleavage products 500M04 (synonym: BF 500-5, plus conjugates) and 500M24. In order to address the relevance assessment for metabolites (based on the Scientific Opinion on Evaluation of the Toxicological Relevance of Pesticide Metabolites for Dietary Risk Assessment, EFSA Journal 2012), BASF proposed (presubmission meeting with BfR in November 2012) a stepwise approach for limited genotoxicity testing of metabolites by read across groupings and the TTC Cramer Class III. This proposal provides a rationale and a starting point for the tox testing of metabolites considered as representative plant metabolites.

3.3.2 Metabolism in livestock

For Annex I inclusion (Directive 91/414/EEC) metabolism studies were carried out in two livestock species (lactating goats, laying hens) and in the rat. In ruminants and poultry, pyraclostrobin (BAS 500 F) is rapidly absorbed, distributed and excreted. In goats dosed with 12 mg/kg feed, the residues in fat and muscle mainly consisted of unchanged parent and its N-desmethoxy metabolite (synonym: 500M07, BF 500-3). Metabolites are formed in liver and kidney by hydroxylation of the chlorophenyl and the tolyl ring and by cleavage of the molecule. Low extractability could be observed in liver, but the parent compound was present in all matrices. In hens dosed with 12 mg/kg feed, the residues were below 0.010 mg/kg; consequently no further investigations were carried out. In fat and eggs, pyraclostrobin and the desmethoxy metabolite 500M07 formed the major part of the residue whereas in liver hydroxylation reactions were predominant. As in plant matrices, cleavage products (as 500M04 plus conjugate 500M05 and 500M49 / 500M51) have been identified in tissues, milk and eggs.

The studies are still meeting today's requirements. Upon request of the Australian authority, an in-vitro comparison study was performed for goat and cow cell cultures. The study which is provided in context of the AIR 3 dossier confirmed the comparable pathway in both test species.

In order to address the relevance assessment for metabolites (based on the Scientific Opinion on Evaluation of the Toxicological Relevance of Pesticide Metabolites for Dietary Risk Assessment, EFSA Journal 2012), BASF proposed (presubmission meeting with BfR in November 2012) a stepwise approach for limited genotoxicity testing of metabolites by read across groupings and the TTC Cramer Class III. This proposal provides a rationale for the tox testing of metabolites considered as representative livestock metabolites.

3.3.3 Metabolism in fish

A bioaccumulation study has been performed in 1999. It was provided in context of the Annex I inclusion according to Directive 91/414/EEC. The study includes the identification of metabolites in edible and inedible portions of bluegill sunfish.

Pyraclostrobin is registered in the majority of crops being intended as fish feed item. In most of these crops residue levels above LOQ occur. In addition, the conduct of a fish metabolism is a new data requirement according to Regulation 283/2013; a working document on the study conduct was published in II/2013. The study is currently ongoing in rainbow trouts; it will be completed in II/2014. In order to allow a full comparison, in-vitro investigations on fish cell cultures will be provided as supplemental information.

3.3.4 Metabolism in rotational crops

A confined rotational crop study was performed in context of the Annex I inclusion (Directive 91/414/EEC). The residue levels and the nature of residues were investigated in three different succeeding crops (radish, lettuce, wheat) at an application rate of 900 g as/ha. In the study the ^{14}C-chlorophenyl and ^{14}C-tolyl labelled pyraclostrobin was applied to bare soil. The total residues in the edible parts of the succeeding crops were very low after all plant back intervals. There is no accumulation of pyraclostrobin or its degradation products in the parts of plants used for human food or animal feed consumption. The study is still considered scientifically valid; it is meeting the requirements included in OECD guideline 502.

In order to prove that no metabolite consisting solely of the pyrazole moiety is formed in soil (see 3.4.1) and taken up by plants, preliminary investigations with the ^{14}C-pyrazole labelled pyraclostrobin were performed. ^{14}C-pyrazole labelled pyraclostrobin was applied at the maximum seasonal rate of 500 g as/ha to bare soil; after an aging period of 30 DAT crops were planted / sown. The investigations of total radioactivity in representative plant matrices are indicating very limited uptake. The study will be completed in II/2014 and included in the AIR 3 dossier.

3.3.5 Residue trials in plants

The previous residue data package prepared for Annex I inclusion according to Directive 91/414/EEC has been reviewed to identify which new trials are necessary to have a complete data package for the intended GAPs. During the first annex I inclusion, grapes, banana (import tolerance) and small grain cereals were submitted as representative uses.
The representative uses in this application are potatoes, small grain cereals and maize. In case of potatoes, two residue studies will be provided in context of the supplemental dossier. They have been evaluated before during national approval processes, but were not yet subject of any peer review. In order to support their intended use pattern, several new residue studies for cereals and maize have been conducted using the representative formulation BAS 500 06 F.

3.3.6 Livestock feeding studies

In order to set MRLs for food of animal origin, livestock feeding studies have been performed in cows and poultry. The cow feeding study was already provided in context of the Annex I inclusion according to Directive 91/414/EEC and is still considered as valid. For the USA registration, a poultry feeding study was conducted. After discussions with the RMS Germany, the poultry study is provided as supplemental information. In the study, animals were dosed at three dose levels. Even at the highest dose level, no detectable residues were found.

3.3.7 Effects of processing

The high temperature hydrolysis study was submitted during the Annex I submission according to Directive 91/414/EEC and is therefore considered as peer reviewed. Pyraclostrobin was hydrolytically stable under all test conditions employed in this study. New wheat and oat processed fraction studies will be included in the AIR 3 dossier. A processing study performed in maize was previously submitted within draft Registration Reports to several authorities. Since it has not been peer reviewed until this point in time it will be additionally provided in the AIR 3 dossier.

3.3.8 MRLs

Pyraclostrobin was included in Annex I to Directive 91/414/EEC on 01 June 2004. A summary of current MRLs can be found at the Commission website (http://ec.europa.eu/sanco_pesticides/public/index.cfm). Under Regulation (EC) No 396/2005, EFSA provided a reasoned opinion on the review of the existing MRLs; the final version was published in 2011. The points raised by EFSA for crops which are not discussed in this dossier will be covered by a separate submission. Refernces according to article 12 like Overall, the renewal of approval is not expected to substantively impact the current MRLs.

3.3.9 Consumer Exposure

In accordance with current practice, dietary exposure assessments will be conducted using the EFSA PRIMo Model. No intake exceedences are anticipated based on the ADI / ARfD values of 0.03 mg/kg bw/d, respectively. Since Annex I inclusion in 2004, the consumer exposure has been assessed several times by EFSA and national authorities in context of the MRL re-evaluation (Art. 12) and the setting of MRLs for new uses (Art. 10).

3.4 Environmental fate and behaviour

All relevant information on the first Annex I review and the endpoints used in environmental risk assessments can be found in the monograph of pyraclostrobin and in the SANCO/1420/2001-Final document (EU Review Report). Furthermore, information on environmental endpoints is given in chapter 1 of this document.

For the current renewal of approval under Regulation 1107/2009, a data gap analysis according to new guidelines, new guidance documents and new procedures in kinetic evaluations and exposure assessments was performed, and new studies / evaluations were initiated where considered necessary.

Furthermore, a literature search is being performed, and scientific publications will be included into the dossier when considered endpoint relevant and being of sufficient high quality. Hence, adequate summaries will be provided in the appropriate dossier chapters.

3.4.1 Soil

Concerning route of degradation in soil, metabolism studies with ^{14}C-chlorophenyl and ^{14}C-tolyl labelled pyraclostrobin showed high amounts of bound residues and also some mineralization. In order to prove that no metabolite consisting solely of the pyrazole moiety is missed, an aerobic soil metabolism and a soil photolysis study with ^{14}C-pyrazole labelled pyraclostrobin were performed. The results clearly confirm the understanding of pyraclostrobin degradation in soil. No new metabolites were found.

Concerning the rate of degradation in aerobic soil, a new laboratory study was performed with parent in four soils since the old study did not provide a full material balance. The degradation rates for parent are in the same range as obtained in the old studies. In addition, the degradation rates for the minor metabolite BF 500-3 were estimated. For the major soil metabolites BF 500-6 and BF 500-7 extra metabolite studies were done since no reliable degradation rate could be calculated from the parent study. For the soil metabolites BF 500-4 and BF 500-5 which appear in soil in measurable amounts only under strong anaerobic conditions, aerobic degradation rate studies are initiated to allow for groundwater risk assessment under the new regulation 1107/2009. Due to their structure, the expected DT_{50} is very short.

A new field dissipation study (4 sites: DK, DE, IT, FR) addresses the degradation behaviour of pyraclostrobin in soil according to the new requirements of 1107/2009, i.e. dissipation processes like photolysis are excluded.

Where necessary, kinetic re-evaluations of the already peer-reviewed studies according to FOCUS are performed and will be provided in the supplemental dossier.

Due to deficiencies of the old studies (missing material balance), new (confirmatory) adsorption values will be generated for metabolites BF 500-6 and BF 500-7. Both metabolites have extremely low water solubilities and adsorb very quickly to soil. Therefore, adsorption tests can be done only with one concentration and no Freundlich isotherm can be provided. In order to allow a groundwater leaching assessment also for the anaerobic metabolites BF 500-4 and BF 500-5, adsorption studies are initiated.

3.4.2 Water

An aerobic mineralization study according to guideline OECD 309, Aerobic Mineralization in Surface Water, was performed to fulfill the new data requirement according to Regulation 1107/2009.

Since irradiation is an important degradation/dissipation route for pyraclostrobin in water and the old irradiated water/sediment study did not provide a full material balance, a new irradiated water/sediment study including full material balance was performed. The route of degradation in surface waters was confirmed.

Furthermore, kinetic re-evaluations of the already peer-reviewed studies are performed according to FOCUS and will be provided in the supplemental dossier.

3.4.3 Air

Based on its physical-chemical properties, pyraclostrobin has no potential for volatilisation (vapour pressure 2.6 x 10^{-8} Pa at 20°C). No new data on volatilization will be generated. The half-life in air will be calculated according to the newest guideline (Atkinson).

3.4.4 Predicted environmental concentrations (PEC)

Predicted environmental concentrations will be calculated and reported in the supplementary dossier for the compartments soil, groundwater, surface water and sediment. For the calculations current modelling tools and guidance for the parameter selection as recommended by FOCUS will be applied.

The parameter selection will be based on the available studies including open literature if the assessment concludes the appropriateness of the study and the reported values.

3.5 Ecotoxicology

Relevant information on the first Annex I review and the endpoints used in environmental risk assessments can be found in the monograph of pyraclostrobin and in the SANCO/1420/2001-Final document (EU Review Report). Furthermore, information on ecotoxicological endpoints is given in chapter 1 of this document.

A number of additional studies has been conducted in order to cover new requirements as well as to address the risk of new representative formulations, which constitute a significant part of ecotoxicologial studies.

Furthermore, a literature search is being performed, and scientific publications will be included into the dossier when considered endpoint relevant and being of sufficient high quality. Hence, adequate summaries will be provided in the appropriate dossier chapters.

3.5.1 Terrestrial vertebrates

Birds

For pyraclostrobin one acute toxicity study in bobwhite quail is available. This study was already evaluated during the previous Annex I inclusion process and is still of relevance for deriving the acute toxicity endpoint. One acute toxicity study with the canary is being conducted on request of US-EPA and will be submitted in the AIR 3 dossier.

The two short-term toxicity studies in bobwhite quail and mallard duck evaluated during the previous Annex I inclusion process are no longer part of the required data as outlined in the new EFSA GD and the new EU Regulation 283/2013.

Two reproductive toxicity studies are available for pyraclostrobin, one in bobwhite quail and one in mallard duck. Both studies were already evaluated during the previous Annex I inclusion process and are still of relevance for deriving the reproductive toxicity endpoint.

An updated risk assessment will be conducted in line with EFSA's Bird and Mammal Guidance Document (2009), considering all available toxicity data.

To assess the risk of the new representative formulations, acute toxicity studies in bobwhite quail were conducted with BAS 500 06 F and BAS 516 07 F.

Mammals

For pyraclostrobin one acute toxicity study in rat is available. This study was already evaluated during the previous Annex I inclusion process and is still of relevance for deriving the acute toxicity endpoint.

The reproductive toxicity endpoint previously submitted for Annex I inclusion requires revision due to new guidance by EFSA for birds and mammals risk assessment. In accordance to the latest EFSA GD, the relevant studies for deriving the reproductive toxicity endpoint for pyraclostrobin is the two-generation reproduction toxicity study in rat, as well as the developmental toxicity studies in rat and rabbit. All three studies were already evaluated during the previous Annex I inclusion process.

Updated risk assessments will be submitted that follow the latest guidance of EFSA (2009). Envisaged refinement parameters for higher tier risk assessments include new studies on residue decline in young plants under Northern and Southern European conditions. In addition, new studies are available on ecological parameters like choice of focal species, PT and PD and on the ecologically relevant chronic toxicity endpoint for the wild mammal reproductive risk assessment. Further, a field-effect study was conducted in Central Europe and will be used as weight of evidence for the acute and long-term risk assessment to mammals.

To assess the risk of the new representative formulations at higher tier, acute dietary studies were conducted on rat and wood mouse to provide more realistic information about the potential risk to small mammals. Further, a synopsis document will be compiled to summarize the available data on acute oral and dietary testing with formulations. A body-burden modeling will be submitted as supporting line of evidence.

Amphibians

New literature data indicate potential risk of pyraclostrobin to amphibians. To address this topic a study was performed under worst-case laboratory conditions. In addition a semi-field study was conducted to evaluate the risk to amphibians under more relevant exposure conditions. These results will be presented and discussed in detail together with further literature information within the supplemental dossier.

3.5.2 Aquatic organisms

The standard acute and chronic studies on fish, daphnids, algae and sediment dwellers are available and have already been evaluated during the previous Annex I inclusion process. These studies are still of relevance for deriving the acute and chronic toxicity endpoints to be used in the aquatic risk assessment. Further data were generated to cover standard requirements in other countries (particularly in the US) and were not evaluated during the Annex I inclusion process. These data include studies on marine organisms conducted for marine/estuarine risk assessment. The ecotoxicological endpoints generated on these species are partly lower (e.g. for mysids) or are higher or in line (e.g. fish data) with previous endpoints. However, the extensive information available for fresh water organisms including a mesocosm study with a wide range of taxa and relevant, more realistic exposure conditions provide the pertinent information for risk assessment of edge of field freshwater ecosystems, and the overall aquatic risk assessment will not be changed significantly due to the additional data.

To more specifically address the risk from sediment exposure, a spiked sediment study on *C. riparius* has been conducted with the active substance. The endpoints indicate low risk from sediment exposure. The endpoints obtained in the alga study on *Pseudokirchneriella subcapitata* have been recalculated resulting in a new endpoint for one of the assessment parameters. However, the changes are minor and of no impact on the overall risk assessment.

An outdoor mesocosm study is available, which has already been previously evaluated by the RMS, but which was not included in the List of Endpoints in the EU Review Report. This study has been re-evaluated according to current mesocosm evaluation requirements and provides essential information for the risk assessment of aquatic organisms, including aquatic macro-invertebrates, molluscs, phyto- and zooplankton. Fish, however, are not sufficiently addressed in the mesocosm study. Instead a number of additional species as well as different exposure scenarios were tested allowing to considerably reduce any uncertainties regarding the risk to fish. This information has been largely available already during the Annex I inclusion process, however, additional information from new studies is available which further supports the previous assessment.

Several additional metabolites were considered for ecotoxicological testing mainly based on new e-fate studies. All results obtained so far indicate low ecotoxicological potential of these metabolites. Toxicity values are either orders of magnitude above respective values for the active substance or above the limit of solubility.

The required studies (plus studies for other countries) were conducted for the new representative formulations. The results are largely in line with those previously evaluated and confirm the dominant impact of the active substance pyraclostrobin on the aquatic toxicity of the formulations.

3.5.3 Terrestrial organisms

Honey bees

The acute oral and contact toxicity study conducted with the active substance (which has been evaluated during the Annex I inclusion process) was repeated since the old study showed some weakness in the response of the toxic reference. The new results confirm the low acute toxicity to honey bees, which is further confirmed by the results of the studies with both representative formulations.

In order to address new data requirements for chronic toxicity and effects on larvae/bee brood two new studies will be submitted: A semi-field study, showing that no unacceptable lethal or sublethal effects on honeybee colonies and bee brood development occur at rates of 1.25 L BAS 500 06 F/ha, and a laboratory chronic toxicity study, which is still ongoing.
Further, two studies to determine residues in honey bee food items will be submitted for refinement of the default exposure values stated in the new EFSA Guidance Document on Honey Bee Risk Assessment.

Non-target arthropods

Complete data packages of NTA studies will be submitted for both new representative formulations. The data for the new representative formulation BAS 500 06 F are in line with endpoints generated for the previous representative formulation (BAS 500 00 F). Data for the second representative formulation BAS 516 07 F indicate lower toxicity as compared to the previous formulation.

Soil organisms

New studies will be submitted for earthworm reproduction with the active substance (currently ongoing), the representative formulations (BAS 500 06 F and BAS 516 07 F) and two metabolites (BF 500-6 and BF 500-7). The metabolites showed no and the formulations medium toxicity.
Furthermore, field studies on natural occurring earthworm populations were conducted with both formulations indicating low risk to earthworms under realistic field conditions (including elevated application rates).

The toxicity of both new representative formulations and of the two soil metabolites was tested on Collembola and that of BAS 500 06 F also on soil mites. For consistency of the data package a soil mite study with BAS 516 07 F is in preparation. As for earthworms, the metabolites showed no chronic toxicity to Collembola. Both, Collembola and soil mites, showed less sensitivity to the formulations than earthworms.

New studies on nitrogen transformation were conducted for the two new representative formulations. For BAS 516 07 F in addition a soil respiration study is available. No unacceptable effects were observed at concentrations above expected environmental concentrations.

Non-target plants

The data from the available studies with the two new representative formulations indicate low risk to plants. Further studies will be conducted with BAS 516 07 F.

3.6 Definition of the residues

3.6.1 Plant & animal

In the previous Annex I inclusion process the following residue definitions were defined.

End-Point	**Active Substance: Pyraclostrobin**
	EU agreed endpoints (SANCO/1420/2001; Monograph 12945/ECCO/BBA/01, Vol. 1, list of endpoints) and endpoints intended for risk assessment
Residue definition in plant matrices for risk assessment	Pyraclostrobin (parent)
Residue definition in plant matrices for monitoring	Pyraclostrobin (parent)
Residue definition in animal matrices for risk assessment	For all matrices (except liver and milk fat): Pyraclostrobin (parent) For liver (except poultry liver) and milk fat: Pyraclostrobin and its metabolites analysed as the hydroxypyrazoles BF 500-5 and BF 500-8, sum expressed as pyraclostrobin
Residue definition in animal matrices for monitoring	Pyraclostrobin (parent)

Plant
In order to support the current residue definition for risk assessment in plant matrices, dietary exposure assessments will be provided for the metabolites 500M04, 500M24 and 500M76. The metabolites have been found in relevant plant matrices in levels below 10% TRR, but did not show structural similarity to the parent molecule. They have not been detected in significant amounts in the rat metabolism study.
The current residue definition for MRL setting and monitoring purposes, which is also in accordance with the one established by CXL, is considered as most suitable for supporting international trade.

Animal
In order to support the common moiety residue definition for risk assessment in animal matrices, dietary exposure assessments will be provided for the metabolites 500M04, 500M49 and 500M51. The metabolites have been found in relevant animal matrices, but did not show structural similarity to the parent molecule. They have not been detected in significant amounts in the rat metabolism study.
The current residue definition for MRL setting and monitoring purposes, which is also in accordance with the one established by CXL, is considered as most suitable for supporting international trade.

3.6.2 Soil, water and air

Following the previous Annex I evaluation, the active substance pyraclostrobin is given in the residue definition for soil, water and air. The future residue definition for the environmental compartments depends on the final results of the risk assessments for the metabolites (for details see below). Currently, the available new data do not indicate a change of the old residue definition (parent only) for monitoring purposes.

Soil
Risk assessments for soil organisms will be provided for parent and soil metabolites BF 500-6 and BF 500-7.
Metabolites BF 500-3, BF 500-4 and BF 500-5 do occur in amounts > 5% AR (applied radioactivity) only under strong anaerobic conditions. Due to their transient nature and immediate degradation under aerobic conditions, a terrestrial risk assessment is not considered necessary. Moreover, ecotox tests under anaerobic conditions, which would ensure sufficient exposure, do not provide living conditions for test organisms.
However, due to its occurrence in anaerobic sediment, a risk assessment for BF 500-3 will be provided for sediment organisms where exposure is considered possible over a longer time-period.

Groundwater
A groundwater risk assessment will be provided for pyraclostrobin and its metabolites BF 500-3, BF 500-4, BF 500-5, BF 500-6 and BF 500-7. Overall, the leaching risk is considered very low for all compounds either due to their high adsorption and/or their fast degradation in soil.

Surface water
Aquatic risk assessments will be provided for parent and the aqueous photoproducts BF 500-11, BF 500-13 and BF 500-14 occuring in the irradiated water/sediment studies. Risk assessments for sediment will be done for parent and metabolite BF 500-3.

Air
None of the metabolites showed any volatility so that the residue definition for air monitoring is parent only.

3.7 Overview of compounds currently identified for the environmental compartments

Compound designation	Reference code (Reg.No.)	Molecular weight	Structure
Pyraclostrobin (BAS 500 F)	304428	387	BF 500-3 500M07 "des-methoxy"	340266	357	BF 500-4 500M73 "aniline"	358672	300	BF 500-5 500M04 "OH-pyrazole"	298327	194	BF 500-6 500M01 "azoxy"	364380	611	 cis-trans isomerization possible
BF 500-7 500M02 "azo"	369315	596	 cis-trans isomerization possible
BF 500-11 500M60	411847	277	BF 500-13 500M62	412785	247	
Compound designation	Reference code (Reg.No.)	Molecular weight	Structure
BF 500-14 500M76	413038	387	
3.8 Classification and Labelling

The classification and labelling according to Table 3.1 of Regulation (EC) No. 1272/2008 as amended by Commission Regulation (EC) No. 790/2009 is given as follows:

Classification:

Hazard class and Category:	Acute Tox. 3
Skin Irrit. 2	
Aquatic Acute 1	
Aquatic Chronic 1	
H-statements:	H331, H315, H400, H410

Labelling:

Pictogram:	GHS06, GHS09
Signal word:	Danger
H-statements:	H331, H315, H410

4 LIST OF STUDIES TO BE GENERATED, STILL ONGOING BUT NOT EVALUATED AND/OR NOT PEER REVIEWED

Reference is made to the notification of an active substance according to article 2 in the framework of the application for renewal of the active substance pyraclostrobin.

5 IDENTIFIED AREAS FOR WHICH DETAILED RE-EVALUATION IS NEEDED IN DOSSIER FROM APPLICANT AND IN EVALUATION BY RMS/Co-RMS.

Based on new information and new guidance available the following areas need to be re-evaluated in detail:

Identity, physical/chemical/technical properties and methods of analysis

Identity
- New five batch analysis representing current commercial production

Physical and chemical properties
- New information on the physical and chemical properties of the technical active substance according to modified registration requirements
- A number of new studies to characterize the physical and chemical properties of the two new representative formulations

Analytical methods
- Updated analytical methods for the active substance
- Validated analytical methods for the determination of the active substance and of dimethyl sulfate in the new representative formulations
- New residue analytical methods for risk assessment and MRL setting purposes according to current guidance requirements
- New analytical methods for soil/sediment, water and air according to current guidance requirements

Mammalian toxicology

- New subchronic inhalation studies relevant for setting an AEOLinhalation
- Immunotoxicity studies performed upon request of US-EPA according to OPPTS guidelines
- Genotoxicity studies for a number of metabolites; in addition acute and subchronic toxicity studies for one of the metabolites
- A number of acute toxicity studies and dermal penetration studies for the two new representative formulations

Residues

- New metabolism studies in plant and lifestock because of extension of uses and 1107/2009 data requirements
- Definition of the relevant residue for dietary risk assessment in light of the revised policy (as published in the EFSA Scientific Opinion of July 2012)
- New residue data (plant, processing)

Environmental fate and behaviour

- New kinetic evaluations of previously submitted data considering new scientific and technical developments
- New metabolism and degradation studies (laboratory and field) because of new developments and 1107/2009 requirements
- New adsorption/desorption studies for metabolites

Ecotoxicology

Birds and mammals
- New risk assessments according to the latest Guidance Document of EFSA (2009)

Amphibians
- Literature information and new studies addressing the risk to amphibians according to the new requirement in Regulation 1107/2009

Aquatic organisms
- New studies with active substance, new representative formulations and additional metabolites
- Consideration of proposed new Guidance Document and new PEC-calculations

Honey bees
- Acute and chronic risk to honey bees and bee brood according to new data requirements in Regulation 1107/2009

Non-target arthropods
- New studies with new representative formulations

Soil organisms
- New chronic studies with active substance, new representative formulations and metabolites

Non-target plants
- New studies with new representative formulations

6 Appendix

Overview of the GAPs of the representative uses intended to be used as the basis for the risk assessments provided in the supplemental dossier.

GAP for the representative formulation BAS 500 06 F

Version history[1]

Date	Data points containing amendments or additions and brief description	Document identifier and version number
18-July-2014		BASF DocID 2014/1162238 (version 1)
09-June-2015	The document was amended in order to correct an error regarding the data protection claim of one study (KCA 5.2.3/1). New or changed text is marked in yellow.	BASF DocID 2015/1109582 (version 2)
05-August-2015	The document was amended in order to correct an error (KCA 5.1.1/1 was not characterized as vertebrate study). New or changed text is marked in blue.	BASF DocID 2015/1183829 (version 3)
27-Feb-2017	The following new references have been added: KCA 5.1.1/2-4 KCA 5.1.2/2-3 KCA 5.2.4/1 and KCA 5.2.5/1 KCA 5.4.2/1-2 KCA 5.4.3/2-4 KCA 5.6.1/1 KCA 5.8.1/27 KCA 5.8.1/39-49 The new references and the necessary re-numbering of already contained studies are marked in green.	BASF DocID 2017/1032490 (version 4)
30-May-2017	The document was amended in order to correct errors (KCA 5.1.1/4, KCA 5.2.4/1 and KCA 5.2.5/1 were not characterised as vertebrate studies). Furthermore, a new reference has been added (KCA 5.8.1/53). New or changed text is marked in grey.	BASF DocID 2017/1175847 (version 5)

[1] It is suggested that applicants adopt a similar approach to showing revisions and version history as outlined in SANCO/10180/2013 Chapter 4 How to revise an Assessment Report

CA 1.2 Producer

Manufacturer of pyraclostrobin (legal entity):

BASF SE
67056 Ludwigshafen
Germany
Crop Protection Division:
P.O. Box 120
67114 Limburgerhof
Germany

Contact person: Please refer to CA 1.1 Applicant.

CA 1.3 Common Name Proposed or ISO-accepted and synonyms

Pyraclostrobin

CA 1.4 Chemical Name (IUPAC and CA nomenclature)

IUPAC: Methyl N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxymethyl}phenyl)-(N-methoxy)carbamate

CA: Carbamic acid, [2-[[[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxy]methyl]phenyl]methoxy-, methyl ester

CA 1.5 Producer's Development Code Numbers

BASF Number: BAS 500 F

Table of Contents

CA 3 FURTHER INFORMATION ON THE ACTIVE SUBSTANCE

Pyraclostrobin was included in Annex I of Directive 91/414/EEC on 1 June 2004 (entry into force) under Inclusion Directive 2004/30/EC for **the use as fungicide**. This use was amended on 22 April 2009 (entry into force) by Inclusion Directive 2009/25/EC to **the use as fungicide or plant growth regulator**. Both Annex I inclusion decisions were based on the same endpoints and provisions.
It is the intention of the applicant to achieve the renewal of approval for the active substance pyraclostrobin for the use as fungicide as well as the use as plant growth regulator. Therefore both uses are addressed in the chapters below if appropriate.

CA 3.1 Use of the Active Substance

Pyraclostrobin is a strobilurine **fungicide** which is used worldwide in many crops for the control of a broad range of important pathogens from the classes of ascomycetes, basidiomycetes, deuteromycetes and oomycetes. Pyraclostrobin is active against different fungal stages both on the plant surface and in the plant tissue. After application to the plant, the active ingredient is taken up via the leaf and then translocated at low rates via the transpiration flow. Due its relatively low mobility, it shows local systemic and translaminar activity. Because of its very high intrinsic activity, pyraclostrobin has been observed to have systemic effects in a number of authorized uses. By that, it can control fungal stages which have already become established in deeper tissue layers. Pyraclostrobin is thus suitable for preventative and curative treatments. Since the vapour pressure of pyraclostrobin is very low, a marked gas phase activity was not observed.
In addition to the **fungicidal effects, plant physiology is also affected** by the application of pyraclostrobin. Among these effects higher yield and better product quality in absence of diseases as well as improvement of the assimilation rate and delayed senescence have been reported. Some studies showed better stress tolerance to abiotic stresses (e.g. drought or frost). Furthermore, a reduction of physiological leaf spots in cereals has been observed after treatment with pyraclostrobin-containing products. Based on these effects, pyraclostrobin is approved as **plant growth regulator** in the EU in addition to its approval as fungicide.

CA 3.2 Function

Pyraclostrobin is used as a fungicide to control harmful diseases in a broad range of crops. In addition to the fungicidal effects, plant physiology is also affected by the application of pyraclostrobin (use as plant growth regulator). For details please see M-CA 3.1 and M-CA 3.6.

CA 3.3 Effects on Harmful Organisms

Pyraclostrobin is active against different fungal stages on and in the plant. When applied protectively, pyraclostrobin prevents not only the germination of fungal spores landing on the plant surface but also re-infection, since during these extremely energy-consuming phases fungi react very sensitively to disturbances of their mitochondrial respiratory chain. Due to its ability to penetrate into the leaf and its further translocation as well as its high intrinsic activity, it can also control fungal stages which have already become established in deeper tissue layers. Pyraclostrobin is thus suitable for preventative and curative treatments.

CA 3.4 Field of Use Envisaged

Agriculture

CA 3.5 Harmful Organisms Controlled and Crops or Products Protected or Treated

Pyraclostrobin is used to control a broad range of important fungal diseases such as

- *Alternaria* spp.
- *Bipolaris* spp.
- *Blumeriella* spp.
- *Botrytis* spp.
- *Cercospora* spp.
- *Colletotrychum* spp.
- *Drechslera* spp.
- *Exserohilum* spp.
- *Fusarium* spp.
- *Gnomonia* spp.
- *Guignardia* spp.
- *Hemileia* spp.
- *Kabatiella* spp.
- *Leptosphaeria* spp.
- *Monilinia* spp.
- *Neofabrea* spp.
- *Phomopsis* spp.
- *Phyllosticta* spp.
- *Plasmopara* spp.
- *Podosphaera* spp.
- *Puccinia* spp.
- *Pyrenophora* spp.
- *Ramularia* spp.
- *Rhynchosporium* spp.
- *Sclerotinia* spp.
- *Septoria* spp.
- *Sphaerotheca* spp.
- *Stemphylium* spp.
- *Uncinula* spp.
- *Uromyces* spp.
- *Venturia* spp.
- *Wilsonomyces* spp.

Pyraclostrobin is used in a wide range of crops including (representative uses in bold):

Cereals

Corn

Beets

Legume crops
- Dry pulses (dry harvest)
  - Beans: field beans
  - Peas: chickpeas, field peas, chickling vetch
- Legume vegetables (fresh harvest)
  - Beans (with and without pods)
  - Peas (with and without pods)

Vegetables
- Brassica vegetables
  - Head cabbage
  - Leafy cabbage
  - Flowering cabbage
  - Brussel sprouts
- Bulb vegetables
  - Onions (incl. spring onions)
  - Shallot
  - Garlic
- Root and tuber vegetables
  - Carrots
  - **Potato**
  - Radish
  - Parsnip
- Stem vegetables
  - Leek
  - Celery
  - Asparagus
  - Fennel
- Fruiting vegetables
  - Cucurbits with edible peel (cucumber, gherkins, courgette)
  - Cucurbits with inedible peel (melon, pumpkin, zucchini)
  - Tomato
  - Aubergine
  - Pepper
- Leafy vegetables and herbs
  - Lettuce and similar
  - Fresh herbs
  - Cichory, witloof

Perennial crops
- Berries and small fruits
  - Strawberries
  - Currants
  - Raspberries
- Grapes
- Hop
- Nuts
- Pomefruit
- Stonefruit

Others
- Ornamentals
- turf

CA 3.6 Mode of Action

Use as fungicide:
Pyraclostrobin belongs to the QoI group of fungicides. The mode of action is the inhibition of mitochondrial respiration resulting from a blockage of the electron transport from ubihydroquinone to cytochrome c by means of a binding to the ubihydroquinone oxidation centre (Qo) of the cytochrome bc1 complex (Complex III). This disrupts the mitochondrial electron transport chain, thus blocking phosphorylation further down in the respiratory chain. In consequence, this leads to a reduction of energy-rich ATP which is required to support a range of essential processes in the fungal cell such as maintenance of membrane potentials and concentration gradients up to DNA, RNA and protein biosynthesis. In the end, the various fungal development processes of spore germination, formation of infection structures, mycelium growth and sporulation are permanently disrupted.

Use as plant growth regulator:
In addition to the effects on yield through inhibition of fungal pathogens, pyraclostrobin also delivers a positive effect on yield through influence on the plant metabolism and physiology.
A decrease in ethylene levels has been demonstrated in several lab studies after treatment with pyraclostrobin. This can explain the observed delay in senescence. The reduction in ethylene levels can result in a variety of cellular changes being involved in yield gain (e.g. by an increased and longer photosynthetic performance during the vegetation period of a treated crop):
- enhancement of cytokinin levels resulting in increased chlorophyll concentrations in the leaves
- higher catalase and superoxide dismutase (SOD) activities reducing reactive O_2^--levels producing e.g. H_2O_2, resulting in reduced chlorophyll degradation

Furthermore, studies demonstrated that pyraclostrobin increases nitrate reductase, improving nitrogen assimilation and nitrogen use efficiency.

CA 3.7 Information on Occurrence or Possible Occurrence of the Development of Resistance and Appropriate Management Strategies

QoI resistant strains of some plant pathogenic fungal species were identified in some areas after intensive use and high selection pressure. Information which species are affected and to what extent can be followed in the annual minutes of the QoI Working Group of the Fungicide Resistance Action Committee (FRAC) on the FRAC web page (www.frac.info). Most important resistance mechanisms to QoIs are target site mutations, in particular the G143A in the cytochrome *b* (cyt *b*). G143A leads to strong resistance and reduced field efficacy. Two other mutations, F129L and G137R have been described, which lead to lower resistance factors. All QoI fungicides are in the same cross-resistance group and should be managed accordingly.

However, until now several fungal species did not develop field resistance to QoI fungicides. These include different rust species, *Pyrenophora teres* and others. *Puccinia triticina* experienced a comparable selection pressure as *Blumeria graminis* (a species which developed QoI resistance 1-2 years after market launch), but so far no sensitivity changes have been detected. Also, no adaptation has been found for the soybean rust pathogen *Phakopsora pachyrhizi*, despite intensive use of QoIs in large areas. The reason for this was elucidated by Grasso *et al*. (2006), who showed that the structure of the target gene is responsible: If an intron sequence follows directly after codon 143, the G143A does not occur, because the glycine codon 143 is part of the signal sequence which is essential for the intron recognition and plays an essential role in splicing during mRNA maturation. If this codon is altered, no functional complex III can be formed. Therefore it can be concluded, that for a species with an intron sequence directly after codon 143, the G143A is unlikely to occur. However, mutations F129L or G137R are possible. F129L occurs frequently in some European populations of *P. teres*, but due to low resistance factors caused by F129L, field efficacy of pyraclostrobin remains good (Semar *et al.* 2007). In other species like *P. triticina* or *P. pachyrhizi*, no mutations in the cyt *b* gene have been reported so far. The gene structure around codon 143 seems to be highly conserved within a species, even for isolates with a diverse geographic, host plant or historic (year of isolation) background. *C*yt *b* of thousands of *P. teres* isolates was analyzed in our laboratory in the last decade and all of them were identical. No G143A mutated isolates showed up in *P. triticina* or *P. pachyrhizi* after many years of QoI selection pressure which confirms the high intraspecific conservation of this gene sequence. Therefore, it is likely that the whole population of a species contains the intron at the same position when it has been detected for some isolates. However, *Botrytis cinerea* seems to be an exception. Two types of cyt *b* gene, (with and without intron, Jiang *et al.* 2009) exist in *B. cinerea* and the genotype without intron developed G143A in various crops and regions. So far published “intron pathogens” are listed in Table 3.7-1.

Table 3.7-1: Plant pathogenic fungi with intron after codon 143 in the cytochrome *b* gene

Pathogen	Disease	Host	Reference
Alternaria dauci	Leaf blight	Carrots	Stammler 2012
Alternaria grandis	Early blight	Tomatoes, potatoes	Stammler 2012
Alternaria solani	Early blight	Tomatoes, potatoes	Grasso *et al*. 2006
Alternaria tomatophila	Early blight	Tomatoes, potatoes	Stammler 2012
Bipolaris maydis	Southern leaf blight	Corn	Stammler 2012
Cercospora zea-maydis	Gray leaf spot	Corn	Stammler 2012
Cochliobolus carbonum	Northern leaf spot	Corn	Stammler 2012
Guignardia bidwellii	Black rot	Grapes	Miessner *et al.* 2011
Hemileia vastatrix	Rust	Coffee	Grasso *et al*. 2006
Monilinia fructicola	Blossom blight, brown rot	Stonefruits	Miessner & Stammler 2010
Monilinia laxa	Blossom blight, brown rot	Stonefruits	Miessner & Stammler 2010
Phakopsora pachyrhizi	Rust	Soy beans	Grasso *et al.* 2006
Phyllosticta citricarpa	Citrus black spot	Citrus species	Stammler *et al.* 2012
Puccinia spp.	Rust	Cereals, corn, others	Grasso *et al.* 2006
Pyrenophora teres	Net blotch	Barley	Grasso *et al.* 2006
Setosphaeria turcica	Northern leaf blight	Corn	Stammler 2012
Uromyces appendiculatus	Rust	Beans	Grasso *et al.* 2006

Resistance management strategies including modifiers such as limiting the number of QoI-applications, alternation and combination with other modes of action have been worked out by the FRAC QoI Working Group per crop and pathogen. These recommendations are annually reviewed and actual yearly sensitivity monitoring data are considered for adaptating the resistance management strategies in order to maintain the activity against various plant pathogens in different crops and regions. The current recommendations are available on the FRAC webpage (www.frac.info).

CA 3.8 Methods and Precautions Concerning Handling, Storage, Transport or Fire

Report:	CA 3.8/1 Anonymous, 2016 a Safety data sheet - Pyraclostrobin techn. 2016/1223395
Guidelines:	EEC 1907/2006
GLP:	no

Personal protection: Control parameters

Components with workplace control parameters: No occupational exposure limits known.

Exposure controls

Personal protective equipment

Respiratory protection:
Suitable respiratory protection for lower concentrations or short-term effect: Particle filter with high efficiency for solid and liquid particles (e.g. EN 143 or 149, Type P3 or FFP3).

Hand protection:
Suitable chemical resistant safety gloves (EN 374) also with prolonged, direct contact (Recommended: Protective index 6, corresponding > 480 minutes of permeation time according to EN 374): E.g. nitrile rubber (0.4 mm), chloroprene rubber (0.5 mm), butyl rubber (0.7 mm) and other

Eye protection:
Safety glasses with side-shields (frame goggles) (e.g. EN 166)

Body protection:
Body protection must be chosen depending on activity and possible exposure, e.g. apron, protecting boots, chemical-protection suit (according to EN 14605 in case of splashes or EN ISO 13982 in case of dust).

General safety and hygiene measures
Handle in accordance with good industrial hygiene and safety practice. Wearing of closed work clothing is recommended. Store work clothing separately. Keep away from food, drink and animal feeding stuffs.

Precautions for safe handling

No special measures necessary if stored and handled correctly. Ensure thorough ventilation of stores and work areas. When using do not eat, drink or smoke. Hands and/or face should be washed before breaks and at the end of the shift. Remove contaminated clothing and protective equipment before entering eating areas.

Protection against fire and explosion:
Prevent electrostatic charge - sources of ignition should be kept well clear - fire extinguishers should be kept handy. Avoid influence of heat.
In addition, for crystalline pyraclostrobin:
Avoid dust formation. Dust can form an explosive mixture with air.

Conditions for safe storage, including any incompatibilities

Segregate from foods and animal feeds.
Further information on storage conditions: Keep away from heat. Protect against moisture. Protect from direct sunlight.

Storage stability:
Storage duration: 24 months

Protect from temperatures above: 40 °C
Changes in the properties of the product may occur if substance/product is stored above indicated temperature for extended periods of time.

Fire-fighting measures

Extinguishing media

Suitable extinguishing media: dry powder, foam, water spray
Unsuitable extinguishing media for safety reasons: carbon dioxide, water jet

Special hazards arising from the substance or mixture

Carbon monoxide, hydrogen chloride, carbon dioxide, nitrogen oxides, organochloric compounds might be released in case of fire.

Advice for fire-fighters

Special protective equipment:
Wear self-contained breathing apparatus and chemical-protective clothing.

Further information:
Keep containers cool by spraying with water if exposed to fire. Dispose of fire debris and contaminated extinguishing water in accordance with official regulations. Collect contaminated extinguishing water separately, do not allow to reach sewage or effluent systems. In case of fire and/or explosion do not breathe fumes.

CA 3.9 Procedures for Destruction or Decontamination

Report:	CA 3.9/1 Anonymous, 2016 a Safety data sheet - Pyraclostrobin techn. 2016/1223395
Guidelines:	EEC 1907/2006
GLP:	no

Waste treatment methods

Must be disposed of or incinerated in accordance with local regulations.

Contaminated packaging:
Contaminated packaging should be emptied as far as possible and disposed of in the same manner as the substance/product.

Methods and material for containment and cleaning up

For small amounts: Pick up with suitable appliance and dispose of.

For large amounts: Sweep/shovel up.
Dispose of absorbed material in accordance with regulations. Collect waste in suitable containers, which can be labeled and sealed. Clean contaminated floors and objects thoroughly with water and detergents, observing environmental regulations. Cleaning operations should be carried out only while wearing breathing apparatus.

CA 3.10 Emergency Measures in Case of an Accident

Report:	CA 3.10/1 Anonymous, 2016 a Safety data sheet - Pyraclostrobin techn. 2016/1223395
Guidelines:	EEC 1907/2006
GLP:	no

First-aid measures

Description of first aid measures

First aid personnel should pay attention to their own safety. If the patient is likely to become unconscious, place and transport in stable sideways position (recovery position). Immediately remove contaminated clothing.

If inhaled:
Keep patient calm, remove to fresh air, seek medical attention.

On skin contact:
Immediately wash thoroughly with soap and water, seek medical attention.

On contact with eyes:
Wash affected eyes for at least 15 minutes under running water with eyelids held open, consult an eye specialist.

On ingestion:
Immediately rinse mouth and then drink 200-300 ml of water, seek medical attention.

Most important symptoms and effects, both acute and delayed

The most important known symptoms are skin irritation caused by skin contact or irritation of the respiratory tract.

Indication of any immediate medical attention and special treatment needed

Treatment: Treat according to symptoms (decontamination, vital functions), no specific antidote known.

Personal precautions, protective equipment and emergency procedures

Use personal protective clothing. Avoid contact with the skin, eyes and clothing. Avoid dust formation.

Environmental precautions

Do not discharge into drains/surface waters/groundwater. Do not discharge into the subsoil/soil.

Table of Contents

The table below provides an overview on the metabolites being of relevance for the analytical method section including the different code numbers that are available for each metabolite. Due to historic reasons (e.g. use of different metabolite codes in different study reports), it is unfortunately not possible to use always only one and the same metabolite code for a certain metabolite. In the following chapters and study summaries synonym metabolite codes are given in brackets where deemed to be helpful.

Table 4-1: Pyraclostrobin: Substances and metabolites, structures, codes, synonyms

Code Numbers			Description	Compound found in	Structure

CA 4 ANALYTICAL METHODS

CA 4.1 Methods used for the generation of pre-approval data

CA 4.1.1 Methods for the analysis of the active substance as manufactured

(a) Determination of the pure active substance in the active substance as manufactured and specified in the dossier submitted in support of approval under Regulation (EC) No 1107/2009

Pyraclostrobin is determined according to method APL0250/01, which was submitted and evaluated within the previous Annex I inclusion process and which was included in the DAR. Please consider that APL0250/01 is a newly allocated method number replacing the previous method number CP266. The analytical method is described in BASF DocID 1996/11507 and the validation in BASF DocID 1997/10691.

After Annex I inclusion the following CIPAC method has been developed and will be submitted within this chapter. A summary can be found below.

Report:	CA 4.1.1/1 Anonymous, 2007a Determination of Pyraclostrobin in Pyraclostrobin technical, Pyraclostrobin technical concentrate, Pyraclostrobin emulsifiable concentrates and Pyraclostrobin water dispersible granules (CIPAC MT 657) 2007/1017547
Guidelines:	none
GLP:	no

Principle of the method
The content of pyraclostrobin is determined by reverse phase high performance liquid chromatography with UV detection and external calibration. The separation of the samples is achieved by using gradient elution, and quantification of the active ingredient by UV-detection at 275 nm and comparison with reference material.

Chromatographic conditions (typical)

Column:	stainless steel, 250 x 4.6 (i.d.) mm, packed with Zorbax Eclipse XDB-C 18 or equivalent material with the same selectivity
Mobile phase:	water - acetonitrile - acetic acid, 750 + 250 + 1 (v/v)
Column temperature:	ambient

Flow rate program:

time (min)	Flow rate (ml/min)
0	1.0
7.3	1.0
7.5	2.0
13.8	2.0
14.0	1.0
16.0	1.0

Detector wavelength:	275 nm
Injection volume:	5 µl
Run time:	approximately 16 min
Retention time:	approximately 6.3 min

Validation

The method was peer-reviewed in a CIPAC ring test with the following results:

Repeatability r	= 17 g/kg at 996 g/kg active substance content
Reproducibility R	= 20 to 29 g/kg at 996 g/kg active substance content

(b) Determination of significant and relevant impurities and additives (such as stabilisers) in the active substance as manufactured

Significant impurities and additives:

Confidential information - data provided in Document J.

Relevant impurities:

Dimethyl sulfate is determined according to method M97/0028/02, which was submitted and evaluated within the previous Annex I inclusion process and which was included in the confidential part of the DAR. The analytical method is described in BASF DocID 1999/11896 and the validation in BASF DocID 1999/11956.

CA 4.1.2 Methods for risk assessment

Note: The order of the study summaries is differing compared to the information given in the application submitted for renewal of approval. In case references are summarized that were not contained in the application or in case references listed in the application are not contained in this chapter, comments are made where appropriate.

(a) Methods in soil, water, sediment, air and any additional matrices used in support of environmental fate studies

Since the analytical methods for determination of residues of pyraclostrobin and its metabolites in soil, water and air presented in the previous dossier are rather old, new analytical methods were developed for environmental matrices according to newest guidelines and considering the current state of art techniques used in analytical laboratories.

In addition to the studies listed in the application for renewal of approval, two further methods are submitted for completeness: A parent only method for soil (CA 4.1.2/2) and a multi-pesticide method for water (CA 4.1.2/3). These studies were used in the new field soil dissipation study (CA 7.1.2.2.1/2) for application verification analytics of petri dish soil samples directly after application and for spray broth analysis.

Soil

Pyraclostrobin (BAS 500 F) and its metabolites

Report:	CA 4.1.2/1 Tilting N., Sopena-Vazquesz F., 2014a Validation of analytical method L0166/01: Determination of BAS 500 F (Pyraclostrobin) and its metabolites Reg.No. 364380 (500M01), Reg.No. 369315 (500M02) and Reg.No. 340266 (500M07) in soil using LC/MS/MS 2013/1184817
Guidelines:	SANCO/825/00 rev. 8.1 (16 November 2010), SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the methods

Soil samples (5 g) are placed into a PP tube and extracted with 25 mL acetonitrile by mechanical shaking for 30 min at 225 rpm. Subsequently, the sample is centrifuged and the liquid phase is decanted and evaporated to dryness. The extraction is repeated with 25 mL acetonitrile / water (80/20, v/v). After centrifugation, the liquid phase from the second extraction is separated and used to re-dissolve the dried residue from the first extraction. An additional dilution with acetonitrile / water (80/20, v/v) was performed when necessary (final volume = 50 mL) before LC-MS/MS measurement.

The method was validated at two fortification levels (0.001 and 0.01 mg kg^{-1}) for soils from different origins: two LUFA standard soils (LUFA 5M and LUFA 2.2 soils) and two soils freshly collected from the field (Italian and German field soil).

Recovery findings

The method L0166/01 was proved to be suitable to determine residues of pyraclostrobin and its metabolites BF 500-6 (500M01), BF 500-7 (500M02) and BF 500-3 (500M07) in different soils using LC-MS/MS with a limit of quantification (LOQ) of 0.001 mg kg^{-1} and a limit of detection (LOD) of 0.0002 mg kg^{-1}. Validation experiments were conducted in four different soils for pyraclostrobin and its metabolites BF 500-6, BF 500-7 and BF 500-3. The mean recovery values for pyraclostrobin and its metabolites were between 70 and 110%. The detailed results are given in Table 4.1.2-1 and Table 4.1.2-2.

Table 4.1.2-1: Validation results of a residue analytical method for pyraclostrobin and its metabolites BF 500-6, BF 500-7 and BF 500-3 in soil (LUFA 5M and LUFA 2.2)

		358 → 132	5	0.001	96.8	2.8
			5	0.01	95.8	6.0

Linearity	Good linearity (regression coefficients ≥ 0.977) was observed in the range of 0.01 ng mL^{-1} to 0.75 ng mL^{-1} for pyraclostrobin and its metabolites BF 500-6, BF 500-7 and BF 500-3.
Specificity	The method L0166/01 allows the specific determination of pyraclostrobin and its metabolites BF 500-6, BF 500-7 and BF 500-3 in soil. This was demonstrated on the basis of four different soils using the highly specific detection technique LC-MS/MS. Each compound could be determined at two different mass transitions. Significant interferences (> 30% of LOQ) were not observed at the retention times and mass transitions considered for each analyte.
Limit of Quantification	The limit of quantification was 0.001 mg kg^{-1}.
Repeatability	The relative standard deviations (RSD, %) for all fortification levels were below 20%. The detailed values are shown in Table 4.1.2-1 and Table 4.1.2-2.
Reproducibility	Reproducibility of the method was not determined within this validation study.
Conclusion	**The method L0166/01 used LC-MS/MS for the final determination of pyraclostrobin and its metabolites BF 500-6 (500M01), BF 500-7 (500M02) and BF 500-3 (500M07) in different soils with a limit of quantification (LOQ) of 0.001 mg kg^{-1} for pyraclostrobin and each metabolite.** **It could be demonstrated that method L0166/01 fulfils the requirements with regard to specificity, repeatability, limit of quantification and recoveries and is therefore applicable to correctly determine residues of pyraclostrobin and its metabolites BF 500-6, BF 500-7 and BF 500-3 in all tested soils.**

Report: CA 4.1.2/2
Zangmeister W., 2010a
Validation of analytical method L0161/01: Determination of BAS 500 F in soil at LOQ 0.001 mg/kg
2010/1075848
Guidelines: SANCO/825/00 rev. 7 (17 March 2004), SANCO/3029/99 rev. 4 (11 July 2000), EEC 91/414 Annex II (Part A Section 4), EEC 91/414 Annex III (Part A Section 5)
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the methods

Soil samples (5 g) are placed into a PP tube and extracted with 25 mL methanol/water (80/20, v/v) by mechanical shaking for 30 min at 225 rpm. Subsequently, the sample is centrifuged for 5 minutes at 4000 rpm (20ºC). An additional dilution with methanol/water (80/20, v/v) was performed when necessary before LC-MS/MS measurement.

The method was validated at fortification levels of 0.001 and 0.01 mg kg^{-1} for LUFA standard soils (LUFA 2.2 and LUFA 5M).

Recovery findings

The method L0161/01 was proved to be suitable to determine residues of pyraclostrobin in soils using LC-MS/MS with a limit of quantification (LOQ) of 0.001 mg kg^{-1}. Validation experiments were conducted in two different soils for pyraclostrobin. The mean recovery values for pyraclostrobin were between 70 and 110%. The detailed results are given in Table 4.1.2-3.

Table 4.1.2-3: Validation results of a residue analytical method for pyraclostrobin in soil (LUFA 2.2 and LUFA 5M)

Soil	Analyte	m/z	No. of replicates	Fortification level [mg kg^{-1}]	Mean Recovery [%]	RSD [%]
LUFA 2.2	pyraclostrobin (BAS 500 F)	388 → 194	5	0.001	96.6	1.1
			5	0.01	93.7	4.4
		388 → 163	5	0.001	95.6	2.7
			5	0.01	94.0	3.5
LUFA 5M	pyraclostrobin (BAS 500 F)	388 → 194	5	0.001	93.0	3.0
			5	0.01	89.5	1.0
		388 → 163	5	0.001	93.1	1.0
			5	0.01	90.6	3.8

Linearity	Good linearity (regression coefficients ≥ 0.999) was observed in the range of 0.025 ng mL^{-1} to 1.00 ng mL^{-1} for pyraclostrobin.
Specificity	The method L0161/01 allows the specific determination of pyraclostrobin in soil. This was demonstrated on the basis of two different soils using the highly specific detection technique LC-MS/MS. Pyraclostrobin could be determined at two different mass transitions. Significant interferences (> 30% of LOQ) were not observed at the retention times and mass transitions considered for pyraclostrobin.
Limit of Quantification	The limit of quantification was 0.001 mg kg^{-1}.

Note: BASF DocID 2008/1042150 was erroneously included in the renewal dossier submitted in July 2014 and had therefore to be exchanged by BASF DocID 2005/1026675.

Principle of the methods

The samples are diluted with a mixture of acetonitrile/water and acidified with formic acid prior to analysis. Final determination is performed by HPLC/MS using a YMC Pro C18 analytical column and a gradient mixture of water – acetonitrile with formic acid as modifier at a flow rate of 700 µL/min. Detection is accomplished using positive ion electrospray ionization mass spectrometry. The identity of the test item was proven by coincidence of the retention times with the retention times of the authentic reference item peaks and furthermore by MS-detection (m/z 388).

Recovery findings

The method APL0500/01 was proven to be suitable to determine various pesticide residues including pyraclostrobin in water using HPLC/MS with a limit of quantification (LOQ) of 0.001 mg L^{-1} and a limit of detection (LOD) of 0.0005 mg L^{-1}. Validation experiments were conducted in Ft-mix-water for various pesticides including pyraclostrobin. The mean recovery values for all compounds were between 70 and 110%. The detailed results are given for pyraclostrobin in Table 4.1.2-4.

Table 4.1.2-4: Validation results of a residue analytical method for pesticides in water by HPLC/MS

Analyte	No. of replicates	Fortification level [mg kg^{-1}]	Mean Recovery [%]	RSD [%]
Pyraclostrobin (BAS 500 F)	5	0.001	99.4	2.2
	5	0.01	104.9	3.0

Linearity

Linear regression was used for calibration using five calibration levels, which were prepared in water/acetonitrile/formic acid (80/20/0.1, v/v/v). Good linearity (regression coefficients > 0.995) was observed in the range of 0.5 ng/mL to 130 ng/mL.

Specificity

The identification and quantification of pyraclostrobin were based on the retention time and the use of reference items and by MS-detection. Under the described conditions, the method is specific for the determination of pyraclostrobin in water.
Under the given chromatographic conditions, no significant co-elution of one of the active ingredient peaks with an unknown component was observed.
As the method is only used for dose verification of known substances and known nominal concentrations, no additional confirmatory technique is necessary.

Matrix Effects

No matrix effects were investigated within an independent experiment, therefore instrument recovery samples would be implemented within each analytical series, if no further information on matrix effects of the investigated matrix is available. Alternatively, matrix-matched standards would be used.

Limit of Quantification

The limit of quantification (LOQ) is defined by the lowest fortification level successfully tested, resulting in an LOQ of 1 µg L^{-1} for pyraclostrobin.

Limit of Detection

The limit of detection (LOD) is defined by the lowest calibration level used, corresponding to a concentration of 0.5 µg L^{-1} for pyraclostrobin.

Repeatability

The relative standard deviations (RSD, %) for all fortification levels were below 20%. The detailed values are shown in Table 4.1.2-4.

Standard Stability

An assessment of stability was not considered to be mandatory within this validation study. The duration of a complete analytical run is always below 24 hours and samples are always injected promptly after sample preparation.

Stability of Working Solutions	An assessment of stability was not considered to be mandatory within this validation study. The duration of a complete analytical run is always below 24 hours and samples are always injected promptly after sample preparation.
Reproducibility	Reproducibility of the method was not determined within this validation study.
Conclusion	**The method APL0500/01 used HPLC/MS for the final determination of different pesticides in water with a limit of quantification (LOQ) of 0.001 mg L^{-1} for each compound including pyraclostrobin.** **It could be demonstrated that method APL0500/01 fulfils the requirements with regard to specificity, repeatability, limit of quantification and recoveries and is therefore applicable to correctly determine residues of pesticides including pyraclostrobin in water.**

Report:	CA 4.1.2/4 Tilting N., 2012a Validation of method L0182/01: Determination of BAS 500 F and its metabolites Reg.No. 412053 (500M59), Reg.No. 411847 (500M60), Reg.No. 412785 (500M62), Reg.No. 413038, and Reg.No. 377613 in ground- surface- and tapwater using LC-MS/MS 2012/1009641
Guidelines:	SANCO/3029/99 rev. 4 (11 July 2000), EEC 91/414 Annex II (Part A Section 4), EEC 91/414 Annex III (Part A Section 5), SANCO/825/00 rev. 8 (30 June 2010)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the method

The BASF method L0182/01 was developed for the determination of BAS 500 F (pyraclostrobin) and its metabolites BF 500-12 (500M59), BF 500-11 (500M60), BF 500-13 (500M62), BF 500-14 (500M76) and BF 500-15 (500M78) in water samples. A 50 mL sample aliquot is acidified by adding 500 µL of formic acid and extracted by SPE. After washing with 5 mL acidified water, the SPE column is dried. The column is eluted with 2 x 5 mL ethyl acetate and the combined extracts are evaporated at 40°C. Determination is conducted by HPLC-MS/MS. The limit of quantitation (LOQ) of the method for pyraclostrobin is 0.003 µg L^{-1} and for the metabolites the LOQ is 0.03 µg L^{-1} in water.
As matrix effects were observed during method development, matrix matched standards were used for calibration.

Recovery findings

The method proved to be suitable to determine pyraclostrobin and its metabolites BF 500-12, BF 500-11, BF 500-13, BF 500-14 and BF 500-15 in water. Validation experiments were conducted in ground-, surface- and tap water. Samples were spiked with the analytes at the limit of quantification (0.003 µg L^{-1} for pyraclostrobin, 0.03 µg L^{-1} for the metabolites) and 10 times higher (0.03 µg L^{-1} for pyraclostrobin, 0.3 µg L^{-1} for the metabolites). All average recovery values (mean of five replicates per fortification level and analyte) were between 70 and 110%. The detailed results are given in Table 4.1.2-5.

Table 4.1.2-5: Results of the method validation for the determination of pyraclostrobin and its metabolites in groundwater, surface water and tap water

			5	0.3	103.3	4.8
		tap water	5	0.03	95.8	2.8
			5	0.3	99.4	3.1

Linearity	Good linearity ($r \geq 0.99$) was observed in the range of 0.005 ng mL^{-1} to 1.0 ng mL^{-1} for the two ion transitions of pyraclostrobin and its metabolites BF 500-11, BF 500-12, BF 500-13, BF 500-14 and BF 500-15 in three different water types (ground-, surface- and tap water).
Specificity	The method successfully determines pyraclostrobin and its metabolites BF 500-11, BF 500-12, BF 500-13, BF 500-14 and BF 500-15 in water. This was demonstrated on the basis of three different water types (groundwater, surface water and tap water) using HPLC-MS/MS, and monitoring two mass transitions for each analyte. The tested untreated water samples showed no significant interferences (< 30%) at the retention time of the analytes. Due to the high selectivity and specificity of HPLC-MS/MS an additional confirmatory technique was not necessary.
Limit of Quantification	The method has a limit of quantification of 0.003 µg L^{-1} for pyraclostrobin and 0.03 µg L^{-1} for each metabolite.
Repeatability	The relative standard deviations (RSD, %) for all fortification levels were below 20%.
Reproducibility	Reproducibility of the method was not determined within this validation study.
Conclusion	**The method L0182/01 for the analysis of pyraclostrobin (BAS 500 F) and its metabolites BF 500-12 (500M59), BF 500-11 (500M60), BF 500-13 (500M62), BF 500-14 (500M76) and BF 500-15 (500M78) in ground-, surface- and tap water used HPLC-MS/MS for final determination, with limit of quantification of 0.003 µg L^{-1} for pyraclostrobin and 0.03 µg L^{-1} for each metabolite.** **It could be demonstrated that the method fulfils the requirements with regard to specificity, repeatability, limit of quantitation and recoveries and is therefore applicable to correctly determine pyraclostrobin and its metabolites in ground- surface- and tap water samples.**

Report:	CA 4.1.2/5 Obermann M., 2014a Validation of analytical method L0182/02 for the determination of BF 500-5 (Reg.No. 298327), metabolite of BAS 500 F, in ground- and surface water by LC-MS/MS 2014/1004891
Guidelines:	SANCO/825/00 rev. 8.1 (16 November 2010), SANCO/3029/99 rev. 4 (11 July 2000), EPA 850.7100
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

The objective of this validation study was to demonstrate the applicability and repeatability of method L0182/02 for the determination of BF 500-5 (500M04) in ground- and surface water by using HPLC-MS/MS. This method is complementary to method L0182/01, which is validated for pyraclostrobin and several of its other metabolites.

Principle of the method

A 50 mL water sample aliquot is acidified with formic acid and concentrated on a C18 SPE column. After eluting with ethyl acetate the eluate is evaporated to dryness and reconstituted with acetonitrile/water [20/80, v/v] before determination by HPLC-MS/MS.
The limit of quantitation (LOQ) of the method is 0.03 µg L^{-1} in water.

Recovery findings

Method L0182/02 was proved to be suitable to determine residues of BF 500-5 in ground- and surface water to a limit of quantification (LOQ) of 0.03 µg L^{-1}. Samples were spiked with the analyte at the limit of quantification (0.03 µg L^{-1}) and 10 times higher (0.3 µg L^{-1}). All average recovery values (mean of five replicates per fortification level) were between 70 and 110%. The detailed results are given in Table 4.1.2-6.

Table 4.1.2-6: Results of the method validation for the determination of BF 500-5 in ground- and surface water

Analyte	m/z	Matrix	Replicates	Fortification level [µg L^{-1}]	Mean recovery [%]	RSD [%]
BF 500-5 (500M04)	195->117	groundwater	5	0.03	98	5.9
			5	0.3	102	6.0
		surface water	5	0.03	110	5.6
			5	0.3	110	4.0
	195->153	groundwater	5	0.03	103	7.9
			5	0.3	101	6.7
		surface water	5	0.03	108	7.2
			5	0.3	105	1.9

Linearity	Good linearity ($r \geq 0.996$) was observed in the range of 0.05 ng mL^{-1} to 1.0 ng mL^{-1} for the two ion transitions of BF 500-5 in two different water types (ground- and surface water).
Specificity	The method successfully determines residues of BF 500-5 in ground- and surface water using HPLC-MS/MS, and monitoring two mass transitions. The tested untreated water samples showed no significant interferences (< 30%) at the retention time of the analytes. Due to the high selectivity and specificity of HPLC-MS/MS an additional confirmatory technique was not necessary.
Limit of Quantification	The method has a limit of quantification of 0.03 µg L^{-1}.
Repeatability	The relative standard deviations (RSD, %) for all fortification levels were below 10%, see Table 4.1.2-6.
Reproducibility	Reproducibility of the method was not determined within this validation study.
Conclusion	**The method L0182/02 for the analysis of BF 500-5 (500M04) in ground- and surface water used HPLC-MS/MS for final determination, with limit of quantification of 0.03 µg L^{-1}.** **It could be demonstrated that the method fulfils the requirements with regard to specificity, repeatability, limit of quantification and recoveries and is therefore applicable to correctly determine residues of BF 500-5 in ground- and surface water samples.**

Air

Pyraclostrobin (BAS 500 F)

Report: CA 4.1.2/6
Penning H., 2012a
Validation of analytical method L0197/01: Method for the determination of BAS 500 F (Pyraclostrobin) in air by LC-MS/MS
2012/1220256
Guidelines: SANCO/825/00 rev. 8.1 (16 November 2010), SANCO/3029/99 rev. 4 (11 July 2000)
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the method

BASF method L0197/01 was developed for the determination of BAS 500 F - pyraclostrobin in air samples. The analyte is spiked to Tenax adsorption tubes. After sucking air through the glass tubes at 35°C and a relative humidity of $\geq$ 80% for 6 hours at approximately 90 L h^{-1}, the tube content is extracted by ultrasonication using acetone. Final determination of pyraclostrobin is achieved by LC-MS/MS. The limit of quantification is defined as the lowest fortification level used in the validation process corresponding to a concentration of 4.44 ng pyraclostrobin per L air.

Recovery findings

The results from the fortification experiments at two spiking levels (2.40 µg and 24.0 µg of the analyte) showed that the recoveries were between 70 and 110% (see Table 4.1.2-7).

Because no interferences in the control samples were observed, no blank correction was necessary. Therefore, in the following result table, only uncorrected recovery data are presented for two mass transitions of pyraclostrobin. All mean recovery values were in the range 103% – 108%. For each fortification level the %RSD values were <20% (range: 1.4 – 4.3%).

Table 4.1.2-7: Results of method validation of pyraclostrobin in air (uncorrected data)

Test system	Analyte	Replicates	Fortification level [ng L^{-1}]	1. Transition (388 -> 194)			2. Transition (388 -> 163)		
				Mean recovery [%]	SD [+/- %]	RSD [%]	Mean recovery [%]	SD [+/- %]	RSD [%]
Air	Pyraclostrobin	6	4.44	103	4.2	4.1	103	4.5	4.3
		6	44.4	108	1.6	1.5	108	1.6	1.4

Linearity

Good linearity ($r > 0.99$) was observed in the range of 0.24 ng mL^{-1} to 2.4 ng mL^{-1} for both mass transitions of pyraclostrobin.

Specificity

Under the described conditions method L0197/01 is specific for the determination of pyraclostrobin in air. Significant interferences (> 30% of LOQ) were not observed at the retention time and mass transitions of pyraclostrobin.

Due to the high selectivity and specificity of LC-MS/MS an additional confirmatory technique was not necessary. Two mass transitions of pyraclostrobin were quantified.

Limit of Quantification

Limit of quantification should take into account relevant human and eco-toxicological-based limit values or exposure levels. Based on the equation described in SANCO/825/00 rev. 8.1, the limit of quantification should comply with the concentration C (mass of test item per volume air) calculated from the $AOEL_{inhalative}$. The $AOEL_{inhalative}$ value at time of method development was proposed to be 0.015 mg (kg body weight)$^{-1}$ day^{-1}.

Considering a body weight of 60 kg, a safety factor of 0.1 and an average respiratory volume of 20 m^3 per day, the limit of quantification (C) for the air method should be 0.0045 µg L^{-1}. Based on a collected air volume of 540 L, the amount spiked on the adsorber was 2.4 µg.

The lowest fortification level used for validation was 4.44 ng L^{-1} air and is therefore defined as limit of quantification.

Repeatability

The relative standard deviations (RSD, %) for all fortification levels were below 20%, see Table 4.1.2-7.

Reproducibility

Reproducibility of the method was not determined within this validation study.

Conclusion

Method L0197/01 was validated at concentrations of 4.44 ng L^{-1} air and 44.4 ng L^{-1} air. This method fulfils the requirements with regard to specificity, repeatability, limit of quantification and recoveries and is therefore applicable to correctly determine residues of pyraclostrobin in air.

(b) Methods in soil, water and any additional matrices used in support of efficacy studies

Not relevant

(c) Methods in feed, body fluids and tissues, air and any additional matrices used in support of toxicological studies

As pyraclostrobin is classified as toxic, a residue analytical method in body fluids and tissues is required. Consequently, method 439/0, which was originally developed for animal matrices, had been adapted to blood. The adapted method was evaluated in the previous Annex I inclusion process and was considered to be suitable. It is based on LC-UV and uses LC-MS as confirmatory technique. In order to provide a method using up-to-date technology, method L0151/01 was developed and also validated for blood. The relevant data are provided below (see CA 4.1.2/19).

Methods for concentration control in feed or other matrices are reported, where necessary, along with the respective toxicological studies. Additionally, the following standalone validation studies are presented.

Report:	CA 4.1.2/7 Catchpole G., Hidding B., 2016 a Reg.No. 5916421 (metabolite of BAS 500 F, Pyraclostrobin) - Validation of an analytical method for the analysis of Reg.No. 5916421 in plasma using HPLC-MS (control procedure: 13/0173_04)
	2016/1327657
Guidelines:	EC 1107/2009 of the European Parliament, SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the methods

The aim of the study was the validation of an analytical method for the quantitative analysis of Reg.No. 5916421 (500M24, metabolite of pyraclostrobin) in the vehicle plasma by high performance liquid chromatography with MS detection (HPLC MS) according to control procedure number 13/0173 04. The study was performed by BASF SE, Experimental Toxicology and Ecology, Ludwigshafen, Germany.

30 µL of the plasma sample (mouse plasma) are extracted with acetonitrile. After protein precipitation, the sample is centrifuged. The clear supernatant is analyzed by LC-MS/MS using an Ascentis Express C18 column and an acetonitrile/water gradient with 0.01% formic acid as modifier. Detection is accomplished in ESI+ mode at a mass transition of 226 m/z → 150 m/z for quantification and 226 m/z → 145 m/z for confirmation. The results are calculated by direct comparison of the sample peak responses to those of external matrix-matched standards.

The limit of quantification (LOQ) of the method is 50 ng mL^{-1} for Reg.No. 5916421 in plasma.

Recovery findings

The method is suitable to determine residues of Reg.No. 5916421 in plasma. Samples are fortified with the analyte at the limit of quantification of 50 ng mL^{-1}, 20 times higher (1,000 ng mL^{-1}) and 200 times higher (10,000 ng mL^{-1}).

Mean recovery values (mean of five replicates per fortification level) are between 99 and 105% (see table below). Regarding the blank plasma sample and the solvent blank, no peak was observed in both chromatograms at the retention time of the test substance.

Table 4.1.2-8: Characteristics for the analytical method used for validation of Reg.No. 5916421 residues in plasma

Matrix	Analyte	Mass transition	Fortification Level [ng mL^{-1}]	Number of replicates	Mean Recovery [%]	RSD [%]	Overall Recovery [%]	RSD [%]
Plasma	Reg.No. 5916421	266→150	50	5	102	2.0	100	2.7
			1000	5	99	3.4		
			10000	5	100	2.1		
		266→145	50	5	105	8.5	103	5.6
			1000	5	105	2.6		
			10000	5	100	1.9		

Linearity Good linearity (r^2 > 0.99) is observed in both calibration curves covering the low (4 ng mL^{-1} to 75 ng mL^{-1}) and high concentration range (75 ng mL^{-1} to 1200 ng mL^{-1}) using matrix-matched standards.

Specificity Highly selective determination of the analyte using LC-MS/MS detection and monitoring two mass transitions was applied. There were no interferences at the corresponding retention time in any of the control specimens (blank value < 30 % LOQ).

Matrix Effects Matrix effects are negated by using matrix-matched standards, leading to acceptable recovery values.

Limit of Quantification The limit of quantification (LOQ) is defined by the lowest fortification level successfully tested. LOQ is 50 ng mL^{-1} for Reg.No. 5916421 in plasma.

Limit of Detection The limit of detection (LOD) is calculated based on the signal to noise ratio S/N = 3 of the peak from the lowest fortification level, resulting in a value of 0.6 ng mL^{-1}.

Repeatability The relative standard deviations (RSD, %) for all fortification levels are below 20%.

Standard Stability	An assessment of stability was not considered to be mandatory within this validation study. The duration of a complete analytical run is always below 24 hours and samples are always injected promptly after sample preparation.
Stability of Working Solutions	An assessment of stability was not considered to be mandatory within this validation study. The duration of a complete analytical run is always below 24 hours and samples are always injected promptly after sample preparation.
Reproducibility	Reproducibility of the method was not determined within this validation study.

Conclusion

Control procedure number 13/0173_04 for the analysis of Reg.No. 5916421 (500M24, metabolite of pyraclostrobin) in plasma uses HPLC-MS/MS for final determination, with a limit of quantification of 50 ng mL^{-1}.
It could be demonstrated that the method fulfils the requirements with regard to specificity, repeatability, limit of quantification and recoveries and is therefore applicable to correctly and accurately determine residues of Reg.No. 5916421 in plasma.

Report:	CA 4.1.2/8 Catchpole G., Hidding B., 2016 d Validation of an analytical method for the analysis of Reg.No. 411847 (metabolite of BAS 500 F, Pyraclostrobin) in plasma using HPLC-MS (control procedure: 99/0251_01) 2016/1321627
Guidelines:	EC 1107/2009 of the European Parliament, SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the methods

The aim of the study was the validation of an analytical method for the quantitative analysis of Reg.No. 411847 (500M60, metabolite of pyraclostrobin) in the vehicle plasma by high performance liquid chromatography with MS detection (HPLC MS/MS) according to control procedure number 99/0251 01-03. The study was performed by BASF SE, Experimental Toxicology and Ecology, Ludwigshafen, Germany.
The plasma sample (mouse plasma) is extracted with acetonitrile (1 part plasma + 9 parts acetonitrile). After protein precipitation, the sample is centrifuged. The clear supernatant is analyzed by LC-MS/MS using a Luna C18 column and an acetonitrile/water gradient with 0.01% formic acid as modifier. Detection is accomplished in ESI+ mode at a mass transition of 278 m/z → 194 m/z for quantification and 278 m/z → 163 for confirmation. The results are calculated by direct comparison of the sample peak responses to those of external matrix-matched standards.
The limit of quantification (LOQ) of the method is 50 ng mL^{-1} for Reg.No. 411847 in plasma.

Recovery findings

The method is suitable to determine residues of Reg.No. 411847 in plasma. Samples are fortified with the analyte at the limit of quantification of 50 ng mL^{-1}, 10 times higher (500 ng mL^{-1}) and 100 times higher (5000 ng mL^{-1}).

Mean recovery values (mean of five replicates per fortification level) are between 92 and 102% (see table below). Regarding the blank plasma sample and the solvent blank, no peak was observed in both chromatograms at the retention time of the test substance.

Table 4.1.2-9: Characteristics for the analytical method used for validation of Reg.No. 411847 residues in plasma

Matrix	Analyte	Mass transition	Fortification Level [ng mL^{-1}]	Number of Replicates	Mean Recovery [%]	RSD [%]	Overall Recovery [%]	RSD [%]
Plasma	Reg.No. 411847	278 → 194	50	5	102	1.5	97	6.7
			500	5	92	9.1		
			5000	5	98	4.3		
		278 → 163	50	5	102	1.1	97	6.6
			500	5	92	8.9		
			5000	5	98	4.3		

Linearity	Good linearity (r^2 > 0.99) is observed in both calibration curves covering the low (4 ng mL^{-1} to 73 ng mL^{-1}) and high concentration range (49 ng mL^{-1} to 586 ng mL^{-1}) using matrix-matched standards.
Specificity	Highly selective determination of the analyte using LC-MS/MS detection and monitoring two mass transitions was applied. There were no interferences at the corresponding retention time in any of the control specimens (blank value < 30 % LOQ).
Matrix Effects	Matrix effects are negated by using matrix-matched standards, leading to acceptable recovery values.
Limit of Quantification	The limit of quantification (LOQ) is defined by the lowest fortification level successfully tested, resulting in an LOQ of 50 ng mL^{-1} for Reg.No. 411847 in plasma.
Limit of Detection	The limit of detection (LOD) is calculated based on the signal to noise ratio S/N = 3 of the peak from the lowest fortification level, resulting in a value of 0.01 ng mL^{-1}.
Repeatability	The relative standard deviations (RSD, %) for all fortification levels are below 20%.
Standard Stability	An assessment of stability was not considered to be mandatory within this validation study. The duration of a complete analytical run is always below 24 hours and samples are always injected promptly after sample preparation.
Stability of Working Solutions	An assessment of stability was not considered to be mandatory within this validation study. The duration of a complete analytical run is always below 24 hours and samples are always injected promptly after sample preparation.
Reproducibility	Reproducibility of the method was not determined within this validation study.

Conclusion

Control procedure number 99/0251_01-03 for the analysis of Reg.No. 411847 (500M60, metabolite of pyraclostrobin) in plasma uses HPLC MS/MS for final determination, with a limit of quantification of 50 ng mL^{-1}.

It could be demonstrated that the method fulfils the requirements with regard to specificity, repeatability, limit of quantification and recoveries and is therefore applicable to correctly and accurately determine residues of Reg.No. 411847 in plasma.

Report:	CA 4.1.2/9 Catchpole G., Hidding B., 2016 b Validation of an analytical method for the analysis of Reg.No. 413038 (metabolite of BAS 500 F, Pyraclostrobin) in plasma using HPLC (control procedure: 99/0249_01) 2016/1311551
Guidelines:	EC 1107/2009 of the European Parliament, SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the methods

The aim of the study was the validation of an analytical method for the quantitative analysis of Reg.No. 413038 (500M76, metabolite of pyraclostrobin) in the vehicle plasma by high performance liquid chromatography with MS detection (HPLC MS/MS) according to control procedure number 99/0249 01. The study was performed by BASF SE, Experimental Toxicology and Ecology, Ludwigshafen, Germany.

The plasma sample (mouse plasma) is extracted with acetonitrile (1 part plasma + 9 parts acetonitrile). After protein precipitation, the sample is centrifuged. The clear supernatant is analyzed by LC-MS/MS using a Luna C18 column and an acetonitrile/water gradient with 0.01% formic acid as modifier. Detection is accomplished in ESI+ mode at a mass transition of 388 m/z → 164 m/z for quantification and 388 m/z → 132 for confirmation. The results are calculated by direct comparison of the sample peak responses to those of external matrix-matched standards.

The limit of quantification (LOQ) of the method is 50 ng mL^{-1} for Reg.No. 413038 in plasma.

Recovery findings

The method is suitable to determine residues of Reg.No. 413038 in plasma. Samples are fortified with the analyte at the limit of quantification of 49 ng mL^{-1}, 20 times higher (980 ng mL^{-1}) and 100 times higher (9800 ng mL^{-1}).

Mean recovery values (mean of five replicates per fortification level) are between 92 and 98% (see table below). Regarding the blank plasma sample and the solvent blank, no peak was observed in both chromatograms at the retention time of the test substance.

Table 4.1.2-10: Recoveries for Reg.No. 413038 (metabolite of pyraclostrobin) in plasma

Matrix	Analyte	Mass transition	Fortification Level [ng mL^{-1}]	Number of Replicates	Mean Recovery [%]	RSD [%]	Overall Recovery [%]	RSD [%]
Plasma	Reg.No. 413038	388 → 164	49	5	94	6.1	95	4.4
			980	5	92	2.3		
			9800	5	98	0.6		
		388 → 132	49	5	92	5.0	94	4.3
			980	5	92	2.3		
			9800	5	98	0.4		

Linearity	Good linearity ($r^2 \geq 0.999$) was observed in the range of 3.92 ng/mL to 1176.0 ng/mL using the two mass transitions described. 12 calibration levels, split into two distinct mass ranges (3.92 ng/mL – 73.5 ng/mL and 73.5 ng/mL – 1176.0 ng/mL), were used.
Specificity	Highly selective determination of the analyte using LC-MS/MS detection and monitoring two mass transitions was applied. There were no interferences at the corresponding retention time in any of the control specimens (blank value < 30 % LOQ).
Matrix Effects	Matrix effects are negated by using matrix-matched standards, leading to acceptable recovery values.
Limit of Quantification	The limit of quantification (LOQ) is defined by the lowest fortification level successfully tested, resulting in an LOQ of 49 ng mL^{-1} for Reg.No. 413038 in plasma.
Limit of Detection	The limit of detection (LOD) is calculated based on the signal to noise ratio S/N = 3 of the peak from the lowest fortification level, resulting in a value of 0.02 ng mL^{-1}.
Repeatability	The relative standard deviations (RSD, %) for all fortification levels are below 20%.
Standard Stability	An assessment of stability was not considered to be mandatory within this validation study. The duration of a complete analytical run is always below 24 hours and samples are always injected promptly after sample preparation.
Stability of Working Solutions	An assessment of stability was not considered to be mandatory within this validation study. The duration of a complete analytical run is always below 24 hours and samples are always injected promptly after sample preparation.
Reproducibility	Reproducibility of the method was not determined within this validation study.

Conclusion

Control procedure number 99/0249 01 for the analysis of Reg.No. 413038 (500M76, metabolite of pyraclostrobin) in plasma uses HPLC MS/MS for final determination, with a limit of quantification of 49 ng mL^{-1}.
It could be demonstrated that the method fulfils the requirements with regard to specificity, repeatability, limit of quantification and recoveries and is therefore applicable to correctly and accurately determine residues of Reg.No. 413038 in plasma.

Report:	CA 4.1.2/10 Catchpole G., Hidding B., 2017 a Validation of an analytical method for the analysis of Reg.No. 399379 (metabolite of BAS 500 F, Pyraclostrobin) and Reg.No. 298327 (metabolite of BAS 500 F, Pyraclostrobin) in plasma using HPLC-MS (control procedure: 14/0701_04)
Guidelines:	2016/1333356 EC 1107/2009 of the European Parliament, SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the methods

The aim of the study was the validation of an analytical method for the quantitative analysis for Reg.No. 399379 (500M106, metabolite of pyraclostrobin) and Reg.No. 298327 (500M04, metabolite of pyraclostrobin) in the vehicle plasma by high performance liquid chromatography with high-resolution MS detection (HPLC MS) according to control procedure number 4/0701 04-01. The study was performed by BASF SE, Experimental Toxicology and Ecology, Ludwigshafen, Germany.

The plasma sample (mouse plasma) is extracted with acetonitrile (1 part plasma + 9 parts acetonitrile). After protein precipitation, the sample is centrifuged. The clear supernatant is analyzed by LC-high-res-MS using a Accucore C18 column and an acetonitrile/water gradient with 0.01% formic acid as modifier. Detection is accomplished in positive full scan mode at an exact mass of m/z 330.10038 for Reg.No. 399379, and m/z 195.03197 for Reg.No. 298327. The results are calculated by direct comparison of the sample peak responses to those of external matrix-matched standards.

The limit of quantification (LOQ) of the method is 50 ng mL^{-1} for both analytes in plasma.

Recovery findings

The method is suitable to determine residues of Reg.No. 399379 and Reg.No. 298327 in plasma. Samples are fortified with the analyte at the limit of quantification of 50 ng mL^{-1}, 10 times higher (500 ng mL^{-1}) and 100 times higher (5000 ng mL^{-1}).

Mean recovery values (mean of five replicates per fortification level) are between 92 and 98% (see table below). Regarding the blank plasma sample and the solvent blank, no peak was observed in both chromatograms at the retention time of the test substance.

Table 4.1.2-11: Recoveries for Reg.No. 399379 and Reg.No. 298327 (metabolites of pyraclostrobin) in plasma

Matrix	Analyte	m/z (+/- 3 mDa)	Fortification Level [ng mL^{-1}]	Number of Replicates	Mean Recovery [%]	RSD [%]	Overall Recovery [%]	RSD [%]
Plasma	Reg.No. 399379	330.10038	50	4*	75	6.8	90	11.8
			500	5	97	5.3		
			5000	5	94	3.5		
	Reg.No. 298327	*195.03197*	50	4*	102	8.0	98	6.2
			500	5	93	3.2		
			5000	5	101	1.3		

* Outlier identified

Linearity Good linearity ($r^2 \geq 0.999$) was observed in the range of 4.104 ng/mL to 102.6 ng/mL and 76.95 ng/mL to 615.6 ng/mL (Reg.No. 399379) and 3.864 ng/mL to 72.45 ng/mL and 72.45 ng/mL to 579.6 ng/mL (Reg.No. 298327) using the accurate m/z described. At least six calibration levels distributed over each concentration range were used.

Specificity Highly selective determination of the analytes using LC with high resolution MS-detection was used, therefore no additional confirmatory technique is needed. There were no interferences at the corresponding retention time in any of the control specimens (blank value < 30 % LOQ).

Matrix Effects Matrix effects are negated by using matrix-matched standards, leading to acceptable recovery values.

Limit of Quantification The limit of quantification (LOQ) is defined by the lowest fortification level successfully tested, resulting in an LOQ of 50 ng mL^{-1} for both analytes in plasma.

Limit of Detection The LODs of the entire analytical procedure following any sample dilution steps were assessed and found to be < 4.104 ng/mL (Reg.No. 399379) and 0.0546 ng/mL (Reg.No. 298327), which correspond to < 8.2 % and < 1 % of the respective LOQ.

Repeatability The relative standard deviations (RSD, %) for all fortification levels are below 20%.

Standard Stability An assessment of stability was not considered to be mandatory within this validation study. The duration of a complete analytical run is always below 24 hours and samples are always injected promptly after sample preparation.

Stability of Working Solutions	An assessment of stability was not considered to be mandatory within this validation study. The duration of a complete analytical run is always below 24 hours and samples are always injected promptly after sample preparation.
Reproducibility	Reproducibility of the method was not determined within this validation study.

Conclusion

Control procedure number 14/0701_04 for the analysis of Reg.No. 399379 and Reg.No. 298327 (metabolites of pyraclostrobin) in plasma uses HPLC with high resolution MS-detection for final determination, with a limit of quantification of 50 ng mL^{-1}.
It could be demonstrated that the current analytical method fulfills the requirements with regard to specificity, linearity, repeatability, limit of quantification and accuracy and is therefore applicable to correctly quantify Reg.No. 399379 (500M106, metabolite of pyraclostrobin) and Reg.No. 298327 (500M04, metabolite of pyraclostrobin) in plasma.

Report:	CA 4.1.2/11 Catchpole G., Hidding B., 2016 c Reg.No. 399379 (metabolite of BAS 500 F, Pyraclostrobin) - Validation of an analytical method for the analysis of Reg.No. 399379 (metabolite of BAS 500 F) in 1% Carboxymethyl cellulose in drinking water (w/v) using HPLC-UV 2016/1230128
Guidelines:	SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the methods

The aim of the study was the validation of an analytical method for the quantitative analysis of Reg.No. 399379 (500M106, metabolite of pyraclostrobin) in the vehicle 1% carboxymethyl cellulose in drinking water (w/V) by high performance liquid chromatography with UV detection (HPLC-UV) according to control procedure number 14/0701 03-01. The study was performed by BASF SE, Experimental Toxicology and Ecology, Ludwigshafen, Germany.

The vehicle samples (1% carboxymethyl cellulose in drinking water) are transferred into appropriate volumetric flasks with 10 mL acetonitrile/water (1/1, v/v) and filled up to the mark with acetonitrile to obtain concentrations within the tested calibration range. After filtering the samples (cellulose filter, 0.2 µm) residues of Reg.No. 399379 are determined by HPLC-UV using a Chromolith Performance RP18e column and an acetonitrile/water gradient with 0.1% formic acid as modifier. Detection is accomplished at a wavelength of 278 nm (with 360 nm reference). The results are calculated by direct comparison of the sample peak responses to those of external matrix-matched standards.

The limit of quantification (LOQ) of the method is 0.1 mg mL^{-1} (10 mg per 100 mL) in aqueous 1% carboxymethyl cellulose for Reg.No. 399379.

Recovery findings

The method is suitable to determine residues of Reg.No. 399379 in 1% carboxymethyl cellulose in drinking water (w/v). Samples are fortified with the analyte at the limit of quantification (0.1 mg mL^{-1}), 50 times higher (5 mg mL^{-1}) and 2500 times higher (250 mg mL^{-1}).

Mean recovery values (mean of five replicates per fortification level) are between 99 and 104% (see table below). Regarding the blank vehicle sample, no peak was observed in the chromatogram at the retention time of the test substance.

Table 4.1.2-12: Recoveries for Reg.No. 399379 (metabolite of pyraclostrobin) in 1% carboxymethyl cellulose in drinking water (w/V)

Matrix	Analyte	Wave-length	Fortifi-cation Level [mg mL^{-1}]	Number of replicates	Mean Recovery [%]	RSD [%]	Overall Recovery [%]	RSD [%]
1% CMC in drinking water (w/v)	Reg.No. 399379	278 nm	0.1	5	99	0.3	101	2.7
			5	5	104	0.5		
			250	5	99	0.8		

Linearity Good linearity ($r^2 > 0.99$) is observed in the calibration curve covering the range of 0.005 mg mL^{-1} to 0.051 mg mL^{-1} using matrix-matched standards.

Specificity There were no interferences at the corresponding retention time in any of the control specimens (blank value < 30 % LOQ).
Since UV-detection is used, no other signal suppression or depression can be expected.
As the method is only used for dose verification of known substances and known nominal concentrations, no additional confirmatory technique is necessary.

Matrix Effects The effects of the sample matrix on HPLC-UV response is not tested within this validation study. Matrix-matched standards are used and lead to very good recovery values.

Limit of Quantification The limit of quantification (LOQ) is defined by the lowest fortification level successfully tested, resulting in an LOQ of 0.1 mg mL^{-1} (10 mg per 100 mL) in 1% carboxymethyl cellulose in drinking water (w/V) for Reg.No. 399379.

Repeatability The relative standard deviations (RSD, %) for all fortification levels are below 20%.

Standard Stability An assessment of stability was not considered to be mandatory within this validation study. The duration of a complete analytical run is always below 24 hours and samples are always injected promptly after sample preparation.

Stability of Working Solutions An assessment of stability was not considered to be mandatory within this validation study. The duration of a complete analytical run is always below 24 hours and samples are always injected promptly after sample preparation.

Reproducibility Reproducibility of the method was not determined within this validation study.

Conclusion

Control procedure number 14/0701 03-01 for the analysis of Reg.No. 399379 (500M106, metabolite of pyraclostrobin) in 1% carboxymethyl cellulose in drinking water (w/V) uses HPLC UV for final determination, with a limit of quantification of 0.1 mg mL^{-1}.
It could be demonstrated that the method fulfills the requirements with regard to specificity, repeatability, limit of quantification and recoveries and is therefore applicable to correctly and accurately determine residues of Reg.No. 399379 in 1% carboxymethyl cellulose in drinking water (w/v).

Report:	CA 4.1.2/12 Tanaka T., 2016 a Validation for determination method of Reg.No. 399379 (metabolite of BAS 500 F, Pyraclostrobin) in 0.5 w/v% carboxymethyl cellulose solution 2016/1230112
Guidelines:	OECD Principles of Good Laboratory Practice
GLP:	yes (certified by Ministry of Health, Labour and Welfare, Tokyo, Japan)

Principle of the methods

The aim of the study was the validation of an analytical method for the quantitative analysis of Reg.No. 399379 (500M106, metabolite of pyraclostrobin) in the vehicle (0.5 w/v% carboxymethyl cellulose sodium salt aqueous solution) by high performance liquid chromatography with UV detection (HPLC-UV) according to control procedure number 14/0701_03-01. The study was performed by Biosafety Research Center, Shizuoka, Japan.

The vehicle samples are transferred into appropriate volumetric flasks with acetonitrile and filled up to the mark with acetonitrile to obtain concentrations within the tested calibration range. After filtering the samples (Millex-LH, PTFE, pore size: 0.45 µm) residues of Reg.No. 399379 are determined by HPLC-UV using a L-column ODS and an acetonitrile/water gradient with 0.1% formic acid as modifier. Detection is accomplished at a wavelength of 278 nm. The results are calculated by direct comparison of the sample peak responses to those of external standards.

The limit of quantification (LOQ) of the method is 0.5 mg/mL in aqueous 0.5% carboxymethyl cellulose for Reg. No. 399379.

Recovery findings

The method is suitable to determine residues of Reg.No. 399379 in 0.5 % carboxymethyl cellulose in aqueous solution (w/v). Samples are fortified with the analyte at the limit of quantification (0.5 mg/mL and at 100 mg/mL).

Mean recovery values (mean of five measurements per fortification level) are between 93 and 109% (see table below). Regarding the blank vehicle sample, no peak was observed in the chromatogram at the retention time of the test substance.

Table 4.1.2-13: Recoveries for Reg.No. 399379 (metabolite of pyraclostrobin) in aqueous 0.5% carboxymethyl cellulose (w/v)

		108	108				
		108	108				

Linearity Good linearity ($r^2 > 0.99$) is observed in the calibration curve covering the range of 0.01 mg/mL to 0.1 mg/mL using solvent standards.

Specificity There were no interferences at the corresponding retention time in any of the control specimens (blank value < 30 % LOQ).
Since UV-detection is used, no other signal suppression or depression can be expected.
As the method is only used for dose verification of known substances and known nominal concentrations, no additional confirmatory technique is necessary.

Matrix Effects	Since UV detection is used, no signal suppression or depression can be expected.
Limit of Quantification	The limit of quantification (LOQ) is defined by the lowest fortification level successfully tested, resulting in an LOQ of 0.5 mg/mL in 0.5% carboxymethyl cellulose in aqueous solution (w/v) for Reg.No. 399379.
Repeatability	The relative standard deviations (RSD, %) for all fortification levels are below 20%.
Standard Stability	Standard solutions were measured after preparation and after 24-hour storage in the autosampler (10°C) 3 times repeatedly and were found to be stable over this time period.
Stability of Sample Solutions	Sample solutions of the test substance formulation were measured just after preparation and after 24-hour storage in the autosampler (10°C) and were found to be stable over this time period.
Reproducibility	Reproducibility of the method was not determined within this validation study.

Conclusion

The analytical method for the analysis of Reg.No. 399379 (500M106, metabolite of pyraclostrobin) in 0.5 % carboxymethyl cellulose in aqueous solution (w/v) uses HPLC UV for final determination, with a limit of quantification of 0.5 mg/mL.
It could be demonstrated that the method fulfills the requirements with regard to specificity, repeatability, limit of quantification and recoveries and is therefore applicable to correctly and accurately determine residues of Reg.No. 399379 in 0.5 % carboxymethyl cellulose in aqueous solution (w/v).

(d) Methods in body fluids, air and any additional matrices used in support of operator, worker, resident and bystander exposure studies

No exposure studies were conducted with pyraclostrobin. Consequently, such methods of analysis are not required.

(e) Methods in or on plants, plant products, processed food commodities, food of plant and animal origin, feed and any additional matrices used in support of residues studies

The analytical methods for the determination of pyraclostrobin in **foodstuffs of plant origin** were evaluated in the previous Annex I inclusion process and during more recent evaluations performed by EFSA in context of MRL applications. Pyraclostrobin residues in commodities of plant origin can be determined by LC-MS/MS with LOQs of 0.02 mg/kg or 0.01 mg/kg. The BASF methods 421/0, 445/0 and 535/1 (synonym: L0076/01) allow the determination of pyraclostrobin and its metabolite 500M07 (BF 500-3) in multiple crops. The metabolite 500M07 is not part of the residue definition in Europe. The data generation methods are fully validated in separate GLP studies; furthermore, an extensive set of concurrent fortification experiments exist from supervised field trials or processing studies.

The analytical methods for the determination of pyraclostrobin in **foodstuffs of animal origin** were evaluated in the previous Annex I inclusion process. Pyraclostrobin residues in commodities of animal origin can be determined by HPLC-UV methods with a validated LOQ of 0.01 mg/kg in milk and 0.05 mg/kg in muscle, liver, kidney, fat and eggs (BASF methods 439/0 and 446).

Information on the residue definition relevant for the EU is shown in Table 4.1.2-8.

Table 4.1.2-14: Residue definition - pyraclostrobin

End-Point	Active Substance: Pyraclostrobin	
	EU agreed endpoints (SANCO/1420/2001; Monograph 12945/ECCO/BBA/01, Vol. 1, list of endpoints)	Residue definitions proposed in context of this dossier

Residue definition in animal matrices for monitoring	Pyraclostrobin (parent)	Pyraclostrobin (parent)

* synonym: 500M04
** synonym: 500M85

The general suitability of the residue analytical methods provided for data generation and risk assessment has been confirmed by EFSA in the recently published Reasoned Opinion on MRLs (Review of established MRLs according to Reg. 396/2005 (Art. 12); EFSA Journal 2011;9(8):2344). They are supported by appropriate extractability investigations performed with sample material generated in course of the metabolism studies in crops and livestock.

Food of plant origin

Pyraclostrobin (BAS 500 F)

Due to the broad use of pyraclostrobin containing formulations, the scope of the methods has been considerably expanded over the past years. In 2011, EFSA re-evaluated the safety of the established EU MRLs according to Reg. 396/2005, Art. 12. In context of the evaluation the following data gap has been identified:

- a validated method for enforcement of pyraclostrobin in coffee beans.

The method summarized below has been used for the analysis of the samples generated during supervised field trials in Brazil. The independent laboratory validation study for method 421/0 in coffee is included in M-CA 4.2 (see CA 4.2/1).

Report:	CA 4.1.2/13 Leite R., 2005a Validation study of the SOP-PA.0243 for determination of Pyraclostrobin and its metabolite (BF 500-3) residues in coffee (grain), soybean (grain) and wheat (grain) 2005/1037978
Guidelines:	INMETRO NIT DICLA- 028 Rev. 01 (Sept. 2003), NBR ISO/IEC 17025/2001
GLP:	yes (certified by Instituto Nacional de Metrologia, Normalizacao e Qualidade Industrial - INMETRO, Rio de Janeiro, Brazil)

Principle of the method

SOP-PA.0243:

After extraction of the plant material with a methanol/water/hydrochloric acid mixture and subsequent centrifugation of an aliquot, an aliquot of the supernatant is transferred into a culture tube containing water. For purification, liquid/liquid partitioning with cyclohexane is performed. The cyclohexane is evaporated to dryness and the residue dissolved in methanol/water for LC-MS/MS quantification. For pyraclostrobin, the transition ions m/z = 388 -> 194 and m/z = 388-> 163 and for BF 500-3 m/z = 358 -> 164 and m/z = 358 -> 132 can be used for quantification.

Recovery findings

The method proved to be suitable for analysis of pyraclostrobin and BF 500-3 in coffee (grain), soybean (grain) and wheat (grain) to a limit of quantitation of 0.02 mg/kg for each analyte.
In all matrices tested, the mean recovery values were between 70 and 110%. The detailed results are given in Table 4.1.2-9.

Table 4.1.2-15: Recovery results of BAS 500 F and BF 500-3

Crop, Commodity	Test Substance	Fortification level (mg/kg)	No. of tests	Average Recovery (%)	Rel. Standard Deviation (%)
Coffee, grain	BAS 500 F	0.02, 2.0	10	101 [1] / 104 [2]	5.0 [1] / 4.0 [2]
	BF 500-3	0.02, 2.0	10	96 [3] / 96 [4]	5.0 [3] / 4.0 [4]
Soybean, grain	BAS 500 F	0.02, 2.0	10	92 [1] / 92 [2]	5.0 [1] / 4.0 [2]
	BF 500-3	0.02, 2.0	10	85 [3] / 85 [4]	4.0 [3] / 4.0 [4]
Wheat, grain	BAS 500 F	0.02, 2.0	10	103 [1] / 106 [2]	6.0 [1] / 5.0 [2]
	BF 500-3	0.02, 2.0	10	100 [3] / 100 [4]	7.0 [3] / 6.0 [4]

[1] For transition 388 → 194; [2] For transition 388 → 163; [3] For transition 358 → 164; [4] For transition 358 → 132

Linearity

Good linearity was observed in the range of 0.25 to 5.0 ng/mL for pyraclostrobin and BF 500-3 (external reference standard).

Specificity

The method determines parent pyraclostrobin and its metabolite BF 500-3 in coffee (grain), soybean (grain) and wheat (grain). There were no known interferences from plant components or from reagents, solvents and glassware used.

Limit of Quantification

The limit of quantification was defined by the lowest fortification level successfully tested, which was 0.02 mg/kg for each analyte in all sample materials.

Repeatability

The relative standard deviations (RSD, %) for all commodities and all fortification levels were well below 20%. The detailed values are shown in Table 4.1.2-9.

Reproducibility

The reproducibility of the method was not estimated as identical samples were not evaluated by an independent laboratory. However, based on the performance of the method, its reproducibility is expected to be good.

Conclusion

The method for analysis of pyraclostrobin and its metabolite BF 500-3 (500M07) uses LC-MS/MS for final determination, which is a modern and highly specific technique. The limit of quantitation is 0.02 mg/kg for each analyte.
It could be demonstrated that the method fulfils the requirements with regard to specificity, repeatability, limit of quantitation and recoveries.

Metabolite 500M04 and its glycoside conjugates

The method was developed in order to perform analysis of representative samples generated during supervised field trials. It is intended to support dietary risk assessment for the metabolite 500M04 and its conjugates as they were found in levels up to 5 – 10% TRR in the crop metabolism studies (mainly in leaf and green matter samplings). For proving the suitability of the enzymatic cleavage step applied, the glycoside 500M79 was selected; it was synthesized and exemplarily tested in fortification experiments.

Report:	CA 4.1.2/14 Courtois J., 2014a Validation of analytical method L0220/01 for the determination of metabolite 500M79 (Reg.No. 5937091) in plant matrices by LC-MS/MS 2014/1001721
Guidelines:	SANCO/3029/99 rev. 4 (11 July 2000), EEC 91/414 Annex II (Part A Section 4), EEC 91/414 Annex III (Part A Section 5), SANCO/825/00 rev. 8.1 (16 November 2010), OECD-ENV/JM/MONO/(2007)17 (OECD No. 72)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Report:	CA 4.1.2/15 Eilers B. et al., 2014a Method for the determination of 500M79 (Reg.No. 5937091) in plant matrices by LC-MS/MS 2014/1001641
Guidelines:	not applicable
GLP:	no

Principle of the method

BASF Method No. L0220/01:

Metabolite 500M79 is extracted from plant matrices using a mixture of methanol, water and hydrochloric acid. An aliquot of the extract is evaporated to dryness and dissolved in water. Subsequently the analyte is hydrolyzed using enzymatic cleavage to 500M04 (BF 500-5). It is followed by reversed phase C18-column clean-up. The final determination of 500M04 is performed by UPLC-MS/MS. The results are expressed in 500M04. For 500M79 the ion transitions *m/z* = 195 → 153 and *m/z* = 195 → 150 can be used for quantification.

Recovery findings

The method proved to be suitable for analysis of metabolite 500M79 in plant matrices at a limit of quantitation of 0.01 mg/kg.
In all matrices tested (lettuce heads, white cabbage, leek), the mean recovery values were between 78 and 82%. The detailed results are given in Table 4.1.2-10.

Results of stability investigations of calibration and fortification solutions as well as stability investigations of the final volumes are summarized in Table 4.1.2-11, Table 4.1.2-12 and Table 4.1.2-13. The results show that fortification solutions in acetonitrile and calibration standards in acetonitrile/water (50/50, v/v) are stable over the investigated time of 30 days.

		Overall final volume stability									98

Linearity	The linearity of the UPLC-MS/MS detector was tested using at least 5 standard solutions at concentrations between 0.025 and 2.5 ng/mL. Standards were injected and the response was plotted against concentration. Linear correlations with coefficients ≥0.999 were obtained for metabolite 500M79.
Specificity	The method L0220/01 determines residues of metabolite 500M79 in plant matrices. Significant interferences (> 20 or 30%) were not observed at the retention times and mass transitions considered for the analyte. UPLC-MS/MS, using two mass transitions, is a highly specific detection technique and therefore no additional confirmatory technique is required.
Limit of Quantification	The limit of quantification (LOQ) was defined as the lowest fortification level successfully tested. The limit of quantification was 0.01 mg/kg for the analyte (metabolite 500M79).
Repeatability	The relative standard deviations (RSD, %) for all commodities and all fortification levels were well below 20%. The detailed values are shown in Table 4.1.2-10.
Reproducibility	The reproducibility of the method was not estimated as identical samples were not evaluated by an independent laboratory. However, based on the performance of the method, its reproducibility is expected to be good.
Conclusion	**The results show that 500M79 can be hydrolyzed to 500M04 (BF 500-5) with BASF method No. L0220/01. The limit of quantitation was defined by the lowest fortification level successfully tested which was 0.01 mg/kg in all matrices. Validation criteria with mean recoveries between 70-110%, relative standard deviation ≤ 20% and blank values ≤ 30% were always met. No separate confirmation technique was necessary as two parent-daughter ion transitions were monitored during LC-MS/MS determination and evaluated.**

Report:	CA 4.1.2/16 Jose W.F.P. de, 2015 a Validation of BASF Method Number L0076/09 for the determination of BAS 500 F and its metabolite 500M07 in citrus (whole fruit), dry beans (seeds), tomato (whole fruit), soybeans (grain) and wheat (grain) using HPLC-MS/MS and UPLC-MS/MS 2015/3004795
Guidelines:	Resolucao RDC No. 4 - ANVISA (18/01/2012)
GLP:	yes (certified by Instituto Nacional de Metrologia, Normalizacao e Qualidade Industrial - INMETRO, Rio de Janeiro, Brazil)

Principle of the methods

Residues of pyraclostrobin and its metabolite 500M07 are extracted from plant matrices with a mixture of methanol / water / HCl (2 mol/L) (70/25/5, v/v/v). After centrifugation, an aliquot is alkalized and partitioned against cyclohexane. Then, after evaporation to dryness, residues are dissolved in methanol/water (50/50, v/v) and filtered before injection. Final determination is performed by HPLC- and UPLC-MS/MS monitoring ion transition at m/z 388→194 (for quantitation) and at m/z 388→163 (for confirmation) for pyraclostrobin and at m/z 358→164 (for quantitation) and at m/z 358→132 (for confirmation) for its metabolite 500M07 in ESI positive mode. Analysis by HPLC is accomplished on a Thermo Scientific, Betasil C18 column applying a methanol-pure water gradient and analysis by UPLC is accomplished on an Acquity BEH C18 column applying an acetonitrile-pure water gradient. For both analyses 0.1% formic acid is used as modifier.

Recovery findings

Method validation acceptance criteria were fully met with mean recovery values between 70 and 110%. The relative standard deviations (RSD, %) for all commodities and all fortification levels were well below 20%. Method validation data are summarized in the tables below.

Table 4.1.2-20: Recovery results from method validation of pyraclostrobin and its metabolite 500M07 using the analytical method L0076/09 - HPLC

Linearity	Calibration points were distributed over a concentration range of 0.04 to 2.0 ng/mL. Calibration standards were prepared in methanol/water (50/50, v/v). At least six calibration points were used and individual calibration data was presented. Good linearity was observed in the range of 0.04 to 2 ng/mL (external reference standard, injected in triplicate) with a correlation coefficient ≥0.99.
Specificity	Highly selective determination of pyraclostrobin and its metabolite 500M07 using LC-MS/MS monitoring two mass transitions. There were no interferences at the retention time corresponding to BAS 500 F and its metabolite 500M07 in any of the control specimens of citrus, dry beans, tomato, soya bean and wheat grain (blank value < 30 % LOQ).
Matrix Effects	Analysis of matrix-matched standards and solvent standards showed no significant matrix effects, except for pyraclostrobin in soya beans. Therefore, solvent-based calibration standard solutions were used for quantification, except for pyraclostrobin in soya beans, where matrix-matched calibration standard solutions were used.
Limit of Quantification	The limit of quantitation (LOQ) representing the lowest validated fortification level with sufficient recovery and precision was 0.01 mg/kg for pyraclostrobin and its metabolite 500M07.
Limit of Detection	The LOD is set at 20% of the LOQ, or 0.002 mg/kg, which corresponds to 0.04 ng/mL for the measurement solution.
Repeatability	The relative standard deviations (RSD, %) for all fortification levels are below 20%.
Standard Stability	Pyraclostrobin and its metabolite 500M07 have been shown to be stable in methanol, the solvent used for preparation of stock solution, intermediate solutions and fortification standard solutions for up to 68 days, and in calibration solutions prepared by serial dilution of the intermediate solutions with methanol/water (50/50, v/v) for up to 34 days, when stored under refrigerator conditions.
Stability of Working Solutions	Pyraclostrobin and its metabolite 500M07 were shown to be stable after extraction with a mixture consisting of methanol/Milli-Q water/2 mol/L HCl solution (70/25/5, v/v/v) for a time interval of 0 to 7 days for all matrices, when stored under refrigerator conditions. The final volume dissolved with a mixture of methanol:Milli-Q water (50/50, v/v) was also investigated and pyraclostrobin and its metabolite 500M07 were shown to be stable for up to 7 days.
Reproducibility	Reproducibility of the method was not determined within this validation study.

Conclusion

The method L0076/09 uses highly specific LC-MS/MS for final determination of pyraclostrobin and its metabolite 500M07. The method is sufficiently validated for the commodities citrus (whole fruit), dry beans (seeds), tomato (whole fruit), soya bean (grain) and wheat (grain). Thereby, it could be demonstrated that the method fulfills the requirements with regard to linearity, specificity, repeatability, limit of quantitation and recoveries.

Food of animal origin

For proving the suitability of the method used in the cow feeding study, the common moiety method has been validated for further metabolites being identified in the livestock metabolism studies. Due to the high amounts found, specific attention was given to the metabolite 500M04 which occurs in amounts of max. 30% TRR (milk). The requirement to present validation data for key metabolites is included in the OECD Guidance Document on Pesticide Residue Analytical Methods (ENV/JM/MONO(2007)17). The principle of the common moiety approach from 2000 was kept; only the final quantitation technique (LC-MS/MS instead of GC-MS) was changed.

Report:	CA 4.1.2/17 Eilers B., Taraschewski I., 2014b Validation of analytical method 446/2 (L0058/03) for the determination of BAS 500 F (Reg.No. 304428) and its metabolites 500M04 (Reg.No. 298327) and 500M85 (Reg.No. 399530) in animal matrices by LC-MS/MS 2013/1400972

Note: This reference was erroneously not included in the study list of the application.

Principle of the method

BASF Method No. 446/2 (L0058/03):

After a partition into acetonitrile/iso-hexane the total residues were cleaved by boiling in aqueous sodium hydroxide to yield hydroxpyrazole(s), which can be extracted using ethyl acetate. After acidification and phase separation, the organic layer was taken. The final determination of 500M04 (BF 500-5) and 500M85 (BF 500-8) is performed by HPLC-MS/MS. Pyraclostrobin was determined as 500M04; for 500M04 the ion transitions *m/z* = 195 → 117 and *m/z* = 195 → 153 and for 500M85 the transitions *m/z* = 211 → 138 and *m/z* = 211 → 166 can be used for quantification.

Recovery findings

The method proved to be suitable for analysis of pyraclostrobin and its metabolites 500M04 (BF 500-5) and 500M85 (BF 500-8) in animal matrices at a limit of quantitation of 0.01 mg/kg.
In all matrices tested, the mean recovery values were between 62 and 95%. The detailed results are given in Table 4.1.2-14.

Table 4.1.2-22: Recovery results of BAS 500 F, 500M04 and 500M85

Matrix	Test Substance	Fortification level (mg/kg)	No. of tests	Average Recovery (%)	Rel. Standard Deviation (%)
Muscle	BAS 500 F	0.01, 0.1	10 (5 per level)	77.7 [1] / 77.5 [2]	4.3 [1] / 4.2 [2]
	500M04	0.01, 0.1	10 (5 per level)	86.8 [3] / 86.6 [4]	7.5 [3] / 7.0 [4]

[1] For transition *m/z* 195 → 117; [2] For transition *m/z* 195 → 153; [3] For transition *m/z* 195 → 117;
[4] For transition *m/z* 195 → 153; [5] For transition *m/z* 211 → 138; [6] For transition *m/z* 211 → 166

Linearity

The linearity of the HPLC-MS/MS detector was tested using six standard solutions at concentrations between 0.05 and 2.5 ng/mL. Standards were injected in duplicate and the response plotted against concentration. Linear correlations with coefficients ≥0.99 were obtained for pyraclostrobin and its metabolites 500M04 and 500M85.

Specificity

The method L0058/03 determines residues of pyraclostrobin and its metabolites 500M04 and 500M85 in animal matrices. Significant interferences (> 30% of LOQ) were not observed at the retention times and mass transitions considered for each analyte. HPLC-MS/MS, using two mass transitions, is a highly specific detection technique and therefore a confirmatory technique is not required.

Limit of Quantification

The limit of quantification (LOQ) was defined as the lowest fortification level successfully tested. The limit of quantification was 0.01 mg/kg for all analytes.

Repeatability

The relative standard deviations (RSD, %) for all commodities and all fortification levels were well below 20%. The detailed values are shown in Table 4.1.2-14.

Reproducibility

The reproducibility of the method was not estimated as identical samples were not evaluated by an independent laboratory. However, based on the performance of the method, its reproducibility is expected to be good.

Conclusion

The method for analysis of pyraclostrobin and its metabolites in animal matrices uses LC-MS/MS for final determination, which is a modern and highly specific technique. The limit of quantitation is 0.01 mg/kg for each analyte.
It could be demonstrated that method L0058/03 fulfils the requirements with regard to specificity, repeatability, limit of quantification and recoveries and is therefore applicable to correctly determine residues of pyraclostrobin and its metabolites 500M04 (BF 500-5) and 500M85 (BF 500-8) in animal matrices.

Method L0151/01 for the determination of pyraclostrobin in food of animal origin is also provided for enforcement purposes. The independent laboratory validation study is included in M-CA 4.2 (see CA 4.2/3). In order to allow an efficient enforcement of pyraclostrobin parent residues using up-to-date technology (LC-MS/MS) method L0151/01 replaces the previously submitted and evaluated LC-UV method 439/0. It was also validated in blood. As required in SANCO 825/00 and the relevant OECD guidance document, the validation data include a confirmatory technique (second transition).

Report:	CA 4.1.2/19 Hopf B., 2010a Validation of the analytical method L0151/01: Method for the determination of BAS 500 F (Reg.No. 304428) in animal matrices 2010/1018944
Guidelines:	EPA 860.1340: Residue Chemistry Test Guidelines - Residue Analytical Method, SANCO/825/00 rev. 7 (17 March 2004), SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Report:	CA 4.1.2/20 Hopf B., 2011a Technical procedure: Method for the determination of BAS 500 F (Reg.No. 304428) in animal matrices - BASF Method Number L0151/01 2011/1018046
Guidelines:	not applicable
GLP:	no

Principle of the method

BASF method L0151/01:

Pyraclostrobin (BAS 500 F) is extracted with acetonitrile. An aliquot of the extract is centrifuged and partitioned at alkaline conditions against cyclohexane. An aliquot of the organic phase is evaporated to dryness and dissolved in a mixture of acetonitrile and water. The final determination of pyraclostrobin is performed by HPLC-MS/MS, monitoring two parent-daughter ion transitions.

The limit of quantitation (LOQ) of the method for cow liver, kidney, fat, muscle, milk, skim milk, cream and hen egg is 0.01 mg/kg. The LOQ for swine blood is 0.01 mg/L.

Recovery findings

The recoveries of pyraclostrobin in fortified cow muscle, kidney, fat, liver, milk, skim milk, cream, hen egg and swine blood samples are summarized in Table 4.1.2-15. The recoveries of pyraclostrobin ranged from 79.0 to 101.6% at the transition *m/z* 388 → *m/z* 194 and 79.8 to 101.1% at the transition *m/z* 388 → *m/z* 163. The CV ranged from 2.1 to 5.7% and 2.2 to 6.4%, respectively.

The recovery results in liver and egg after storage of extract solutions and final volumes (at 10x LOQ) are summarized in Table 4.1.2-16. Extract solutions, which were stored for 7 days and further worked-up thereafter, showed that the analyte was stable under refrigerated conditions. Also the solutions prepared for the final determination by HPLC-MS/MS had been kept in the refrigerator for 7 days. Their re-analysis after storage led to quite comparable recoveries.

Results of stability investigations of calibration and fortification solutions are summarized in Table 4.1.2-17. The results show that fortification solutions in acetonitrile and calibration standards in acetonitrile/water (50/50, v/v) are stable over the investigated time of 30 days.

14	104.8	105.0	101.8	103.2
30	100.6	98.2	98.6	100.2
Stability of BAS 500 F in acetonitrile/water (0.25 ng/mL)				
0	0.254	0.257	0.254	0.254
8	0.255	0.262	0.254	0.259
14	0.261	0.257	0.254	0.252
30	0.249	0.248	0.247	0.246

Linearity	Good linearity was observed in the range of 0.025 to 1.0 ng/mL pyraclostrobin.
Specificity	No significant interferences from the sample matrix were reported.
Limit of quantitation	The limit of quantitation was defined by the lowest fortification level successfully tested, which was 0.01 mg/kg for the analyte in cow liver, kidney, fat, muscle, milk, skim milk, cream and hen egg and 0.01 mg/L for swine blood.
Repeatability	The coefficients of variation with respect to recoveries following fortifications at the limit of quantification were between 0.8 and 8.9%. The values obtained are indicative of the method having satisfactory repeatability.
Reproducibility	The reproducibility of the study is proven with the use in an independent laboratory validation. The summary of the ILV study is included under M-CA 4.2/3. Due to the fact, that for the fortified matrices recoveries and RSDs provided in context of the original report and the related ILV were always well in the ranges specified in the current guidelines (e.g. SANCO/825/00 rev. 8.1), it can be stated, that BASF method L0151/01 shows a good reproducibility.
Conclusion	**The results show that BASF method No. L0151/01 is suitable to determine residues of pyraclostrobin in matrices of animal origin such as cow muscle, kidney, fat, liver, milk, skim milk, cream as well as swine blood and hen egg. In all matrices tested, the mean recovery values were between 70 and 110%. The relative standard deviations (RSD, %) for all commodities and all fortification levels were well below 20%.** **Furthermore, it could be proven in this study that the analyte was stable in the extract solvent and in the solution used as final volume. Also the fortification solutions and calibration standards proved to be stable over a period of 30 days.**

In order to support the poultry feeding study, the common residue analytical method used for sample analysis is provided as supplemental information. The poultry feeding study was submitted to US EPA. Main purpose of the submission within this dossier is to allow a comprehensive evaluation of all basic studies. Due to the favourable residue behaviour in hen tissues and eggs observed within the metabolism study, the poultry feeding study has not been submitted in Europe before.

Report: CA 4.1.2/21
Malinsky D.S.,Riley M.E., 2000a
Method validation of BASF analytical method D9902: Method for determination of residues of BAS 500F and its metabolite BF 500-16 in hen tissues using LC/MS/MS
2000/5004
Guidelines: EPA 860.1340
GLP: yes
(certified by United States Environmental Protection Agency)

Principle of the method: *Method D9902*

Analytical Method D9902 was developed in order to determine residues of pyraclostrobin, metabolite BF 500-16 and related metabolites in hen tissues. Validation of the method was conducted on four hen tissues (egg, liver, muscle and fat). The method involves a common moiety approach for total residue determination. Pyraclostrobin and its metabolite BF 500-16 (500M77) are base hydrolyzed into metabolite BF 500-5 (500M04) and BF 500-9 (Reg.No. 402733, a derivative used for determination only and therefore not included in the metabolite list), respectively, so BF 500-5 and BF 500-9 are the final analytes of the method. Other compounds sharing the BF 500-5 and BF 500-9 moieties are also expected to undergo the same hydrolytic conversion to the analytes mentioned.

As a first step, egg, liver, and muscle samples are extracted as well as hydrolyzed in a sodium hydroxide solution. Fat samples are handled somewhat differently. Fat is first partitioned with hexane and acetonitrile before hydrolysis. After hydrolysis, an aliquot of the fat extract is purified by partitioning with ethyl acetate. For egg, liver and muscle aliquots after hydrolysis, samples are purified by ENV and silica solid phase extraction column chromatography. For all matrices, the final analytes BF 500-5 and BF 500-9 are measured by LC-MS/MS. The limit of quantitation of the method is 0.05 mg/kg for each analyte and for all matrices.

Recovery Findings

Good recoveries of pyraclostrobin were obtained in the four hen matrices over the fortification range tested (0.05 mg/kg and 0.10 mg/kg). Generally, recoveries for the parent were higher, averaging near 100% for all matrices. For the BF 500-16, recoveries were lower, averaging between 58-71% for the various matrices, but the deviation between samples was quite low. The overall average recoveries of pyraclostrobin and BF 500-16 in hen matrices were 103%±17 (n=32) and 65%±10 (n=32), respectively. Detailed results are shown in Table 4.1.2-18.

Table 4.1.2-26: Recovery results from method validation of BAS 500 F and BF 500-16 in animal matrices

Animal	Commodity	Test Substance	Fortification level (mg/kg)	No. of tests	Average recovery (%)	Rel. Standard Deviation (%)
Hen	Egg	BAS 500 F	0.05; 1.0	8 (4 per level)	104	16
		BF 500-16	0.05; 1.0	8 (4 per level)	62	11
	Liver	BAS 500 F	0.05; 1.0	8 (4 per level)	104	24
		BF 500-16	0.05; 1.0	8 (4 per level)	71	8
	Muscle	BAS 500 F	0.05; 1.0	8 (4 per level)	110	12
		BF 500-16	0.05; 1.0	8 (4 per level)	58	7
	Fat	BAS 500 F	0.05; 1.0	8 (4 per level)	103	17
		BF 500-16	0.05; 1.0	8 (4 per level)	65	15

Linearity

Good linearity was observed in the range of 2.5 to 25 pg/µL for BF 500-5 and BF 500-9 (external reference standard).

Specificity

The method determines parent pyraclostrobin and its metabolite BF 500-16 in hen tissues and eggs. There were no known interferences from plant components or from reagents, solvents and glassware used.

Limit of Quantification

The limit of quantification was defined by the lowest fortification level successfully tested, which was 0.05 mg/kg for each analyte in all sample materials.

Repeatability

The relative standard deviations for pyraclostrobin and BF 500-16 obtained from fortified egg, liver, muscle and fat samples were between 12 - 24% and 7 -15%, respectively. The detailed values are shown in Table 4.1.2-18.

Reproducibility	The reproducibility of the method was not estimated as identical samples were not evaluated by an independent laboratory. However, based on the performance of the method, its reproducibility is expected to be good.
Conclusion	**The method D9902 for analysis of pyraclostrobin and its metabolite BF 500-16 (500M77) uses HPLC-MS/MS for final determination, which is a modern and highly specific technique. The limit of quantitation is 0.05 mg/kg for each analyte.** **It could be demonstrated that the method fulfils the requirements with regard to specificity, repeatability, limit of quantitation and recoveries.**

(f) Methods in soil, water, sediment, feed and any additional matrices used in support of ecotoxicology studies

Methods for concentration control are reported, where necessary, along with the respective ecotoxicological studies.

(g) Methods in water, buffer solutions, organic solvents and any additional matrices resulting from the physical and chemical properties tests

Where necessary, these methods are reported along with the respective studies.

CA 4.2 Methods for post-approval control and monitoring purposes

(a) Methods for the determination of all components included in the monitoring residue definition as submitted in accordance with the provision of point 6.7.1 in order to enable Member States to determine compliance with established maximum residue levels (MRLs); they shall cover residues in or on food and feed of plant and animal origin

Based on the residue definition for MRL setting and enforcement, residue analytical methods are required for the parent molecule pyraclostrobin in both, food of plant and animal origin.

The enforcement methods evaluated in the previous Annex I inclusion process were considered as suitable. They are supported by appropriate extractability investigations performed with sample material generated in course of the metabolism studies in crops and livestock.

The following conclusion on residue analytical methods for food of plant and animal origin was derived from the EFSA Reasoned Opinion on MRLs (European Food Safety Authority; Review of the existing maximum residue levels (MRLs) for pyraclostrobin according to Article 12 of Regulation (EC) No 396/2005. EFSA Journal 2011;9(8):2344. [92 pp.] doi:10.2903/j.efsa.2011.2344. Available online: www.efsa.europa.eu/efsajournal).

Analytical methods for residues (Annex IIA, point 4.2, enforcement purposes)

Food/feed of plant origin (principle of method and LOQ for methods for monitoring purposes)	LC-MS/MS	0.02 mg/kg (hops, high oil content, high water content, acidic and dry commodities)
	HPLC-UV	0.02 mg /kg (high fat content, acidic and dry commodities)
Food/feed of animal origin (principle of method and LOQ for methods for monitoring purposes)	HPLC-UV	0.01 mg/kg (milk) 0.05 mg/kg (muscle, liver, kidney, fat, egg)

In addition, the QuEChERS method (determination using GC-MS and/or LC-MS/MS) is sufficiently validated at the LOQ of 0.01 mg/kg for the determination of pyraclostrobin in plant matrices. The use of the multi residue method for the determination of pyraclostrobin residues is widely published in the Internet.
In order to demonstrate the use of the QuEChERS method as additional enforcement method, two articles from literature are exemplarily summarized in this chapter. The first publication is describing the application of the method in coffee (CA 4.2/2). In the second publication comparative extractability investigations are described (CA 4.2/4). Both publications were not mentioned in the application for the renewal of approval.

Food of plant origin

Pyraclostrobin (BAS 500 F)

In context of the re-evaluation of existing MRLs, EFSA identified the lack of an enforcement method for coffee as data gap. For proving that the residue analytical method 421/0, which is recommended as enforcement method in other plant matrices, is suitable for coffee and tea, the subsequent independent laboratory validation study has been performed. Due to their matrix constituents, coffee and tea are considered as matrices which are difficult to analyze.

Report:	CA 4.2/1 Scherthan D., 2011a Independent laboratory validation of the BASF analytical method 421/0: Method for determination of BAS 500 F and its metabolite BF 500-3 residues in plant matrices using LC/MS/MS 2011/1268146
Guidelines:	EPA 860.1340: Residue Chemistry Test Guidelines - Residue Analytical Method, SANCO/825/00 rev. 8.1 (16 November 2010), SANCO/3029/99 rev. 4 (11 July 2000), EEC 91/414 Annex II (Part A Section 4), EEC 91/414 Annex III (Part A Section 5), EEC 96/46 (16.07.1996)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the method

BASF method 421/0

Pyraclostrobin and its metabolite BF 500-3 (500M07) were extracted from plant matrices (green coffee and green tea) using a mixture of methanol/water 70/30. A 0.5% aliquot of the extract was removed and cleaned by C18; Polar Plus micro-column. The final determination of BAS 500 F and its metabolite BF 500-3 was performed by HPLC-MS/MS.

Recovery findings

The recoveries of pyraclostrobin and its metabolite BF 500-3 in fortified green tea and green coffee are summarized in Table 4.2-1 and Table 4.2-2. The recoveries of pyraclostrobin ranged from 79.3 to 86.6% at the transition *m/z* 388 → *m/z* 194 and at the transition *m/z* 388 → m/z 163. The CV ranged from 2.9 to 5.6% and 3.0 to 5.9%, respectively.

Table 4.2-1: Recoveries of pyraclostrobin in plant matrices

Matrix	Fortification level (mg/kg)	Transition *m/z* 388 → *m/z* 194		Transition *m/z* 388 → *m/z* 163	
		Mean recovery (%)	CV (%)	Mean recovery (%)	CV (%)
Green tea	0.02 (n=5)	79.9	8.6	78.9	8.9
	0.2 (n=5)	80.3	2.6	79.6	2.8
	Overall Mean (n=10)	**80.1**	**5.6**	**79.3**	**5.9**
Green coffee	0.02 (n=5)	87.7	4.0	87.0	4.4
	0.2 (n=5)	85.4	1.8	85.2	1.6
	Overall Mean (n=10)	**86.6**	**2.9**	**86.1**	**3.0**

Table 4.2-2: Recoveries of BF 500-3 (500M07) in plant matrices

Matrix	Fortification level (mg/kg)	Mean recovery (%)	CV (%)
Transition *m/z* 358 → *m/z* 164			
Green tea	0.05 (n=5)	72.6	4.5
	0.5 (n=5)	97.0	7.2
	Overall Mean (n=10)	**84.8**	**5.9**
Green coffee	0.05 (n=4)	84.8	5.7
	0.5 (n=5)	84.2	8.6
	Overall Mean (n=9)	**84.5**	**7.2**
Transition *m/z* 358 → *m/z* 132			
Green tea	0.05 (n=5)	87.5	9.6
	0.5 (n=5)	86.8	1.3
	Overall Mean (n=10)	**87.2**	**5.5**
Green coffee	0.05 (n=5)	81.7	10.8
	0.5 (n=5)	89.4	1.4
	Overall Mean (n=10)	**85.6**	**6.1**

Linearity	Good linearity was observed in the range of 0.5 to 5.0 ng/ml pyraclostrobin. Coefficients of determination (R^2) were in the linearity experiments always higher than 0.999.
Specificity	Due to matrix effects, metabolite BF 500-3 was tested by 0.05 mg/kg at transition *m/z* 358 → *m/z* 132.
Limit of quantitation	The limit of quantitation was defined by the lowest fortification level successfully tested which was 0.02 mg/kg except of the metabolite BF 500-3, which was tested by 0.05 mg/kg at transition *m/z* 358 → *m/z* 132 due to matrix effects.
Repeatability	The coefficients of variation with respect to recoveries following fortifications at the limit of quantification were between 2.9 and 6.1%. The values obtained are indicative of the method having satisfactory repeatability.
Reproducibility	In context of this ILV study, the reproducibility of the BASF method 421/0 was tested by a laboratory not involved in method development. As can be seen from the results, a high reproducibility was achieved.
Conclusion	**The results show that BASF method No. 421/0 is suitable to determine pyraclostrobin and its metabolite BF 500-3 (500M07) in the plant matrices green coffee and green tea at a limit of quantitation of 0.02 mg/kg (except for the metabolite BF 500-3, which was tested by 0.05 mg/kg at transition 358 → 132 due to matrix effects).**

Report: CA 4.2/2
Dias C.M. et al., 2013a
Multi-residue method for the analysis of pesticides in arabica coffee using liquid chromatography/tandem mass spectrometry
2014/1145909
Guidelines: none
GLP: no

This entry is taken from public literature and was not included in the study list of the application.

Principle of the method A multi-residue method for the determination of 123 pesticides (including isomers) in green coffee beans was developed.
The method includes a modified acetonitrile-based extraction procedure (modified QuEChERS) and C18 d-SPE clean-up. The final determination was performed by UPLC-MS/MS with a triplequadrupole instrument in the MRM mode. The column used was a Shim-Pack ODS XR-II, the eluent system consisted of 2 mobile phases (A: 10 mmol/L ammonium acetate containing 0.01% formic acid & B: methanol) which were used applying gradient elution. The oven temperature reported was 60°C.

Recovery findings For all analytes, the recoveries were in the range of 70.7 and 108.8% at fortification levels between 0.01 and 0.1 mg/kg. No detailed information was given for pyraclostrobin.

Linearity Good linearity ($R^2 \geq 0.992$) was observed in the range of 0.01 to 0.1 mg/kg for all analytes.

Specificity The method was excellent, allowing unequivocal identification of the target pesticides in green coffee bean extracts. However, despite the clean-up step applied, high matrix effects were still observed, thus requiring matrix-matched standard calibration for reliable quantification in routine analysis.

Limit of Quantification The limits of quantification ranged from 0.11 to 40.12 µg/kg for all analytes. For pyraclostrobin the limit of quantification was at 0.62 µg/kg $[M + H]^+$ and at 1.36 µg/kg $[M + NH_4]^+$.

Repeatability The relative standard deviations (RSD, %) for all analytes analysed and all fortification levels were well below 20%.

Reproducibility The reproducibility of the method was not estimated as identical samples were not evaluated by an independent laboratory.

Conclusion **The method for analysis, representing a modified QuEChERS method, uses LC-MS/MS for final determination, which is a modern and highly specific technique. Considering the good results obtained in this study with regard to all parameters studied, the proposed method could be used for the quantification of multi-residue pesticides including pyraclostrobin in coffee and is promising for use in routine monitoring.**

Food of animal origin

Pyraclostrobin (BAS 500 F)

In order to allow an efficient enforcement of pyraclostrobin parent residues using up-to-date technology (LC-MS/MS) method L0151/01 replaces the previously submitted LC-UV method 439/0. It was also validated in blood. As required in SANCO 825/00 and the relevant OECD guidance document, the validation data include a confirmatory technique (second transition).

Report:	CA 4.2/3 Schacherl A., 2010a Independent laboratory validation (ILV) of an analytical method for the determination of BAS 500 F (Reg.No. 304428) in animal matrices 2010/1123694
Guidelines:	SANCO/825/00 rev. 7 (17 March 2004), OECD Guidance Document on Pesticide Residue Analytical Methods (ENV/JM/MONO(2007)17 - 13-Aug-07
GLP:	yes (certified by Umweltministerium Baden-Wuerttemberg, Stuttgart)

Principle of the method

BASF method L0151/01 (ILV):

Pyraclostrobin (BAS 500 F) is extracted with acetonitrile. An aliquot of the extract is centrifuged and partitioned at alkaline conditions against cyclohexane. An aliquot of the organic phase is evaporated to dryness and dissolved in a mixture of acetonitrile and water. The final determination of pyraclostrobin is performed by HPLC-MS/MS, monitoring two parent-daughter ion transitions.

The limit of quantitation (LOQ) of the method for cow liver, kidney, fat, muscle, milk, skim milk, cream and hen egg is 0.01 mg/kg. The LOQ for swine blood is 0.01 mg/L.

Recovery findings

The recoveries of pyraclostrobin in fortified bovine muscle, cow fat, kidney, milk, hen egg and swine blood samples are summarised in Table 4.2-3. The recoveries of pyraclostrobin ranged from 72 to 104% at the transition *m/z* 388 → *m/z* 194 and at the transition *m/z* 388 → *m/z* 163. The CV ranged from 3 to 5% and 1 to 5%, respectively.

The results of the matrix effect evaluation are summarized in Table 4.2-4, and indicate that no significant matrix effect was present for meat, fat, kidney, milk and blood. For egg the matrix effect was significant. To compensate ion enhancement or suppression effects for the analysis of egg, bracketed standards prepared in blank matrix were used.

The measured concentration of the stored matrix pyraclostrobin standards was for fat 98% and for egg 102% of the initial amount. Therefore, pyraclostrobin can be regarded as stable in final egg and fat sample extracts for at least 3 days.

Table 4.2-3: Recoveries of pyraclostrobin in animal matrices

Matrix	Fortification level (mg/kg)	n	Transition 388 → 194*		Transition 388 → 163**	
			Mean recovery (%)	CV (%)	Mean recovery (%)	CV (%)

	0.01 + 0.1	**10**	**72**	**4**	**73**	**4**

* used for quantification; ** used for confirmation

Table 4.2-4: Evaluation of matrix effects for pyraclostrobin analysis

Matrix	Nominal concentration (ng/mL)	Mean determined concentration (ng/mL)	% of nominal	Matrix effect
Meat	0.5	0.511	102.2	2.2
	5	5.06	101.1	1.1
Fat	0.5	0.522	104.4	4.4
	5	4.94	98.8	-1.2
Kidney	0.5	0.480	96.0	-4.0
	5	5.01	100.1	0.1
Milk	0.5	0.512	102.4	2.4
	5	5.09	101.8	1.8
Egg	0.5	0.362	72.4	-27.6
	5	3.15	63.0	-37.0
Blood	0.5	0.504	100.8	0.8
	5	4.99	99.8	-0.2

Linearity

Good linearity was observed in the range of 0.02 to 100 ng/mL pyraclostrobin. Coefficients of determination (R^2) were in the linearity experiments always higher than 0.999.

Specificity

No significant interferences from the sample matrices were reported.

Limit of quantitation

The limit of quantitation was defined by the lowest fortification level successfully tested which was 0.01 mg/kg for the analyte in meat, fat, kidney, milk and hen egg and 0.01 mg/L for swine blood.

Repeatability

The coefficients of variation with respect to recoveries following fortifications at the limit of quantification were between 1 and 5%. The values obtained are indicative of the method having satisfactory repeatability.

Reproducibility

The reproducibility of the BASF method L0151/01 was estimated in context of this ILV. Due to the fact, that for the fortified matrices recoveries and RSDs provided in context of the original report and the related ILV were always well in the ranges specified in the current guidelines (e.g. SANCO/825/00 rev. 8.1), it can be stated, that BASF method L0151/01 shows a good reproducibility.

Conclusion

The results show that BASF method No. L0151/01 is suitable to determine residues of pyraclostrobin in animal matrices such as muscle, fat, kidney, milk, hen egg and swine blood at a limit of quantitation of 0.01 mg/kg (for swine blood 0.01 mg/L).
No significant matrix effect was present for meat, fat, kidney, milk and blood. For egg the matrix effect was significant. It was compensated using bracketed standards.

Comparison of extractability using different extraction methods

Report: CA 4.2/4
Lagunas-Allue L. et al., 2012a
Comparison of four extraction methods for the determination of fungicide residues in grapes through gas chromatography-mass spectrometry
2012/1366723
Guidelines: none
GLP: no

This entry is taken from public literature and was not included in the study list of the application.

Four extraction methods were assessed and compared for the analysis of pyraclostrobin in grape samples. Red grapes (variety: Tempranillo) were chopped into small pieces, homogenized using a crusher and spiked with pyraclostrobin prior to extraction.

Principle of the methods

Matrix solid phase dispersion (MSPD):
The sample was mixed with C_{18} and transferred to a column filled with adsorbent (silica). Dichloromethane/ethyl acetate (1:1, v:v) was added for elution. The eluent was concentrated and subjected to GC–MS, SIM analysis where Tetradifon (used as internal standard) was added.

Microwave assisted extraction (MAE):
MAE experiments were performed using an MARS-microwave sample preparation unit equipped with a solvent detector. Samples were extracted with a hexane/acetone (1:1, v:v) mixture in a Teflon-lined extraction vessel under high temperature. Tetradifon was added after extraction and samples were analyzed by GC–MS, SIM.

Soli-liquid extraction (SLE) using ethyl acetate:
The samples were extracted with ethyl acetate and then centrifuged. The organic phase was dried and the extract was concentrated in the TurboVap®. Tetradifon was added and the sample was analyzed by GC–MS, SIM.

	QuECheRS method: Homogenized samples were extracted with acetonitrile (including 1.0% HAc, v:v). An aliquot of the extract was centrifuged and clean-up was achieved with dispersive solid-phase extraction (d-SPE) method. Tetradifon was added and the sample was analyzed by GC–MS, SIM. All samples obtained after applying the different extraction procedures were analyzed by GC-MS, working in the selected ion monitoring mode (SIM). The GC column used was a HP-5MS with a length of 30 m, an inner diameter of 0.25 mm and a film thickness of 0.25 µm. Injection temperature was at 250°C, Helium was used as carrier gas at constant flow rate of 1.5 mL/min. For pyraclostrobin, the target ion was *m/z* 132 and qualifier ions were *m/z* 164 and *m/z* 325.
Recovery findings	For pyraclostrobin, average recoveries were > 80% at fortification levels of 0.010 mg/kg and 0.05 mg/kg for all methods tested.
Linearity	Good linearity (≥0.994) was observed in the range of the calculated LOQ to 0.1 mg/kg for all analytes and all methods tested.
Specificity	There were significant differences between the slopes of the regression lines obtained in solvent and grape extracts for pyraclostrobin except for QuEChERS and SLE method. Matrix effects were not reported.
Limit of Quantification	The limits of quantification for pyraclostrobin were in the same dimension for all methods tested (MAE: 0.0058 mg/kg, MSPD: 0.0087 mg/kg, QuEChERS: 0.0143 mg/kg and SLE: 0.0136 mg/kg).
Repeatability	The relative standard deviations (RSD, %) for pyraclostrobin were similar and well below 20% for all the methods tested (MAE: 6.6%, MSPD: 6.7%, QuEChERS: 10.1%, Ethyl acetate: 8.3% at a fortification level of 0.05 mg/kg).

Comparison of the four methods

Regression lines

There were no significant differences between the extraction methods for pyraclostrobin confirmed by the slopes and intercepts of the regression line (each point on this graph represented a single sample analyzed by two separate methods) close to 0 and 1 at 10 different fortification levels. Pyraclostrobin showed a good agreement between all the methods. The coefficients of determination (R^2) for pyraclostrobin ranged from 0.97 to 0.99 mg/kg, indicating that after applying one of the four extraction methods only slightly different residues will be measured.

Analysis of real samples

Statistical tests showed that there were no significant differences between the methods for pyraclostrobin, when grape samples collected from the local markets were analyzed.

Conclusion

For pyraclostrobin, the methods showed good results with regard to the parameters studied. No significant differences among the four methods for the extraction of pyraclostrobin were found.
It can be stated, that QuEChERS method is a suitable method to determine pyraclostrobin in plant matrices.

(b) Methods for the determination of all components included for monitoring purposes in the residue definitions for soil and water as submitted in accordance with the provisions of point 7.4.2

According to M-CA 7.4.2 the proposal for the definition of residues for environmental matrices for pyraclostrobin is parent-only. No special analytical methods for monitoring purposes were developed. The methods described under M-CA 4.1.2 for soil and water for risk assessment can be used also for monitoring purposes.

According to SANCO/825/00 rev. 8.1, an independent laboratory validation was performed for pyraclostrobin and its metabolites in drinking- and surface water.

Water

Pyraclostrobin (BAS 500 F)

The purpose of the study was to demonstrate that BASF Analytical Method L0182/02, "Determination of BAS 500 F (Pyraclostrobin) and its metabolites BF 500-5 (Reg. No. 298327), BF 500-12 (Reg. No. 412053), BF 500-11 (Reg. No. 411847), BF 500-13 (Reg. No. 412785), BF 500-14 (Reg. No. 413038) and BF 500-15 (Reg. No. 377613) in drinking- and surface- water by LC/MS/MS", could be performed successfully at an outside facility with no prior experience using the method.

~~**Report:**~~	~~CA 4.2/5~~ ~~Rutt D.,Jones G., 2014b~~ ~~Independent Laboratory Validation of BASF Method Number L0182/02: Determination of BAS 500 F (Pyraclostrobin) and its metabolites BF 500-5 (Reg. No. 298327), BF 500-12 (Reg. No. 412053), BF 500-11 (Reg. No. 411847), BF 500-13 (Reg. No. 412785), BF 500-14 (Reg. No. 413038) and BF 500-15 (Reg. ~~**Guidelines:**~~	~~EPA 850.6100, SANCO/825/00 rev. 8.1 (16 November 2010)~~
~~**GLP:**~~	~~yes~~ ~~(certified by United States Environmental Protection Agency)~~

Note: This report is already covering metabolite BF 500-5 (500M04). A separate report as included in the study list of the application is consequently not submitted.

Report:	CA 4.2/5 Bianca C.M., 2015 a Independent laboratory validation of BASF method L0182/02: BAS 500 F (Pyraclostrobin) and its metabolites BF 500-5 (Reg.No. 298327), BF 500-12, BF 500-11, BF 500-13, BF 500-14, BF 500-15 in ground- and surface-water by LC/MS/MS 2015/7001873
Guidelines:	EPA 850.6100, SANCO/825/00 rev. 8.1 (16 November 2010)
GLP:	yes (certified by United States Environmental Protection Agency)

Note: After dossier submission in July 2014 a new amended report became available, which is replacing BASF DocID 2014/7000022.

Principle of the method

A 50 mL water sample aliquot is extracted by acidification with formic acid followed by solid phase extraction on a C18 SPE column. Residues are then eluted twice with ethyl acetate. The extracts are concentrated to dryness and reconstituted in acetonitrile/water (20/80, v/v).
Final determination is performed by LC-MS/MS using an Atlantis T3 analytical column and a gradient mixture of water – acetonitrile with formic acid as modifier at a flow rate of 500 µL/min. Detection is accomplished using positive ion electrospray ionization tandem mass spectrometry (MS/MS-ESI+) monitoring two mass transitions for quantification and confirmation: 389 → 195 and 389 → 164 for pyraclostrobin, 196 → 154 and 196 → 118 for 500M04, 370 → 194 and 370 → 278 for 500M59, 278 → 194 and 278 → 149 for 500M60, 248 → 132 and 248 → 164 for 500M62, 389 → 242 and 389 → 301 for 500M76 and 177 → 135 and 177 → 132 for 500M78.

Recovery findings

Method L0182/02 was proven to be suitable to determine residues of pyraclostrobin and its metabolites 500M04, 500M59, 500M60, 500M62, 500M76 and 500M78 to the respective limit of quantification in surface water. For drinking water, the method was validated as well for all analytes, with the exception of analyte 500M78. However, as only the parent molecule is relevant for the residue definition for enforcement in drinking water for Europe, 500M78 could be eliminated in the ILV study in the drinking water. The mean recovery values of the validation experiments were between 70 and 120%, which fulfills the legal requirements for mean recovery values. The detailed results are given in Table 4.2-5.

Table 4.2-5: Results of the method validation for the determination of pyraclostrobin and its metabolites in drinking water

Linearity	Linear regression was used for calibration using six calibration levels. Matrix-matched standards were used for calibration. For pyraclostrobin, good linearity ($r^2 \geq 0.99$) was observed in matrix-matched standards in the range of 0.005 ng/mL to 0.1 ng/mL in drinking and surface water. For metabolites 500M04, 500M59, 500M60, 500M62 and 500M76, good linearity ($r^2 \geq 0.99$) was observed in the range of 0.05 ng/mL to 1.0 ng/mL in drinking and surface water. For metabolite 500M78, good linearity ($r^2 \geq 0.98$) was observed in matrix-matched standards in the range of 0.05 ng/mL to 1.0 ng/mL in surface water.
Specificity	The method L0182/02 allows the specific determination of pyraclostrobin and its metabolites 500M04, 500M59, 500M60, 500M62, 500M76 and 500M78 in water. Due to the high selectivity and specificity of LC-MS/MS an additional confirmatory technique was not necessary. The tested untreated water samples showed no significant interferences (< 30%) at the retention time of the analytes.
Matrix Effects	Matrix-matched standards were used for the calibration of validation experiments.
Limit of Quantification	The method has a limit of quantification (LOQ) of 0.003 µg L^{-1} for pyraclostrobin and 0.03 µg L^{-1} for each metabolite.
Limit of Detection	The limit of detection (LOD) is estimated as 20% of the LOQ with 0.0006 µg/L for pyraclostrobin and 0.006 µg/L for each metabolite.
Standard Stability	The stability has been investigated within the original validation study and has not been considered within the ILV.
Stability of Working Solutions	The stability has been investigated within the original validation study and has not been considered within the ILV.
Repeatability	The relative standard deviations (RSD, %) for all fortification levels were below 20%.
Reproducibility	In context of this ILV study, the reproducibility of this analytical method was estimated. As can be seen from the results, a high reproducibility was determined.

Conclusion

The method L0182/02 for the analysis of pyraclostrobin (BAS 500 F) and its metabolites 500M04, 500M59, 500M60, 500M62, 500M76 and 500M78 in surface water and drinking water used HPLC-MS/MS for final determination, with a limit of quantification of 0.003 µg L^{-1} for pyraclostrobin and 0.03 µg L^{-1} for each metabolite.
It was demonstrated that the method L0182/02 fulfills the requirements with regards to specificity, repeatability, limit of quantification, and recoveries and is therefore applicable to correctly determine pyraclostrobin and metabolites 500M04, 500M59, 500M60, 500M62 and 500M76 in drinking and surface water. Additionally, method L0182/02 was proven to be suitable to determine residues of metabolite 500M78 in surface water.

(c) Methods for the analysis in air of the active substance and relevant breakdown products formed during or after application, unless the applicant shows that exposure of operators, workers, residents or bystanders is negligible

A validated analytical method for air is described in CA 4.1.2/6.

However, as pyraclostrobin has a very low vapour pressure of 2.6 x 10^{-8} Pa (for details see M-CA 2.2), it is considered to be non-volatile. Consequently, inhalation exposure of operators, workers, residents or bystanders to vapours of pyraclostrobin is negligible. Further information can be found in M-CP 7.2.

(d) Methods for the analysis in body fluids and tissues for active substances and relevant metabolites

Independent laboratory validation data for the determination of pyraclostrobin in blood are provided above (see CA 4.2/3, BASF Doc ID 2010/1123694).

CA 5 TOXICOLOGICAL AND METABOLISM STUDIES ON THE ACTIVE SUBSTANCE

CA 5.1 Studies on Absorption, Distribution, Metabolism and Excretion in Mammals

An overview on the metabolites being identified in the rat metabolism studies from 1999 and 2014 is provided in the table below. Additionally, the table includes also those metabolites which have been detected in the *in-vitro* comparison study (BASF DocID 2014/1001562) and the rat metabolism study where metabolite 500M106 was administered to rats (BASF DocID 2015/1198492).

In order to increase the readability of the table, information from other test systems have been deleted. If not stated otherwise in the occurrence column, the metabolites indicated for rats have been found in the corresponding *in-vivo* study (BASF DocID 1999/11781). Metabolites which were (re)confirmed in the new *in-vivo*-plasma study (BASF DocID 2014/1136557) are specifically indicated. If not indicated otherwise, pyraclostrobin was used as test item.

Table 5.1-1: Notations of parent and metabolites of pyraclostrobin

CA 5.1.1 Absorption, distribution, metabolism and excretion by oral exposure

Studies submitted in context of the Annex I inclusion according to Directive 91/414

In order to provide information on the adsorption, distribution, metabolism and excretion in rats, two studies were provided for the previous Annex I listing process and are considered as peer reviewed and still valid. Due to the importance of the studies for dietary exposure assessment, but also for allowing a direct comparison between these "old" and newly performed studies, relevant information of these studies is summarized below based on the previous Annex II dossier.

- In study BASF DocID 1998/10997, the absorption, distribution, elimination and biokinetics of ^{14}C-BAS 500 F in male and female Wistar rats were investigated at dose levels of 5 and 50 mg/kg bw. The experiments were mainly performed with ^{14}C tolyl-labelled BAS 500 F. An additional experiment investigating the balance and excretion pattern was performed with ^{14}C-BAS 500 F labelled in the chlorophenyl-ring. Samples from this study were transferred to the metabolism laboratory for pathway elucidation.
- The purpose of the second study (BASF DocID 1999/11781) was the identification and characterization of metabolites in rats. In context of this study, further dosing experiments were performed.

Dosing and dose groups

In Table 5.1.1-1, details on dosing are provided for those experiments, which were finally used for metabolism investigations. Besides these experiments, animals of both sexes were dosed at 5 and 50 mg/kg bw for the determination of pharmacokinetic parameters in blood and plasma (10 time points after dosing: 0.5 – 120 hours) and for tissue distribution (four time points).
Additional samples were also collected from animals of dose groups B, C and D for deriving information on the potential presence of volatile metabolites (only D), but also radioactivity levels in further organs (heart, liver, spleen, bone, skin, lung, ovaries, bone marrow, carcass, muscle, kidney, testes, brain, pancreas, uterus, adipose tissue, stomach, thyroid glands, adrenal glands, blood, GIT).

Table 5.1.1-1: Details on dosing in studies BASF DocID 1998/10997 and 1999/11781

Dose group (Designation)	Nominal dose [mg/kg bw]	Label	Number of doses	Number of animals [per label] *	Samples investigated in the study
B	5	tolyl	1	4 + 4	urine, feces
C	5	tolyl	14 +1	4 + 4	urine, feces
D	50	tolyl, chlorophenyl	1	4 + 4	urine, feces
DX	50	tolyl, chlorophenyl	1	10 + 10	urine, feces
R	5	tolyl	1	7 + 5	bile
S	50	tolyl	1	4 + 8	bile
V	5	tolyl, chlorophenyl	1	4 + 4	plasma, liver, kidney (8 hours after dosing)
W	50	tolyl, chlorophenyl	1	4 + 4	plasma, liver, kidney (8 hours)

* male + female

Excretion balance

During the first 48 hours after single oral dosing with 5 or 50 mg/kg bw (tolyl-label, dose groups B and D), 10 - 13% of the administered radioactivity was excreted in urine and 74 - 91% in feces. After 120 hours, the total amount of radioactivity excreted in urine was in the range of 11 - 15% and in feces in the range of 81 - 92% of the administered dose. Radioactivity remaining in tissues and organs 120 hours post dosing was less than 1 µg eq/g at a dose level of 50 mg/kg bw and less than 0.1 µg eq/g at a dose level of 5 mg/kg bw.

An excretion pattern as described above was also obtained after repeated oral administration (14 x unlabelled at 50 mg/kg bw, 1 x labelled at 5 mg/kg bw, dose group C) and after single oral administration of 50 mg/kg bw of the chlorophenyl-labelled test substance (dose group D). After single oral administration of 50 mg/kg bw, no radioactivity was detectable in the exhaled air with either label used. The overall recovery of radioactivity was in the range of 91.4 - 105.0% in all experiments (see Table 5.1.1-2 and Table 5.1.1-3).

Within 48 hours after administration of 5 or 50 mg/kg bw of ^{14}C-BAS 500 F (dose groups R and S), approximately 35 - 38% of the administered radioactivity was excreted via bile. As compared to the radioactivity excreted in the feces 48 hours after single oral administration (about 74 - 91%), the 0 - 48 hours biliary excretion (about 35 - 38%) is considerably lower. From this comparison, it may be concluded that not all of the administered test substance becomes systemically available, i.e. absorption is incomplete. If it is assumed that the amount of radioactivity excreted via bile and urine represents the bioavailable amount of ^{14}C-BAS 500 F, the **bioavailability is approximately 50%**.

Table 5.1.1-2: Excretion balance at 48 h post dosing, including biliary excretion (in % of dose)

Pharmacokinetics

In rats exposed to a single oral dose of 50 mg/kg bw of ^{14}C-BAS 500 F, the plasma concentration/time curve showed 2 peaks. The first plasma peak was reached 0.5 hour post dosing with peak levels of 1.96 µg eq/g in males and 2.62 µg eq/g in females. At the second plasma peak occurring after 8 hours in males and after 24 hours in females, plasma levels were 2.04 and 1.77 µg eq/g in males and females, respectively. After the second peak, plasma concentrations declined to levels of 0.08 µg eq/g in males and 0.05 µg eq/g in females at 120 hours post dosing. Plasma levels declined monophasically with half-lives of 20.7 and 19.7 hours in males and females, respectively.

In rats exposed to a single oral dose of 5 mg/kg bw of ^{14}C-BAS 500 F, the plasma concentration/time curve also showed 2 peaks. The first plasma peak was reached after 1.0 hour in males and 0.5 hour in females with peak levels of 0.432 µg eq/g and 0.537 µg eq/g, respectively. At the second plasma peak occurring after 8 hours, plasma levels were 0.458 and 0.353 µg eq/g in males and females, respectively. After the second peak, plasma concentrations declined biphasically to levels of 0.006 µg eq/g in males and 0.005 µg eq/g in females at 120 hours post dosing. The initial half-life was found to be 9.0 hours in males and 10.5 hours in females. Terminal half lives in male and female rats were 37.4 and 31.6 hours, respectively.

Increasing the dose level by a factor of about 10 resulted in an increase of the AUC-values by a factor of 9.9 in males and 7.6 in females. At both dose levels, a similar course of the radioactivity with time is found for blood and for plasma. During the first 24 hours post dosing, lower concentrations of radioactivity were found in blood indicating that major parts of the radioactivity are in plasma and not bound to cellular blood constituents.

Table 5.1.1-4: Pharmacokinetic parameter

	5 mg/kg bw		50 mg/kg bw	
	males	**females**	**males**	**females**
1st Cmax (µg eq/g)	0.432	0.537	1.96	2.62
1st Tmax (h)	1.0	0.5	0.5	0.5
2nd Cmax (µg eq/g)	0.458	0.353	2.04	1.77
2nd Tmax (h)	8	8	8	24
Initial T1/2 (h)	9.0	10.5	-	-
Terminal T1/2 (h)	37.4	31.6	20.7	19.7
AUC (µg eq x h / g)	9.46	8.74	93.97	66.41
Total clearance (g/min)	8.81	9.54	8.87	12.4

Tissue distribution
Following one single oral dose of ^{14}C-BAS 500 F at a dose level of 50 mg/kg bw, tissue radioactivity concentration was measured 0.5, 24, 36 and 72 hours after dosing. At the low dose level of 5 mg/kg bw, the corresponding radioactivity measurements were done 0.5, 8, 20 and 42 hours after application. In general, tissue radioactivity levels in both sexes were in the same range at the respective time points and dose levels. The pattern of distribution and elimination in various organs and tissues was also similar. Throughout the time course of the experiments, highest radioactivity concentrations were found in the GI tract. Liver (factor: 4 – 5) and to a lesser extent kidneys (factor: 2) had higher values than the plasma. Most other organs and tissues had values similar to the ones of the plasma. Radioactivity concentrations were lowest in bone and brain. All other tissues had values comparable to or less than the ones for the plasma. There is no evidence of a cumulative potential of BAS 500 F.

Proposed metabolic pathway in rats
After oral application, BAS 500 F is rapidly and almost quantitatively metabolized. Only minor amounts of parent were detected in plasma (below 0.01% of dose) and liver (below 0.4% of dose) whereas in kidney BAS 500 F formed the major part of radioactivity identified. BAS 500 F was metabolised by N-desmethoxlyation, various hydroxylation reactions, cleavage of the ether bond and further oxidation of the two resulting molecule parts. Combinations of these reactions and the conjugation of the resulting OH-groups with glucuronic acid or sulphate led to a large number of observed metabolites. The metabolic pathway is presented below (Figure 5.1.1-1).

Grouping of metabolites for supporting the dietary risk asessment
Pyraclostrobin is intensively metabolized in rats, but also in plant and livestock matrices. In order to perform an indicative dietary exposure assessment, the metabolites occurring in plants, succeeding crops and animal tissues (plus milk and eggs) were grouped in total into 6 groups (see M-CA 6.7 and 6.9). The groups are based on substructural elements.

- Group 1: Desmethoxy metabolite 500M07 (synonym: BF 500-3)
- Group 2: Chlorphenyl pyrazole derivatives
- Group 3: Anthranilic acid derivatives
- Group 4: Hydroxylated metabolites (chlorphenyl pyrazole moiety)
- Group 5: Hydroxylated metabolites (tolyl moiety)
- Group 6: Photo metabolite 500M76

In order to decide for which group the toxicological endpoints (ADI, ARfD) of the parent molecule are applying, the metabolites being identified in the *in-vivo* rat metabolism study were grouped following the same principles. In cases where metabolites show more than one substructural element, assignment occurred to all relevant groups. In a next step, the average amounts of the metabolites across all dose groups were roughly estimated; overlapping peaks are indicated. Depending on the estimated quantities (expressed in % of dose), either the weight of evidence approach was selected or additional toxicological investigations were initiated (see section M-CA 5.8). As supplemental information, the evaluation on toxification / detoxification reactions which was done by Austrian AGES was considered. (T. Coja, presentation at the Fresenius Conference Mainz, March 2012).

Group1: Desmethoxy metabolite 500M07

The desmethoxylation reaction is an important metabolic degradation step in rats. The metabolite 500M07 is metabolic precursor of multiple metabolites identified in rats. In total, 50 - 60 % of dose can be assigned to the metabolite 500M07 and its subsequent degradation products. Due to these findings, the endpoints of pyraclostrobin are also applying to the desmethoxy metabolite 500M07. This conclusion is corroborated by the evaluations of AGES within an EFSA project on the definition of the relevant residue for risk assessment purposes. Simple demethylation of a ring or side chain did not result in any toxification.

Table 5.1.1-5: Grouping of metabolites: Metabolites resulting from desmethoxylation

Substance/ Metabolite Code	Structure	Occurrence [mean, % of dose]
500M06		Urine: 2%* Bile: 4%* Plasma: < 0.01% Liver: 0.1%

500M45		Feces: 4.5%
500M52		Urine: 1.5%*

* sum of several, co-eluting metabolites

Group 2: Chlorphenyl pyrazole derivatives

Chlorphenyl pyrazole derivatives were almost exclusively found in urine. No bile experiment has been performed with the chlorophenyl ring label. In rats, the cleavage step resulting in the chlorophenyl pyrazole derivatives is by far less pronounced than desmethoxylation or hydroxylation. As in plant and livestock matrices metabolites as 500M04, 500M05 and 500M79 are clearly exceeding 10% TRR, additional tox testing was performed (see M-CA 5.8). The metabolites cannot be considered as fully covered by the investigations performed with the parent compound.

Table 5.1.1-6: Grouping of metabolites: Metabolites resulting from cleavage reactions of the ether bond (chlorophenyl pyrazole derivatives)

Substance/ Metabolite Code	Structure	Occurrence [mean, % of dose]
500M03		Urine: 1.5%*
500M04		Urine: 1.5%*
500M05		Urine: 1.5%*
500M21		Feces: 1%

* sum of several, co-eluting metabolites

Group 3: Anthranilic acid derivatives

Anthranilic acid derivatives were almost exclusively found in urine. In rats, the cleavage step of the ether bond is by far less pronounced than any desmethoxylation or hydroxylation step. As in plant and livestock matrices metabolites as 500M24, 500M49 and 500M51 are close or slightly above 10% TRR, additional tox testing was performed (see M-CA 5.8). The metabolites cannot be considered as fully covered by the investigations performed with the parent compound.

Table 5.1.1-7: Grouping of metabolites: Metabolites resulting from cleavage reactions of the ether bond (anthranilic acid derivatives)

Substance/ Metabolite Code	Structure	Occurrence [mean, % of dose]
500M22		Urine: 1.3%* Bile: 1.6%
500M23		Urine: 1.3%*
500M24		Urine: 1.6%
500M25		Urine: 0.6%*
500M26		Urine: 0.6%*

500M40		Urine: 0.3%*
500M48		Urine: 0.3%*
500M51		Urine: 0.3%

* sum of several, co-eluting metabolites

Group 4: Hydroxylated metabolites (chlorphenyl pyrazole moiety)

Hydroxylation reactions are an important metabolic degradation step in rats. In total, about 20 - 30 % of dose can be assigned to metabolites hydroxylated in the chlorphenyl pyrazole moiety. Due to these findings, the endpoints of pyraclostrobin are also applying to group 4 metabolites. This conclusion is corroborated by the evaluations of AGES within an EFSA project on the definition of the relevant residue for risk assessment purposes. Simple hydroxylation of a ring or side chain without any further cleavage did not result in any toxification.

Table 5.1.1-8: Grouping of metabolites: Metabolites resulting from hydroxylation reactions

Substance/ Metabolite Code	Structure	Occurrence [mean, % of dose]
500M06		Urine: 2%* Bile: 4%* Plasma: < 0.01% Liver: 0.1%
500M08		Urine: < 1%* Feces: 40%

500M46		Bile: 22%, Plasma: < 0.015% Liver: 0.1%
500M52		Urine: 1.5%*

* sum of several, co-eluting metabolites

Group 5: Hydroxylated metabolites (tolyl moiety)

Hydroxylation reactions are an important metabolic degradation step in rats. In total, about 10% of dose can be assigned to metabolites hydroxylated in the tolyl moiety. Due to these findings, the endpoints of pyraclostrobin are also applying to group 5 metabolites. This conclusion is corroborated by the evaluations of AGES within an EFSA project on the definition of the relevant residue for risk assessment purposes. Simple hydroxylation of a ring or side chain without any further cleavage did not result in any toxification.

Table 5.1.1-9: Grouping of metabolites: Metabolites resulting from hydroxylation reactions

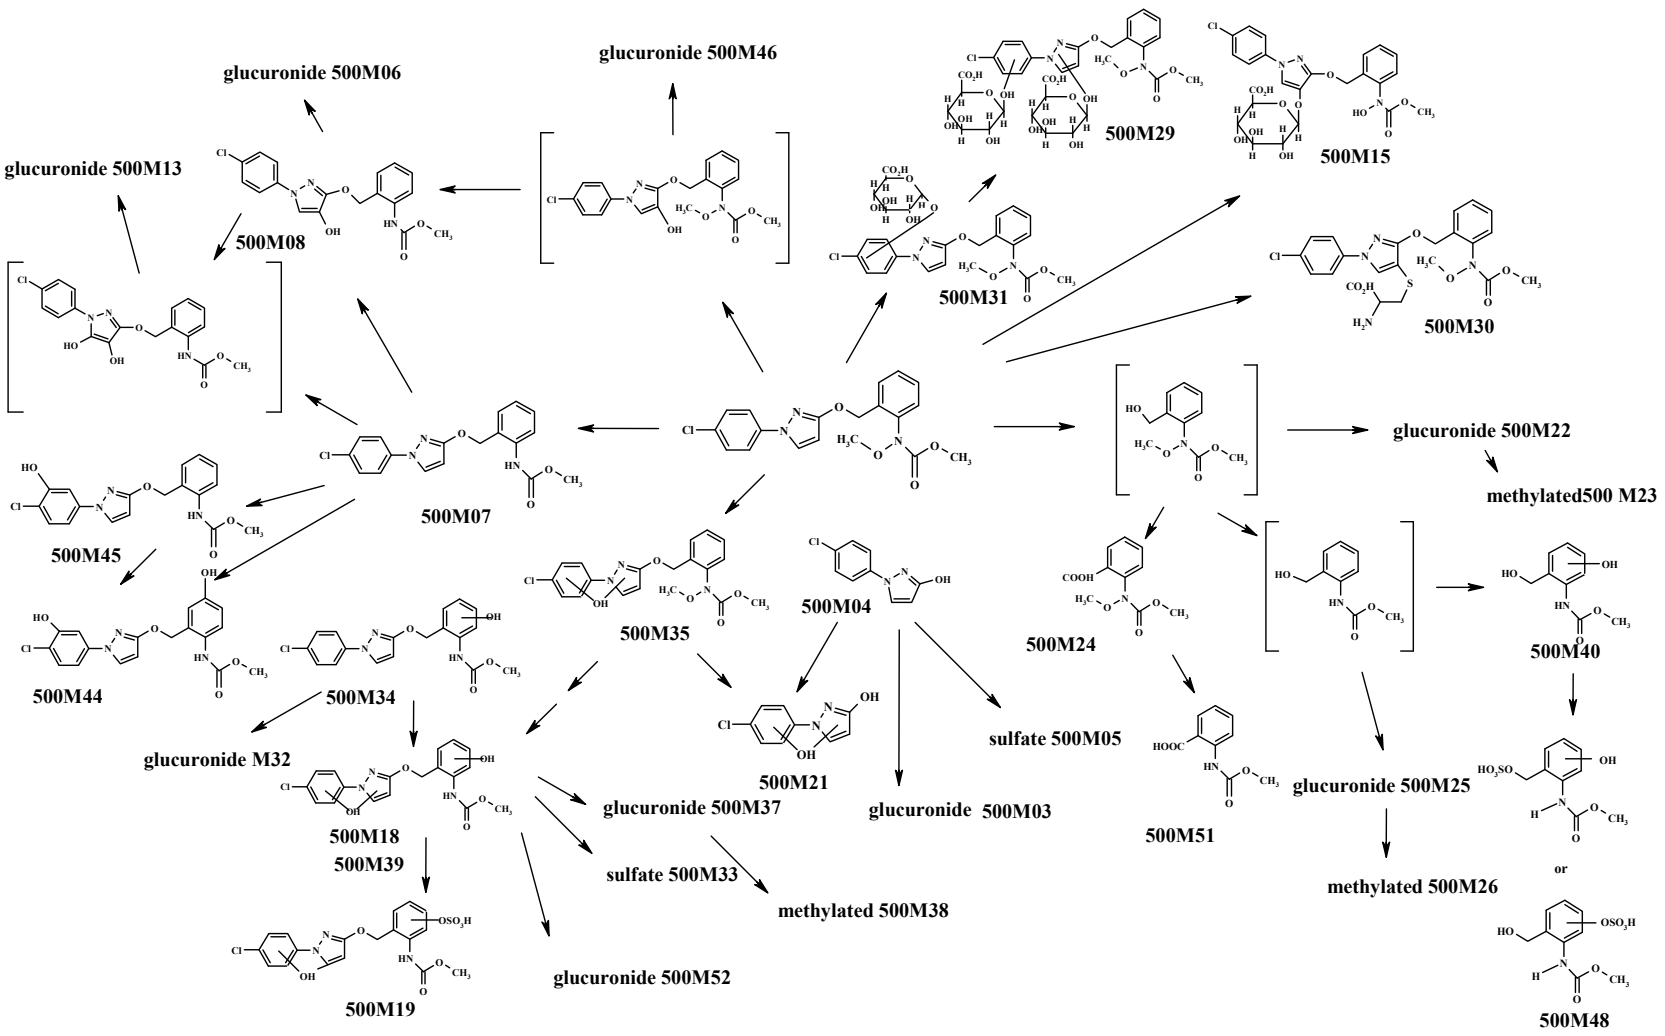
500M44		Feces: 1.5%
500M52		Urine: 1.5%*

* sum of several, co-eluting metabolites

Group 6: Photo metabolite 500M76

The metabolite 500M76 was only found in wheat forage samples. As it is formed by a photolytic re-arrangement reaction on leaf surfaces, its presence in the rat metabolism study can be excluded. Due to this fact and for supporting an assessment according to the TTC approach, genotoxicity investigations have been performed (see M-CA 5.8).

Figure 5.1.1-1: Proposed metabolic pathway of pyraclostrobin in rats



New study

The objective of the new study was to further investigate metabolites in rat plasma samples after oral dosing of pyraclostrobin (BAS 500 F) in order

- to analyse rat plasma samples at different time points after dosing
- to specifically address metabolites being present at short time intervals after dosing for covering the time point of the first plasma peak; the previously submitted study provides mainly information on the second plasma peak (tmax of both peaks: see Table 5.1.1-4)
- to compare the results with those obtained in the previous rat metabolism study

In July 2014 only a GLP interim report was available for dossier submission. At this time the primary focus was to qualify the metabolites in plasma. Further investigations including peak assignment and quantification of metabolites being identified by MS have been carried out in the second half of 2014. The final report containing also these data is now included in the updated dossier. In addition to the study summary of the interim report, the OECD summary of the final report is provided below as well.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 F (pyraclostrobin, Reg No. 304428)
Description: ^{14}C-BAS 500 F: tolyl-ring-U-C14, specific activity 6.68 MBq/mg
^{13}C-BAS 500 F: Pyrazole-3-C-13
Batch/purity #: ^{14}C-BAS 500 F: 566-5011 / 99.3 % (radiochemical), 95.7 % (chemical)
^{13}C-BAS 500 F: 1026-1018 / 99.8 % (chemical)
Stability of test compound: stable for 33 hours in dosing solution

2. Vehicle and/or positive control:
1 % (w/w) aqueous solution of carboxymethyl cellulose mixed with Cremophor EL suspension in a ratio of 9+1 (w/w)

3. Test animals: Rat
Species: Wistar rats
Strain: Crl:WI(Han)
Sex: female and male
Age: 10 – 12 weeks
Weight at dosing: female: 200 g (mean), male: 312 g (mean)
Source: Charles River Laboratories, Sulzfeld, Germany
Acclimation period: 7 days
Diet: Kliba 3433 diet (Provimi Kliba SA) *ad libitum*
Water: Tap water *ad libitum*
Housing: Makrolon cages type 3
Environmental conditions:
Temperature: 21-24 °C
Humidity: 40-54 %
Air changes: not reported
Photo period: Day/night rhythm of 12 h

B. STUDY DESIGN AND METHODS

1. Dates of work: May 13, 2014 – June 12, 2014 (for structural identification part)
Further investigations are ongoing.

2. Study design

All experiments were performed with Wistar rats of strain Crl:WI(Han). For each of the 8 exsanguination time points, 1 female (PFx) and 1 male (PMx) rat were dosed once orally. The rats were dosed with a mixture of unlabelled, ^{13}C- and ^{14}C-labelled pyraclostrobin in an approximate ratio of 9+9+2 resulting in a specific activity of approx. 40.000 dpm /µg in the dose solution. The application formulation was administered orally via gavage.

The nominal dose level was 50 mg/kg body weight (corresponding to the high dose in the previous studies).

Figure 5.1.1-2: Structural formula of unlabelled pyraclostrobin

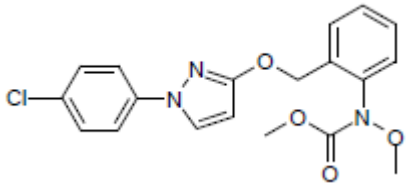

Figure 5.1.1-3: Structural formula of ^{13}C-labelled pyraclostrobin

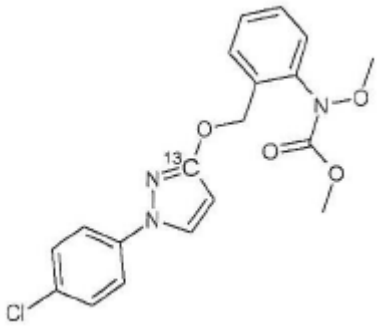

Figure 5.1.1-4: Structural formula of ^{14}C-pyraclostrobin labelled at the tolyl ring

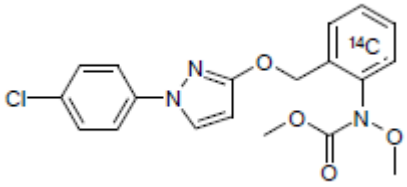

Sampling and Sample Storage

For each designated time point (0.25, 0.5, 1, 2, 3, 4, 8 and 16 h) blood was sampled from 1 female (PFx) and 1 male (PMx) rat. Blood sampling was done by exsanguination under isoflurane anaesthesia.

The blood was collected in tubes containing either EDTA or lithium heparin (LiHep) as anticoagulant. Subsequently, blood samples were split into two aliquots (1/4 as a blood aliquot and 3/4 for the generation of plasma). The aliquot for the generation of plasma was centrifuged at 3000 rpm for 10 min. The supernatant (plasma) and pellet (clot) were collected. Blood, plasma and clot from the individual time points were stored under frozen conditions.

Workup Procedure of EDTA and LiHep Plasma Samples

Prior to processing of the plasma, the radioactivity was measured by LSC. Thereafter, the plasma samples were mixed with acetonitrile and centrifuged in order to precipitate the proteins. The supernatants were analysed by radio-HPLC.

Workup of the Blood Pool Sample (EDTA)
For HPLC method development, but also recovery determinations and investigations on non-released radioactivity, a pool sample was prepared. For this purpose, aliquots of 0.5 mL blood of each time point (0.25, 0.5, 1, 2, 3, 4, 8 and 16 h) were pooled.
The pooled blood sample was centrifuged twice to obtain plasma. The radioactivity in plasma was analysed by LSC and set to 100 % TRR. Thereafter, the plasma was mixed with acetonitrile and subsequently centrifuged to obtain the supernatant and the protein pellet. This work-up step was performed twice. In both cases the supernatants were concentrated to dryness and dissolved in CH_3CN/H_2O/Triton-X100 (700/300/25, v/v/v) to obtain concentrated plasma supernatants. The samples were analysed with HPLC methods LC04 and LC02, respectively, but also subjected to mass spectroscopic investigations. The protein pellet was washed with acetonitrile and sonicated. The resulting wash fractions were pooled and filled up to the mark with acetonitrile.
The protein pellet was finally cut with a scalpel and dried in a nitrogen stream. The dried protein pellet was dissolved in Tris buffer. Protease (*S. griseus*) was added and the mixture was incubated overnight at 37 °C. Then, additional protease and Tris buffer were added. After 4 h of incubation (37 °C), the sample was centrifuged. The supernatant was transferred into a volumetric flask and the volume was adjusted with acetonitrile for LSC measurement. The supernatant was concentrated, dissolved in CH_3CN/H_2O/Triton-X100 (700/300/25, v/v/v) and analysed by HPLC.

HPLC method LC02 (used for the identification of metabolites)
The column used was a Gemini C18, the eluent system consisted of 2 mobile phases (A: H_2O + CH_3CN + HCOOH, 950+50+1 & B: CH_3CN + H_2O + HCOOH, 950+50+1) which were used applying gradient elution.

HPLC method LC04 (used for the identification and quantification of metabolites)
The column used was a Synergi Hydro-RP, the eluent system consisted of 2 mobile phases (A: H_2O + CH_3CN + HCOOH, 900+100+1 & B: CH_3CN + H_2O + HCOOH, 900+100+1), which were used applying gradient elution.

II. RESULTS AND DISCUSSION

1. Determination of the recovered radioactivity in plasma supernatant

In order to determine the radioactivity, which was recovered in the plasma supernatant after acetonitrile precipitation, an EDTA blood pool sample over all time points was generated. As next step, plasma was obtained and precipitation carried out. Thereby, 84.0 % of the TRR was recovered in the plasma supernatant. This recovery was taken to calculate the concentrations of the plasma supernatants of the individual time points.

2. Radioactive residues in plasma and plasma supernatants

For time points 0.25 and 0.5 h of the EDTA plasma, the radioactivity accounted for 1.429 and 1.343 mg/kg, respectively. Thereafter, the concentration reached almost a steady state (from time point 1 to 16 h) and was generally higher (from 3 h: 2.615 mg/kg to 16 h: 3.030 mg/kg). Only at time point 4 h, the concentration decreased to 1.288 mg/kg. The plasma concentrations are in accordance to the previous rat metabolism study of pyraclostrobin. The results of the LiHep plasma were similar to those of the EDTA plasma.

3. Mass spectroscopic investigations

High resolution HPLC-ESI-MS was used to confirm the identity of the active substance BAS 500 F and for the assignment of the metabolites obtained from plasma supernatants after acetonitrile precipitation. The parent compound and several metabolites were detected. All these metabolites are either described in the previous *in-vivo* metabolism in rats (BASF DocID 1999/11781) or in a new comparative *in-vitro*-metabolism study (BASF DocID 2014/1001562). The metabolites 500M104, 500M106, 500M107 and 500M108 have been newly identified in this *in-vivo* study.

Table 5.1.1-10: Summary of metabolites identified in plasma samples of a new rat study (BASF DocID 2014/1136557)

Component	Structure	Metabolite also identified in
500M108		2014/1001562 (*in-vitro*)
500M29		1999/11781 (*in-vivo* rat)

500M30		1999/11781 (*in-vivo* rat)
BAS 500 F (500M00)		1999/11781 (*in-vivo* rat)
500M106		2014/1001562 (*in-vitro*)

4. HPLC investigations: Identification of pyraclostrobin and its metabolites in plasma samples

Analysis of the EDTA plasma supernatants of the different time intervals by radio HPLC, led to comparable metabolite patterns. The unchanged parent compound pyraclostrobin was identified for all time points. Thereby, the concentration of pyraclostrobin ranged from 0.068 mg/kg (0.5 h) to 0.290 mg/kg (16 h). HPLC analysis of the LiHep plasma supernatants led to comparable results as those of the EDTA samples.

5. Proposed metabolic pathway in rat plasma

In rat plasma, the following metabolic transformation steps have been observed:

- Desmethoxylation of the side chain
- Hydroxylation of the chlorophenyl pyrazole ring system
- Hydroxylation of the tolyl ring system
- Desmethylation of the side chain
- Cleavage of the amide bond in the side chain

The combination of these reactions followed by conjugation steps results in the formation of several metabolites (Table 5.1.1-10). The proposed pathway in plasma is shown in the figure below.

III. CONCLUSION

The metabolism is accordance with previous investigations, but also with the findings of the *in-vitro* metabolism study summarized in 5.1.2/1. In addition to already known metabolites, 500M104, 500M106, 500M107 and 500M108 have been newly identified in rat plasma samples by high resolution MS.

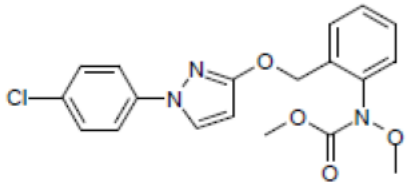

Figure 5.1.1-7: Structural formula of ^{13}C-labelled pyraclostrobin

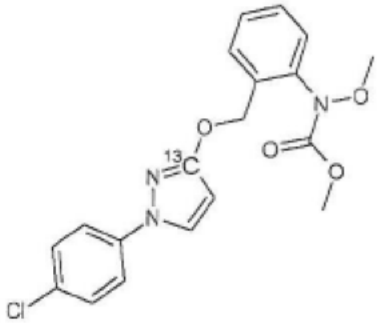

Figure 5.1.1-8: Structural formula of ^{14}C-pyraclostrobin labelled at the tolyl ring

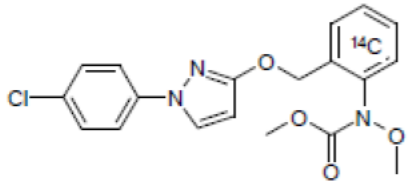

Sampling and Sample Storage

For each designated time point (0.25, 0.5, 1, 2, 3, 4, 8 and 16 h) blood was sampled from 1 female (PFx) and 1 male (PMx) rat. Blood sampling was done by exsanguination under isoflurane anaesthesia.

The blood was collected in tubes containing either EDTA or lithium heparin (LiHep) as anticoagulant. Subsequently, blood samples were split into two aliquots (1/4 as a blood aliquot and 3/4 for the generation of plasma). The aliquot for the generation of plasma was centrifuged at 3000 rpm for 10 min. The supernatant (plasma) and pellet (clot) were collected. Blood, plasma and clot from the individual time points were eventually stored at ≤ -10°C.

Workup Procedure of EDTA and LiHep Plasma Samples

Prior to processing of the plasma, the radioactivity was measured by LSC. Thereafter, the plasma samples were mixed with acetonitrile and centrifuged in order to precipitate the proteins. The supernatants were analysed by radio-HPLC.

The concentrations of the EDTA and LiHep plasma supernatants were calculated as [Concentration of corresponding plasma] * [% TRR of plasma supernatant of blood pool sample] / 100.

The plasma supernatants were concentrated to dryness and dissolved upon sonication in CH_3CN/H_2O/Triton-X100 (700/300/25). Afterwards, the supernatants were analysed by radio-HPLC with methods LC04 and LC02. The HPLC runs of the LiHep plasma supernatants are only exemplarily shown for time points 0.25 h and 0.5 h. For the summary of the quantitative HPLC runs, the metabolite concentrations were re-calculated with the calculated plasma supernatant concentrations. The EDTA supernatant (0.25 h to16 h and 3 h) and the LiHep supernatants (0.25 h and 0.5 h) were additionally analysed with HPLC method LC05, in order to estimate metabolite quantities.

Workup of the Blood Pool Sample (EDTA)

For HPLC method development, but also recovery determinations and investigations on non-released radioactivity, a pool sample was prepared. For this purpose, aliquots of 0.5 mL blood of each time point (0.25, 0.5, 1, 2, 3, 4, 8 and 16 h) were pooled.

The pooled blood sample was centrifuged twice to obtain plasma. The radioactivity in plasma was analysed by LSC and set to 100% TRR. Thereafter, the plasma was mixed with acetonitrile and subsequently centrifuged to obtain the supernatant and the protein pellet.

1.0 mL of the supernatant were concentrated to dryness and dissolved in CH_3CN/H_2O/Triton-X100 (700/300/25, v/v/v) to obtain concentrated plasma supernatants. The samples were analysed with HPLC methods LC04 and LC02, respectively. The concentrated plasma supernatant was additionally analysed with HPLC method LC05, in order to estimate metabolite quantities. The protein pellet was washed with acetonitrile and sonicated. The resulting wash fractions were pooled and filled up to the mark with acetonitrile.
The protein pellet was finally cut with a scalpel and dried in a nitrogen stream. The dried protein pellet was dissolved in Tris buffer. Protease (*S. griseus*) was added and the mixture was incubated overnight at 37 °C. Then, additional protease and Tris buffer were added. After 4 h of incubation (37 °C), the sample was centrifuged. The supernatant was transferred into a volumetric flask and the volume was adjusted with acetonitrile for LSC measurement. The supernatant was concentrated, dissolved in CH_3CN/H_2O/Triton-X100 (700/300/25, v/v/v) and analysed by HPLC method LC02.

HPLC method LC02 (used for confirmation of metabolites)
The column used was a Phenomenex Synergi 4 µm Hydro-RP, the eluent system consisted of 2 mobile phases (A: H_2O + CH_3CN + HCOOH, 900+100+1 & B: CH_3CN + H_2O + HCOOH, 900+100+1) which were used applying gradient elution.

HPLC method LC04 (used for the characterization and quantification of metabolites)
The column used was a Phenomenex Gemini 5 µm C18, the eluent system consisted of 2 mobile phases (A: H_2O + CH_3CN + HCOOH, 950+50+1 & B: CH_3CN + H_2O + HCOOH, 950+50+1), which were used applying gradient elution.

HPLC method LC05 (used for quantification)
The column used was a Thermo Scientific Accucore aQ 2.6 µm, the eluent system consisted of 2 mobile phases (A: H_2O + HCOOH, 1000+1 & B: CH_3CN + HCOOH, 1000+1), which were used applying gradient elution.

II. RESULTS AND DISCUSSION

Determination of the recovered radioactivity in plasma supernatant
In order to determine the radioactivity which was recovered in the plasma supernatant after acetonitrile precipitation, an EDTA blood pool sample over all time points was generated, plasma was obtained and the precipitation was carried out. Thereby, 84.0% of the TRR was recovered in the plasma supernatant. This recovery was taken to calculate the concentrations of the plasma supernatants of the individual time points.
Since the concentrations of the LiHep plasma samples were similar to those of the EDTA samples and the metabolite patterns in the plasma supernatants were also comparable, the determined recovery of 84.0% was also taken to calculate the concentrations of the LiHep plasma supernatants of the individual time points.

Radioactive residues in plasma and plasma supernatants

A summary of the radioactive residues in plasma and plasma supernatants of EDTA and LiHep samples is shown in Table 5.1.1-11. The radioactive residues in plasma were measured, while the radioactive residues in the EDTA plasma supernatants were calculated based on the measurements of the EDTA blood pool sample. For time points 0.25 h and 0.5 h of the EDTA plasma, the radioactivity accounted for 1.429 mg/kg and 1.343 mg/kg, respectively. Thereafter, the concentration reached almost a steady state (from time point 1 h to 16 h) and was generally higher compared to time points 0.25 h and 0.5 h (from 3 h: 2.615 mg/kg to 16 h: 3.030 mg/kg). Only at time point 4 h, the concentration decreased to 1.288 mg/kg. The plasma concentrations are in accordance to the previous rat metabolism study of pyraclostrobin (BASF DocID 1999/11781). The results of the LiHep plasma were similar to those of the EDTA plasma.

Table 5.1.1-11: Summary of metabolites identified in plasma samples

Anticoagulant	Time Interval [h]	Plasma (Measured) [mg/kg]	Plasma Supernatant (Calculated)[1] [mg/kg]
EDTA	0.25	1.429	1.201
	0.5	1.343	1.129
	1	2.953	2.482
	2	2.775	2.332
	3	2.615	2.197
	4	1.288	1.083

	16	3.909	3.286

[1] Calculation explained in the study

Mass spectroscopic investigations

In order to identify metabolites in plasma, a concentrated plasma supernatant sample of the EDTA blood pool sample of time points 0.25 h to 16 h was subjected to HPLC-MS analysis. Accurate masses were obtained via high resolution HPLC-MS analysis. Due to a high matrix load, MS/MS analysis was possible only in one case. Generally, more than one possible metabolite or isomer could be assigned to one accurate mass. Hence, for the analysis of the pool plasma supernatant a metabolite was regarded as identified when its accurate mass was detected upon HPLC-MS analysis, the metabolite was identified in rat plasma of a previous study (BASF DocID 1999/11781) and / or the metabolite was identified in an *in-vitro* study with human hepatocytes (BASF DocID 2014/1001562). These assumptions complied with the unchanged parent compound pyraclostrobin and metabolites 500M108, 500M29, 500M15, 500M46, 500M06, 500M104, 500M107 and 500M30. Moreover, MS/MS data confirmed the structure of 500M46.

HPLC analysis of the LiHep plasma supernatant (0.25 h) with HPLC method LC02 led to a peak at 72.1 mm, which was approximately the retention time of reference item 500M106. Metabolite 500M106 was identified in an in vitro study with human hepatocytes (BASF DocID 2014/1001562). In the same study, metabolite 500M107 was also identified, which is a conjugate of 500M106. Therefore, the LiHep plasma supernatant (0.25 h) was screened via HPLC-MS for corresponding accurate masses. Thereby, the accurate masses of 500M106 and 500M107 were detected (see Table 5.1.1-12).

Table 5.1.1-12: Summary of metabolites identified in plasma samples

Component	Structure	Metabolite also identified in
500M108		2014/1001562 (*in-vitro*)

Identification and Quantification of pyraclostrobin and its metabolites in plasma samples

Plasma supernatants (both EDTA and LiHep) were analysed with HPLC method LC04 for characterization of the radioactive residues and quantification of pyraclostrobin and metabolite 500M106. HPLC method LC02 was used for confirmation of the metabolite pattern. The peak assignment for pyraclostrobin and metabolite 500M106 was done by comparing the retention times with those of the corresponding reference items.

Analysis of EDTA plasma supernatants of the different time intervals with HPLC method LC04, led to comparable metabolite patterns. The unchanged parent compound pyraclostrobin was identified for all time points. Thereby, the concentration of pyraclostrobin ranged from 0.068 mg/kg (0.5 h) to 0.290 mg/kg (16 h). Analysis of the EDTA plasma supernatants with HPLC method LC02 confirmed the presence of the parent compound for time points 0.25, 1, 2, 3, 4 and 16 h. For time points 0.5 and 8 h the signal of pyraclostrobin was not confirmed, which was probably due to relatively low concentrations of the compound.

Comparable with the results of the EDTA samples, the parent compound pyraclostrobin was identified with HPLC method LC04 and LC02 for time point 0.25 h. For time point 0.5 h pyraclostrobin was only identified with HPLC method LC02. Additionally, for time point 0.25 h a peak at 72.1 mm was detected with HPLC method LC02, which corresponded approximately to the retention time of reference item 500M106. Therefore, the same sample was analysed via HPLC-MS, whereby the accurate mass of 500M106 was detected. Hence, the peak at 72.1 mm was assigned to metabolite 500M106.

The concentrated plasma supernatant of the pool blood sample was also analysed with HPLC methods LC04 and LC02. Thereby, the metabolite pattern was generally comparable with the metabolite patterns of the plasma supernatants of the individual time points.

The protease solubilizate of the pellet (0.25 h - 16 h) was analysed with HPLC method LC02, which resulted in a pattern of 5 peaks.

Since HPLC method LC04 and LC02 did not correspond to the method of the HPLC-MS analyses, peak assignment of the MS-identified metabolites was not possible. Therefore, four selected samples (EDTA plasma supernatant 3 h, concentrated plasma supernatant of the EDTA blood pool sample 0.25 h - 16 h, LiHep plasma supernatants 0.25 h and 0.5 h) were additionally analysed with HPLC method LC05, which is identical to the method of HPLC-MS.

Peak assignment was based on comparison of the ^{14}C pattern and retention times of the HPLC-MS analysis of the EDTA blood pool sample (0.25 h - 16 h) with the ^{14}C pattern of the same sample analysed with HPLC method LC05. Similar to HPLC method LC04, analysis of the EDTA blood pool sample (0.25 h. - 16 h) resulted in broad peaks, which were not baseline-separated. Generally, more than one metabolite could be assigned to such a broad peak. Hence, the peaks were classified as regions (Region 1 to 4), to which the identified components were assigned. Region 1 included 500M108 and 500M29, Region 2 500M15 and 500M108, Region 3 500M46 and 500M06 and Region 4 500M104, 500M107 and 500M30. Since the resolution of pyraclostrobin and metabolite 500M106 was better, pyraclostrobin and metabolite 500M106 were assigned to discrete peaks.

In all four samples, the relative amounts of Region 1, Region 3 and Region 4 were similar. The amounts of Region 1, Region 3 and Region 4 ranged for the EDTA plasma supernatant 3 h from 0.337 mg/kg to 0.560 mg/kg, for the concentrated plasma supernatant of the EDTA blood pool sample 0.25 h - 16 h from 0.172 mg/kg to 0.268 mg/kg, for the LiHep plasma supernatant 0.25 h from 0.158 mg/kg to 0.227 mg/kg and for the LiHep plasma supernatant 0.5 h from 0.227 mg/kg to 0.331 mg/kg. In all four samples, Region 2 was the least abundant region and accounted from 0.044 mg/kg (LiHep 0.5 h) to 0.111 mg/kg (EDTA 3 h).

Pyraclostrobin was identified in all four samples and the quantities corresponded well to the results of the analyses of the EDTA plasma supernatant samples with HPLC method LC04. Metabolite 500M106 was only detected in the LiHep plasma supernatant of 0.25 h, where it was the least abundant component.

Proposed metabolic pathway of pyraclostrobin in rat plasma samples

The metabolites of pyraclostrobin which were detected in rat plasma can be deduced from the typical phase I and II reactions:

- Desmethoxylation of the side chain
- Hydroxylation of the chlorophenyl pyrazole ring system
- Hydroxylation of the tolyl ring system
- Desmethylation of the side chain
- Cleavage of the amide bond in the side chain
- The combination of these reactions followed by conjugation steps results in a huge number of metabolites.

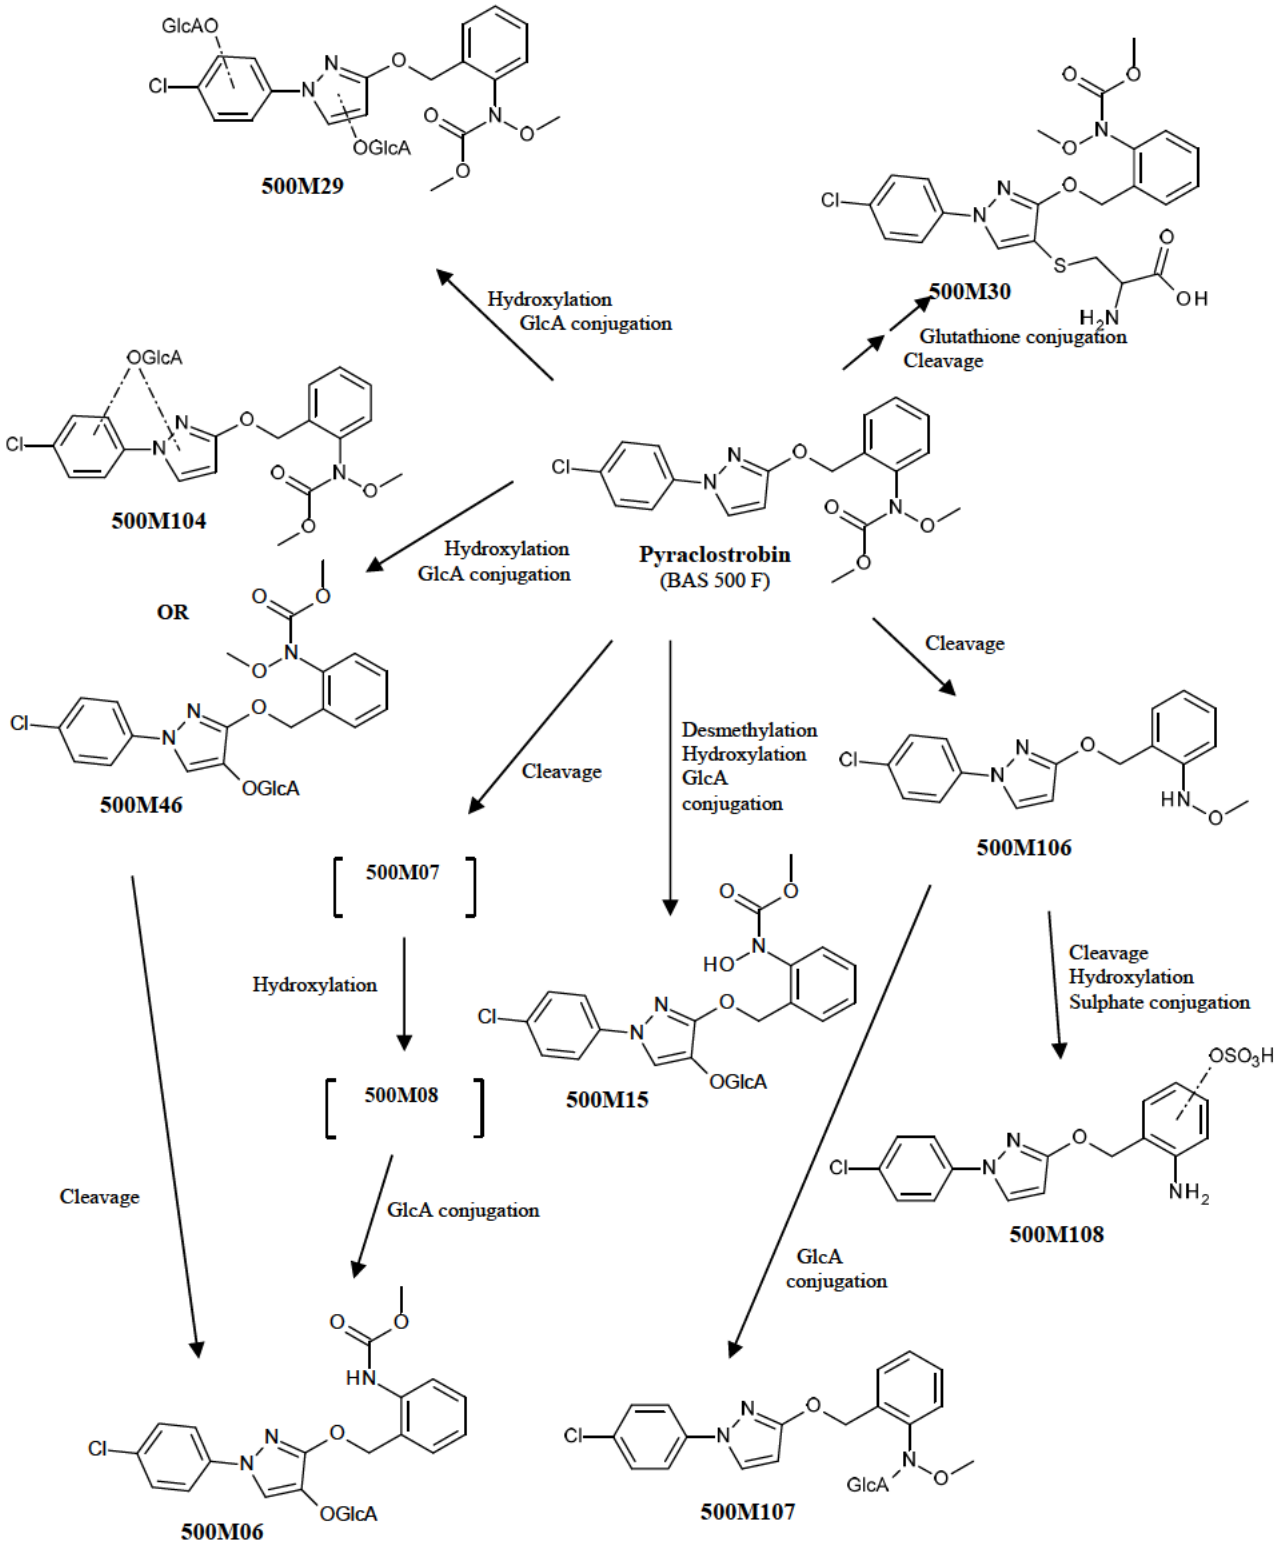
Hydroxylation and glucuronic acid conjugation of the chlorophenyl and the pyrazole ring of pyraclostrobin yield metabolite 500M29. Hydroxylation and glucuronic acid conjugation of only the pyrazole ring result in metabolite 500M46 and 500M104. Metabolite 500M30 is a cysteine conjugation product of pyraclostrobin, wherein cysteine is bound via its sulphur to the pyrazole ring. 500M30 is probably generated via conjugation of pyraclostrobin with glutathione, followed by enzymatic cleavage of the glutamic acid and the glycine of glutathione.
Desmethoxylation of pyraclostrobin yields the intermediate 500M07. Hydroxylation of the pyrazole ring of 500M07 results in the intermediate 500M08. Both, 500M07 and 500M08 were previously identified in a rat metabolism study of pyraclostrobin (BASF DocID 1999/11781). Glucuronic acid conjugation of 500M08 results in metabolite 500M06. 500M06 might also be generated via N-desmethoxylation of 500M46.
Desmethylation of the N-methoxy side chain of pyraclostrobin, followed by hydroxylation of the pyrazole ring and glucuronic acid conjugation results in metabolite 500M15. Cleavage of the methylcarboxy group of pyraclostrobin yields metabolite 500M106. Conjugation of the secondary amine group of 500M106 with glucuronic acid results in metabolite 500M107. Cleavage of the methoxy moiety of 500M106, followed by hydroxylation and sulphate conjugation of the tolyl moiety results in metabolite 500M108.

III. CONCLUSION

The objective of this study was to further investigate the fate and kinetic behavior of pyraclostrobin (BAS 500 F) after a single oral application of 50 mg/kg. For designated time points, one female (PFx) and one male (PMx) rat were dosed with a mixture of ^{14}C-labelled, ^{13}C and unlabeled pyraclostrobin. Blood was sampled in presence of EDTA or lithium heparin (LiHep) and plasma was obtained.
For time points 0.25 h and 0.5 h of the EDTA plasma, the radioactivity accounted for 1.429 mg/kg and 1.343 mg/kg, respectively. Thereafter, the concentration reached almost a steady state (from time point 1 h to 16 h) and was generally higher compared to time points 0.25 h and 0.5 h (from 3 h: 2.615 mg/kg to 16 h: 3.030 mg/kg). Only at time point 4 h, the concentration decreased to 1.288 mg/kg. The results of the LiHep plasma were comparable to those of the EDTA plasma. The plasma concentrations are in accordance to the previous rat metabolism study of pyraclostrobin.

Analysis of the EDTA plasma supernatants of the different time intervals with HPLC, led to comparable metabolite patterns. The unchanged parent compound pyraclostrobin was identified for all time points. Thereby, the concentration of pyraclostrobin ranged from 0.068 mg/kg (0.5 h) to 0.290 mg/kg (16 h). HPLC analysis of the LiHep plasma supernatants led to similar results as those of the EDTA samples.
Via HPLC-MS analysis of plasma supernatant samples the accurate masses corresponding to the parent compound pyraclostrobin and the following metabolites were detected: 500M108, 500M29, 500M15, 500M46, 500M06, 500M104, 500M107, 500M30 and 500M106. Thereby, all metabolites which were identified in plasma of the previous rat metabolism study were confirmed (pyraclostrobin, 500M06, 500M15 and 500M46). Moreover, metabolites which were identified in the *in-vitro* comparison study were also detected in rat plasma (500M108, 500M104, 500M107 and 500M106).
The identified metabolites were quantified exemplarily in four samples (EDTA plasma supernatant 3 h, concentrated plasma supernatant of the EDTA blood pool sample 0.25 h - 16 h and LiHep plasma supernatants 0.25 h and 0.5 h). HPLC peaks which contained more than one component were classified as region (Region 1 to 4). Region 1 included 500M108 and 500M29, Region 2 500M15 and 500M108, Region 3 500M46 and 500M06 and Region 4 500M104, 500M107 and 500M30. In all four samples, the relative amounts of Region 1, Region 3 and Region 4 were similar. The amounts of Region 1, Region 3 and Region 4 ranged for the EDTA plasma supernatant 3 h from 0.337 mg/kg to 0.560 mg/kg, for the concentrated plasma supernatant of the EDTA blood pool sample 0.25 h - 16 h from 0.172 mg/kg to 0.268 mg/kg, for the LiHep plasma supernatant 0.25 h from 0.158 mg/kg to 0.227 mg/kg and for the LiHep plasma supernatant 0.5 h from 0.227 mg/kg to 0.331 mg/kg. In all four samples, Region 2 was the least abundant region and accounted from 0.044 mg/kg (LiHep 0.5 h) to 0.111 mg/kg (EDTA 3 h). Pyraclostrobin was identified in all four samples and the quantities corresponded well to the analyses of the EDTA plasma supernatant samples of the different time intervals (0.25 h to 16 h). Metabolite 500M106 was only detected in the LiHep plasma supernatant of 0.25 h, where it was the least abundant component (0.030 mg/kg).

Figure 5.1.1-9: Proposed metabolic pathway of pyraclostrobin in rat plasma samples



In the *in-vitro* comparison study (see M-CA 5.1.2), the metabolites 500M106 (plus its conjugate 500M107) and 500M02 were predominantly found in human cell cultures and in rabbit, but only in minor amounts in species as rat, mouse and dog for which chronic studies are available.
Based on these results, a metabolism study has been conducted, where metabolite 500M106 was dosed. The study was not part of the supplemental dossier provided in July 2014, but is added to this updated dossier. The OECD study summary can be found below.
The investigations had the following goals:

- To get a comparison to the *in-vitro* situation
- To investigate whether the rat is an appropriate species for further toxicological testing.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: ^{14}C-Reg. No. 399379 (Metabolite of BAS 500 F, Pyraclostrobin)
Reg. No. 399379 (Metabolite of BAS 500 F, Pyraclostrobin)

Description:	pyrazole-3-C14 label, unlabelled Reg. No. 399379
Chemical name:	N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxymethyl}phenyl) Omethylhydroxylamine (IUPAC-Name)
Test substance No:	15/0106-2 (^{14}C-labelled), 14/0701-1 (unlabelled)
Lot/Batch #:	1166-1010 (^{14}C-labelled), L83-166 (unlabelled)
CAS#:	not indicated by the sponsor
Development code:	Pyraclostrobin: BAS 500 F Reg. No. 399379 : 500M106 (synonym: M500F106)
Purity:	Radiochemical purity of labelled test item: > 95-99.7% Purity of unlabelled test item: 97.1% (tolerance ± 1.0%)
Specific activity:	6.42 MBq/mg
Stability of test compound:	The stability of the test substance in the test-substance preparation over the test period was verified by analyses.

2. Vehicle and/or positive control: see "preparation of dosing solutions"

3. Test animals:

Species:	Rat
Strain:	Crl: WI (Han) (SPF)
Sex:	male
Age:	10 weeks old at start of acclimatization
Weight at dosing:	Average: 353 g
Source:	Charles River, Sulzfeld, Germany
Acclimation period:	5 days
Diet:	Kliba lab diet (mouse / rat "GLP"), meal Origin: Provimi Kliba SA, 4303 Kaiseraugst, Switzerland ad libitum prior to and during the experiment.
Water:	Tap water *ad libitum*
Housing:	During acclimatization animals housed in groups (up to five animals in Polysulfonate Cages (2000P; H Temp (PSU), 2065 qcm, Tecniplast). During the balance experiment animals were kept individually in Plastic Metabolism Cages (Tecniplast, Italy), labelled with the project number, animal number, dose and time of administration.

Environmental conditions:	
Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	15 per hour
Photo period:	12 h light / 12 h dark

4. Preparation of dosing solutions

Stock solutions in acetonitrile were prepared for the radio-labelled and non-labelled test substance, yielding nominal concentrations of 13.2 and 35.2 mg/g, respectively.
In order to achieve the required specific activity, appropriate amounts of the radio-labelled and non-labelled test-substance solutions were taken and the organic solvent (acetonitrile) was evaporated to dryness. Respective amounts of the aqueous vehicle [0.5% carboxymethylcellulose (CMC) in tap water] were added. Based on the current data, the nominal concentration of the test substance in the test-substance preparation was 1.0 mg/mL and the nominal specific activity of the test-substance preparation was 3.4 MBq/mL.
The preparation was stirred and sonicated in order to produce a homogeneous preparation.
Before start and at the end of the administration, samples were taken to determine the amount of radioactivity in the preparation and to demonstrate the correct concentration of the test substance, its homogeneity and its radiochemical purity.

B. STUDY DESIGN AND METHODS

1. Dates of experimental work March 11, 2015 to March 08, 2016

2. Study design

Sampling, pooling, combining and storage
Four male rats received a single oral dose of a mixture of ^{14}C-labelled and unlabelled 500M106. The test item preparation was applied at a nominal rate of 10 mg/kg bw. Urine was sampled in time intervals of 0-6, 6-12, 12-24 hours and afterwards in 24 hours intervals for up to 168 hours after treatment. Faeces was sampled in 24 hour intervals for up to 168 hours after treatment. After 168 hours, animals were sacrificed. In addition to the excreta samples the total amount of radioactive residue was measured in the carcass of each animal. For balance estimates the cage wash was also checked for radioactivity.
Samples were stored in a freezer, and all samples were transferred to the Agricultural Center of BASF SE (Limburgerhof, Germany) under frozen conditions.
At the Agricultural Center, samples were pooled (urine samples from several time intervals of individual animals) or combined (faeces samples of several animals of one time interval). For urine, equal portions, i.e. 30%, were taken per sampling interval and pooled to obtain the time interval 0-48 hours for each animal. This time interval was in focus as the major fraction of radioactive residues (% dose) was excreted within 48 hours and simultaneously the fraction was not diluted with urine sampled at later time intervals containing less than 1% of the administered dose. Additionally, equal portions of urine samples, i.e. 10%, were taken per sampling interval and animal. These aliquots were pooled and combined (for all four animals) to obtain one single sample for the time interval 48-168 hours. For faeces, equal portions, i.e. 50%, were taken per animal and combined for each sampling interval.

Table 5.1.1-13: Summary of dose groups and dosing parameters

Test Item	Reg. No. 399379 (500M106, metabolite of pyraclostrobin)
No. of doses and route of administration	Single oral dose[1]
Number of treated animals (gender)	4 (male)
Animals used for evaluation	1-4
Nominal dose [mg/kg bw]	10
Mean dose achieved [mg/kg bw]	10.3
Label	Pyrazole-3C-14 label, unlabelled (C12)
Ratio of isotopes ^{14}C :^{12}C in application formulation	1:1
Specific radioactivity used [dpm/g]	187307[2]
Radioactive dose [MBq/animal]	11.34
Duration of experiment	168 h
Sampling and analysis	Urine and faeces

1 Application was performed at Department of Experimental Toxicology and Ecology of BASF SE (GV/TB, Ludwigshafen, Germany

2 Corrected value is 187140 and shows an abbreviation of 0.09%, which has no influence on the outcome of the study. Therefore, the uncorrected value was further used for calculations.

Determination of radioactivity

Appropriate aliquots (generally five) of homogenized solid samples were weighed and combusted by means of an automatic sample oxidiser. The $^{14}CO_2$ formed during combustion was trapped by an absorption liquid, and the collected radioactivity was measured by Liquid Scintillation Counting (LSC). For the quantification of radioactivity in liquid samples, a liquid scintillation counter was used. Aliquots of liquid samples were mixed with a sufficient volume of a suitable scintillator prior to measurements. All data were corrected using appropriate quench curves and are expressed in disintegrations per minute (dpm).

Each cage side was washed with 10% RBS® cleaner in drinking water and acetone at the end of the experiment. After weighing the urine and cage wash samples they were mixed with scintillation cocktail and analyzed for radioactivity without any additional treatment.

Carcass was suspended in deionized water and was homogenized using a WARING Blender. Aliquots of the suspension was dried by lyophilisation, dissolved with Soluene®-350, filled up with isopropanol, bleached with perhydrol solution (30% H_2O_2) and Hionic Fluor was added before measurement of radioactivity by LSC.

HPLC analysis / spectroscopy

For the detection of metabolites in urine and faeces samples were analysed by two analytical methods (Radio-HPLC / HPLC-UV). One used for quantitative determination, and the other used for confirmation. Metabolites of 500M106 were identified by HPLC-MS/MS analysis of a urine sample of male rat 2 (0 - 48 h) and an acetonitrile extract of combined faeces (rat 1-4, 24-48 h). Based on retention time comparison known for the metabolite standards, the MS signals/peaks were assigned to the selected radioactive peaks. For confirmation, semi-quantitative comparison of the radioactive and MS peaks was performed, if feasible. Metabolite patterns (radioactive and MS) were compared between matrices.

Sample preparation for analysis

Homogenization
Faeces was homogenized along with dry ice using an analytical mill. The TRR values for faeces were calculated as the sum of extracted radioactive residues (ERR) and residual radioactive residues (RRR) after solvent extraction.

Extraction and Calculation of the Total Radioactive Residue (TRR)
The TRR in urine was determined by direct liquid scintillation counting of three aliquots.
Homogenized individual faeces samples were extracted three times with sufficient amounts of acetonitrile using a dispersing tube. The extracts were separated from the solid by centrifugation. The acetonitrile extracts of the three steps were pooled and aliquots were radioassayed. The results of the acetonitrile extractions referred to extractable radioactive residues (ERR). The solid residue was homogenized using a spatula, aliquots were combusted for the determination of the residual radioactive residues (RRR). The TRR was calculated as the sum of the ERR and RRR.
Homogenized, combined faeces samples were also extracted three times with acetonitrile. After each extraction step, the extract was separated and the solid residue was subjected to the next extraction step. The acetonitrile extracts of the three steps were pooled, adjusted to a defined volume with acetonitrile and appropriate aliquots were measured by LSC. The solid residue was further extracted two times with sufficient amounts of water. The water extracts of the two steps were also centrifuged, filtered, pooled, adjusted to a defined volume with water, and aliquots were radioassayed (LSC). The solid residue after extraction with water was dried, homogenized and additionally extracted three times with a mixture of acetonitrile and acetone (4/1, v/v). After each extraction step, the extract was separated from the solid by centrifugation and filtration, and the solid residue was subjected to the next extraction step. The solid residue was transferred with methanol into a crystal bowl for drying.
The results of the acetonitrile, water and acetonitrile / acetone extractions referred to ERR. The residues after solvent extraction were dried, homogenized and weighed aliquots were measured by LSC for the determination of the RRR. The TRR was calculated as the sum of the ERR and RRR.

Investigation of the Residual Radioactive Residues after Solvent Extraction
Combined faeces samples with residual radioactive residues above 1% of the dose after solvent extraction of combined faeces samples were subjected to a sequential solubilization procedure. Various enzyme incubations (protease, pepsin and pancreatin) were applied in order to analyse the residues under physiological conditions and to subsequently categorize the released radioactive residues as bioavailable. In addition, an artificial solubilization method was applied (alkaline treatment) in order to release radioactive residues being categorized as non-bioavailable.

The residue after solvent extraction was dried, a sufficient amount of protease was added, and the mixture was re-suspended in 0.1 M Tris buffer (at pH 7) and incubated at 37°C upon shaking for 20 hours. Thereafter the sample was centrifuged. The supernatant was filtered, adjusted to a defined volume with an appropriate solvent and aliquots were analyzed by LSC. Additionally, supernatants containing sufficient amounts of radioactive residues were subjected to HPLC analysis. The solid residue was dried and subjected to pepsin solubilization, simulating an artificial gastric juice. Therefore, the dried residue after protease incubation was mixed with an artificial gastric juice (6.4 g pepsin, 4 g NaCI, 84 mL 2 M HCl, 2 L water) incubated at 37°C upon shaking for approximately 24 hours. Thereafter the sample was centrifuged. The supernatant was filtered, adjusted to a defined volume with an appropriate solvent and aliquots were analyzed by LSC. The solid residue was dried and subjected to pancreatin solubilization. Therefore, the dried residue after pepsin incubation was mixed with an artificial intestinal juice (10 g pancreatin per 1 L potassium dihydrogen phosphate buffer at pH 7.5) and incubated at 37°C upon shaking overnight. Thereafter the sample was centrifuged. The supernatant was filtered, adjusted to a defined volume with acetonitrile and aliquots were analyzed by LSC. The solid residue was dried, homogenized, and aliquots were combusted for the determination of the radioactive residues after enzyme solubilization. Thereafter, the solid residue was subjected to alkaline treatment, where 2-4 g of the dried sample was mixed with 30 mL 2N sodium hydroxide. The mixture was boiled at 100°C for 1.5 hours under reflux. The sample was centrifuged, and the supernatant was filtered. The volume was determined and aliquots were analyzed by LSC. The solid residue was dried, homogenized using an analytic mill and aliquots were combusted for the determination of the radioactive residues.

Investigation of Metabolite Patterns and Identification of Metabolites

In general, urine samples were diluted with water prior to HPLC analysis. Pooled extracts and protease solubilizates of combined faeces were either injected directly, concentrated to dryness and re-dissolved in a mixture of acetonitrile, water and Triton X-100 or diluted with water or a mixture of acetonitrile, water and Triton X-100 prior to HPLC analyses (only for faeces extracts).

- *Urine*

Pooled urine samples (interval 0-48 hours) from rats were analyzed by radio-HPLC, in order to investigate the metabolic pattern and quantities. Therefore, appropriate urine aliquots were analyzed using HPLC method LC01 for quantitative evaluation and LC02 or LC05 for confirmatory analysis after dilution with water.

For identification of metabolites, an aliquot of urine sampled from rat 3 within 48 hours after treatment was subjected to HPLC-MS/MS without prior sample preparation. Peak assignment was conducted by comparison of the metabolic profile and the retention times obtained by radio-HPLC and HPLC-MS/MS analyses.

- *Faeces*

Pooled acetonitrile, water and acetonitrile/acetone extracts of combined faeces samples as well as protease solubilizates, containing sufficient amounts of radioactive residues, were analyzed by radio-HPLC, in order to investigate the metabolic pattern and quantities.
For identification of metabolites, an aliquot of the pooled acetonitrile extract of combined faeces sampled 24-48 hours after treatment was subjected to HPLC-MS/MS after concentration to dryness and dissolving in a mixture of water and acetonitrile (1/1, v/v). Additionally, aliquots of the pooled acetonitrile/acetone extracts of combined faeces sampled 0-24 hours after treatment were fractionated. In total seven fractions were separated and filled up to a defined volume with acetonitrile. Aliquots of fraction 3, comprising peaks at 26.1 min and 26.8 min, and fraction 5, comprising peaks at 33.8 min and 34.9 min, were concentrated to dryness, dissolved in a mixture of water and acetonitrile (1/1, v/v) supported by ultra-sonication and subjected to HPLC-MS/MS analysis.
The HPLC method used for metabolite identification was identical to HPLC method LC01. Peak assignment was conducted by comparison of the metabolic profile and the retention times obtained by radio-HPLC and HPLC-MS/MS analyses.

II. RESULTS AND DISCUSSION

1. Excretion of Radioactive Residues of 500M106

The portions of radioactive residues, which were excreted via urine or faeces after application of a single oral dose of 10 mg/kg bw 500M106 to male rats are summarized in Table 5.1.1-14.
In general, the excretion was completed within the observation period of 168 hours, ranging from for 101.83 to 105.82% of the dose. Thereby, the main excretion route was via faeces and detected portions of radioactive residues ranged from 84.61 to 89.89% of the dose within 168 hours, where the major fraction was excreted within 24 hours (approximately 61-71% of the dose) and being completed within 48 h (approximately 82-85 % of the dose within 0-48 h). The excretion via urine ranged from 15.93 to 17.84% of the dose within 0-168 hours and the main portion was excreted within 48 h (approximately 14 to 17% of the dose).

Table 5.1.1-14: Excretion of Radioactive Residues via Urine and Faeces after a Single Oral Administration of 10 mg/kg bw 500M106 to Male Rats

Matrix	Time interval [h]	Animals			
		Rat 1	Rat 2	Rat 3	Rat 4

2. Extractability and Solubilization of Radioactive Residues from Faeces

For the determination of the extractability of the radioactive residues in faeces, the combined samples were extracted three times with acetonitrile and twice with water. The residue after acetonitrile and water extraction was further extracted three times with a mixture of acetonitrile and acetone. The results are summarised in Table 5.1.1-15.
The ERR from faeces was moderate ranging from 52.0 to 74.2% TRR, where most of the radioactive residues were extracted with acetonitrile ranging from 42.0 to 69.2% TRR, and only low amounts were subsequently extracted with water (up to 12.7% TRR) and with the mixture of acetonitrile and acetone (up to 2.6% TRR). Due to the high residue levels (above or equal to 21.7% TRR), the RRR after solvent extraction was subjected to sequential solubilization procedure (Table 5.1.1-16). Portions of radioactive residues were released by protease incubation (up to 4.2% TRR), pepsin incubation (up to 1.1% TRR) and pancreatin incubation (up to 3.7% TRR). In total, up to 8% TRR was released by enzyme incubations. In addition, alkaline treatment (at 100°C) was applied solubilizing portions for up to 26.5% TRR leading to final radioactive residues being below or equal to 8.9% TRR.

Table 5.1.1-15: Extractability of Combined Faeces Samples Obtained from Male Rats 1-4 after a Single Oral Dose of 10 mg/kg bw 500M106

[1] Total radioactive residue (TRR) was calculated as the sum of the combined acetonitrile extract, combined water extract and the residue after acetonitrile and water extraction.
[2] Extractable Radioactive Residue (ERR) was calculated as sum of the combined acetonitrile extract, combined water extract and combined acetonitrile / acetone extract.
[3] RRR = Residual radioactive Residue after solvent extraction with acetonitrile, water and acetonitrile / acetone extraction.

3. Identification, Characterisation and Quantification of Residues

3.1. Identification, Characterization and Quantification of Metabolites in Urine

Structure elucidation of metabolites in urine was based on HPLC-MS/MS analysis of the pooled urine sampled from rat 3 within 48 hours. The following metabolites were identified (order by retention time of the HPLC-MS/MS analysis):

- 500M109 (isomers) - 12.4 min 13.1 min and 15.9 min
- 500M03 - 13.9 min
- 500M05 -15.9 min
- 500M04 - 18.4 min
- 500M21 - 20.6 min

Metabolites 500M05, 500M109 and two not identified compounds were not separated by radio-HPLC and co-eluted in one peak at 20.5 min (15.9 min, RT of HPLC-MS/MS analysis).

The two unidentified compounds are most likely adducts of 500M05 and urine matrix. Further, metabolites 500M109 and 500M03 co-eluted in one peak during the analysis of the pooled and combined urine sample. The results of the quantitative analysis of urine are summarised in Table 5.1.1-17 and Table 5.1.1-18.
For all rats, 500M109 and 500M04 were identified as the main components in urine sampled within 48 hours ranging from 2.95 to 5.16% and 3.26 to 6.10% of the dose, respectively. All other metabolites were present at lower quantities ranging from 0.36-2.63% of the dose (0-48 hours). In pooled and combined urine sampled within 48-168 hours, metabolites 500M109/500M03, 500M05/500M109, 500M04 and 500M21 were present at similar low levels ranging from 0.12 to 0.49% of the dose. The administered compound 500M106 was not detected in urine sampled within 168 hours.
The excreted amount via urine within 168 hours ranged from 15.93 (rat 3) to 17.84% of the dose (rat 4), where 10.77 (rat 3) to 14.93% of the dose (rat 4) were identified in urine sampled within 48 hours. Additional 1.95 (rat 4) to 4.46% of the dose (rat 2) were characterized by HPLC, whereby each peak (up to 10 further peaks per sample) was below or equal to 0.83% of the dose. Furthermore, 1.16% of the dose recovered in urine sampled within 48-168 hours, were identified by HPLC.

Table 5.1.1-17: Summary of Radioactive Residues in Urine Obtained from Rat 1-4 (0-168 h)

Metabolite Identity	Composition of Radioactive Residues [% Dose]

[1] For metabolite 500M109, no unambiguous structure is assigned, but given as a generic structure. Several isomers of 500M109 elute in three different peaks (RT 16.0-16.2 min, RT 17.6-18.4 min and RT 20.2-20.5 min), and is even co-eluting with metabolite 500M05 and two matrix adducts of metabolite 500M05 (RT 20.2-20.5 min), where the metabolite ratio could not be determined. Hence, the sum of peaks RT 16.0-16.2 min and RT 17.6-18.4 min is given additionally. Values in italics were not considered for the calculation of "totals".

Table 5.1.1-18: Identified Metabolites and Components in Urine and Faeces Sampled within 168 hours from Male Rats after Single Oral Treatment with 10 mg/kg bw ^{14}C-500M106

Metabolite	Structure	Urine[1]	Faeces

Metabolite	Structure	Urine[1]	Faeces
		Composition of Radioactive Residues [% Dose]	
500M21		1.01	not detected
500M73 / 500M112[3]		not detected	31.90
500M105		not detected	0.39
500M117		not detected	0.33

[1] The sum of the mean values of 4 animals (0-48 h) plus the concentration determined in the pooled urine combined from 4 animals (48-168 h) is given.

[2] For metabolite 500M109, no unambiguous structure is assigned, but given as a generic structure. Several isomers of 500M109 elute in three different peaks (RT 16.0-16.2 min, RT 17.6-18.4 min and RT 20.2-20.5 min), and is even co-eluting with metabolite 500M05 and two matrix adducts of metabolite 500M05 (RT 20.2-20.5 min), where the metabolite ratio could not be determined. Hence, the sum of peaks RT 16.0-16.2 min and RT 17.6-18.4 min is given additionally.

[3] According to HPLC-MS/MS analysis, metabolite 500M073 accounted for the main portion of radioactive residues in the peak, where metabolites 500M073 and 500M112 co-eluted.

3.2. Identification, Characterization and Quantification of Metabolites in Faeces

Structure elucidation of metabolites in faeces was based on HPLC-MS/MS analysis of the pooled acetonitrile extract of combined faeces (rat 1-4) sampled within 24-48 hours and two fractions obtained from the pooled acetonitrile /acetone extract of combined faeces (rat 1-4) sampled within 0-24 hours. The following metabolites were identified (order by retention time of the HPLC-MS/MS analysis):

- 500M04 - 19.2 min
- 500M117 - 24.1 min
- 500M105 - 30.8 min
- 500M112 - 31.0 min
- 500M73 - 31.6 min
- 500M01 - 38.5 min
- Isomer of 500M01 - 37.5 min
- 500M02 - 40.0 min
- Isomer of 500M02 - 37.5 min

Metabolites 500M73 and 500M112 were not readily separated by radio-HPLC and co-eluted in one peak at 35.0 min. According to HPLC-MS/MS analysis, metabolite 500M73 accounted for the main portion of radioactive residues in the peak. In one quantitative analysis (acetonitrile extract of combined faeces 0-24 h) isomers of metabolite 500M01 and 500M02 were detected, which were not separated by radio-HPLC and co-eluted in one peak at 41.4 min.
Extracts and solubilizates of combined faeces samples, containing sufficient amounts of radioactive residues, were analyzed by HPLC. The results of the investigation of faeces extracts and solubilizates are summarised in Table 5.1.1-19 to Table 5.1.1-22.
The peak comprising metabolites 500M73/500M112 was the main peak for the time interval 0-24 hours (27.06% of the dose) and was approximately 4-fold higher than the next abundant metabolites 500M01 and 500M02 accounting for 6.31% and 7.64% of the dose, respectively. Further identified metabolites in the pooled acetonitrile extracts were metabolite 500M04 (2.50% of the dose) and isomers of 500M01/500M02. After 24 hours the excreted concentration of all identified metabolites decreased and ranged from 1.13-3.77% of the dose within 24-48 hours and from 0.08-0.24% of the dose within 48-72 hours. Metabolite 500M04 was detected at trace amounts (up to 0.07% of the dose per sampling interval or 0.16% of the dose in total) within 72-168 h. Further, metabolites 500M73/500M112 and 500M02 were detected at low levels within 72-120 h (0.01-0.06% of the dose and 0.01-0.10% of the dose, respectively). The administered test item 500M106 was not detected at any sampled time interval.
Residues in the pooled acetonitrile / acetone extracts of combined faeces (time intervals 0-24 h, 24-48 h and 48-72 h) were quantified by HPLC.
Metabolites 500M04, 500M117, 500M105, 500M73/500M112 and 500M02 were detected at low levels (up to 0.72% of the dose) in all investigated samples. The administered test item 500M106 was not detected at any sampled time interval.

Residues in the protease solubilizates from the RRR of combined faeces (time intervals 0-24 h, 24-48 h and 48-72 h) were also quantified by HPLC. The metabolite 500M04 was determined in all investigated samples with the highest concentration (1.08% of the dose) for the time interval 0-24 h. In addition, metabolite 500M117 was detected at trace amounts (up to 0.05% of the dose) in samples of the time intervals 0-24 h and 24-48 h. The administered test item 500M106 was not detected at any sampled time interval.
Taken together, all identified metabolites in combined faeces reached their highest concentration within the time interval 0-24 hours and decreased continuously afterwards (in concordance with the TRR). Furthermore, the applied test item 500M106 was not detected in any sample, indicating a rapid and sufficient biotransformation.
Metabolites 500M73/500M112 accounted for the main portion of radioactive residues (27.81% of the dose) in combined faeces sampled within 0-24 h. Metabolites 500M01 and 500M02 were present at levels of 6.31 and 7.79% of the dose, respectively, whereby additional 1.63% of the dose were detected representing isomers of metabolites 500M01 and 500M02. Metabolite 500M04 was quantified at considerable levels in the extracts as well as in the investigated protease solubilizate, accounting in sum for 4.33% of the dose.
Further identified metabolites M500117 and M500105 were present at low levels accounting for 0.19 and 0.27% of the dose in combined faeces 0-24 h.
In combined faeces 24-48 h, metabolites 500M073/500M112 and 500M02 were the main components (3.83 and 3.33% of the dose, respectively). Furthermore, metabolites 500M04 and 500M01 were present at considerable levels (1.55 and 1.62% of the dose, respectively) and metabolites 500M117 and 500M105 at low levels (0.13 and 0.11% of the dose, respectively).
Within 48-72 hours all identified metabolites were present only at low levels ranging from 0.1-0.2% of the dose, except for metabolites 500M117 and 500M105 being identified at trace levels (both 0.01% of the dose).
Metabolite 500M04 was further detected in all samples until the end of the experiment (72-168 h: in sum 0.16% of the dose) and metabolites 500M73/500M112 and 500M02 were quantified at low concentration in faeces sampled within 72-120 h (0.07 and 0.10% of the dose, respectively).
Out of 81.05% of the dose recovered in faeces sampled within 0-168 hours, 59.91% of the dose were identified in extracts and solubilizates (Table 5.1.1-22). Moreover, 2.11% of the dose were characterized by HPLC, whereby each peak was below or equal to 0.26% of the dose. Assuming the case that the maximum not identified peak of each investigated sample represents the same component, these components would not exceed in sum 0.6% of the dose in the investigation period of 0-168 h. In addition, 0.92% of the dose were characterized by their extraction behaviour. The sum of radioactive residues after solvent extraction for all time intervals accounted for 21.58% of the dose. The RRR was further investigated by applying different enzyme incubations and alkaline treatment. In sum, additional 14.58% of the dose were characterized by their solubilization behaviour. The main portion of radioactive residues was released by exhaustive hot alkaline treatment (up to 8.32% of the dose / time interval). The final residue accounted for 3.87% of the dose (in sum; 0-168 h). The highest final residue was observed within the first 24 hours accounting for 2.64% of the dose.

[1] According to HPLC-MS/MS analysis, metabolite 500M073 accounted for the main portion of radioactive residues in the peak, where metabolites 500M073 and 500M112 co-eluted.

[2] Assuming the worst case that the maximum characterized peak in each investigated extract / solubilizate contains the same unidentified component, leads to a not identified compound accounting for in sum approximately 0.6% of the dose.

[3] Only the water extract from combined faeces 24-48 h is given, as the water extract from combined faeces 0-24 h was analysed by HPLC and hence being already considered in the "total identified" and "sum of characterized HPLC Peaks".

n.a. not analyzed
n.d. not detected

4. Metabolic Pathway

The proposed metabolic pathway of the test item 500M106 is illustrated in Figure 5.1.1-10 and Figure 5.1.1-11. The major transformation steps in the metabolic pathway are:

- Cleavage of the N-O bond of the phenylamine moiety followed by (a) hydroxylation, (b) dimerization with subsequent N-oxidation or (c) formation of formaldehyde adducts
- Cleavage of the ether bridge between the pyrazole and phenylamine moiety followed by conjugation (sulphation / glucuronidation) or hydroxylation and sulphation

Cleavage of N-O bond of the phenylamine moiety of the administered compound 500M106 leads to metabolite 500M73, which might be subsequently hydroxylated (500M112) or dimerized forming an azo-group linking the aniline moieties (metabolite 500M02 or an isomer). Further, N-oxidation of the recently formed azo-group ends up in metabolite 500M01 (or an isomer). Besides dimerization and hydroxylation, formation of formaldehyde adducts was observed (500M105 and 500M117). It is not clear whether 500M105 and 500M117 are “real metabolites” or formed during workup.
Furthermore, cleavage of the C-O bridge between the pyrazole and phenylamine moiety of 500M106 leads to metabolite 500M04 being subsequently conjugated with glucuronic acid (500M03) or sulphate (500M05). Further, metabolite 500M04 can be hydroxylated at any position of the chlorophenyl or pyrazole ring, which is indicated as a generic bond in the structure of 500M021, followed by sulphation and resulting in metabolite 500M109 (or an isomer).

Figure 5.1.1-10: Proposed Metabolic Pathway of 500M106 in Male Rats (Part 1)

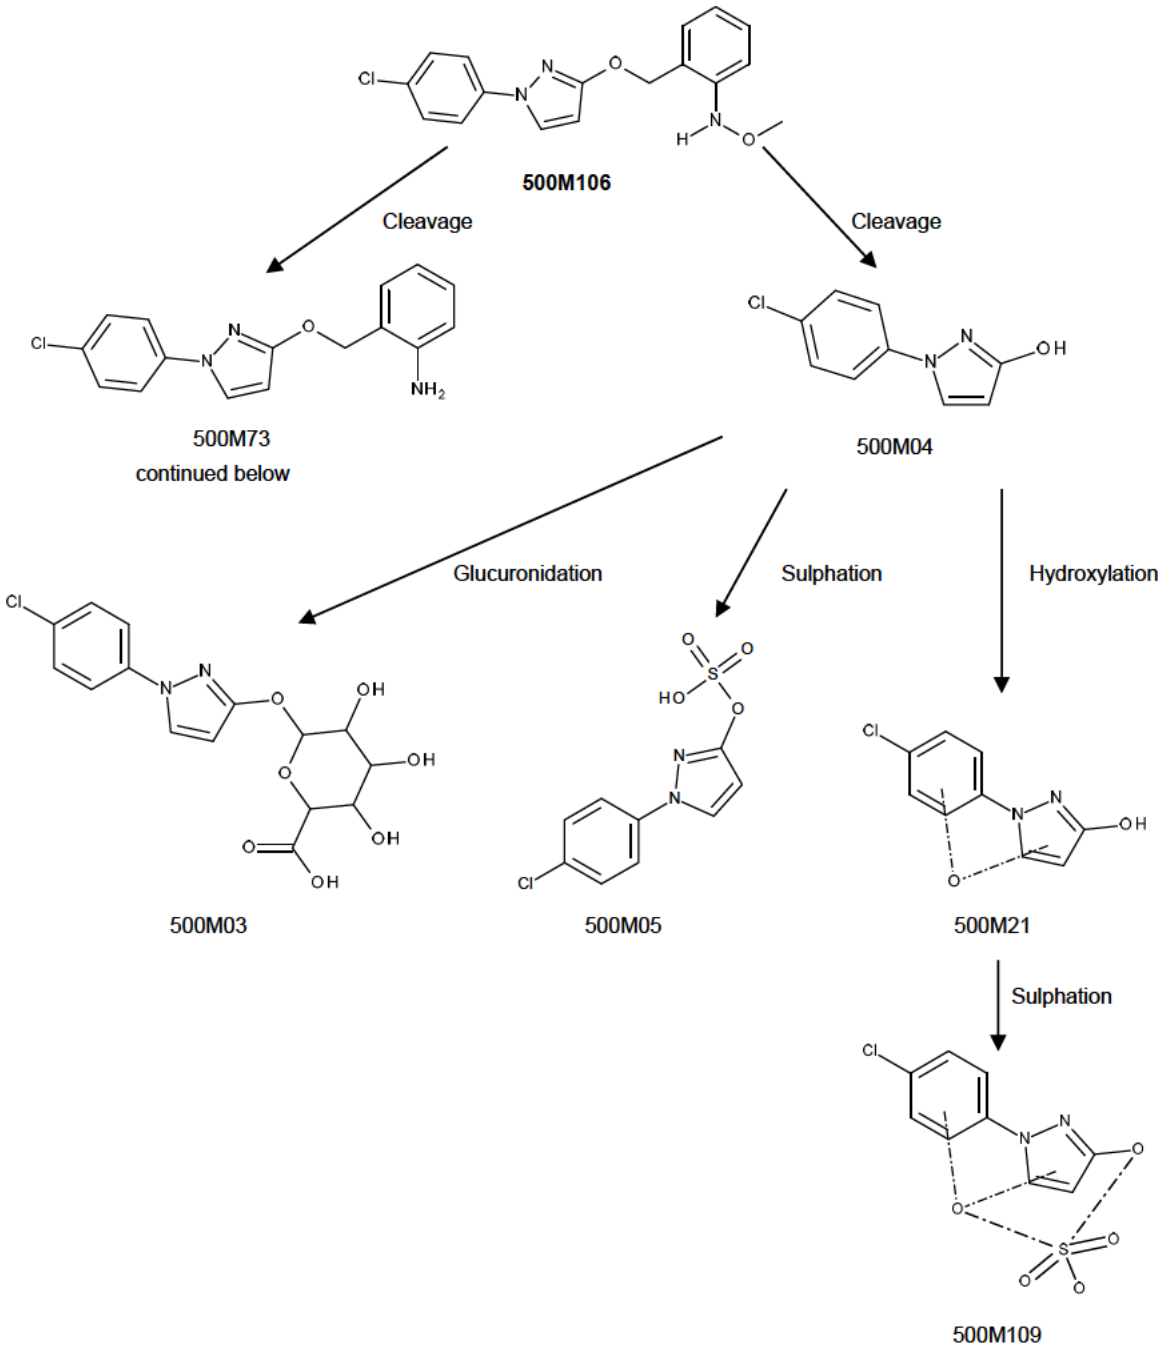

Figure 5.1.1-11: Proposed Metabolic Pathway of 500M106 in Male Rats (Part 2)

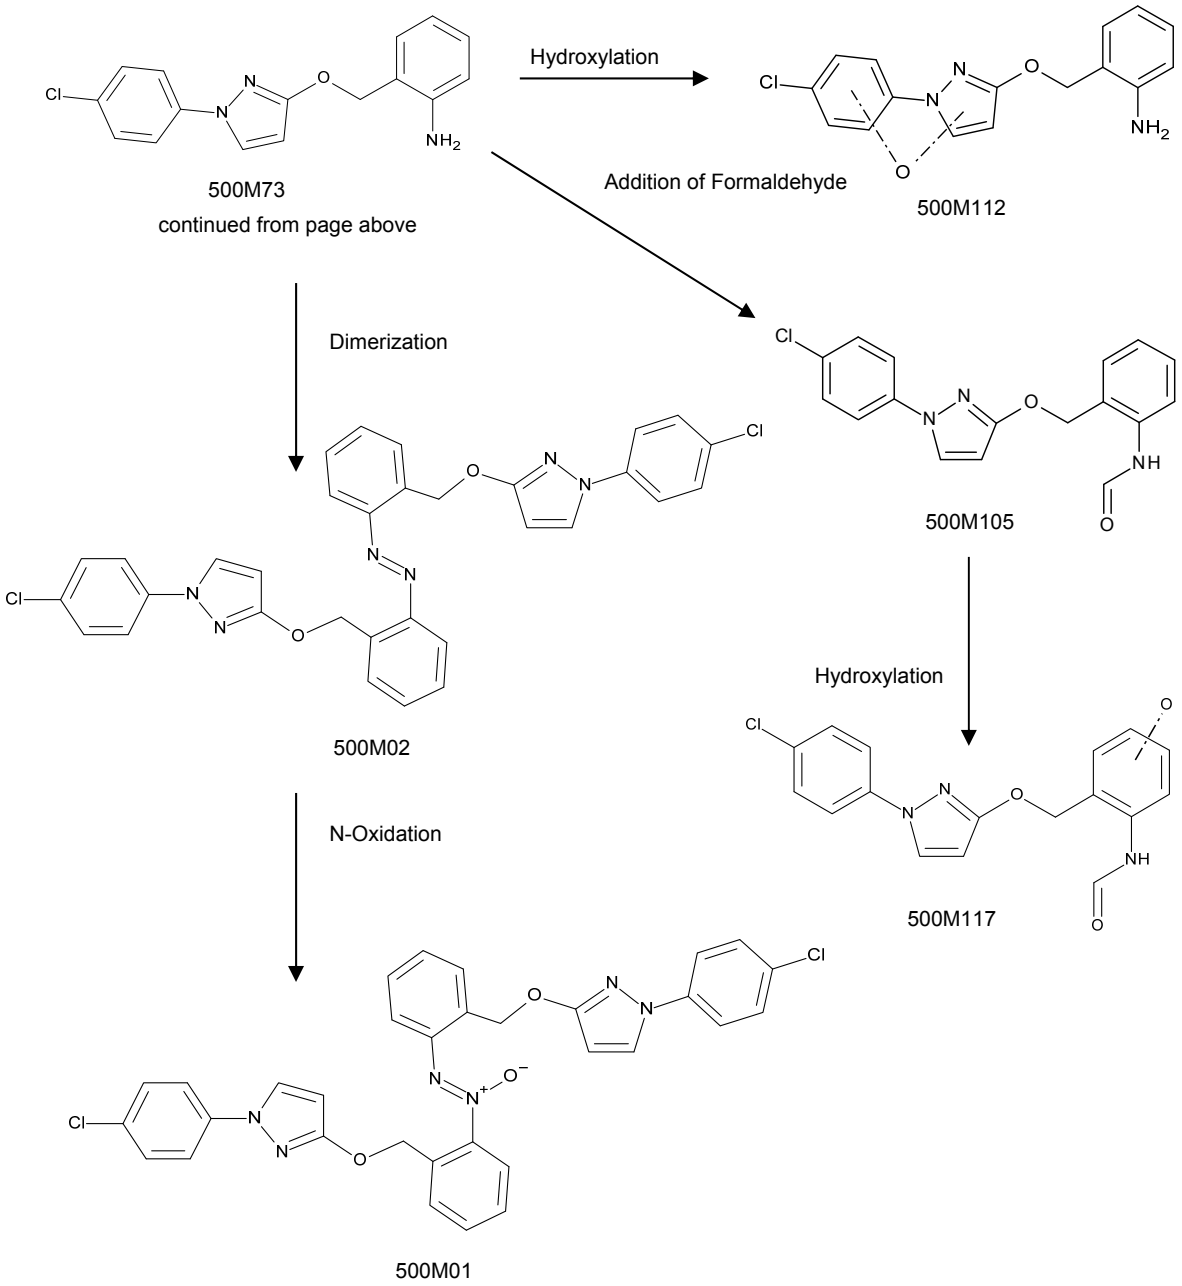

III. CONCLUSION

The metabolism of metabolite 500M106 was investigated in male rats after single oral administration of a nominal dose of 10 mg/kg bw. Metabolites were identified by HPLC-MS/MS and quantified by radio-HPLC. Urine and faeces were sampled within different time intervals up to 168 hours after treatment of male Wistar rats with 500M106 within a kinetics study.

The excretion was complete within the observation period, whereby the main excretion route was via faeces and detected portions of radioactive residues ranged from 84.61 to 89.89% of the dose within 168 hours. The excretion via urine ranged from 15.93 to 17.84% of the dose.

The combined faeces samples were extracted three times with acetonitrile and twice with water. The residue after acetonitrile and water extraction was further extracted three times with a mixture of acetonitrile and acetone.

The extractability of radioactive residues from faeces was moderate and the main portion of the radioactive residues was extracted with acetonitrile ranging from 42.0 to 69.2% TRR. Only low amounts were subsequently extracted with water and with the mixture of acetonitrile and acetone leading to radioactive residues after solvent extraction above or equal to 21.7% TRR. The residual radioactive residues after solvent extraction were subjected to a sequential solubilization procedure. Amounts up to 4.2% TRR were released by enzyme incubation (up to 8% TRR in total) and high portions were solubilized by applying hot alkaline treatment accounting for up to 26.5% TRR.

Reasonable efforts were made to identify successfully all metabolites being present for at least 1% of the administered dose.

Metabolites 500M109, 500M03, 500M05, 500M04 and 500M21 were identified in urine sampled within 48 h, whereby metabolites 500M109 and 500M04 were quantified as the main components accounting for up to 3.82 and 4.63% of the dose, respectively (average of 4 animals). Further detected metabolites were present at levels in a range from 0.89-1.91% of the dose (average of 4 animals). In pooled and combined urine sampled within 48-168 hours, metabolites 500M109/500M03, 500M05/500M109, 500M04 and 500M21 were present at similar low levels ranging from 0.12 to 0.49% of the dose. The administered compound 500M106 was not detected in urine sampled within 168 h.

Metabolites 500M04, 500M117, 500M105, 500M73/500M112, 500M01 and 500M02 as well as isomers of 500M01 and 500M02 were identified in faeces, thereby metabolites 500M73/500M112 accounted for the main fraction (in total 31.90% of the dose). Metabolites 500M01 and 500M02 were the next most abundant metabolites accounting for 8.02 and 11 .47% of the dose. Metabolite 500M04 was present at 6.18% of the dose and the remaining metabolites 500M117 and 500M105 accounted for up to 0.39% of the dose.

The applied compound 500M106 was not detected in faeces sampled within 168 h.

The major biotransformation steps in the metabolic pathway of 500M106 in male rats are:

- **Cleavage of the N-O bond of the phenylamine moiety followed by (a) hydroxylation, (b) dimerization with subsequent N-oxidation or (c) formation of formaldehyde adducts**
- **Cleavage of the ether bridge between the pyrazole and phenylamine moiety followed by conjugation (sulphation / glucuronidation) or hydroxylation and sulphation**

CA 5.1.2 Absorption, distribution, metabolism and excretion by other routes

New study

In accordance with the requirements of Commission Regulation No. 283/2013 and No. 1107/2009 and in alignment with RMS Germany a **comparative *in-vitro* metabolism study** was performed and is summarized below.

The aim of this study was

- to compare the *in-vitro* metabolism in hepatocytes (and microsomes) between animal species used for toxicological testing and humans
- to determine whether metabolic profiles are similar and
- to investigate whether a unique human metabolite occurs.

Since no guidelines exist for this type of study, the investigations were performed using a study design that has been aligned with the RMS Germany.

I. MATERIAL AND METHODS

A. MATERIALS

1. **Test Material:** BAS 500 F (pyraclostrobin, Reg No. 304428)
Description: see table below
Batch # / purity: see table below (for structures of ^{13}C-pyrazole and ^{14}C-tolyl label: see Figure 5.1.1-3 and Figure 5.1.1-4).

Pyraclostrobin (^{14}C tolyl label)	566-5103	95%	6.8 MBq/mg
Pyraclostrobin (^{14}C chlorophenyl label)	579-6301	99.2%	6.15 MBq/mg
Pyraclostrobin (^{13}C pyrazole label)	1026-1018	99.8% (chem.)	n.a.
Pyraclostrobin	01815-65	99.9% (chem.)	n.a.

Stability of test compound: Stable during testing

2. Vehicle and/or positive control:

Hepatocytes
Positive control: Hepatocytes were incubated with ethoxy coumarin and testosterone instead of the active substance to validate the metabolic activity of the hepatocytes.
Microsomes
Positive control: Microsomes were incubated with testosterone instead of the active substance to prove the metabolic activity of the microsomes.

3. Test animals: Mammals
Species: Dog, rabbit, rat and human (all male and female)
Strain: Beagle dog (only for microsomes), rabbit (NZ), Wistar rats, human (sources: Xenotech or Gibco, Germany)

B. STUDY DESIGN AND METHODS

The study was carried out at the Agricultural Research Centre of BASF SE in Limburgerhof, Germany.

1. Dates of work: February 25, 2014 – July 11, 2014

2. Test system preparation

The radiolabelled and non-radiolabelled test materials were prepared with the following specifications. The radiolabeled test item (solution in toluene) was evaporated under nitrogen and taken up in an appropriate volume of DMSO. For the radiolabelled stock solutions, a concentration of approximately 5mg/mL was determined. For the preparation of the stock solution of the unlabelled test items, pyraclostrobin was dissolved in methanol.

For the preparation of the application solution for experiments with 10 µM pyraclostrobin, specific amounts of unlabelled and ^{13}C-labelled were combined, concentrated to dryness in a stream of nitrogen, mixed with the desired amount of radiolabelled test item and diluted with DMSO. For the preparation of the different application solutions for experiments with 1 µM, 3 µM and 5 µM pyraclostrobin, calculated amounts of ^{14}C-labelled test item were diluted with DMSO. The actual concentrations of radiolabelled pyraclostrobin in the application solutions were determined by LSC of aliquots of diluted subsamples. The purity of each application solution was confirmed by HPLC analysis.

Hepatocytes
Cryopreserved hepatocytes from dog, rabbit, rat and human were stored in liquid nitrogen. On each incubation day, the cells were thawed according to a protocol provided by the supplier using appropriate kits. Aliquots of the resulting cell suspensions in hepatocyte incubation medium were diluted with phosphate-buffered saline (PBS), and the number of viable cells was measured using an automated cell counter. The cell suspensions were then adjusted to the desired cell density of 2 x 10^6 viable cells per mL with incubation medium. In the case of dog, rabbit and rat hepatocytes, male and female cells were combined in this final step in a ratio of 1:1. The human hepatocytes were purchased as a mixture of male and female cells.

Microsomes
All preparations contained 20 mg microsomal protein per mL. For the tests, the liver microsomes of male and female animals of one species were pooled in a ratio of 1:1, relative to the protein content. The human liver microsomes were already pooled by the supplier.

1. *In-vitro* assays
The application media were incubated at a final concentration of approximately 3 and 10 µM with hepatocytes and 10 µM with microsomes.

Hepatocytes
As the previously conducted *in-vivo* rat metabolism study with pyraclostrobin showed extensive phase II-metabolism, hepatocytes were chosen as main test system for the present study. On each incubation day, the application solutions in DMSO (mix of ^{14}C-labelled, ^{13}C-labelled and unlabelled test item) were diluted with the corresponding incubation media by a factor of 100 to prepare the respective application media for hepatocyte incubations. Each sample comprised of equal amounts of the application medium and of the hepatocyte cell suspension in one of the wells of a 24-well cell culture plate (maximum concentration of DMSO: 0.5%).

For human hepatocytes, the reactions were performed for 30 min, 60 min and 180 min at approximately 37°C. In case of rabbits and rats, experiments with shorter incubation intervals were additionally performed (10 min and 30 min). Incubation was terminated by pipetting the incubation mixture into a weighed tube containing cold ethanol (final concentration of 70%) and cell lysis was assisted by ultrasonication. In this stage, the samples were stored frozen prior to concentration.

In addition, two negative controls, two positive controls and a blank control (application medium with DMSO instead of test item) were performed for each species. Under these conditions no metabolisation should occur. For the **"stability control"**, the application medium was mixed only with incubation medium instead of cell suspension. For the **"zero incubation control"** (t = 0 min), the reaction was stopped immediately after addition of the cell suspension. The stability control was performed for all test systems, but also covers all test concentrations.
In the **positive controls**, 10 µM testosterone or ethoxycoumarin instead of the active substance was incubated with hepatocytes from the different species to prove the metabolic activity of the different hepatocytes.

Microsomes
On each incubation day, appropriate amounts of the application solutions in DMSO (mix of ^{14}C-chlorophenly labelled, ^{13}C-labelled and unlabeled test item) were directly dosed resulting in a final dilution of 1:200. Each sample (2 mL total volume) comprised 1 mg of microsomal protein, a NADPH generating system and potassium phosphate buffer (approximately 0.1 M, pH 7.4). The reactions were performed at 37 °C for 90 min in a shaking water bath and stopped by adding 4.7 mL cold ethanol and sonicating for 5 minutes. Additionally, for each species negative and positive controls were performed.

The negative controls were the "heat denatured control" and the "t=0 control". In addition, the "buffer control" was performed. Under these conditions no or only very limited metabolisation or degradation should occur. For the heat denatured control, the liver microsomes were inactivated by incubating in hot water (> 95 °C) for 10 minutes before pipetting them into the mixture. For the buffer control, the application solution was mixed only with buffer. For the "t=0" control, the enzymatic reaction was stopped immediately after adding the NADPH generating system by adding 4.7 mL of cold ethanol. In the **positive control**, the different liver microsomes were incubated with testosterone instead of the active substance to prove the metabolic activity of the different liver microsomes.

In each experimental setup, the incubation of the substrates as well as all control assays were performed in triplicate.

2. Work-up of samples
The stopped incubation mixture was centrifuged and concentrated to volumes of approx.0.5 (hepatocytes) or 2 mL (microsomes) by a centrifugal evaporator. The supernatant and the pellet were frozen separately. All samples were stored in a freezer at -18°C or below.

Analysis of the supernatants
All supernatants were analysed by reversed phase HPLC. The metabolites detected in the supernatants of human hepatocytes or human liver microsomes at relative concentrations above 5% of the applied radioactivity (5% AR) were identified by HPLC MS/MS analysis of selected samples. For all other samples, the radio HPLC peaks were assigned to the identified metabolites by comparison of retention times and metabolite patterns, as well as by HPLC MS analysis of at least one of three replicate supernatant samples. The metabolite patterns formed by incubation with the animal hepatocytes were compared to the metabolite pattern formed with human hepatocytes. In addition, the metabolite patterns arising after incubation with liver microsomes (focusing on phase I metabolism) were also investigated.

Work-up of the residual pellet
If the radioactivity measurement of the supernatants after concentration and centrifugation of the terminated incubation mixtures yielded less than 90% of the applied radioactivity, the pellets after centrifugal evaporation were resuspended in 50 µL water each and mixed with 90 µL acetone and 360 µL acetonitrile (assisted by ultrasonication). After centrifugation, the radioactive residues in the extract supernatants were determined by LSC of aliquots. The remaining second pellets were resuspended in 300 µL water, and the radioactive residues in the suspended samples were measured by LSC.

II. RESULTS AND DISCUSSION

1. Control Experiments

The blank controls performed for each species without test item showed no significant amounts of radioactivity (LSC measurements), and no radioactive peaks were detected by HPLC analysis.

The triplicates of each negative control (stability control without cells and zero incubation control) were comparable and showed nearly identical HPLC profiles, which contained only one peak corresponding to the unchanged active substance pyraclostrobin. Hence, no or very little metabolisation or degradation of pyraclostrobin occurred without influence of hepatocytes and microsomes.
The positive controls showed that the metabolic activity of the hepatocytes with respect to Phase I and Phase II metabolic reactions was sufficiently high. The portions of metabolized testosterone and ethoxycoumarin reached values above 80% of the radioactive residues recovered.
The positive controls showed that the metabolic activity of the microsomes with respect to Phase I metabolic reactions was also sufficiently high; the defined threshold values (greater than 50% metabolism) were reached in all cases.

2. Viability of the Hepatocytes

The hepatocyte suspensions were adjusted to a cell density of 2 x 10^6 viable cells per mL to achieve a final cell density of approximately 10^6 cells per mL in the incubation assays. After incubation for 180 min, the viability of the cells was determined using a luminescent cell viability assay. The viability of the human hepatocytes incubated with 10 µM pyraclostrobin (measured in Relative Luminescence Units, RLU) was 55 and 46% of the viability of the cells incubated without test item for the chlorophenyl label and the tolyl label, respectively. In order to select an appropriate second concentration of the test item with a higher viability of the cells, concentrations of 1 µM, 3 µM and 5 µM pyraclostrobin were tested with human hepatocytes. Since the viability of human hepatocytes was at or above 90% of the viability of the cells incubated without test item for both labels, a concentration of 3 µM pyraclostrobin was chosen. The viability of the animal cells incubated with 10 µM pyraclostrobin was in the range of 79 to 105% for rat and in the range of 87 to 116% for rabbit. The viability of the cells incubated with 3 µM pyraclostrobin (chlorophenyl label and tolyl label, respectively) was 91 and 94% of the viability of the cells incubated without test item for human hepatocytes, 100 and 106% for rat hepatocytes and 102 and 96% for rabbit hepatocytes.

3. Determination of radioactivity in supernatants and pellets

Hepatocytes: In most of the samples, the radioactive residues recovered in the concentrated supernatants after terminating the incubations were below 90% of the applied radioactivity. For this reason, the respective incubation vials with the residual pellets were extracted with acetone / acetonitrile. The radioactive residues in the acetone / acetonitrile extracts were below 12.3% AR in all experiments. The extracts obtained were analyzed by HPLC; if sufficiently resolved, the metabolite amounts being present were considered for final quantitation (see Table 5.1.2-1 and Table 5.1.2-2). The radioactive residues in the final pellets of all experiments with pyraclostrobin were below or equal to 7.6% AR. Therefore, no further workup was performed.

Microsomes: After incubation of pyraclostrobin with liver microsomes; the radioactive residues recovered in the concentrated supernatants were often also below 90% of the applied radioactivity. Therefore, the residual pellets were extracted with acetone / acetonitrile in the same manner as the hepatocyte samples. The extracts obtained were analyzed by HPLC; if sufficiently resolved, the metabolite amounts being present were considered for final quantitation (see Table 5.1.2-3). The radioactive residues in the acetone / acetonitrile extracts (with one exception) were below 9% AR. The radioactive residues in the final pellets of the experiments with pyraclostrobin were below 11% AR. Therefore, no further workup was performed.

4. Kinetics of biodegradation of pyraclostrobin after incubation with hepatocytes

Pyraclostrobin is present in most of the samples after incubation with human hepatocytes. The mean % AR decreased in chlorophenyl and tolyl label from 73.20 and 67.31% AR at 0 minutes to 64.57 and 55.35 % AR after 30 minutes to 40.07 and 37.50% AR after 60 minutes and to 2.55 and 3.84% AR after 180 minutes of incubation in the experiments with 10 µM pyraclostrobin. At the concentration of 3 µM pyraclostrobin, the portion of the active substance showed a faster decrease of both labels from 81.33 and 79.38% AR (chlorophenyl and tolyl label) at 0 minutes to 52.98 and 42.31% AR after 30 minutes and 16.12 and 14.48% AR after 60 minutes and after 180 minutes no pyraclostrobin was detected any more.

After incubation with rat hepatocytes, pyraclostrobin was detected in all control samples with 0 minutes incubation (between 65.52 to 77.87% AR for both labels and concentrations). In the chlorophenyl labelled samples of 10 µM pyraclostrobin with rat hepatocytes the mean % AR decreased to 36.95% AR after 10 minutes and after 30 and 180 minutes, no pyraclostrobin was detected. Similar results were obtained for the tolyl labelled samples with 10 µM pyraclostrobin with rat hepatocytes; here the mean % AR decreased from 30.64% AR after 10 minutes to 0.63% AR after 30 minutes and after 180 minutes no pyraclostrobin was detected. Samples with 3 µM pyraclostrobin were incubated for 0 and 180 minutes. After 180 minutes no pyraclostrobin was detected any more.

After incubation with rabbit hepatocytes, pyraclostrobin was detected in all control samples with 0 minutes incubation (between 63.30 to 84.88% AR for both labels and concentrations). The mean % AR decreased in chlorophenyl and tolyl label from 8.86 and 7.07% AR after 10 minutes to 2.45 and 1.94% AR after 30 minutes of incubation in the experiments with 10 µM pyraclostrobin. After 180 minutes no pyraclostrobin was detected in any label or applied concentration. Detailed results are shown in Table 5.1.2-1 and Table 5.1.2-2 for chlorophenyl and tolyl labelled samples, respectively. The order of the metabolites is in accordance with the original report.

From the results is can be concluded that the transformation of pyraclostrobin proceeded faster in animal hepatocytes, whereas rabbit hepatocytes transformed pyraclostrobin faster than rat hepatocytes.

5. Metabolites formed after incubation of pyraclostrobin with hepatocytes Chlorophenyl label

HPLC-MS analysis of samples after incubation with human hepatocytes with chlorophenyl labelled pyraclostrobin allowed identification of nine metabolites being present in amounts greater than 5% AR (500M03, 500M108, 500M04, 500M103, 500M104, 500M107, 500M73, 500M106 and 500M02) in both concentrations and one additional metabolite 500M88 at 10 µM pyraclostrobin.

Each of these ten metabolites was also present in at least one sample from the incubation with animal hepatocytes.

In rat hepatocyte samples, the metabolites 500M108, 500M04, 500M104 and 500M88 were identified. In rat samples incubated with 10 µM pyraclostrobin, the detected metabolites 500M108, 500M04 and 500M88 represent a mean portion below 5% AR and metabolite 500M104 represents a mean % AR above 5% AR. Rat samples incubated with 3 µM pyraclostrobin showed the formation of metabolite 500M104, which represent a mean portion below 5% AR. Additionally, the regioisomers of metabolite 500M108 were formed.

After incubation of rabbit hepatocytes with 10 µM pyraclostrobin each metabolite identified in human hepatocyte samples was formed and identified. Metabolites 500M03, 500M103, 500M104, 500M107 and 500M88 were detected below a mean portion of 5% AR and metabolites 500M108, 500M04, 500M73, 500M106 and 500M02 represent values below as well as above 5% AR. In rabbit samples incubated with 3 µM pyraclostrobin (chlorophenyl label), the detected metabolites 500M103, 500M104, 500M73 and 500M106 represent a mean portion below 5% AR and metabolites 500M03 and 500M108 represent a mean % AR above 5% AR.
The amounts of metabolites being identified in different test species and after designated incubation times are summarized in Table 5.1.2-1. The structural formula of the metabolites are depicted in Table 5.1-1**:**

Tolyl label

HPLC-MS analysis of samples after incubation with human hepatocytes with tolyl labelled pyraclostrobin allowed identification of eight metabolites (500M108, 500M103, 500M104, 500M107, 500M88, 500M73, 500M106 and 500M02), whereas metabolite 500M88 was only observed in incubation samples with 10 µM pyraclostrobin and metabolite 500M107 was only detected in incubation samples with 3 µM pyraclostrobin.

Each of these eight metabolites was also present in at least one sample from the incubation with animal hepatocytes.

In rat hepatocyte samples incubated with 10 µM pyraclostrobin metabolites 500M88, 500M108 and 500M103 and 500M88 represent a mean portion below 5% AR and metabolite 500M104 represents a mean % AR above as well as below 5% AR. Rat samples incubated with 3 µM tolyl labelled pyraclostrobin showed only the formation of metabolite 500M104 representing a mean portion below 5% AR.

After incubation of rabbit hepatocytes with 10 µM pyraclostrobin each metabolite identified in human hepatocyte samples was formed and identified. Metabolites 500M103, 500M104, 500M107 and 500M88 were detected below a mean portion of 5% AR and metabolites 500M108, 500M73, 500M106 and 500M02 represent values below as well as above 5% AR. In rabbit samples incubated with 3 µM pyraclostrobin (tolyl label), the mean % AR of the detected metabolites 500M103 and the regioisomers of metabolite 500M108 was above 5% AR.

The amounts of metabolites being identified in different test species and after designated incubation times are summarized in Table 5.1.2-2. The structural formula of the metabolites are depicted in Table 5.1-1**:** .

- = not detected

In summary, the *in-vitro* comparative experiments with hepatocytes showed that the metabolites, which were identified in human hepatocyte samples, are also seen in animal hepatocyte samples.

6. Kinetics of biodegradation of pyraclostrobin after incubation with microsomes

The *in-vitro* metabolism with focus on the phase I metabolic reactions was investigated with 10 µM chlorophenyl labelled pyraclostrobin incubated with human liver microsomes and with liver microsomes from rat, rabbit and dog for 0 minutes (control) and 90 minutes. An additional control after 90 minutes was performed with inactivated liver microsomes (heat denatured control).

After incubation with human and animal liver microsomes, pyraclostrobin was detected in all heat denatured control samples at 0 and 90 min with a mean % AR above 87, except after incubation of rabbit liver microsomes for 0 minutes. Besides 29.49% AR pyraclostrobin, further substances were detected indicating that metabolism of the active substance has already started.

After 90 minutes incubation with human liver microsomes, the active substance decreased to 44.70% AR. The incubation of rat and rabbit liver microsomes delivered a higher decrease of pyraclostrobin with 15.37 and 2.99% AR, respectively. This higher conversion rate indicates a faster metabolic capacity of rat and rabbit microsomes. After the incubation of pyraclostrobin with dog liver microsomes the active substance decreased to 64.42% AR.

7. Metabolites formed after incubation of pyraclostrobin with microsomes

HPLC-MS analysis of the samples incubated with human liver microsomes allowed identification of five metabolites. Three of these metabolites represent a mean portion above 5% AR with metabolite 500M04 (14.00% AR), 500M88 (9.96% AR) and 500M02 (7.25% AR). The metabolites 500M73 (2.94 %AR) and 500M106 (4.16 % AR) are present in amounts below 5 % AR. After incubation with rat liver microsomes, the three metabolites 500M04, 500M88 and 500M73 were detected. After incubation of rabbit liver microsomes, each of the 5 metabolites was identified, which was seen in human liver microsome samples. After incubation of dog liver microsomes four metabolites were observed with metabolites 500M04, 500M88, 500M73 and 500M02. The quantitative results are summarized in Table 5.1.2-3.

In summary, the *in-vitro* comparative experiments with microsomes showed that the metabolites, which were identified in human microsome samples, are also seen in animal microsome samples.

Table 5.1.2-3: Comparison of metabolites of pyraclostrobin (chlorophenyl label) formed after incubation with human, rat, rabbit and dog microsomes

BAS 500 F	44.70	15.37	2.99	64.42
500M106	4.16	-	6.35	-
500M02	7.25	-	7.91	0.82

III. CONCLUSION

In the *in-vitro* comparison study, some differences were noted between the different test species. The metabolic degradation of pyraclostrobin is considerably faster in rat and rabbit hepatocytes compared to human cells. In deviation to human, no or very low amounts of parent were detected after incubation periods of 10 or 30 min. Metabolites as e.g. 500M04, 500M108, 500M103, 500M104 and 500M88 are common to all test species.
In human and rabbit, cleavage of the amide bond resulting in the formation of the metabolite 500M106 is major degradation pathway. Subsequently, 500M106 is further metabolized by conjugation with glucuronic acid to 500M107. In human and rabbit, the metabolite 500M02 which is formed by dimerization has been also identified.
In rat hepatocytes, hydroxylation and conjugation to 500M104 seems to be more pronounced compared to human and rabbits.

In order to investigate the impact of conjugation reactions (Phase II) on kinetics, further investigations on liver microsomes were carried out. As additional test species, dogs were included. The investigations confirm the picture obtained with hepatocytes. In dogs, trace amounts of 500M02 were found.

The study did not show any human metabolite, which was not found either in rabbit or rat.

The table below provides an overview on all investigated test systems and incubation periods including indications on the amounts of detected metabolites (+ representing a detected mean portion of < 5 % AR for all time intervals, ++ representing a mean portion above 5 % AR from at least one time interval).

* investigations performed at one incubation period (180 min)
** detected at short incubation periods of 10 and 30 min
n.d. = not detected

In order to get a better understanding of the findings of the *in-vitro* comparison study, *in-vitro* mechanistic investigations were performed. Goal of the experiments was to identify the enzyme involved in the formation of metabolite 500M106 in human cell cultures, but also to investigate whether this enzyme is also present in rats.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:	^{14}C-BAS 500 F (pyraclostrobin, Reg. No. 304428), see Figure 1.1
	WWL229 (inhibitor of human carboxylesterase 1), see Figure 1.2
Description:	BAS 500 F: tolyl-ring-U-C14 label WWL229: unlabeled
Chemical name:	BAS 500 F: methyl-N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxymethyl}phenyl)-(N-methoxy)carbamate (IUPAC-Name) WWL229: not applicable
Test substance No:	not reported
Lot/Batch #:	BAS 500 F: 566-5501; WWL229: 104M4753V
CAS#:	BAS 500 F : 175013-18-0 ; WWL229: 1338575-28-2
Development code:	Pyraclostrobin: BAS 500 F (Reg.No. 304428)
Purity:	BAS 500 F: Radiochemical purity: 99.5% (RHPLC); chemical purity: 98.3% WWL229: 98.8% (HPLC)
Specific activity:	BAS 500 F: 6.31 MBq/mg (specific activity a.i.); 30 MBq/g (specific activity) WWL229: not applicable
Stability of test compound:	The test item was stable over the test period. Stability controls (test item without hepatocytes and liver cytosol) were performed as negative controls. No degradation of pyraclostrobin, neither without nor with WWL229, was observed within 180 min under these experimental conditions without cells.

2. Vehicle and/or positive control: Human hepatocytes were incubated with 7-ethoxycoumarin and testosterone instead of the active substance to validate the metabolic activity of the hepatocytes.

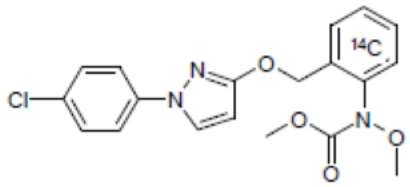

Figure 1.2: Structural formula of unlabelled WWL229

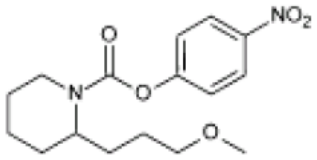

B. STUDY DESIGN AND METHODS

The study was carried out at the Agricultural Research Centre of BASF SE in Limburgerhof, Germany.

1. Dates of experimental work (analytical phase): September 17, 2015 to August 30, 2016

2. Study design

Stock solution

The stock solution of pyraclostrobin (BAS 500 F) was prepared as follows: a weighed aliquot was evaporated to dryness with nitrogen and dissolved in acetonitrile. Aliquots were diluted and analyzed by liquid scintillation counting (LSC) in order to determine the actual concentration (0.978 mg/mL).

The stock solutions of radiolabeled ^{14}C-testosterone and 7-ethoxycoumarin were also prepared within the *in-vitro* metabolism study (BASF DocID 2014/1001562), and the concentrations were determined by LSC analysis (0.591 mg/mL and 0.464 mg/mL, respectively).

WWL229 was purchased as oil. A defined weight was mixed with dimethylsulphoxide (DMSO) and application medium (hepatocytes) or application buffer (cytosol).

Application solution

Aliquots of the application solutions containing pyraclostrobin without inhibitor as well as aliquots of the application solutions containing testosterone and 7-ethoxycoumarin were obtained from the *in-vitro* metabolism study (BASF DocID 2016/1061381).

The application solutions used for incubations with hepatocytes and incubation with cytosol were prepared as follows:
The solvent from a defined volume of the stock solution was evaporated with nitrogen, and the test item was dissolved in 2 mL DMSO. For incubation with hepatocytes a nominal concentration of 3 µM pyraclostrobin was used. For incubation with liver cytosol a nominal concentration of 10 µM pyraclostrobin was intended. The specific radioactivity of the test item accounted for 378,600 dpm/µg. The actual concentration of radiolabeled pyraclostrobin in this application solution was determined by LSC of aliquots of diluted subsamples (0.226 mg/mL (3 µM) and 0.756 mg/mL (10 µM)).
For the preparation of the application solution for experiments with 10 µM testosterone a specific amount of the stock solution of the radiolabeled testosterone was evaporated with nitrogen and dissolved in DMSO (0.4 mL). The actual concentration of testosterone in the application solution was determined by LSC of aliquots of diluted subsamples (0.591 mg/mL). The specific radioactivity accounted for 402,345 dpm/µg.
For the preparation of the application solution for experiments with 10 µM 7-ethoxycoumarin a specific amount of the solid radiolabeled 7-ethoxycoumarin obtained from the supplier was dissolved in DMSO (0.325 mL). The actual concentration of 7-ethoxycoumarin in the application solution was determined by LSC of aliquots of diluted subsamples (0.464 mg/mL). The specific radioactivity accounted for 898,800 dpm/µg.
As application solution for blank experiments (negative controls), 1.0 mL DMSO was used.

Test system

Preparation of human hepatocytes

Cryopreserved human hepatocytes (pool of 50 male and 50 female donors) were purchased from XenoTech. The hepatocytes were stored in liquid nitrogen. On the incubation day, cells were thawed according to the protocol provided by the supplier using appropriate kits.

Preparation of human liver cytosol

Cryopreserved human liver cytosol was purchased from XenoTech (as a mixture from males and females). The cytosol was stored in an ultra-freezer at approximately -80°C. On the incubation day, the cytosol was thawed on ice. Aliquots of the cytosol were heat-denatured by keeping at 95°C or above for 10 minutes.

In-vitro assays

In-vitro assay for incubation with human hepatocytes

On the incubation day, the application solution was diluted with hepatocyte incubation medium to prepare the respective application medium. Human hepatocytes were incubated with application media containing 3 µM pyraclostrobin without and with 20 µM WWL229 (all final concentrations in the incubation mixture). The final concentration of DMSO was 0.5% for all experiments. Aliquots of the application media were analyzed by LSC to calculate the amounts of applied radioactivity per well and of total applied pyraclostrobin per assay (representing 100% AR in 1200 µL per well: 1.31 µg or 1.32 µg for incubation without or with WWL229, respectively). The purity of the application media for the *in-vitro* assays was determined by HPLC analyses using HPLC methods LC01 and LC02.

In the case of testosterone and 7-ethoxycoumarin, the incubations were performed at final concentrations of 10 µM each. The purity of the application medium and the retention time of testosterone were determined by HPLC analysis using HPLC methods LC01 and LC04 (optimized for testosterone), respectively. The purity of the application medium and the retention time of 7-ethoxycoumarin were determined by HPLC analysis using HPLC methods LC01 and LC03 (optimized for 7-ethoxycoumarin, radio- and UV-Vis detection), respectively. Additionally, the possible conversion products of 7-ethoxycoumarin were analyzed using HPLC method LC03 to determine the respective retention times.

The reactions were performed for 60 min and 180 min at 37°C and at 5% CO_2 in an incubator.

Two negative controls (stability and zero incubation control), two positive controls (with testosterone and 7-ethoxycoumarin) and a blank control (cells in incubation medium without test item) were performed.

In the negative controls no metabolism should occur. For the "stability control", the application medium was mixed with incubation medium instead of the cell suspension. The stability and the blank controls were incubated for 180 min. For the "zero incubation control" (t = 0 min), the reaction was stopped immediately after addition of the cell suspension.

In the positive controls, testosterone or 7-ethoxycoumarin instead of the test item were incubated with hepatocytes for 180 min, in order to determine their metabolic activity. To prove the metabolic activity, at least 50% of testosterone and 30% of 7-ethoxycoumarin should be metabolized, respectively.

Each experimental setup was performed in triplicates.

In-vitro assay for incubation with human liver cytosol

On the incubation day, the application solution was diluted with 10 mM phosphate buffer pH 7.4 to obtain the application buffer for incubation with human liver cytosol. Human liver cytosol was incubated with application buffer containing 6 µM pyraclostrobin without and with 20 µM WWL229 (all final concentrations in the incubation mixture). Aliquots of the application buffer were analyzed by LSC to calculate the amounts of applied radioactivity per vial and of total applied pyraclostrobin per assay (representing 100% AR in 500 µL per vial: 1.29 µg or 1.32 µg for incubation without or with WWL229, respectively). The final concentration of DMSO was 0.5%.

The purity of the test item in the application buffers for the *in-vitro* assays was determined by HPLC analysis using HPLC methods LC01 and LC02. The application buffers were equilibrated for five minutes in a water bath prior to addition of the human liver cytosol. The incubations were performed for 60 min and 180 min in a water bath at 37°C (± 2°C) under gentle shaking at 200 rpm.

Three negative controls (stability control, zero incubation control and control with heat-denatured liver cytosol) were performed. In the negative controls no metabolism should occur. For the "stability control", the application buffer was mixed with phosphate buffer instead of liver cytosol. The stability controls and the controls with heat-denatured liver cytosol were incubated for 180 min. For the "zero incubation control" (t = 0 min), the reaction was stopped immediately after addition of the cytosol.

Each experimental setup was performed in triplicates.

Sampling and sample storage

After incubation for 0 min, 60 min or 180 min, the reaction was terminated by mixing with ice-cold ethanol (final concentration of ethanol: 70%). The terminated incubation mixtures were concentrated at room temperature using a centrifugal evaporator. The tubes were weighed after concentration and the supernatants were pipetted into separate vials. The remaining pellet ("pellet 1") was weighed again. The volume of the supernatant collected from each tube was calculated from the difference of the two weights prior to and after removal of the supernatant (using a density of 1 g/mL) and recorded in the raw data. The weight of each pellet 1 was calculated by subtraction of the weight of the tube.

The radioactive residues in the supernatants were determined by LSC analysis of aliquots. Additionally, aliquots of the supernatants were analyzed using HPLC method LC02 and selected replicates of supernatants were subjected to HPLC-MS. For positive controls of hepatocytes with testosterone and 7-ethoxycoumarin HPLC methods LC04 and LC03, respectively, were used. The supernatants and pellets (pellet 1) were stored separately in a freezer at -18°C.

Workup procedure of the residual pellet
If the supernatant contained less than 90% of the applied radioactivity (90% AR), the corresponding pellet was extracted with a mixture of acetonitrile / acetone (80/20, v/v). The radioactive residues in the resulting extract and in the final pellet were determined by LSC. An aliquot of the pellet extract was also analyzed by HPLC method LC02 and one selected replicate from human liver cytosol (without WWL229, 180 min) was subjected to HPLC-MS analysis. In the case of the first replicate of human liver cytosol incubated with pyraclostrobin and WWL229 for 0 min, pellet 1 was again extracted with acetonitrile / acetone as described resulting in extract 2 of pellet 1. The radioactive residues in the suspended samples were measured by LSC.

Instrumental methods
HPLC method LC01 (used for analysis of application medium)
The column used was an Accucore aQ (ThermoScientific) 2.6 µm, the eluent system consisted of 2 mobile phases (A: water + 0.1% formic acid & B: acetonitrile + 0.1% formic acid), which were used applying gradient elution.

HPLC method LC02 (used for analysis of pyraclostrobin and its biotransformation products)
The column used was an Accucore aQ (ThermoScientific) 2.6 µm, the eluent system consisted of 2 mobile phases (A: water + 0.1% formic acid & B: acetonitrile + 0.1% formic acid), which were used applying gradient elution.

HPLC method LC03 (used for analysis of 7-ethoxycoumarin and its biotransformation products)
The column used was a TCI ODS-AX10 (TCI Chemicals) 5 µm, the eluent system consisted of 2 mobile phases (A: 50 mM Ammonium Formate (pH 3.5; adjusted with formic acid) + acetonitrile (950/50, v/v) & B: acetonitrile + 50 mM Ammonium Formate (pH 3.5; adjusted with formic acid) (950/50, v/v)), which were used applying gradient elution.

HPLC method LC04 (used for analysis of testosterone)
The column used was a Kinetex C18 (Phenomenex) 2.6 µm, the eluent system consisted of 2 mobile phases (A: water + 0.1% formic acid & B: methanol + acetonitrile + 0.1% formic acid (500/500, v/v)), which were used applying gradient elution.

The HPLC, recovery values observed using HPLC method LC02 ranged from 94.08 to 109.22% of the radioactive residues in the supernatants. The recovery values of the acetonitrile / acetone extracts from pellet 1 ranged from 98.8 to 109.3% of the extracted radioactive residues.

Mass Spectrometry (MS)
HPLC-MS analysis was performed on a Thermo Fisher Scientific LTQ (Linear Trap Quadrupole) FT (Fourier Transform) Ultra hybrid mass spectrometer hyphenated to an HP 1200 chromatography system with electrospray ionisation (ESI) in positive-ion mode. The column used was an Accucore aQ (ThermoScientific) 2.6 µm, the eluent system consisted of 2 mobile phases (A: water + 0.1% formic acid & B: acetonitrile + 0.1% formic acid), which were used applying gradient elution. From the triplicates of each experimental setup, selected replicates of the supernatants and of one pellet extract were analysed by HPLC-MS using the LTQ FT Ultra mass spectrometer. Chromatographic separation was performed under the same conditions as used in the analytical laboratory for quantitative evaluation (HPLC method LC02).

II. RESULTS AND DISCUSSION

Control experiments

In order to determine the metabolic activity of the human hepatocytes, positive controls were performed incubating cells with testosterone or 7-ethoxycoumarin instead of the test item. All triplicates of the controls showed similar HPLC profiles. The positive controls with testosterone showed that the metabolic activity of the hepatocytes with respect to phase I metabolic reactions was sufficiently high. The mean portion of metabolized testosterone accounted for 89% (desired value: 50%).

HPLC analyses of the positive controls with 7-ethoxycoumarin revealed portions of approximately 25-27% AR of unchanged 7-ethoxycoumarin. The phase I metabolite 7-hydroxycoumarin was not detected. The phase II metabolites 7-hydroxycoumarin glucuronide and 7-hydroxycoumarin sulphate were recovered accounting for approximately 9 and 2% AR, respectively. The mean portions of metabolised 7-ethoxycoumarin amounted to 65% (desired value: 30%).

Stability controls (test item without hepatocytes), zero incubation controls (incubation stopped immediately) and blank controls (cells in incubation medium without test item) were performed as negative controls. No degradation of pyraclostrobin, neither without nor with WWL229, was observed within 180 min under these experimental conditions without cells.

All triplicates of the zero incubation controls showed similar HPLC profiles. In general, they all consisted only of the characteristic peak of the active substance pyraclostrobin.

The blank controls performed without the test item showed no significant amounts of radioactivity (LSC measurements of the supernatants after addition of the incubation mixtures to ice-cold ethanol and subsequent concentration). Furthermore, no radioactive peaks were detected by HPLC analysis.

Negative controls, stability controls (test item without liver cytosol), heat-denatured controls (test item with heat-denatured human liver cytosol) and zero incubation controls (incubation stopped immediately) were performed in triplicates. The stability controls and heat-denatured controls were performed with an incubation time of 180 minutes. No degradation of pyraclostrobin, neither without nor with WWL229, was observed within 180 min under the experimental conditions.

All triplicates of the zero incubation control showed similar HPLC profiles. In general, they all consisted only of the characteristic peak of the active substance pyraclostrobin.

Viability of the hepatocytes

After incubation for 180 min, the viability of the cells was determined using the luminescent cell viability assay. The viability of the human hepatocytes incubated with 3 µM pyraclostrobin was 102% in comparison to untreated cells. The viability of the human hepatocytes incubated with 3 µM pyraclostrobin and 20 µM WWL229 accounted for 30% in comparison to untreated cells.

Identified metabolites
The supernatants after incubation of human hepatocytes and human liver cytosol with pyraclostrobin without and with WWL229 were analyzed using HPLC method LC02. The residual pellets after centrifugal evaporation were extracted with a mixture of acetonitrile and acetone whenever radioactive residues were below 90% AR in the supernatants. Obtained extracts were also analyzed by HPLC using method LC02. Already identified metabolites within a parallel *in-vitro* metabolism study (BASF DocID 2014/1001562) were in focus of quantitative evaluation.

In samples of human hepatocytes, the unchanged parent compound BAS 500 F and its biotransformation products 500M103, 500M107, 500M73, 500M106, 500M02 as well as an isomer of 500M02 were designated. Moreover, metabolite 500M104 and metabolite 500M88 were identified. As the signal-to-noise ratio was low for metabolite 500M106 in samples of human hepatocytes, its presence and identity were confirmed by additional co-chromatography experiments. No evidence was found for the presence of the metabolite 500M108 (analyzed by HPLC-MS) in the XIC-chromatograms and mass spectra of the samples of human hepatocytes incubated within the present study.
In samples of human liver cytosol, the unchanged parent compound BAS 500 F and its biotransformation products 500M73, 500M106, 500M02 as well as an isomer of 500M02 were designated. As expected no evidence was found for the presence of metabolite 500M107 (analyzed by HPLC-MS) in the XIC-chromatograms and mass spectra of the samples of human liver cytosol incubated within the present study.

A summary of metabolites identified in human hepatocytes and liver cytosol is shown in Table 5.1.2-5.

Table 5.1.2-5: Summary of metabolites identified in human hepatocytes and liver cytosol

Component	Structure	Metabolite identified in	
		Human Hepatocytes	Human Liver Cytosol
BAS 500 F Pyraclostrobin		x	x
500M02		x	x
Isomer of 500M02		x	x
500M73		x	x
500M88		x	-
500M103		x	-
500M104		x	-
500M106		x	x
500M107		x	-
500M108		-	-

Radioactive residues in human hepatocytes

After termination of the incubation of human hepatocytes with 3 µM pyraclostrobin without or with 20 µM WWL229 for up to 180 min, the radioactive residues in the supernatants ranged from 78.32 to 88.19% AR (without WWL229) and from 72.75 to 88.46% AR (with WWL229), except for one replicate of the incubation with WWL229 accounting for 90.27% AR. The residual pellets (pellet 1) of the replicates with radioactive residues below 90% AR in the supernatants were suspended in water and extracted with a mixture of acetonitrile and acetone (80/20, v/v). The radioactive residues in extracts ranged from 4.46 to 8.28% AR (without WWL229) and from 2.96 to 5.43% AR (with WWL229), except for one replicate of the incubation with WWL229 (11.59% AR). The radioactive residues in the final pellets were below 1% AR for zero incubation controls without and with WWL229 and were below or equal to 6.52% AR (without WWL229) and 4.35% AR (with WWL229) after longer incubation. The sum of recovery of radioactive residues in the majority of the assays accounted for more than 90% AR. Although for individual replicates the sum of radioactive residues was lower than 90% AR, this has no significant influence on the objective of this study.
Besides, the recovery of radioactive residues in the supernatants might be underestimated due to assuming the density of 100% water (1 g/mL) for calculation of the supernatant volume, while still ethanol might be present. The recovery of radioactive residues in the supernatants of positive controls amounted to at least 92.8 and 90.0% AR for testosterone and 7-ethoxycoumarin, respectively. Hence, no further workup was necessary.

An overview of the recoveries of radioactive residues after incubation of human hepatocytes with pyraclostrobin (3 µM) with and without WWL229 (20 µM) is shown Table 5.1.2-6.

Table 5.1.2-6: Overview of the recoveries of radioactive residues after incubation of human hepatocytes with pyraclostrobin (3 µM) with and without WWL229 (20 µM)

Incubation time [min]	Sample description	Recovery[1] [% AR]		Sum [% AR]	
		with WWL229	without WWL229	with WWL229	without WWL229
0	Supernatant	81.76	86.58	87.44	94.05
	Extract pellet 1	5.43	6.86

1 The recovery of radioactive residues in the supernatants might be underestimated due to assuming the density of 100% water (1 g/ml) for calculation of the supernatant volume, while still ethanol might be present

Radioactive residues in human liver cytosol

After termination of the incubation of human liver cytosol with pyraclostrobin without and with WWL229 for up to 180 min, the radioactive residues in the supernatants ranged from 94.66 to 103.80% AR, except for samples obtained after incubation without WWL229 for 180 min. The residual pellets (pellet 1) of the replicates with radioactive residues below 90% AR in the supernatants were suspended in water and extracted with a mixture of acetonitrile and acetone (80/20, v/v). The recovery of radioactive residues in the pellet extracts and in the first or final pellets ranged from 15.36% AR to 18.29% AR for the extracts and from 5.40% AR to 11.10% AR for the final pellets or pellet 1. For one replicate from zero incubation controls of experiments performed with WWL229, 58.47% AR were recovered in the supernatant. Albeit the pellet 1 was extracted two times (approximately 7.5% AR in sum), the total recovery accounted for 66.02% AR. This result has no impact on the outcome of the present study, as all remaining samples revealed reliable recoveries.

An overview of the recoveries of radioactive residues after incubation of human liver cytosol with pyraclostrobin (6 µM) with and without WWL229 (20 µM) is shown Table 5.1.2-7.

Table 5.1.2-7: Overview of the recoveries of radioactive residues after incubation of human liver cytosol with pyraclostrobin (6 µM) with and without WWL229 (20 µM)

Incubation time [min]	Sample description	Recovery [% AR]		Sum [% AR]	
		with WWL229	without WWL229	with WWL229	without WWL229
0	Supernatant	58.47	101.63	66.02*	107.20
	Pellet 1		5.56		
	Extract 1 Pellet 1	7.04

	Final pellet		7.43		

* This result has no impact on the outcome of the present study, as it is one replicate of the zero incubation control and all remaining samples revealed reliable recoveries.

** The vial containing pellet 1 broke not being measured. However, almost 100% AR were already recovered in the supernatant.

Metabolites formed after incubation of human hepatocytes with pyraclostrobin without WWL229

Radio-HPLC analyses of the samples after incubation of human hepatocytes with 3 µM pyraclostrobin without 20 µM WWL229 allowed the assignment of the parent compound and seven relevant metabolites known from the previous comparative in-vitro metabolism study performed on human hepatocytes or human liver microsomes with pyraclostrobin. In the following, the sum of the mean % AR recovered in supernatants and extracts of pellets is discussed, if applicable.

All metabolites were already detected after incubation for 60 min. The concentration of pyraclostrobin continuously decreased from 92.06% AR at 0 min to 15.85% AR after 60 min and was no more detected after 180 min. After 60 min, 500M02 was the most abundant metabolite accounting for 23.29% AR, but decreased to 8.99% AR after 180 min. Similarly, metabolite 500M73 and the isomer of 500M02 were detected at concentrations amounting to 15.60% AR and 5.89% AR, respectively, after 60 min decreasing to 6.17% AR and 2.14% AR, respectively, after 180 min. Further detected metabolites after 60 min were 500M103 (3.89% AR), 500M104 (8.52% AR), 500M107 (16.19% AR) and 500M106 (5.23% AR). While metabolites 500M103, 500M107 and 500M106 remained stable between 60 min and 180 min, the concentration of metabolite 500M104 increased to 18.16% AR after 180 min.

Metabolites formed after incubation of human hepatocytes with pyraclostrobin with WWL229

Three of the eight compounds detected in samples from hepatocytes incubated with pyraclostrobin without WWL229 were also recovered in samples of hepatocytes incubated with pyraclostrobin with WWL229, namely 500M103, 500M104 and the parent compound pyraclostrobin. Additionally, metabolite 500M88 was identified in samples after incubation of hepatocytes with pyraclostrobin and WWL229. In the following, the sum of the mean % AR recovered in supernatants and extracts of pellets is discussed, if applicable.

Similar to the incubation without WWL229, the concentration of the parent compound decreased constantly, but to a lesser extent (from 88.24% AR after 0 min to 48.20% AR after 180 min). Metabolites 500M104 and 500M88 were detected after 60 min accounting for 4.99% AR and 1.90% AR, respectively. The concentration of metabolite 500M104 significantly increased to 19.93% AR after 180 min, while the concentration of metabolite 500M88 remained almost stable. Besides, metabolite 500M103 was identified at levels accounting for 5.64% AR after 180 min.

In contrast, metabolites 500M73, 500M107, 500M106, 500M02 and the isomer of 500M02, resulting from an initial cleavage of the ether and / or amide bond of parent pyraclostrobin, were not detected in samples obtained after simultaneous incubation of hepatocytes with pyraclostrobin and WWL229. Instead metabolite 500M88 was formed at low levels resulting from desmethoxylation of the parent compound. These results indicate an inhibition of the biotransformation of pyraclostrobin in the presence of WWL229. This shows that especially the formation of the metabolites 500M73, 500M107, 500M106, 500M02 and the isomer of 500M02 depends on the activity of the enzyme human carboxylesterase 1.

A summary of the relevant components in human hepatocytes incubated with pyraclostrobin with and without WWL229 is shown Table 5.1.2-8.

Metabolites formed after incubation of human liver cytosol with pyraclostrobin without WWL229

Radio-HPLC analyses of the samples after incubation of human liver cytosol with 6 µM pyraclostrobin without 20 µM WWL229 allowed the assignment of the parent compound and four relevant metabolites known from the previous comparative *in-vitro* metabolism study performed on human hepatocytes or human liver microsomes with pyraclostrobin. In the following, the sum of the mean % AR recovered in supernatants and extracts of pellets is discussed, if applicable.

The concentration of pyraclostrobin continuously decreased from 101.80% AR at 0 min to 35.74% AR after 180 min. Metabolite 500M106 was the most abundant metabolite after 60 min amounting to 15.63% AR and remained almost stable (12.67% AR after 180 min). Metabolites 500M73, 500M02 and the isomer of 500M02 were present at low levels after 60 min accounting for 4.00, 5.98 and 2.03% AR, respectively. After 180 min, the concentrations of these metabolites were significantly higher accounting for 11.21% AR for 500M73, 28.59% AR for 500M02 and 9.76% AR for the isomer of 500M02.

Metabolites formed after incubation of human liver cytosol with pyraclostrobin with WWL229
Only the parent compound pyraclostrobin was detected in samples from human liver cytosol incubated with pyraclostrobin with WWL229 ranging from 94.61 to 100.33% AR for all incubation periods. Similar to incubations performed on human hepatocytes, metabolites 500M73, 500M106 and 500M02, formed after an initial cleavage of the ether and / or amide bond of the parent pyraclostrobin, were not detected in samples obtained after simultaneous incubation of human liver cytosol with pyraclostrobin and WWL229. These results indicate an inhibition of the biotransformation of pyraclostrobin to these metabolites in the presence of WWL229 and hence, the involvement of the enzyme human carboxylesterase 1.

A summary of the relevant components in human liver cytosol incubated with pyraclostrobin with and without WWL229 is shown in Table 5.1.2-9.

III. CONCLUSION

In the present *in-vitro* metabolism study performed on human hepatocytes and human liver cytosol with pyraclostrobin (BAS 500 F, Reg. No. 304428), the biotransformation products after incubation without and with WWL229, an inhibitor of human carboxylesterase 1, were compared, in order to investigate a potential influence of WWL229.

For human hepatocytes incubated with pyraclostrobin without WWL229, pyraclostrobin and its biotransformation products 500M103, 500M104, 500M107, 500M73, 500M106, 500M02 as well as an isomer of 500M02 were identified. The parent molecule was time-dependently and completely metabolized after 180 min. In presence of WWL229, the biotransformation was slower, as pyraclostrobin was still present after 180 min and metabolites 500M73, 500M107, 500M106 and 500M02 as well as an isomer of 500M02, formed after an initial cleavage of the ether and / or amide bond of the parent pyraclostrobin, were not detected at all. Instead, formation of metabolite 500M88 was observed at low levels.

For human liver cytosol incubated with pyraclostrobin without WWL229, pyraclostrobin and its biotransformation products 500M73, 500M106, 500M02 as well as an isomer of 500M02 were identified. Similar to the incubations performed on human hepatocytes, metabolites 500M73, 500M106, 500M02 and an isomer of 500M02 were not detected in samples obtained after simultaneous incubation of human liver cytosol with pyraclostrobin and WWL229.

These results indicate an inhibition of the biotransformation of pyraclostrobin in the presence of WWL229. This compound inhibits especially the formation of metabolites 500M106, 500M73 and 500M02 (and isomer) as well as their conjugates showing the involvement of the enzyme human carboxylesterase 1 in the respective metabolic reactions.

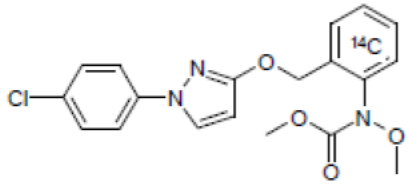
I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:	^{14}C-BAS 500 F (pyraclostrobin, Reg. No. 304428)
Description:	tolyl-ring-U-C14 label, see Figure 1.1
Chemical name:	methyl-N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxymethyl}phenyl)-(N-methoxy)carbamate (IUPAC-Name)
Test substance No:	not reported
Lot/Batch #:	566-5501
CAS#:	175013-18-0
Development code:	Pyraclostrobin: BAS 500 F (Reg. No. 304428)
Purity:	Radiochemical purity: 99.5 % (RHPLC)
Specific activity:	6.31 MBq/mg (specific activity a.i.); 30 MBq/g (specific activity)
Stability of test compound:	The test item was stable over the test period. No degradation of pyraclostrobin, was observed within 20 h under the experimental conditions neither without serum nor in the presence of heat-denatured rat serum.
	For stability controls the application buffer was mixed with aqueous buffer (Tris/HCl buffer) instead of rat serum.

2. Test animals:	Rat
Species:	Wistar rats
Strain:	Crl: WI (Han)
Sex:	male and female
Age:	27-28 weeks (male), 14/16 weeks (female) (age at sampling)
Source:	Charles River Laboratories, Sulzfeld, Germany

Figure 1.3: Structural formula of ^{14}C-pyraclostrobin labelled at the tolyl ring



B. STUDY DESIGN AND METHODS

The study was carried out at the Agricultural Research Centre of BASF SE in Limburgerhof, Germany.

1. Dates of experimental work (analytical phase) June 13, 2016 to September 08, 2016

2. Study design

Stock solution

The stock solution of pyraclostrobin was prepared as follows (within the *in-vitro* metabolism study (BASF DocID 2014/1001562): a weighed aliquot was evaporated to dryness with nitrogen and dissolved in acetonitrile. Aliquots were diluted and analyzed by a liquid scintillation counter (LSC) in order to determine the actual concentration (0.978 mg/mL).

Application solution

The application solution of the test item was prepared as follows (within the parallel in-vitro metabolism study BASF DocID 2016/1061381): The solvent from a defined volume of the stock solution was evaporated with nitrogen, and the test item was dissolved in 2 mL DMSO. The specific radioactivity of the test item accounted for 378,600 dpm/µg. The actual concentration of radiolabeled pyraclostrobin in this application solution was determined within the separate study (0.756 mg/mL) by LSC of aliquots of diluted subsamples. A subsample (0.87 mL) of this application solution was obtained from another *in-vitro* metabolism study (BASF DocID 2016/102596).

Test system

Serum was sampled from untreated male (10 mL pooled from three rats) and female (2x 3 mL pooled from five rats each) Wistar rats (Crl: Wl(Han)). The serum was shipped to the Agricultural Centre of BASF in Limburgerhof, Germany, on dry ice, where samples were stored deep frozen until pooling. One day before incubation, serum samples were thawed in a refrigerator overnight. On the day of incubation, serum samples from female rats were completely pooled, 2.5 mL were taken and mixed with 2.5 mL of male serum to generate a mixture of female and male serum (1/1, v/v) for the experiments. An aliquot of the serum was heat-denatured by incubating at 95°C or above for 10 min.

In-vitro assays

On the incubation day, the application solution was diluted with 50 mM Tris/HCl buffer pH 7.4 to obtain the application buffer for incubation with rat serum. The identity and purity of the test item in the application buffer (and the retention time of pyraclostrobin) was confirmed by HPLC analysis of aliquots. Further aliquots of the application buffer were analyzed by LSC to calculate the amounts of applied radioactivity per vial and of total applied pyraclostrobin per assay (representing 100% AR in 1000 µL per vial: 2.328 µg). The final concentration of pyraclostrobin in the incubation mixtures with rat serum (calculated from the LSC results of the application buffer) was 6.004 µM and is given as rounded value of 6 µM throughout the present report. The deviation from the intended final concentration of 10 µM pyraclostrobin has no impact on the validity of the study. The final concentration of DMSO in the assays was approximately 0.5%.

The application buffer was equilibrated at 37°C for 5 min in a Thermomixer® (Eppendorf) prior to addition of the rat serum. Each sample (1 mL total incubation volume) comprised 0.8 mL of application buffer and 0.2 mL of rat serum in a tube. Incubations were performed for 1 h, 3 h, 5 h and 20 h in a Thermomixer® (Eppendorf) at 37 °C (± 2 °C) under shaking at 700 rpm.

Three negative controls (stability controls, controls with heat-denatured rat serum and zero incubation controls) were performed.
In the negative controls no metabolism should occur. For the “stability controls”, the application buffer was mixed with Tris/HCl buffer instead of rat serum. The stability controls and the controls with heat-denatured serum were incubated for 20 h. For the “zero incubation controls” (t = 0 h), the reaction was stopped immediately after addition of the serum.
Each experimental setup was performed in triplicates.

Sampling and sample storage

The incubation was terminated by addition of 1 mL ice-cold acetonitrile followed by ultrasonication for 5 min. The terminated incubation mixtures were concentrated at room temperature using a centrifugal evaporator (Genevac EZ-2.3 plus). The tubes were weighed after concentration and the supernatants were pipetted into HPLC vials. The tube containing the remaining pellet (“pellet 1”) was weighed again. The volume of the supernatant collected from each tube was calculated from the difference of the two weights prior to and after removal of the supernatant (using a density of 1 g/mL) and recorded in the raw data. The weight of each pellet 1 was calculated by subtraction of the weight of the tube.
The radioactive residues in the supernatants were determined by LSC analysis of aliquots. In addition, aliquots of the supernatants were analyzed by HPLC using HPLC method LC02 and selected replicates of supernatants were subjected to HPLC-MS. The supernatants and pellets (pellet 1) were stored separately in a freezer at -18 °C.

Workup procedure of the residual pellet
If the radioactive residues in the supernatant represented 90% AR or more, the residual pellet was resuspended in 0.35 mL water using a pipette, followed by ultrasonication for 5 min. Three aliquots were subjected to LSC to determine the radioactive residues in pellet 1.
If the radioactive residues in the supernatant accounted for less than 90% AR, the pellet 1 was resuspended in 0.05 mL water, and 0.25 mL of a mixture of acetonitrile / acetone (80/20, v/v) were added. The pellet was extracted for 5 min in an ultrasonication bath, and the extract was separated from the final pellet by centrifugation. Aliquots of the acetonitrile / acetone extract were measured for radioactive residues (LSC). Further aliquots of the acetonitrile / acetone extracts were analyzed using HPLC method LC02. The final pellet was resuspended in 0.35 mL water, ultrasonicated for 5 min, and the radioactive residues in the suspended samples were measured by LSC.

Instrumental methods
HPLC method LC01 (used for analysis of application buffer)
The column used was an Accucore aQ (ThermoScientific) 2.6 µm, the eluent system consisted of 2 mobile phases (A: water + 0.1% formic acid & B: acetonitrile + 0.1% formic acid), which were used applying gradient elution.

HPLC method LC02 (used for analysis of pyraclostrobin and its biotransformation products)
The column used was an Accucore aQ (ThermoScientific) 2.6 µm, the eluent system consisted of 2 mobile phases (A: water + 0.1% formic acid & B: acetonitrile + 0.1% formic acid), which were used applying gradient elution.
The HPLC recovery values observed using HPLC method LC02 ranged from 94.26 to 107.56% of the radioactive residues in the supernatants. The recovery values of the acetonitrile/acetone extracts from pellet 1 ranged from 101.88 to 110.13% of the extracted radioactive residues, except for two samples accounting for 16.29% (pellet extract of a heat-denatured control) and 147.33% (pellet extract of a replicate after 3 h incubation), respectively. This has no impact on the overall conclusion drawn from the study.

Mass Spectrometry (MS)
HPLC-MS analysis was performed on a Thermo Fisher Scientific LTQ (Linear Trap Quadrupole) FT (Fourier Transform) Ultra hybrid mass spectrometer hyphenated to an HP 1200 chromatography system with electrospray ionisation (ESI) in positive-ion mode. The column used was an Accucore aQ (ThermoScientific) 2.6 µm, the eluent system consisted of 2 mobile phases (A: water + 0.1% formic acid & B: acetonitrile + 0.1% formic acid), which were used applying gradient elution. From the triplicates of each experimental setup, selected replicates of the supernatants were analyzed by HPLC-MS using the LTQ FT Ultra mass spectrometer. Chromatographic separation was performed under the same conditions as used in the analytical laboratory for quantitative evaluation (HPLC method LC02).

II. RESULTS AND DISCUSSION

The present *in-vitro* study describes the biotransformation of ^{14}C-pyraclostrobin (BAS 500 F) during incubation with rat serum for up to 20 h. The biotransformation products were compared to the main products observed after incubation of pyraclostrobin with human hepatocytes as well as with human liver microsomes within a previous comparative *in-vitro* metabolism study (BASF DocID 2014/1001562). In addition, several negative controls were conducted.
The radioactive residues of ^{14}C-pyraclostrobin were investigated and quantified in the supernatants after incubation, and the residual pellets after centrifugal evaporation were extracted with a mixture of acetonitrile and acetone, if supernatants contained less than 90% of the applied radioactivity (90% AR). The resulting pellet extracts were also analyzed. All assays were performed in triplicates.

Control Experiments
As negative controls, stability controls (test item without rat serum), heat-denatured controls (test item with heat-denatured rat serum) and zero incubation controls (incubation stopped immediately) were performed in triplicates. The stability controls and heat-denatured controls were performed with an incubation time of 20 h. No degradation of pyraclostrobin, was observed within 20 h under the experimental conditions neither without serum nor in the presence of heat-denatured rat serum. All triplicates of the zero incubation control showed similar HPLC profiles, generally all consisting only of the characteristic peak of pyraclostrobin.

Identified metabolites
The supernatants after incubation of 6 µM pyraclostrobin with rat serum were analyzed using HPLC method LC02. The residual pellets after centrifugal evaporation were extracted with a mixture of acetonitrile and acetone, whenever radioactive residues were below 90% AR in the supernatants. Obtained extracts were also analyzed by HPLC using method LC02. Metabolites already identified within a previous in-vitro metabolism study (BASF DocID 2014/1001562) were in focus of the evaluation. The unchanged parent compound BAS 500 F and its biotransformation products 500M73, 500M106, 500M02 as well as an isomer of 500M02 were identified in rat serum. For extracts of pellets, the assignment was based on comparison of the retention times and metabolite patterns with those acquired by RHPLC analysis of the supernatants. For some supernatants, where the signal-to-noise ratio was too low for an unambiguous metabolite identification, the assignment was additionally based on comparison of the retention time and the metabolite pattern with the results obtained from the analysis of the supernatant sampled after incubation for 20 h.

A summary of metabolites identified in rat serum is shown in Table 5.1.2-10.

Table 5.1.2-10: Summary of metabolites identified in rat serum

Component	Structure
BAS 500 F Pyraclostrobin	500M02	Isomer of 500M02	
500M73	500M106	
Radioactive residues in rat serum

After termination of the incubation of pyraclostrobin with rat serum for up to 20 h, the radioactive residues in the supernatants ranged from 81% AR to 104% AR (means of three replicates for each incubation period). The residual pellets (pellet 1) of the replicates with radioactive residues below 90% AR in the supernatants were suspended in water and extracted with a mixture of acetonitrile and acetone (80/20, v/v). It ranged from 44.24 to 75.81% AR for the extracts, from 13.01 to 25.67% AR for pellet 1 and from 2.53 to 7.36% AR for the final pellet.

The sum of recovery of radioactive residues ranged from 119 to 134% AR (means of three replicates for each incubation period) and accounted for more than 100% for each replicate. This overestimation can be attributed to plastic binding of pyraclostrobin during sample preparation.

An overview on the recoveries of radioactive residues after incubation of 6 µM pyraclostrobin with rat serum is shown Table 5.1.2-11.

Table 5.1.2-11: Overview on recoveries of radioactive residues after incubation of 6 µM pyraclostrobin with rat serum

1 The sum of recovery of radioactive residues accounted for more than 100 % AR due to plastic binding of pyraclostrobin during sample preparation.

Metabolites formed after incubation of pyraclostrobin with rat serum

HPLC analyses of the samples after incubation of 6 µM pyraclostrobin with rat serum allowed the assignment of the parent compound and four relevant metabolites known from the previous comparative *in-vitro* metabolism study (BASF DocID 2014/1001562) performed on human hepatocytes and human liver microsomes with pyraclostrobin. In the following, the sum of the mean % AR recovered in supernatants and extracts of pellets is discussed, if applicable.

The concentration of pyraclostrobin decreased continuously from 142.04% AR or 142.52% AR at 0 h or 1 h, respectively, to 66.29% AR after 20 h. Formation of metabolites 500M73, 500M106, 500M02 and an isomer of 500M02 was observed in trace amounts already after 1 h. The concentration of metabolite 500M106, being the main biotransformation product for all investigated periods, increased time-dependently to up to 48.81% AR after 20 h. Similarly, concentrations of metabolites 500M73, 500M02 and the isomer of 500M02 increased with time amounting to 1.55, 11.03 and 4.27% AR after 20 h, respectively.

These results indicate a significant biotransformation of pyraclostrobin to several metabolites occurring in rat serum within 20 h.

A summary of the relevant components in rat serum with pyraclostrobin is shown Table 5.1.2-12.

Table 5.1.2-12: Summary of relevant metabolites of pyraclostrobin (6 µM) after incubation of rat serum

n.e. not extracted

III. CONCLUSION

In the present *in-vitro* metabolism study with pyraclostrobin (BAS 500 F), the biotransformation of 6 µM pyraclostrobin was investigated after incubation with rat serum for up to 20 hours. Within the first 1 h of incubation, no significant differences were observed in comparison to the zero incubation controls. After 3 h, the concentration of pyraclostrobin started to decrease continuously to 66.29% AR after 20 h. Formation of metabolites 500M73, 500M106, 500M02 and an isomer of 500M02 was observed in trace amounts already after 1 h. The concentration of all metabolites increased time-dependently with metabolite 500M106 being the main biotransformation product for all incubation periods (48.81% AR after 20 h). These results indicate a significant biotransformation of pyraclostrobin occurring in rat serum within 20 h leading to metabolites, which are also formed with human hepatocytes or human liver microsomes.

Overall conclusion

Pyraclostrobin has been extensively studied for absorption, distribution, metabolism and excretion. Endpoints set during the previous Annex I inclusion process reflect the rapid absorption and excretion as well as the extensive metabolism in mammalian systems.

In addition, a new rat study focussing on detailed metabolism in plasma is available, which extends the knowledge obtained during previous studies. Given the degree of metabolism of pyraclostrobin, it is not to be expected to match all metabolites or percentage between the old and new studies. In the recently performed plasma study in rats, several metabolites have been reconfirmed and some new metabolites (500M104, 500M106, 500M107 and 500M108) have been identified.

Since the submission of the supplemental dossier in July 2014, further investigations have been performed; main purpose of these studies was to get a better understanding of the formation, but also the metabolism of the metabolites 500M106, 500M107 and 500M02 which were predominantly found in human and rabbit cell cultures, but only in minor amounts in rats.

When all studies (including the comparative *in-vitro* metabolism and the subsequent investigations on 500M106) are compared, the following general conclusions can be drawn:

- Pyraclostrobin is rapidly excreted via urine and feces.
- Excretion of radioactivity is similar for both sexes. The majority of the radioactivity was excreted via feces (>80% of the dose) and smaller amounts via urine (<15% of the dose). Via bile, about 35% of dose is excreted resulting in a bioavailability of approximately 50%.
- There is no evidence of any cumulative potential of pyraclostrobin. Throughout the time course of the experiments, highest radioactivity concentrations were found in the GI tract. Most organs and tissues had values similar to the ones of the plasma. Liver (factor: 4 – 5) and to a lesser extent kidneys (factor: 2) were tissues with higher values than plasma. Radioactivity concentrations were lowest in bone and brain.

- The metabolite patterns in feces, urine, bile, liver, kidney and plasma were largely comparable for both sexes and for all dose groups investigated.
- In total six transformation steps were observed in rats, which are depicted in the figure below:

  - Desmethoxylation of the side chain
  - Hydroxylation of the chlorophenyl pyrazole ring system
  - Hydroxylation of the tolyl ring system
  - Cleavage of the ether bond resulting in chlorophenyl pyrazole or anthranilic acid derivatives
  - Desmethylation of the side chain
  - Cleavage of the amide bond in the side chain

- The combination of these reactions followed by conjugation steps results in a huge number of metabolites.
- An *in-vitro* comparison of metabolic profiles produced in human hepatocyte / microsome samples and those from several mammalian species has been performed.
- In this study, the same key metabolic degradation steps were observed as under *in-vivo* conditions. Metabolites as 500M04, 500M73, 500M108, 500M103, 500M104 and 500M88 are common to all test species.
- Some quantitative differences were noted between the different test species. In human and rabbit, cleavage of the amide bond resulting in the formation of metabolite 500M106 is the major degradation pathway. Subsequently, 500M106 is further metabolized by conjugation with glucuronic acid to 500M107. In human and rabbit, metabolite 500M02 (which is formed by dimerization) has been also identified.
- However, no unique human metabolite was detected based on the study procedures for comparison at a 5% TRR level.
- Based on these results, in total three metabolites require further consideration:
  - 500M106
  - 500M107 (conjugate of 500M106)
  - 500M02

- For metabolites 500M106 and 500M02, further toxicological studies have been performed (see M-CA 5.8). The glucuronic acid conjugate 500M107 is covered by the investigations of 500M106. The relevant endpoints are considered for estimating the dietary exposure (see M-CA 6.9) as the conversion of parent into the three metabolites cannot be excluded under *in-vivo* conditions.
- For improving the understanding of the formation and metabolism of 500M106, in total four new studies are included in the updated version of the supplemental dossier.
- In a rat metabolism study where 500M106 was dosed to male rats, the same excretion pattern was found as for pyraclostrobin. Two major biotransformation steps in the metabolic pathway of 500M106 were observed:
  - Cleavage of the N-O bond of the phenylamine moiety followed by (a) hydroxylation, (b) dimerization with subsequent N-oxidation or (c) formation of formaldehyde adducts
  - Cleavage of the ether bridge between the pyrazole and phenylamine moiety followed by conjugation (sulphation / glucuronidation) or hydroxylation and sulphation
- The results of the metabolism study demonstrate that rats are an appropriate species for further toxicological testing, but they also show that metabolite 500M02 is covered by the investigations on 500M106 as it has been found in considerable amounts.
- By means of further *in-vitro* investigations, the enzyme resulting in the formation of 500M106 has been identified as human carboxylesterase 1.
- According to literature, this type of enzymes is also present in rats in high amounts, however, in serum instead of the liver. In order to confirm the publications, rat serum was incubated with ^{14}C-pyraclostrobin. The results indicate a significant biotransformation of pyraclostrobin leading to metabolites, which are also formed with human hepatocytes or human liver microsomes. These findings and the fact that in rats the key degradation steps are different (desmethoxylation and hydroxylation) can well explain the outcome of the *in-vivo* study in rats (see M-CA 5.1.1), where 500M106 / 500M107 were detected in minor amounts in plasma.

Altogether and taking the results summarized in M-CA 5.8 into account, the investigations support the use of previous studies for end point setting (ADI: rat, ARfD: rabbit) and interpretation of consumer risk.

When the information from previous and new studies is reviewed in total, the description of proposed endpoints is proposed to be slightly modified as shown below. In this context, the metabolites being considered for dietary exposure assessment are designated as “significant”. After the conduct of the assessments (see M-CA 6.7 and 6.9), none of them was identified as “relevant”.

Proposed endpoints

Rate and extent of absorption:	Rapid absorption: Tmax ~ 1 hour: 50% (based on urinary and biliary excretion within 48 hours)
Distribution:	Widely, highest concentrations in the liver
Potential for accumulation:	No potential for accumulation
Rate and extent of excretion:	Complete within 5 d; mainly via feces (80-90%, biliary excretion amounting to 35%), via urine 11-15%
Metabolism in animals	Extensive (>95%) with more than 50 metabolites Main metabolic pathways included N-desmethoxylation, hydroxylation, cleavage of ether bond and further oxidation of the resulting molecule parts, conjugation with glucuronic acid or sulphate
Toxicologically significant compounds (animals and plants)	Parent and metabolites
Toxicologically significant compounds (environment)	Parent

CA 5.2 Acute Toxicity

Studies submitted in the original Annex I Dossier (2000):
Pyraclostrobin (BAS 500 F) has been tested in various species and via different routes of administration. All studies are scientifically valid. The studies listed in Table 5.2-1 have been evaluated and peer reviewed during the previous Annex I inclusion process.

Table 5.2-1: Summary of already peer-reviewed acute toxicity studies with pyraclostrobin

Route/species/sex	Dose range	Vehicle	Result	Reference (BASF DocID)
Oral Rat, Wistar (CHBB:THOM), m/f	2000, 5000 mg/kg bw	0.5% aqueous Tylose (CMC)	LD_{50} > 5000 mg/kg bw	1998/10965
Dermal Rat, Wistar (CHBB:THOM), m/f	2000 mg/kg bw	0.5% aqueous Tylose (CMC)	LD_{50} > 2000 mg/kg bw	1998/10966
Inhalation Rat, Wistar (CHBB:THOM), m/f	0.31, 1.07, 5.27 mg/L	Acetone	0.31 mg/L < LC_{50} < 1.07 mg/L	1997/11472
Skin irritation Rabbit, (NZW), m/f	0.5 g/animal	None	Irritant	1998/10959
Eye irritation Rabbit, (NZW), m/f	0.1 g/animal	None	Non irritant	1998/10963
Skin sensitisation, Maximisation Test Guinea pig, Dunkin Hartley (Crl:(HA)BR), f	Intradermal: 5% in mixture Freund's adjuvant /Tylose Epidermal: 5% in Tylose	1% aqueous Tylose	Not sensitising	1998/10964

Studies submitted in this AIR 3 dossier (not yet peer-reviewed):
In vivo studies characterising the acute inhalation toxicity profile were performed with pyraclostrobin, which were not submitted during the previous Annex I inclusion process.
In accordance with the requirements of Commission Regulation SANCO/11802/2010 an in vitro NRU Phototoxicity Test in Balb/c 3T3 cells has been performed and is described in detail in chapter M-CA 5.2.7. The respective studies are listed in Table 5.2-2.

Table 5.2-2: Summary of not yet peer-reviewed acute toxicity studies with pyraclostrobin

Type of study	Test substance	Result Classification	Reference (BASF DocID)
Inhalation route - rat	pyraclostrobin (solvent: Solvesso)	4.07 mg/L < LC_{50} < 7.3 mg/L CLP classification not required	2001/1010625
Inhalation route - rat	pyraclostrobin (solvent: acetone)	LC_{50} = 0.58 mg/L CLP classification H331	2002/1012053, 2003/1009200, 2003/1009427
In vitro NRU Phototoxicity Test in Balb/c 3T3 cells	pyraclostrobin	Not phototoxic	2012/1189936, 2014/1092412

Pyraclostrobin has low acute toxicity by the oral and dermal route of administration.

The toxicity by the inhalation route is to a great extent dependent on the vehicle/solvent used to generate an inhalable aerosol. Whereas for pyraclostrobin dissolved in acetone LC_{50} values of 0.31 mg/L < LC_{50} < 1.07 mg/L and 0.58 mg/L were derived (H331 - Toxic if inhaled), generation of an aerosol of pyraclostrobin dissolved in Solvesso revealed a value of 4.07 mg/L < LC_{50} < 7.3 mg/L. More detailed information on the acute inhalation toxicity can be found in M-CA 5.2.3.

Pyraclostrobin is irritant to the skin (H315 - Causes skin irritation), but not irritant to the eye.

In a Maximisation Test pyraclostrobin was not sensitising.

No indications for a phototoxic potential was observed in an in vitro NRU Phototoxicity Test in Balb/c 3T3 cells:

Based on the studies previously peer-reviewed, the following EU agreed endpoints are given in the Review Report of pyraclostrobin (SANCO/1420/2001-Final, 8. September 2004):

Rat LD_{50} oral:	> 5000 mg/kg bw (mouse mortality at ≥ 300 mg/kg bw)
Rat LD_{50} dermal:	> 2000 mg/kg bw
Rat LC_{50} inhalation:	0.69 mg/L
Skin irritation:	Irritating
Eye irritation:	Not irritating
Skin sensitization (test method used and result):	Not sensitising (M & K maximisation test)

The proposed endpoints based on all available studies are shown below in Table 5.2-3.

Table 5.2-3: Proposed acute toxicity endpoints of pyraclostrobin*

Study type/species	Results	Classification	
		EU Dir. 67/548/EEC 2001/59 EC	**Reg. EC 1272/2008 (CLP)**
Acute oral toxicity, rat	LD_{50} > 5000 mg/kg bw		
Acute dermal toxicity, rat	LD_{50} > 2000 mg/kg bw		
Acute inhalation toxicity, rat	**LC_{50} = 0.58 mg/L**	R23	H331
Dermal irritation, rabbit	Irritating	R36	H315
Eye irritation, rabbit	Not irritating		
Maximisation test, guinea pig	Not sensitising (M & K maximisation test)		
In vitro NRU Phototoxicity Test, Balb/c 3T3 cells	**Not phototoxic**		

* new endpoints or values differing from the current agreed EU endpoints are marked in bold

CA 5.2.1 Oral

The acute oral toxicity study of pyraclostrobin was evaluated and peer reviewed during the previous Annex I inclusion process (for further details please see Table 5.2-1). Pyraclostrobin has low acute oral toxicity.

As already mentioned since 2004 in the list of endpoints, a higher acute toxicity of pyraclostrobin was observed in mice administered pyraclostrobin in the course of the in-vivo mouse micronucleus assay. While in the acute oral LD_{50} study in rats pyraclostrobin was administered as a coarsely ground suspension of pyraclostrobin in 0.5% aqueous tylose in bi-distilled water, it was administered in the mouse micronucleus assay (BASF DocID 1998/10460) as solution in olive oil. The detailed results of the range finding toxicity study for setting the dose levels in the main mutagenicity study are provided in a report amendment (see M-CA 5.4.2/1, BASF DocID 2016/1309356).
Even though not designed as a study to determine a LD_{50} in mice, the mortality data in the mouse micronucleus assay are suitable to derive an acute oral toxicity value in mice. Based on the mortality observed in the range finding and main study, acute LD_{50} values of 449, 453 and 451 mg/kg bw can be calculated for male mice, female mice and combined sexes, respectively. This calculation used the Probit analysis according to Finney (Finney, D.J. (1971): "Probit Analysis" Cambridge University Press, pp. 1 – 50) using SAS 9.3.

Besides potential differences in species susceptibility, different bioavailability of pyraclostrobin administered as aqueous suspension or as solution in olive oil is considered to be the main driver for the observed differences in the oral LD_{50} values.

CA 5.2.2 Dermal

The acute dermal toxicity study of pyraclostrobin was evaluated and peer reviewed during the previous Annex I inclusion process (for further details please see Table 5.2-1). Pyraclostrobin has low acute dermal toxicity.

CA 5.2.3 Inhalation

Report: CA 5.2.3/1
[redacted] et al., 2001a
BAS 500 F 40% in Solvesso (technical active ingredient) - Acute inhalation toxicity study in Wistar rats - 4-hour liquid aerosol exposure
2001/1010625
Guidelines: OECD 403, EEC 92/69 B 2, EPA 870.1300
GLP: yes
(certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In an acute inhalation toxicity study, four groups of Wistar CrlGlxBrlHan:Wi (5/sex) were exposed to liquid aerosols of 40% pyraclostrobin in Solvesso at concentrations of 0.89, 1.96, 4.07 and 7.3 mg/L for 4 hours. The animals were observed for 14 days after exposure.

Mortality was observed in 0, 1, 0, and 5 males and 0, 0, 1, 4 females at 0.89, 1.96, 4.07 and 7.3 mg/L, respectively. The following LC_{50} values / LC_{50} ranges were estimated:

LC_{50}, male and female rats	**4.07 mg/L < LC_{50} < 7.3 mg/L**
LC_{50}, female rats	**5.47 mg/L**
LC_{50}, male rats	**4.07 mg/L < LC_{50} < 7.3 mg/L**

Clinical signs observed consisted of visually accelerated respiration, gasping, respiratory sounds, eyelid closure, apathy, squatting posture, piloerection and smeared fur. Except of accelerated respiration all clinical signs were observed after the end of the exposure only. Clinical signs resolved latest by day 7 of the observation period. Gross necropsy of animals dying as well as necropsied at the end of the observation period revealed mainly discolorations in the lung. Additionally, wet and contaminated fur was observed in dead animals exposed to the highest concentration of pyraclostrobin.

The mass mean aerodynamic diameter (MMAD) ranged from 2.7 µm (7.3 mg/L) to 4.3 µm (0.89 mg/L) with geometric standard deviations in the range of 2.5 to 2.7. Greater than 74.9% of the particles had a diameter of ≤ 5.5 µm and thus may have reached the alveolar space of the lung.

The extent of mortality as well as the clinical signs observed at 4.07 mg/L strongly indicate that the LC_{50} is above 5 mg/L. According to the EU CLP (1272/2008) no classification is necessary based on this test.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Pyraclostrobin 40% in Solvesso
(BAS 500 03 F; as given in the Certificate of Analysis)

Description:	Liquid, brown, clear
Lot/Batch #:	2001-1
Purity/content:	38.1%
Stability of test compound:	According to the Certificate of Analysis the test substance was stable until April 2003 when stored under ambient temperature.

2. Vehicle and/or positive control: Solvesso 200

3. Test animals:

Species:	Rat
Strain:	Wistar CrlGlxBrlHan:Wi
Sex:	20 males and 20 females
Age:	males: 8 to 12 weeks; females: 14 to 18 weeks
Weight at dosing:	262 ± 17.8 g (males), 224.0 ± 11.5 g (females)
Source:	Charles River Laboratories, Germany, 97633 Sulzfeld
Acclimation period:	at least one week
Diet:	Kliba rat/mouse/hamster diet, pelleted, Provimi Kliba SA, Kaiseraugst, Switzerland, ad libitum except during exposure
Water:	Tap water ad libitum except during exposure
Housing:	single housing in stainless steel wire mesh cages type DK-III (Becker & Co., Castrop-Rauxel, FRG)
Environmental conditions:	
Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	Fully air-conditioned rooms; number of air-changes not indicated in the report
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1.Dates of work: 11-Apr-2001 to 13-Jun-2001

2. Animal assignment and treatment:
For determination of the acute inhalation toxicity (single 4-hour-exposure) of pyraclostrobin dissolved in Solvesso as a liquid aerosol groups of five male and 5 female rats were exposed to aerosols at four concentrations.

3. Clinical examinations:
For each test group, the body weight of the animals was determined just prior to exposure (day 0), weekly thereafter and at the end of the observation period. A check for overt clinical signs of toxicity or mortality as well as a check for the presence of feed and drinking water was made twice a day on workdays and once daily on weekends and public holidays. Detailed clinical observations were recorded for each animal separately several times during exposure and at least once on each workday of the observation period.

4. Pathology:
At the end of the 14-day observation period the animals were sacrificed with CO_2 and were subjected to gross-pathological examination like those performed for animals which had died before the end of the exposure period.

5. Statistics/Calculations:
The statistical evaluation of the concentration-response relationship was carried out using a computer program. Depending on the data of the concentration-response relationship obtained by the experiment, this program is used to estimate the LC_{50} or to perform a Probit analysis[1]. Estimation of the LC_{50} will produce types "LC_{50} greater than", "LC_{50} approx.", or "LC_{50} smaller than". If the results are type "LC_{50} greater than" or "LC_{50} smaller than", an additional binomial test is carried out, in order to verify these Statements statistically[2].
The calculation of the particle size distribution was carried out in the inhalation laboratory on the basis of mathematical methods for evaluating particle measurements[3].

6. Generation of the test atmosphere / chamber description:
A head-nose inhalation system INA 20 (glass-steel construction, BASF Aktiengesellschaft, volume V $\approx$ 55 l) was used. The animals were restrained in glass tubes and their snouts projected into the inhalation system.

A liquid aerosol was generated. The unchanged test-substance (pyraclostrobin in Solvesso) was used for the test. The aerosol was produced by continuously pumping the test-substance to a two-component atomizer. Using compressed air, the aerosol was generated inside the exposure system.

The exposure system was located inside an exhaust cabin in an air-conditioned laboratory. A supply airflow (compressed air) of 0.65 m³/h for Test groups 1 to 3 and of 0.75 m³/h for Test group 4 was used for the exposure. Additionally, 1.35 and 1.25 m³/h of air was pumped into the exposure system for Test groups 1 to 3 and 4, respectively. The exhaust airflow was 1.8 m³/h. An air change of about 36 times per hour can be calculated by dividing the supply air flow by the volume of the inhalation system. The lower amount of exhaust air, which was adjusted by means of a separate exhaust air system, achieved a positive pressure inside the exposure system. This ensured that the mixture of test substance and air was not diluted with laboratory air in the breathing zones of the animals.

The animals were exposed to the inhalation atmosphere for 4 hours plus an equilibration time for the inhalation system of about 10 minutes.

7. Analytical investigation:

The flows of supply and exhaust air was adjusted and continuously measured with flow meters. Air flows, the temperature and the humidity in the exposure system were recorded four times at about 1-hour intervals.
The oxygen content in the inhalation system was not measured. The air change was judged to be sufficient to prevent oxygen depletion by the breathing of the animals, and the concentrations of the test substance used could not have a substantial influence on oxygen partial pressure.

The **nominal concentration** was calculated from the amount of substance dosed and the supply airflow.

The sampling for determination of the **actual aerosol concentration** was performed with a sampling station using a sampling probe (diameter 7 mm) with quartz wool plug and 3 impingers connected in series filled with sorption solvent.

- Sorption solvent: 2-propanole
- Sampling position: immediately adjacent to the animals' noses
- Sampling flow: 3 l/min
- Sampling velocity: 1.25 m/s
- Sampling frequency: 4 samples at about hourly intervals
- Sample volume: Test group 1: 15 l; Test group 2: 7 l; Test groups 3 and 4: 5 l
  The sampling volumes were adjusted to achieve suitable amounts of test substance for analysis

The quantification of pyraclostrobin was performed by HPLC using a Hewlett Packard HP 1050. The analytical conditions were as follows:

- Colum: metal 250 mm x 4 mm; Polygosil 60-5-C18
- Detection: UV detector at 274 nm
- Injection volume: 10 µl
- Column temperature: ambient
- Mobil phase: 70% Acetonitrile + 0.5 M H_2SO_4 (1000 ml + 5 ml)
  30% bidistilled water + 0.5 M H_2SO_4 (1000 ml + 5 ml)
- Flow rate: 1.2 ml/min

The calibration curve of pyraclostrobin in the solvent (Solvesso) had a linear range from 1.01 to 30.3 mg/50 ml. Samples were taken up in an appropriate volume of solvent, transferred to a calibrated 50 ml flask and filled up to the volume.

The particle size analysis was done using a Stack Sampler Mark III (Andersen) and a vacuum pump (Millipore). The sampling probe had an internal diameter 6.9 mm.
Before sampling, the impactor was assembled and equipped with a backup particle filter. The impactor was connected to the vacuum pump and for each test group samples were taken from the breathing zone of the animals starting not earlier than 30 minutes after the beginning of the exposure. The sample volumes were 45, 27, 12 and 6 l for Test groups 1 to 4, respectively. Two samples were taken for Test group 1 whereas one sample each was taken for Test groups 2 to 4.
After sampling the impactor was taken apart. The impactor stages and the backup particle filter were eluted individually with the solvent indicated above. The samples obtained were analyzed as described above. The amounts of material adsorbed to the walls of the impactor and in the sampling probe (wall losses) were also determined quantitatively.

II. RESULTS AND DISCUSSION

A. MORTALITY

Mortality was observed in Test groups 2 to 4. Details are given in Table 5.2.3-1

Table 5.2.3-1: Mortality of rats exposed for 4 hours to a liquid aerosol of pyraclostrobin in Solvesso

Test group	Concentration [mg/L]	Cumulative mortality		Time of deaths
		Male	Female	
1	0.89	0/5	0/5	-
2	1.96	1/5	0/5	d0
3	4.07	0/5	1/5	d0
4	7.3	5/5	4/5	≤ 4h (6), d0 (2), d1 (1)

h = hour; d0 =post exposure at day 0; d1 = first day after exposure

Based on the observed mortality the following LC_{50} values respectively ranges were determined:

- LC_{50} (both sexes combined) 4.07 mg/L < LC_{50} < 7.3 mg/L
- LC_{50} (female rats) 5.47 mg/L
- LC_{50} (male rats) 4.07 mg/L < LC_{50} < 7.3 mg/L

The 95% confidence interval for the LC_{50} in females is 2.3 - 18.06 mg/L.

B. CLINICAL OBSERVATIONS

Clinical signs observed consisted of visually accelerated respiration, gasping, respiratory sounds, eyelid closure, apathy, squatting posture, piloerection and smeared fur. The maximum incidence and duration of the observations are indicated in Table 5.2.3-2.

Table 5.2.3-2: Clinical signs in rats exposed for 4 hours to a liquid aerosol of pyraclostrobin in Solvesso

Concentration [mg/L]	0.89	1.96	4.07	7.3
Males				
- Total number of animals	5	5	5	5
- Respiration, visually accelerated	5 / ≤1h - d1	5 / ≤1h - d6	5 / ≤1h - d6	5 / ≤1h - ≤ 4h
- Gasping	-	2 / d0 - d1	-	-
- Respiratory sounds	-	-	1 / d1	-
- Eyelid closure	5 / d0	4 / d0	5 / d0	-
- Apathy	-	-	-	1
- Squatting posture	5 / d0	5 / d0 - d3	5 / d0 - d6	1 / d0
- Piloerection	5 / d0 - d1	-	-	-
- Fur, smeared	-	5 / d0 - d1	5 / d0 - d1	1 / d0
Females				
- Total number of animals	5	5	5	5
- Respiration, visually accelerated	5 / ≤1h - d1	5 / ≤1h - d3	5 / ≤1h - d6	5 / ≤1h - d3
- Gasping	-	-	-	1 / d0
- Respiratory sounds	-	-	2 / d1 - d6	1 / d0
- Eyelid closure	5 / d0	2 / d0 - d2	4 / d0	-
- Apathy	-	-	-	2 /d0
- Squatting posture	5 / d0	5 / d0 - d3	4 / d0 - d6	1 / d0 - d3
- Piloerection	5 / d0 - d1	-	-	-
- Fur, smeared	5 / d1	5 / d0 - d3	4 / d0 - d1	2 / d0 - d3

Abbreviations see Table 5.2.3-1; dn = day n after exposure

C. BODY WEIGHT

Mean body weights of male and female animals at 0.89 and 1.96 mg/L as well as males at 4.07 mg/L increased throughout the study period. In females exposed to pyraclostrobin at 4.07 mg/L a body weight loss was observed during the first week. However, these animals re-gained weight during the second week. Overall body weight gain of this group was marginal (+0.3%) compared to that in females at 0.89 mg/L (+4.8%) and 1.96 mg/L (+2.9%). Overall body weight gain in males ranged from 8.5 to 13.3%.

Body weight data for animals exposed to pyraclostrobin at 7.3 mg/L are only available for one surviving female. This female gained weight throughout the study (overall +3.7%).

D. NECROPSY

Gross necropsy of animals dying as well as necropsied at the end of the observation period revealed mainly discolorations in the lung. In dead animals exposed to the highest concentration of pyraclostrobin, wet and contaminated fur was observed additionally. Incidences are given in Table 5.2.3-3.

Table 5.2.3-3: Necropsy findings in rats exposed for 4 hours to a liquid aerosol of pyraclostrobin in Solvesso

Concentration [mg/L]	0.89	1.96	4.07	7.3
Animals dying (males/females)				
Number of affected animals	-/-	1/-	-/1	5/4
Organs without particular findings	-/-	1/-	-/-	-/-
Fur:				
- head and sternal region contaminated wet	-/-	1/-	-/-	5/4
Lung:				
- dark red discoloration, all lobes	-/-	-/-	-/1	4/3
- grey-red discoloration, all lobes	-/-	-/-	-/-	1/1
Animals killed at the end of the observation period (males/females)				
Number of affected animals	5/5	4/5	5/4	-/1
Animals without particular findings	5/5	-/-	-/-	-/-
Lung:				
- grey-red discoloration, all lobes	-/-	4/5	-/-	-/-
- dark red discoloration, all lobes	-/-	-/-	5/4	-/-
- red discoloration, most lobes	-/-	-/-	-/-	-/1

- not detected

E. ATMOSPHERE ANALYSIS

The exposure conditions are summarized in Table 5.2.3-4.

Table 5.2.3-4: Exposure conditions

Test group	Supply air (compressed) [m³/h]	Supply air (conditioned) [m³/h]	Exhaust air [m³/h]	Substance flow [ml/h]	Temp. [°C]	Relative humidity [%]
1	0.65	1.35	1.8	150	23.1	46.5
2	0.65	1.35	1.8	227.5	22.7	56.8
3	0.65	1.35	1.8	550	23.0	55.9
4	0.74	1.25	1.8	400	22.1	57.8

The results of the concentration measurements (mean of 4 measurements) are presented in Table 5.2.3-5.

Table 5.2.3-5: Measurement of concentrations

Test group	Mean concentration [mg/L]	Standard deviation	Nominal concentration [mg/L]
1	0.89	0.12	81.8
2	1.96	0.15	151.2
3	4.07	0.42	299.8
4	7.30	1.09	218.0

The measurements of particle-size distribution revealed mass mean aerodynamic diameters (MMAD) in the range of 2.7 to 4.3 µm with geometric standard deviations in the range of 2.5 to 2.7 (see Table 5.2.3-6).

Table 5.2.3-6: Particle size measurements

Test group	Sample	MMAD [µm]	GSD	Mass % < 3 µm
1	1	4.0	2.5	37.7
1	2	4.3	2.6	35.5
2	1	3.5	2.6	43.3
3	1	3.8	2.7	40.6
4	1	2.7	2.7	54.7

Greater than 35.5% of the particles had a diameter of ≤ 3.0 µm and thus may have reached the alveolar space of the lung.

III. CONCLUSION

Under the conditions of this study the combined 4 hour inhalation LC_{50} was estimated to be 4.07 mg/L < LC_{50} < 7.3 mg/L after exposure to a liquid aerosol of 40% pyraclostrobin in Solvesso. This estimate was true if males or both sexes combined were considered. For females an LC_{50} of 5.47 mg/L was estimated.

Based on the results of this study no classification according EU CLP criteria would be proposed. The extent of mortality as well as the clinical signs observed at 4.07 mg/l strongly indicate that the LC_{50} is above 5 mg/L.

GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In an acute inhalation toxicity study, four groups of Wistar CrlGlxBrlHan:Wi (5/sex) were exposed to liquid aerosols of pyraclostrobin (batch 96/0308; purity 98.2%) in acetone at concentrations of 0.52, 0.65 and 0.85 mg/L for 4 hours. The animals were observed for 14 days after exposure.

Mortality was observed in 0, 5, and 5 males and 1, 4 and 5 females at 0.52, 0.65 and 0.85 mg/L, respectively. The following LC_{50} values were estimated:

LC_{50}, male and female rats	**0.58 mg/L**
LC_{50}, female rats	**0.58 mg/L**
LC_{50}, male rats	**0.58 mg/L**

Clinical signs observed consisted of visually accelerated respiration, attempts to escape, squatting posture and piloerection. Clinical signs resolved latest by day 7 of the observation period. Gross necropsy of animals dying revealed mainly red discolorations in the lung. In most cases all lung lobes were affected. Additionally, wet and contaminated fur was observed in animals dying at the mid concentration level. One mid concentration male displayed lung edema in all lobes.

The mass mean aerodynamic diameter (MMAD) ranged from 1.2 µm (0.52 mg/L) to 1.7 µm (0.85 mg/L) with geometric standard deviations in the range of 2.5 to 2.7. Greater 94.3% of the particles had a diameter of ≤ 5.5 µm and thus may have reached the alveolar space of the lung.

Based on the results of this study pyraclostrobin has to be classified as "Toxic by inhalation" (Category 3) according to the EU CLP (1272/2008).

A. MATERIALS

1. Test Material: Pyraclostrobin (BAS 500 F)

Description:	Viscous melt, brownish-clear
Lot/Batch #:	CP026063
Purity/content:	98.2%
Stability of test compound:	The test material was repeatedly analyzed between 1996 and 2003. The purity did not change over time. The stability of the test substance was guaranteed in the last analysis until February 2007.

2. Vehicle and/or positive control: Acetone

3. Test animals:

Species:	Rat
Strain:	Wistar CrlGlxBrlHan:Wi
Sex:	15 males and 15 females
Age:	males: 8 to 12 weeks; females: 14 to 18 weeks
Weight at dosing:	247.4 ± 12.7 g (males), 223.1 ± 10.3 g (females)
Source:	Charles River Laboratories, Germany, 97633 Sulzfeld
Acclimation period:	at least one week
Diet:	Kliba rat/mouse/hamster diet, pelleted, Provimi Kliba SA, Kaiseraugst, Switzerland, ad libitum except during exposure
Water:	Tap water ad libitum except during exposure
Housing:	single housing in stainless steel wire mesh cages type DK-III (Becker & Co., Castrop-Rauxel, FRG)

Environmental conditions:	
Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	Fully air-conditioned rooms; number of air-changes not indicated in the report
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 27-Aug-2002 to 09-Oct-2002

2. Animal assignment and treatment:
For determination of the acute inhalation toxicity (single 4-hour-exposure) of pyraclostrobin dissolved in acetone as a liquid aerosol groups of five male and 5 female rats were exposed to aerosols at three concentrations. The animals were randomly selected from a pool of animals.

3. Clinical examinations:
For each test group, the body weight of the animals was determined just prior to exposure (day 0), weekly thereafter and at the end of the observation period. A check for overt clinical signs of toxicity or mortality as well as a check for the presence of feed and drinking water was made twice a day on workdays and once daily on weekends and public holidays. Detailed clinical observations were recorded for each animal separately several times during exposure and at least once on each workday of the observation period.

4. Pathology:
At the end of the 14-day observation period the surviving animals were sacrificed with CO_2 and were subjected to gross-pathological examination like those performed for animals which had died prematurely.

5. Statistics/Calculations:
The statistical evaluation of the concentration-response relationship was carried out using a computer program. Depending on the data of the concentration-response relationship obtained by the experiment, this program is used to estimate the LC_{50} or to perform a Probit analysis[1]. Estimation of the LC_{50} will produce types "LC_{50} greater than", "LC_{50} approx.", or "LC_{50} smaller than". If the results are of the type "LC_{50} greater than" or "LC_{50} smaller than", an additional binomial test is carried out, in order to verify these Statements statistically[2].

The calculation of the particle size distribution was carried out in the inhalation laboratory on the basis of mathematical methods for evaluating particle measurements[3].

6. Generation of the test atmosphere / chamber description:
A head-nose inhalation system INA 20 (glass-steel construction, BASF Aktiengesellschaft, volume V ≈ 55 l) was used. The animals were restrained in glass tubes and their snouts projected into the inhalation system.

A liquid aerosol was generated. For test the unchanged test-substance (pyraclostrobin in Solvesso) was used. The aerosol was produced by continuously pumping the test-substance preparation (2:1 (w/w) acetone : pyraclostrobin) to a two-component atomizer. The 2:1 acetone pyraclostrobin mixture was the maximum concentration suitable for pumping and spraying. Using compressed air, the aerosol was generated which was produced inside the exposure system.

The exposure system was located inside an exhaust cabin in an air-conditioned laboratory. A supply airflow (compressed air) of 1.5 m³/h were used for the exposure. The exhaust airflow was set at 1.35 m³/h. An air change of about 27 times per hour can be calculated by dividing the supply air flow by the volume of the inhalation system. The lower amount of exhaust air, which was adjusted by means of a separate exhaust air system, achieved a positive pressure inside the exposure system. This ensured that the mixture of test substance and air was not diluted with laboratory air in the breathing zones of the animals.

The animals were exposed to the inhalation atmosphere for 4 hours plus an equilibration time for the inhalation system of about 10 minutes.

7. Analytical investigation:

The flows of supply and exhaust air was adjusted and continuously measured with flow meters. Air flows, the temperature and the humidity in the exposure system were recorded four times at about 1-hour intervals.
The oxygen content in the inhalation system was not measured. The air change was judged to be sufficient to prevent oxygen depletion by the breathing of the animals, and the concentrations of the test substance used could not have a substantial influence on oxygen partial pressure.

The **nominal concentration** was calculated from the amount of substance dosed and the supply airflow.

The sampling for determination of the **actual aerosol concentration** was performed with a filtration equipment using a sampling probe (diameter 7 mm). The quantification of pyraclostrobin was performed by gravimetric determination. For this pre-weighed filters were placed into the filtration equipment. By means of the vacuum pump metered volumes of the liquid aerosol were drawn through the filter.

- Filter: MN 85/90 BF (d = 47 mm)
- Sampling position: immediately adjacent to the animals' noses
- Sampling flow: 3 l/min
- Sampling velocity: 1.25 m/s
- Sampling frequency: 4 samples at about hourly intervals
- Sample volume: Test group 1: 9 l; Test group 2 and 3: 6 l;
  The sampling volumes were adjusted to achieve suitable amounts of test substance for analysis

The gravimetric method was validated by HPLC analysis in the previously submitted study [BASF DocID 1997/11472]. For each sample the liquid aerosol concentration in mg/L was calculated from the difference between the pre-weighed of the filter and the weight of the dried filter after sampling and, with reference to the sample volume of the inhalation atmospheres.

The particle size analysis was done using a Stack Sampler Mark III (Andersen) and a vacuum pump (Millipore). The sampling probe had an internal diameter 6.9 mm.
Before sampling, the impactor was assembled with pre-weighed glass-fiber collecting disks and equipped with a backup particle filter. The impactor was connected to the vacuum pump and for each test group samples were taken from the breathing zone of the animals starting not earlier than 30 minutes after the beginning of the exposure. The sample volumes were 45, 30 and 24 l for Test groups 1 to 3, respectively. Two samples were taken for Test group 1 whereas each one sample was taken for Test groups 2 and 3.
After sampling the impactor was taken apart. The impactor stages and the backup particle filter were freed of acetone and re-weighed.

II. RESULTS AND DISCUSSION

A. MORTALITY

Mortality was observed in Test groups 2 to 4. Details are given in Table 5.2.3-7.

Table 5.2.3-7: Mortality of rats exposed for 4 hours to a liquid aerosol of pyraclostrobin dissolved in acetone

Test group	Concentration [mg/l]	Cumulative mortality		Time of deaths
		Male	Female	
1	0.52	0/5	1/5	d0
2	0.65	5/5	4/5	h2 (1), h3 (4), d0 (4)
3	0.85	5/5	5/5	h1 (3), d0 (7)

h = hour; d0 =post exposure at day 0; d1 = first day after exposure

Based on the observed mortality the following LC_{50} values respectively ranges were determined (see Report Amendment No. 1):

- LC_{50} (both sexes combined) 0.58 mg/L (0.54 - 0.63 mg/L)
- LC_{50} (female rats) 0.58 mg/L
- LC_{50} (male rats) 0.58 mg/L (0.39 - 0.78 mg/L)

The 95% confidence interval for the LC_{50} in both sexes and in females is given in above in brackets. As no LC_{50} for male rats could be derived by statistical evaluation, a point estimate of the LC_{50} value was calculated as the geometrical mean of the highest test substance concentration causing no lethality and the lowest concentration, at which 100 % lethality occurred in male rats.

B. CLINICAL OBSERVATIONS

Clinical signs observed consisted of visually accelerated respiration, attempts to escape, squatting posture and piloerection. The maximum incidence and duration of the observations are indicated in Table 5.2.3-8.

Table 5.2.3-8: Clinical signs in rats exposed for 4 hours to a liquid aerosol of pyraclostrobin in acetone

Concentration [mg/l]	0.52	0.65	0.85
Males			
- Total number of animals	5	5	5
- Respiration, visually accelerated	5 / h0 - d3	5 / h0 - d3	5 / h0 - d3
- Attempts to escape	1 / h0	-	-
- Squatting posture	5 / d0	-	-
- Piloerection	3 / d0 - d3	-	-
Females			
- Total number of animals	5	5	5
- Respiration, visually accelerated	5 / h0 - d3	5 / h0 - d6	5 / h0 - h3
- Attempts to escape	2 / h0	-	2 / h0
- Squatting posture	4 / d0	1/ d0 - d1	-
- Piloerection	1 / d0 - d1	-	-

Abbreviations see Table 5.2.3-7; dn = day n after exposure; - not detected

C. BODY WEIGHT

Mean body weights of males at 0.52 mg/L increased throughout the study period. In the 4 surviving females exposed to pyraclostrobin at 0.52 mg/L and the one surviving female at 0.65 mg/L a body weight loss was observed during the first week. However, these animals re-gained weight during the second week.

D. NECROPSY

Gross necropsy of animals dying revealed mainly diffuse red discolorations in the lung. At the mid concentration level (0.65 mg/L) wet and contaminated fur was observed. Additionally, one mid dose male displayed edema in all lung lobes. Incidences are given in Table 5.2.3-9.

Table 5.2.3-9: Necropsy findings in rats exposed for 4 hours to a liquid aerosol of pyraclostrobin in acetone

Concentration [mg/l]	0.52	0.65	0.85
Animals dying (males/females)			
Number of affected animals	-/1	5/4	5/5
Organs without particular findings	-/-	-/-	-/-
Fur:			
- head and abdominal region contaminated wet	-/-	5/4	-/-
Lung:			
- red and diffuse discolored lung lobes	-/1	-/-	-/-
- diffuse dark red discoloration, all lobes	-/-	5/4	5/5
- edema, all lobes	-/-	1/-	-/-

- not detected

E. ATMOSPHERE ANALYSIS

The exposure conditions are summarized in Table 5.2.3-10.

Table 5.2.3-10: Exposure conditions

Test group	Supply air (compressed) [m³/h]	Exhaust air [m³/h]	Substance flow[1] [ml/h]	Atomizer pressure [bar]	Temp. [°C]	Relative humidity [%]
1	1.5	1.35	3.2	1.5	23.2 ± 0.3	22.5 ± 5.8
2	1.5	1.35	4.5	1.5	22.8 ± 0.0	17.9 ± 1.8
3	1.5	1.35	6.0	1.6	23.1 ± 0.1	20.8 ± 2.3

[1] Correlated to the substance dilution the substance flows were 2.13 (test group 1), 3.00 (test group 2) and 4.00 ml/h (test group 3).

The low humidity values measured in this study may indicate an influence of the test substance atmosphere on the measuring device. However, if there was any deviation from the guideline recommendations (30% - 70% relative hum.; especially low humidity in liquid aerosols), it is considered not of influence for the test results, because of the relatively short exposure time.

The results of the concentration measurements (mean of 4 measurements) are presented in Table 5.2.3-11.

Table 5.2.3-11: Measurement of concentrations (4 hourly measurements)

Test group	Mean concentration [mg/l]	Standard deviation	Nominal concentration [mg/L]
1	0.52	0.04	0.71
2	0.65	0.06	1.00
3	0.85	0.07	1.33

The measurements of particle-size distribution revealed mass mean aerodynamic diameters (MMAD) in the range of 1.2 to 1.7 µm with geometric standard deviations in the range of 2.5 to 2.7 (see Table 5.2.3-12).

Table 5.2.3-12: Particle size measurements

Test group	Sample	MMAD [µm]	GSD	Mass % < 3 µm
1	1	1.2	2.5	84.5
1	2	1.3	2.6	82.0
2	1	1.4	2.5	79.9
3	1	1.7	2.7	72.4

Greater than 72.4% of the particles had a diameter of ≤ 3.0 µm and thus may have reached the alveolar space of the lung.

III. CONCLUSION

Under the conditions of this study the 4 hour inhalation LC_{50} was estimated to be 0.58 mg/L after exposure to a liquid aerosol of pyraclostrobin dissolved in acetone.

Based on the results of this study pyraclostrobin has to be classified as "Toxic by inhalation" (Category 3) according to the EU CLP (1272/2008).

Overall assessment of inhalation toxicity

Dissolved in acetone pyraclostrobin was toxic to rats when inhaled as an aerosol for 4 hours. A study performed 1997 revealed an acute toxicity value of 0.31 mg/L < LC_{50} < 1.07 mg/L with no and 100% mortality at 0.31 and 1.07 mg/L, respectively. The derived LC_{50} in the List of Endpoints was 0.69 mg/L. A new study performed in 2002 at concentrations of 0.52, 0.65 and 0.85 mg/L, using also acetone as solvent, revealed an LC_{50} of 0.58 mg/L. The LC_{50} values of pyraclostrobin dissolved in acetone are leading to the CLP classification “H331 - Toxic if inhaled”.

A substantially different result was obtained in a second new acute inhalation study performed in 2001, using Solvesso 200 as a solvent, revealing an acute inhalation toxicity value of 4.07 < LC_{50} < 7.3.

Thus, the solvent (used in the acute inhalation studies to generate an inhalable aerosol) is strongly influencing the acute inhalation toxicity of pyraclostrobin. In addition, the size of aerosol particles may modulate the inhalation toxicity.

CA 5.2.4 Skin irritation

The acute skin irritation study of pyraclostrobin was evaluated and peer reviewed during the previous Annex I inclusion process (for further details please see Table 5.2-1). Pyraclostrobin is irritant to the skin.

In the study report (see BASF DocID 1998/10959) it is stated in section 4.1 "that the stability of the test substance over the study period will be investigated by reanalysis and reported in the form of an amendment". A respective amendment was generated (BASF DocID 2000/1018990) and is now included in the updated dossier. Details are shown below.

Report:	CA 5.2.4/1 [redacted] 2000 a Amendment No. 1: BAS 500 .. F - Acute dermal irritation/corrosion in rabbits 2000/1018990
Guidelines:	OECD 404, EEC 92/69 B 4, EPA 81-5
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive summary

The test substance was stable over the study period.

CA 5.2.5 Eye irritation

The acute eye irritation study of pyraclostrobin was evaluated and peer reviewed during the previous Annex I inclusion process (for further details please see Table 5.2-1). Pyraclostrobin is not irritant to the eye.

In the study report (see BASF DocID 1998/10963) it is stated in section 4.1 "that the stability of the test substance over the study period will be investigated by reanalysis and reported in the form of an amendment". A respective amendment was generated (BASF DocID 2000/1018989) and is now included in the updated dossier. Details are shown below.

Report:	CA 5.2.5/1 [redacted] 2000 b Amendment No. 1: BAS 500 .. F - Acute eye irritation in rabbits 2000/1018989
Guidelines:	OECD 405, EPA 81-4, EEC 92/69 B 5
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive summary

The test substance was stable over the study period.

CA 5.2.6 Skin sensitisation

The skin sensitisation study (Maximisation Test) of pyraclostrobin was evaluated and peer reviewed during the previous Annex I inclusion process (for details please see Table 5.2-1). Pyraclostrobin is not sensitising.

CA 5.2.7 Phototoxicity

Report:	CA 5.2.7/1 Cetto V., Landsiedel R., 2012a BAS 500 F (Pyraclostrobin) - In vitro 3T3 NRU Phototoxicity Test 2012/1189936
Guidelines:	OECD 432 (2004) In vitro 3T3 NRU Phototoxicity Test, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.41 No. L 142
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Report:	CA 5.2.7/2 Cetto V., Landsiedel R., 2014a Amenment No. 1 - BAS 500 F (Pyraclostrobin) - In vitro 3T3 NRU phototoxicity test 2014/1092412
Guidelines:	OECD 432 (2004) In vitro 3T3 NRU Phototoxicity test, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.41 No. L 142
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Note: The report amendment (CA 5.2.7/2) corrects some clerical errors, which do not affect the outcome or interpretation of the study.

Executive Summary

Pyraclostrobin (batch COD-001236; purity 99.02%) was tested for its ability to induce phototoxic effects in Balb/c 3T3 cells in vitro. The photo-cytotoxicity was estimated by the means of the Neutral Red Uptake (NRU) method. Three experiments were carried out with and without irradiation with an UVA source. Vehicle and positive controls were included into each experiment. The 1st experiment failed to fulfil the acceptance criteria and the results of the 2nd experiment were confirmed in a 3rd experiment. The latter two experiments fulfilled the acceptance criteria.

Based on an initial range-finding phototoxicity test for the determination of the experimental concentrations, the following concentrations were tested in this study with and without UVA irradiation: 0, 0.5, 1.0, 2.2, 4.6, 10.0, 21.5, 46.4 and 100.0 µg/mL.

Precipitation was seen at the top dose of 100 µg/mL with and without irradiation. In the absence and the presence of UVA irradiation cytotoxicity was noted and EC_{50} values were calculated. Based on the results of the present study, the test substance was predicted to have no phototoxic potential as indicated by Photo-Irritancy-Factor (PIF) values of 1.6 and 0.9 for the 2nd and 3rd experiment, respectively. The threshold for a negative response is ≤ 2. The positive control chlorpromazine led to the expected increased cytotoxicity with UVA irradiation as indicated by PIF values of 29.8 and 40.8.
Thus, under the experimental conditions of this study, pyraclostrobin is not considered to be a phototoxic substance in the in vitro 3T3 NRU Phototoxicity Test using Balb/c 3T3 cells.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:	BAS 500 F (pyraclostrobin)
Description:	Solid, melt, red to brown
Lot/Batch #:	COD-001236
Purity:	99.02% (tolerance ± 1.0%)
Stability of test compound:	Expiry date: 01.10.2015
Solvent used:	Dimethylsulfoxide (DMSO) Even though the report indicated that the stability in DMSO was not determined analytically in the course of this study, the stability of pyraclostrobin in DMSO was demonstrated in earlier studies (e.g. study 08B0308/966022).
2. Control Materials:	
Vehicle control:	DMSO 1% (v/v) in PBS
Positive control compounds:	Chlorpromazine (CPU) was dissolved in DMSO; 8 concentrations tested - 1.9 to 180 µg/mL without radiation, 0.03 to 3.2 µg/mL with radiation
3. Test organisms:	BaIb/c 3T3, clone A31: fibroblast cell line isolated from the muscle tissue of a mouse embryo. The Balb/c 3T3 cell line which was used in this experiment was obtained from the "European Collection of Cell Cultures" Salisbury, Wiltshire SP4 OJG, UK on 09 Aug 2006 and is stored at -196°C (liquid nitrogen).

4. Culture media and reagents:

Culture medium:	Dulbecco's Modified Eagle's Medium (DMEM) supplemented with - 10% (v/v) newborn calf serum (NCBS) - 4 mM L-glutamine - 100 IU penicillin - 100 µg/mL streptomycin
Neutral Red solution:	- 0.4 g Neutral Red powder (NR; Sigma N4638) - 100 mL deionized water
Neutral Red medium:	- 1 mL Neutral Red solution - 79 mL culture medium (DMEM incl. supplements) (incubated overnight at 37° C with 5% CO_2 and filtered with a 0.22 µm filter prior to use)
Other solutions and reagents:	- phosphate buffered saline (PBS) without Ca/Mg - trypsin/EDTA solution (0.05%; 0.02%) - Neutral Red desorb solution (1 mL acetic acid, 50 mL ethanol, 49 mL deionized water)

5. Irradiation source: The Sol 500 solar simulator (Dr. Hönle AG, 82166 Gräfelfing, Germany) used with filter H1 produced wavelength > 320 nm. The exposure rates were determined with UV-meter RM-21 (Dr. Gröbel GmbH, 76275 Ettlingen, Germany).

6. Test concentrations:

Pretest:	Up to 1000 µg/mL with and without irradiation. The EC_{50} values determined were 56.7 µg/mL without and 26.3 µg/mL with UVA irradiation (no detailed data provided in the report).
Main NRU test:	Based on the results of the pretest the following concentrations were used in the main study: Without UVA: 0.5, 1.0, 2.2, 4.6, 10.0, 21.5, 46.4, 100.0 µg/mL With UVA: 0.5, 1.0, 2.2, 4.6, 10.0, 21.5, 46.4, 100.0 µg/mL

B. TEST PERFORMANCE:

1. Dates of experimental work: 04-Jun-2013 to 04-Jul-2013

2. Treatment and NRU Phototoxicity Test:

Two 96 well-plates per substance (test substance or positive control) were used for cultivation of cells (1.5 x 10^5 cells/well). After an attachment period of about 24 hours the cells were washed once with 100 µL PBS and subsequently treated with the respective substance (8 concentrations each with 6 replicates of the test substance or the positive control) and the vehicle control. After pre-incubation for 1 hour in the dark (5% (v/v) CO_2, ≥90% humidity; 37°C) one 96 well-plate per substance was irradiated for 50 minutes with UVA (UV intensity underneath the lid 1.5 - 2.1 mW/cm^2 = 5 J/cm^2) whereas the respective reference plate was kept in the dark for the same period. Thereafter the test- respectively control-substance was removed and the cells washed at least once with 100 µL PBS. After replenishing the wells with culture medium the cells were incubated overnight under the conditions indicated above. The medium was removed 24 hours after the start of treatment and after washing with 100 µL PBS the wells were filled with 100 µL medium containing 50 µg/mL Neutral Red. Subsequently the plates were incubated for another 3 hours. Each step was performed under light protected conditions in the lab to prevent uncontrolled photo activation. Finally, the cells were washed again with 100 µL and the dye was extracted by 100 µL Neutral Red desorb solution. Cytotoxicity was determined by measuring the Neutral Red Uptake by means of a microplate reader (Perkin Elmer, Waltham, Massachusetts, US; Wallac 1420 multilabel counter) equipped with a 550 nm filter to read the absorption of the extracted dye. The absorption shows a linear relationship with the number of surviving cells.

In this study 3 main experiments were conducted. The 1st revealed no indication of phototoxicity but the standard deviation of both vehicle controls of the non-irradiated plate treated with the test substance exceeded the acceptance criteria and therefore the 1st experiment was considered invalid. The data of this experiment were not included in the report. The 2nd and 3rd experiment likewise did not reveal indications for cytotoxicity. The 3rd experiment was performed to confirm the results of the 2nd assay.

3. Evaluation/Assessment

3.1 Cytotoxicity

The mean absorbance values obtained for each test group of every plate were used to calculate the percentage of cell viability relative to the respective vehicle control, which is arbitrarily set at 100 %.

$$Viability^{\S}\ [\%] = \frac{\text{Absorbance}_{\text{mean of the test group}}}{\text{Absorbance}_{\text{mean of the vehicle control}}} \times 100$$

§ The authors of the study denominate the above quotient as 'cytotoxicity', which is strictly speaking not correct. Thus, in this summary the appropriate term 'viability' is used. This applies also to Table 5.2.7-1 to Table 5.2.7-4 .

In case of cytotoxicity, an EC_{50} value (concentration at which the viability is reduced by 50% relative to the respective vehicle control) was calculated by a linear interpolation method (linear dose-response curve). Therefore, two viability values were needed: one between 100% and 50% and one between 50% and 0%. From these two points the concentration that inhibits the Neutral Red uptake by 50% of the respective control was calculated.

For the assessment of the phototoxic potential of a compound two prediction models are currently available:

- The Photo-Irritancy-Factor (PIF) prediction model for substances which allow the comparison of two equi-effective concentrations (EC_{50}) in the concurrently performed experiments in the presence and absence of light. This model includes two special cases: Case 1 accounts for situations in which an EC_{50} can only be calculated in the presence of UVA irradiation. Case 2 accounts for situations where an EC_{50} cannot be calculated in absence and presence of irradiation. These special cases do not apply to this study. Even though described in the report these cases are not described in this summary.
- The Mean Photo Effect prediction model which is used if no EC_{50} was obtained in the absence and presence of UV light. This is not the case in this study. Even though described in the report this prediction model is not described in this summary.

3.2 Photo-Irritancy-Factor (PIF)

For substances which induce a 50 % cytotoxicity (EC_{50}) in the presence and absence of light the Photo-Irritancy-Factor (PIF) is calculated based on comparison of the EC_{50} values in the absence (-UVA) and presence (+UVA) of UVA irradiation.

$$PIF = \frac{EC50\ (-UVA)}{EC50\ (+UVA)}$$ resulting in the following classification rules:

PIF ≥5	phototoxic potential predicted
2 < PIF < 5:	probable phototoxic potential predicted
PIF ≤ 2:	no phototoxic potential predicted

3.3 Other parameters

pH:
The pH was measured at least for the two top doses and for the vehicle controls with and without irradiation.

Osmolarity:
Osmolarity was measured at least for the two top doses and for the vehicle controls with and without irradiation.

Solubility:
Test substance precipitation was checked immediately after treatment and at the end of treatment.

Cell morphology:
Test cultures of all test groups were examined microscopically before staining with NRU, which allows conclusions to be drawn about attachment of the cells.

4. Statistics:

No special statistical tests were performed.
Mean absorbance values and standard deviations were calculated from the single values using calculation software (e.g. MS Excel). The calculations were made using the unedited values. For the report the values were rounded, therefore there may be deviations in the given relative values. If technical errors occurred in single wells (outlier) at least 4 single values per test group were sufficient for calculating reliable mean values. Outliers are defined as values that have half or double the value of the respective mean.

5. Acceptance criteria:

The assay has to be considered valid if the following criteria are met:

- The vehicle control needs to fulfill the following criteria:
  - The mean OD550 value (with and without UVA irradiation) should be > 0.3.
  - Cell viability after irradiation should be at least 80% of the concurrent non-irradiated vehicle control.
  - The standard deviation of the mean values of both vehicle control rows should not exceed ± 15%.
- The positive control chlorpromazine needs to fulfill the following criteria:
  - the EC50 value should be in the ranges:
    With irradiation (+UVA): 0.1 - 2.0 µg/mL
    Without irradiation (-UVA): 7.0 - 90.0 µg/mL
  - and the PIF ≥ 6.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

Osmolarity and pH values were not influenced by test substance treatment. In this study, in the absence and the presence of UVA irradiation precipitation in culture medium was observed at test substance concentrations of ≥ 46.4 µg/mL.

B. CYTOTOXICITY OF THE TEST SUBSTANCE

After treatment with the test substance, clear cytotoxic effects indicated by Neutral Red absorbance values of below 50% of control were observed in the main experiments in the absence and the presence of UVA irradiation (see Table 5.2.7-1 (2nd experiment) and Table 5.2.7-2 (3rd experiment)).

Without UVA irradiation, there was a decrease in the cell number at concentrations ≥ 46.4 µg/mL (EC_{50}: 37.2 µg/mL) in the 2nd experiment and at ≥ 10 µg/mL (EC_{50} 8.6 µg/mL) in the 3rd experiment. With UVA irradiation, there was a decrease in the cell number at concentrations ≥ 21.5 µg/mL (EC_{50}: 23.2 µg/mL) in the 2nd experiment and at ≥ 10 µg/mL (EC_{50}: 10.0 µg/mL) in the 3rd experiment. Cell morphology changes were restricted to the highest concentration (100 µg/mL) in the 3rd experiment with and without UVA irradiation.

Based on the EC_{50} values a PIF of 1.6 and 0.9 were calculated for the 2nd and 3rd experiment, respectively, indicating no phototoxic potential for pyraclostrobin.

C. CYTOTOXICITY OF THE POSITIVE CONTROL

After treatment with the positive control chlorpromazine clear cytotoxic effects indicated by Neutral Red absorbance values of below 50% of control were observed in the absence and the presence of UVA irradiation (see Table 5.2.7-3 (2nd experiment) and Table 5.2.7-4 (3rd experiment)).
In the 2nd and 3rd experiment without UVA irradiation, there was a decrease in viability at ≥ 30.0 µg/mL (EC_{50}: 23.2 µg/mL and 24.0 µg/mL). With UVA irradiation, there was a decrease in viability at ≥ 0.8 µg/mL (EC_{50}: 0.7 µg/mL and 0.6 µg/mL). Cell morphology was distinctively changed in both experiments at ≥ 30 µg/mL and ≥ 0.8 µg/mL without and with UVA irradiation.

Based on the EC_{50} values PIF's of 29.8 and 40.8 were obtained in the 2nd and in the 3rd experiment, respectively, indicating a strong phototoxic potential, thus confirming the sensitivity of the test system.

III. CONCLUSION

According to the results of the present study, pyraclostrobin is not considered to be a phototoxic substance in the in vitro 3T3 NRU Phototoxicity Test.

CA 5.3 Short-Term Toxicity

Studies evaluated in the pyraclostrobin draft monograph of Rapporteur Member State Germany (August 1, 2001) consisted of: short-term toxicity studies (28 - 90 days) with oral administration in three different species (rats, mice, dogs). In addition, a 1-year dog study and a 28-day dermal toxicity study in rats were evaluated. These studies have been evaluated by European authorities and Germany as RMS and were considered to be acceptable. For the convenience of the reviewer, these studies are summarized below in tabular form as extracted from the monograph (see Table 5.3-1).

"The signs of toxicity, as observed in the three species tested, were comparable. The critical clinical effects were reduction of body weight and body weight gain in all three species. In dogs, vomitus and diarrhoea occurred additionally. The target organ in all three species was the duodenum, showing mucosal hypertrophy, which was characterised by an increased ratio of cytoplasm to the nuclei in the villi, and by hyperplastic changes in the epithelial cells.
These substance-related effects were associated with changes of several clinical-chemical parameters. The typical findings included a decrease of protein, glucose and triglycerides. These effects might be associated with diminished vacuolization of hepatocytes as observed histologically.
The increase in serum urea values in mice might be indicative of increased protein catabolism or a slightly impaired renal function. The histopathological examination of the kidneys has shown diminished vacuolisation of proximal tubular epithelial cells.
In all three species investigated, hematological changes with correlating compensatory reactions were observed which were considered indicative of toxic effects on red blood cells. Platelet counts were increased in mice and dogs. Concerning white blood cell parameters, rats demonstrated an increase in white blood cells. In mice, adverse effects on white blood cells as well on lymphatic organs (thymus, mesenteric lymph modes) and the adrenals (decreased vacuolisation of cortical cells) were observed.
Only in the rat liver, an increase of liver cell hypertrophy occurred at high doses. The reduction in liver enzyme activity (alanine aminotransferase, alkaline phosphatase) in both sexes is considered to be of equivocal toxicological significance.
In a 4-week dermal toxicity study in rats, no substance related systemic toxicity was detected up to the highest dose tested (250 mg/kg bw/d).

For rats, a short-term NOAEL of 150 ppm (10.7 mg/kg bw/d) has been established. For dogs, the short-term NOAEL is 200 ppm, equivalent to about 6 mg/kg bw/d, based on the 3-month and 1-year feeding study in this species.
For male mice, the NOAEL in the 3-month study was lower than 50 ppm (9.2 mg/kg bw/d). Taking into consideration all available data for this species, a NOAEL of 30 ppm (ca 4 mg/kg bw/d) can be established for male mice based on the body weight data after 91 days from the carcinogenicity study. For females, the no observed adverse effect level was 50 ppm (12.9 mg/kg bw/d).

Overall, the lowest relevant NOAEL for short-term oral toxicity is 4 mg/kg bw/d, based on the body weight data after 91 days from the carcinogenicity study in mice."

Table 5.3-1: Summary of reviewed pyraclostrobin short-term toxicity studies

Study	Dosages (mg/kg bw/ day)	NOAEL (mg/kg bw/day)	Main adverse effect	Reference (BASF DocID)

References (BASF DocIDs) in italic are submitted the first time in this supplemental dossier. As these report amendment do not affect the outcome and interpretation of the studies they are listed in this table.

Studies submitted in this AIR 3 dossier (not yet peer-reviewed):
Upon request of US-EPA the applicant conducted a 28-day inhalation toxicity study. This study employed atmosphere concentrations of 0, 1, 30 and 300 mg/m³ (0, 001, 0.03 and 0.3 mg/L) and identified a NOAEC of 1 mg/m³. The wide dose spacing between the mid and low concentration by a factor of 30 resulted in a NOAEC, which was not sufficient to allow to pass all US as well as EU exposure scenarios. Therefore, and to demonstrate the reversibility of the observed local effects in the upper respiratory tract, a second 28-day inhalation study was performed at lower concentrations (0, 3, 10 and 30 mg/m³). The results of these studies are listed in Table 5.3-2; comprehensive summaries are provided further below (see CA 5.3.3/1 and CA 5.3.3/2).

Table 5.3-2: Summary of not yet reviewed pyraclostrobin short-term toxicity studies

Study	Dosages (mg/m³)	NOAEC (mg/m³)	Main adverse effect	Reference (BASF DocID)
4-week inhalation (5 day/week) Wistar rat 0, 1, 30, 300 mg/m³	M&F: 1.17 ± 0.3, 30.4 ± 1.2 299 ± 15	1	Mortality and body weight effects at 300 mg/m³, hyperplasia of the duodenal mucosa, local effects in the upper respiratory tract at ≥ 30 mg/m³	2005/1013950
4-week inhalation (5 day/week) Wistar rat 0, 3, 10, 30 mg/m³	M&F: 3.01 ± 0.8 10.1 ± 1.5 29.1 ± 2.9	10	Local irritation in the upper respiratory tract (atrophy/ necrosis of olfactory epithelium)	2014/1003946

For convenience of the reviewer brief summaries of the respective studies were extracted from the monograph of are provided under the respective chapters.

Based on the studies previously peer-reviewed, the following EU agreed endpoints are given in the Review Report of pyraclostrobin (SANCO/1420/2001-Final, 8. September 2004):

Short term toxicity	
Target / critical effect:	Reduced body weight, gastrointestinal tract, red blood cells, diarrhoea (dog), hepatocellular hypertrophy (rat), white blood cells and lymphatic organs (mouse)
Lowest relevant oral NOAEL / NOEL:	90-day mouse[#]: 30 ppm (4 mg/kg bw/d)
Lowest relevant dermal NOAEL / NOEL:	28-day rat: > 250 mg/kg bw/d (systemic)
Lowest relevant inhalation NOAEL/NOEL	No data - not required (because of physical and chemical properties)

[#] based on effects on body weight after 90 days in the carcinogenicity study in male mice

The proposed endpoints based on all available studies are shown below.

Target / critical effect	Reduced body weight, gastrointestinal tract, red blood cells, diarrhoea (dog), hepatocellular hypertrophy (rat), white blood cells and lymphatic organs (mouse), local irritation of the upper respiratory tract (rat inhalation)
Lowest relevant oral NOAEL / NOEL	90-day mouse[#]: 30 ppm (4 mg/kg bw/d)
Lowest relevant dermal NOAEL / NOEL	28-day rat: > 250 mg/kg bw/d (systemic)
Lowest relevant inhalation NOAEL / NOEL	0.01 mg/L (local) 0.3 mg/L (systemic)

[#] based on effects on body weight after 90 days in the carcinogenicity study in male mice

CA 5.3.1 Oral 28-day study

28-day study in rats
Groups of 5 male and 5 female Wistar rats (Chbb: THOM (SPF)) per dose group received pyraclostrobin of two different batches (purity about 94 and 99%) at dietary doses of 0, 20, 100, 500 and 1500 ppm for 28 consecutive days.

Clinical signs of toxicity consisted of a dose-dependent reduction of food consumption and impaired body weight development at ≥ 500 ppm.

Hematology investigations revealed reduced red blood cell counts and hemoglobin concentrations in females at ≥ 500 ppm. Additionally, increased MCV and decreased MCHC values were noted. Clotting analysis revealed a prolonged clotting time in males and females at 500 and/or 1500 ppm.
Changes of clinical chemistry parameters were mainly seen in top dose (1500 ppm) females and consisted of decreased serum cholinesterase activity (in absence of effects on erythrocyte and brain cholinesterase) as well as reduced glucose levels. Minor, but statistically significant changes in males consisted of decreased phosphate and increased total bilirubin levels.

Significantly reduced terminal body weights were observed in both sexes at the top dose level. Secondary to this a number of absolute and relative organ weights displayed statistically significant deviations from the respective control values. Only the increased relative liver and spleen weights were accompanied by treatment-related histopathological findings. These consisted of hepatocellular hypertrophy and decreased fat storage in the liver and increased extramedulary hematopoiesis in the spleen of males and females at 500 and or 1500 ppm. Additionally, mucosal hyperplasia of the duodenum was noted in both sexes at ≥ 1500 ppm.

Conclusion
Based on the described findings at 500 ppm and above, the NOAEL in this study was identified at 100 ppm, which is equivalent to mean daily intakes of 9.0 and 9.6 mg/kg bw/day in male and females rats, respectively.

CA 5.3.2 Oral 90-day study

Note: The main rat 90-day study report (CA 5.3.2/1) together with the 1st report amendment (CA 5.3.2/2) was already submitted and reviewed in the course of the initial registration of pyraclostrobin. This study is submitted for completeness as the basis for the assessment of report amendments submitted under CA 5.3.2/3 to CA 5.3.2/5. Whereas report amendments 1 and 2 correct clerical errors in the original report, amendment 3 provides the result of an additional histopathological evaluation of the spleen for intermediate dose levels. Amendment 4, which was submitted to Japanese authorities, provides a reference for the BASF trimming procedure used in this and other repeated dose studies. To take into account that the majority of the data were already reviewed, the following study summary will be more comprehensive than for other studies already reviewed, but will be less detailed than the summary of new studies.

Report:	CA 5.3.2/5 [redacted] 2004a Amendment to the report for Japanese registration: BAS 500 F - Subchronic oral toxicity study in Wistar rats - Administration in the diet for 3 months 2004/1027673
Guidelines:	EEC 87/302, OECD 408, JMAFF, EPA 82-1
GLP:	yes (certified by Ministerium fuer Arbeit, Soziales, Familie und Gesundheit, Postfach 3180, 6500 Mainz)

Material and Methods:
Pyraclostrobin was administered to groups of 10 male and 10 female Wistar rats at dietary concentrations of 0, 50, 150, 500, 1000 and 1500 ppm for 3 months. Food consumption and body weight were determined each week. The animals were examined for signs of toxicity or mortality at least once a day; moreover, comprehensive clinical examinations and palpations of the animals were performed once a week.

Ophthalmological examinations were carried out prior to the start and towards the end of dosing. Urinalysis, clinical-chemical and hematological examinations were carried out at the end of the administration period. All animals were subjected to gross-pathological assessment, followed by histopathological examinations.

Findings:
The stability and homogeneous distribution of the test substance in the diet were confirmed by analysis. The correctness of the concentrations was analytically demonstrated.

Based on food consumption and body weight data average daily compound intakes of 3.5, 10.7, 35, 69 and 106 mg/kg bw/d in male and of 4.2, 12.6, 41, 80 and 119 mg/kg bw/d in female rats were calculated at dietary dose levels of 50, 150, 500, 1000 and 1500 ppm, respectively.

Like in the 28-day study changes of haematological parameters were mainly observed in females at ≥ 1000 ppm (see Table 5.3.2-2) . In males only some calculated red blood cell parameters (MCV, MCHC) were changed at 500 ppm or above in addition to the changes of reticulocyte counts and prothrombin time.

Table 5.3.2-2: Treatment-related hematology findings in rats administered pyraclostrobin for at least 91 days

A number of treatment-related changes clinical chemistry parameters were observed in both sexes at 500 ppm and above (see Table 5.3.2-3). These were either associated with the impaired nutritional condition at higher dose levels (e.g. ALT, ALP, triglycerides, cholesterol or glucose) or related to the anemia (total bilirubin). Like in the 28-day study a decrease of serum cholinesterase levels was noted in females at ≥ 1000 ppm. As before, these changes were not accompanied by changes of erythrocyte or brain cholinesterase and thus of uncertain toxicological relevance

Table 5.3.2-3: Treatment-related clinical chemistry findings in rats administered pyraclostrobin forat least 91 days

No treatment-related changes of urinalysis parameters were noted.

Most the statistically significant changes of organ weights were secondary to the reduced terminal body weight. Only the changes of liver and spleen weights (Table 5.3.2-4) were corroborated by histopathological findings (see below).

Table 5.3.2-4: Selected mean absolute and relative organ weights of rats administered pyraclostrobin for at least 91 days

$ [ ] mean severity grading; histopathological findings were graded minimal (Grade 1), slight (Grade 2), moderate (Grade 3), marked (Grade 4) and massive/severe (Grade 5). The mean severity is the sum of the gradings divided by the incidence

Histopathology revealed the following findings (Table 5.3.2-5)

- Increased incidence and/or severity of mucosal hyperplasia of the duodenum in males at ≥ 500 ppm and in females at 1500 ppm.
- Increased incidence and severity of centrilobular hepatocyte hypertrophy in males at ≥ 500 ppm and in females at 1500 ppm.
- Diminished indicence and/or severity of hepatocellular fat storage (fatty change, diffuse) in both sexes at 500 ppm and above.
- Increased severity of extramedulary hematopoiesis in the spleen of males at ≥ 1000 ppm. In females at ≥ 1000 ppm increased incidence of this finding was noted.
- As reported in the 3rd Amendment to the report, a slightly decreased severity of hemosiderin deposition in spleen was noted in both sexes at ≥ 1000 ppm.
- Increased incidence and severity of sinusoid distension and histiocytosis in the spleen of both sexes at ≥ 1000 ppm.

The new data provided with report amendment 3 are in line with the other previously reported effects in the spleen.

Conclusion:

The no observed adverse effect level (NOAEL) in this 3-month rat study was 150 ppm (10.7 mg/kg bw/d in males and 12.3 mg/kg bw/d in females), based on reduction of body weight and food consumption, effects on clinical-chemical parameters, liver hypertrophy, and mucosal hypertrophy in the duodenum at 500 ppm and above. At the two highest dose levels (1000 and 1500 ppm), the oral administration of pyraclostrobin to female rats resulted additionally in leucocytosis and effects on red blood cells with compensatory reactions.

Note: The main mouse 90-day study report (CA 5.3.2/6) together with the 1st report amendment (CA 5.3.2/7) was already submitted and reviewed during the previous Annex I inclusion process. This study and it's 1st amendment is submitted for completeness as the basis for the assessment of the 2nd report amendment submitted under CA 5.3.2/8. Whereas report amendment 1 mainly corrects clerical errors in the original report, amendment 2 provides the result of additional histopathological evaluation of the spleen of intermediate dose levels. To take into account that the majority of the data were already reviewed, the following study summary will be more comprehensive than for other studies already reviewed, but will less detailed than the summary of new studies.

Report:	CA 5.3.2/6 [redacted] 1998a BAS 500 F - Subchronic oral toxicity study in B6C3F1 Crl BR mice. Administration in the diet for 3 months 1998/11345

GLP:	yes (certified by Ministerium fuer Arbeit, Soziales und Gesundheit, Postfach 3180, 55021 Mainz)

Report:	CA 5.3.2/8 [redacted] 2003b Amendment No. 2 to the report: BAS 500 F - Subchronic oral toxicity study in B6C3F1 Crl mice - Administration in the diet for 3 months 2003/1013400
Guidelines:	EEC 87/302, OECD 408, EPA 82-1, JMAFF
GLP:	yes (certified by Ministerium fuer Arbeit, Soziales und Gesundheit, Postfach 3180, 55021 Mainz)

Material and Methods:
Pyraclostrobin was administered to groups of 10 male and 10 female B6C3F1 mice at dietary concentrations of 0, 50, 150, 500, 1000 and 1500 ppm for 3 months. Food consumption and body weight were determined each week. The animals were examined for signs of toxicity or mortality at least once a day; moreover, comprehensive clinical examinations and palpations of the animals were performed once a week.

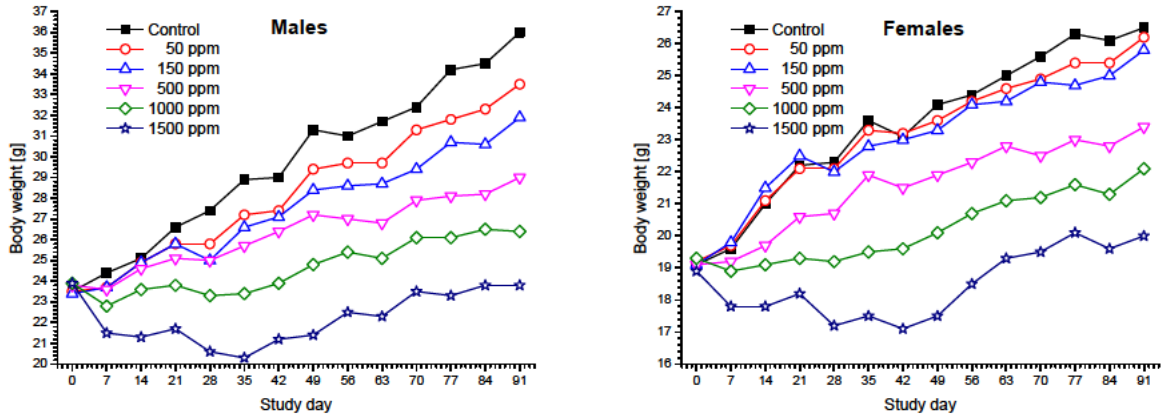
Ophthalmological examinations were carried out prior to the start and towards the end of dosing. Urinalysis, clinical-chemical and hematological examinations were carried out at the end of the administration period. All animals were subjected to gross-pathological assessment, followed by histopathological examinations.

Findings:
The stability and homogeneous distribution of the test substance in the diet were confirmed by analysis. The correctness of the concentrations was analytically demonstrated.

No treatment-related mortality or clinical signs of toxicity were observed throughout the study. However, on top dose females (1500 ppm) died accidentially when squeezed between food hopper and wire top.

Based on food consumption and body weight data average daily compound intakes of 9.2, 30.4, 119, 274 and 476 mg/kg bw/d in male and of 12.9, 40.4, 162, 374 and 635 mg/kg bw/d in female rats were calculated at dietary dose levels of 50, 150, 500, 1000 and 1500 ppm, respectively. As food spilling was observed in all groups irrespective of dose, these values may not represent the real compound intakes.

Figure 5.3.2-2: Body weight development of mice administered pyraclostrobin for at least 91 days



Occasionally, statistically significant increases of food consumption were recorded in both sexes at ≥ 1000 ppm. Due to the above mentioned food spilling it is not clear whether this was related to treatment. At least a dose-dependent trend towards higher mean food intake was observable if the overall mean food consumption is considered (see Table 5.3.2-6).

* $p \leq 0.05$; ** $p \leq 0.01$ (Dunnett's test, two sided)

A dose dependent and statistically significant decrease of body weight and body weight gain was observed in males at ≥ 150 ppm and in females ≥ 500 ppm (Figure 5.3.2-2 and Table 5.3.2-1). In the course of the European evaluation of this study, the body weight development in low dose males was likewise considered to be affected by treatment, even though no statistical significance was obtained.

Changes of haematological parameters were mainly observed in males. In addition to the parameters given in Table 5.3.2-7 calculated red blood cell parameters (MCV, MCH and/or MCHC) were altered in both sexes at 500 ppm and above.
The statistically significant decrease of white blood cell counts in males at ≥ 1000 ppm was mainly due to a decrease in the number of lymphocytes as indicated by the differential blood cell count. In females a numerical, but not statistically significant decrease of white blood cell counts was observed, which in part was also due to a decrease in lymphocyte counts.

Table 5.3.2-7: Treatment-related hematology findings in mice administered pyraclostrobin for at least 91 days

Treatment-related changes clinical chemistry parameters were observed in both sexes at 150 ppm and above (see Table 5.3.2-8). These were associated with the impaired nutritional condition at higher dose levels (e.g. total protein, triglycerides, urea). Other clinical chemistry changes displayed no strict dose dependency and were considered of low or no toxicological relevance.

Table 5.3.2-8: Treatment-related clinical chemistry findings in rats administered pyraclostrobin forat least 91 days

The statistically significant changes of organ weights were considered secondary to the reduced terminal body weight. Except for adrenals in males for all organs (liver, kidney, ovaties/testes), spleen, brain) decreased absolute weights were recorded partially down to 150 ppm. In turn, relative weights were mostly increased with the exception of andrenal gland and ovary weights in females.

[ ] mean severity grading; histopathological findings were graded minimal (Grade 1), slight (Grade 2), moderate (Grade 3), marked (Grade 4) and massive/severe (Grade 5). The mean severity is the sum of the gradings divided by the incidence

Histopathology revealed the following findings (Table 5.3.2-9)

- Decreased lipid in the X-zone of the adrenal cortex of females at 150 ppm and above.
- Increased incidence and/or severity of mucosal hyperplasia of the duodenum in both sexes at ≥ 500 ppm.
- Decreased incidence and/or severity of lipid vacuoles in cells of the proximal epithelial cells of the kidney
- Diminished indicence and/or severity of hepatocellular fat storage (fatty change, diffuse) in males at 500 ppm and above.
- Increased incidence of apoptotic bodies in follicles of mesenteric lymph nodes in females at 150 ppm and in both sexes at 500 ppm and above.
- As reported in the 2nd Amendment to the report, the incidence of hemosiderin deposition was comparable between treated groups and controls whereas the severity was slightly decreased at ≥ 1000 ppm.
- Increased incidence of glandular stomach erosion/ulcer in females at 150 ppm and in both sexes at 500 ppm and above.
- Increased incidence and severity of thymus atrophy accompanied by an increased number of apoptotic bodies in females at 150 ppm and in both sexes at 500 ppm and above.

The new data provided with Report Amendment No. 2 do not alter the conclusions of the study.

Conclusion:
Contrary to the study director and the applicant, the previous EU-review concluded that the dose of 50 ppm (9.2 mg/kg bw/d) represents a LOEL in male mice because body weight and body weight change at this dose level were clearly decreased during the whole study period. Nevertheless, taking into consideration all available data for this species, a NOAEL of 30 ppm (ca. 4 mg/kg bw/d) was established for males, based on the body weight data after 91 days from the carcinogenicity study (dose levels: 0, 10, 30, 120 ppm).
For females, the no observed adverse effect level (NOAEL) was 50 ppm (12.9 mg/kg bw/d), based on effects on body weight, decreased hematocrit and triglyceride values and increased urea values at 150 ppm and above.
At higher dose levels, adverse effects in the gastrointestinal tract (erosions and ulcera in the glandular stomach; thickening of the duodenal mucosa), on red blood cells, on white blood cells and lymphatic organs (thymus, mesenteric lymph modes) as well as on adrenals, liver and kidney (decreased vacuolisation) have been observed.

90-Day Study in Dogs
Pyraclostrobin (Purity 97.09%) was administered to groups of five male and five female purebred Beagle dogs at dietary concentrations of 0, 100, 200 and 450 ppm for 3 months.

Clinical observation revealed repeated vomiting during the first three weeks of treatment as well as diarrhea almost throughout the entire study period was observed at the high dose level. Occasional observation of diarrhea at the mid dose level were considered to be of incidental nature due to isolated occurrence as well as the fact that this was not observed in the 1-year study at the same dose level.

Effects on food consumption and body weight development were restricted to high dose females for which a slight decrease of mean food consumption (-9%) and a slight overall body weight loss was noted (- 0.2 kg vs. + 1.2 kg in control females).

Treatment related hematology findings were restricted to increased platelet counts in high dose females (450 ppm) at the terminal blood collection. However, the total number of platelets was not changed compared to day -1 and no effects on blood clotting (PTT and PT). Likewise, the decrease of glucose and total protein levels in high dose females was considered treatment related, whereas the slight, but statistically significant decrease of glucose levels in mid dose females (200 ppm) was not considered to represent an adverse finding, especially since no comparable effects on glucose levels were observed at the same dose level in the 1-year dog study.

No treatment related effects on organ weights were noted. The only treatment related histopathological change consisted of hypertrophy of the duodenal mucosa in two males and one high dose female.

Conclusion: The no observed adverse effect level (NOAEL) in this 3-month oral dog study was 200 ppm (5.8 mg/kg bw/d in males and 6.2 mg/kg bw/d in females), based on body weight loss and clinico-chemical and hematological changes in females, and vomitus, diarrhoea and hypertrophy of the duodenal mucosa in both sexes at 450 ppm.

1-Year study in dogs
Pyraclostrobin (Purity 98.7%) was administered to groups of five male and five female purebred Beagle dogs at dietary concentrations of 0, 100, 200 and 400 ppm for 12 months.

Like in the 90-day study initially cases of vomiting were observed at the high dose (400 ppm), whereas diarrhea was noted at various occasions throughout the entire study duration. These clinical signs were considered to be treatment related.

A consistent effect on body weight was restricted to high dose females. Mean body weights increased by 0.3 kg and 1.1 kg after 6 and 12 months, respectively, compared to 2.2 and 2.7 kg in control females, respectively. This impairment of body weight development was accompanied by a 14% reduction in overall mean food consumption.
The marginal (-0.1 kg) and temporary mean body weight loss in high dose males at Day 7 was mainly due to one animal (#970183), which displayed an approx. 30% reduced food consumption and a body weight loss by 0.5 kg.

Hematological examinations revealed transiently decreased hemoglobin and hematocrit values in high dose females (day 90) and males (day 180). White blood cell counts (days 180, 362) and increased platelets (days 89, 180, 362) were noted in high dose males. However, similar increases (n.s.) were already noted at Day -9 and the increased platelet counts were not accompanied by significant effects on blood clotting (PTT and PT).

Ophthalmoscopy, clinical-chemical investigations, urinalysis and the pathological investigations did not reveal any test substance related effects.

Conclusion: The no observed adverse effect level (NOAEL) in this 12-month oral dog study was 200 ppm (5.4 mg/kg bw/d in males and females), based on reduced body weight gain and food consumption in females as well as clinical signs (vomitus, diarrhoea) and hematological changes in both sexes at 400 ppm.

CA 5.3.3 Other routes

Regarding other routes of exposure, the applicant performed 28-day studies by the dermal and inhalation route.

28-day dermal toxicity in rats
Pyraclostrobin was administered to groups of 10 male and 10 female Wistar rats by dermal route (6 hours/day; 5 days/week; semi-occlusive dressing) for 4 weeks at doses of 0 (vehicle control: 0.5% aqueous CMC solution), 40, 100 and 250 mg/kg bw/d. No signs of systemic toxicity were observed at any dose level. Dose related signs of local irritation were observed at all dose levels in the area of the treated skin. These consisted of (multifocal or diffuse) scale formation, erythema, epithelial thickening and hyperkeratosis.

28-day inhalation toxicity in rats

Report:	CA 5.3.3/1 [redacted] 2005a BAS 500 F - Subacute inhalation study in Wistar rats - 20 aerosol exposures during 4 weeks 2005/1013950
Guidelines:	OECD 413, EEC 87/302, EPA 870.3465, EPA 870.6200
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz

Executive Summary

In a 28-day inhalation toxicity study, three groups of Wistar Crl:Wi (Han) rats (10/sex) were exposed to liquid aerosols of pyraclostrobin (batch LJ 27822/199/b, purity 98.7%) dissolved in acetone at nominal concentrations of 1, 30 and 300 mg/m³ (0.001, 0.03 and 0.3 mg/L) for 6 hours daily on a 5 application per week basis. Air and acetone groups served as negative and vehicle control groups.
Mortality was observed for 4 male and 3 female rats at the high concentration of 300 mg/m³ (0.3 mg/L) between study days 7 and 24. This concentration is close to the acute 4h LC_{50} of 0.58 mg/L observed for a pyraclostrobin aerosol when dissolved in acetone. Body weight development in high concentration males was impaired. Hematology revealed increased white blood cell counts and an increase in absolute and relative neutrophil numbers. This was probably the result of the inflammatory processes in the respiratory tract. No treatment related clinical chemistry findings were noted between the acetone vehicle control and the treated groups, whereas there were some differences between the air and acetone control.
No treatment-related organ weight changes were observed. The respiratory tract (nasal cavity, larynx and lungs) and the duodenum were identified as target organs as indicated by dose dependent atrophy/necrosis and regeneration/repair of the olfactory epithelium, hyperplasia of the respiratory epithelium of nasal cavity and the larynx, perivascular inflammation of the lungs as well as hyperplasia of the duodenal mucosal. The low dose of 1 mg/m³ was identified as NOAEC.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Pyraclostrobin (BAS 500 F)

Description:	Solid melt / red-brown, clear
Lot/Batch #:	LJ 27882/199/b (ToxChargeIII/Teil2)
Purity/content:	98.7%
Stability of test compound:	According to the Certificate of Analysis the test substance was stable until March 28, 2008 when stored refridgerated.

2. Vehicle and/or positive control: Acetone

3. Test animals:

Species:	Rat
Strain:	Wistar Crl:WI(Han)
Sex:	males and females
Age at dosing:	about 9 weeks
Weight at dosing:	246.3 ± 11.2 g (males), 174.6 ± 9,1 g (females)
Source:	Charles River Laboratories, Germany, 97633 Sulzfeld
Acclimation period:	at least one week In order to accustom the animals to exposure they were treated with supply air for 6 hours under conditions comparable to exposure on 2 days before start of exposure (preflow period).
Diet:	milled mouse/rat laboratory diet "GLP", Provimi Kliba SA, Kaiseraugst, Switzerland, ad libitum except during exposure and motor activity measurements
Water:	Tap water ad libitum except during exposure and motor activity measurements
Housing:	single housing in stainless steel wire mesh cages type DK-III (Becker & Co., Castrop-Rauxel, FRG), floor area approx. 800 cm². The motor activity measurements were conducted in Polycarbonate cages with wire covers from Ehret, Emmendingen, FRG (floor area about 800 cm²) and bedding.
Environmental conditions:	
Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	Fully air-conditioned rooms; number of air-changes not indicated in the report
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN

1. Dates of work: 11-Jan-2005 to 22-Jun-2005
(in-life dates: 24-Jan-2005 to 25-Feb-2005)

2. Animal assignment and treatment

Groups of 10 male and 10 female Wistar rats per test group were exposed in a head-nose inhalation system to atmospheres containing aerosols of BAS 500 F for 6 hours per working day for about 28 days on a 5 days/week basis (20 exposures). Control animal were exposed to acetone. For generation of the aerosols the test substance (non volatile solid melt) was dissolved in acetone. The target concentrations were 0, 1, 30 and 300 mg/m³. Additionally, one group of male and female rats were exposed to the vehicle acetone.

Test group	Target concentration [mg/m³]	No. of animals per sex	Males Animal No.	Females Animal No.
0	Air control	10	1-10	51-60
1	Acetone control	10	11-20	61-70
2	1	10	21-30	71-80
3	30	10	31-40	81-90
4	300	10	41-50	91-100

The animals were allocated to the treatment groups according to weight using a suitable randomization software. The variation of individual weights of the animals used did not exceed 20% of the mean weight of each sex. As the capacity to perform Functional Observational Battery and the Motor Activity measurements (FOB/MA) was limited by the time needed to carry out these examinations, the study was carried out using a block design with a staggered start of treatment: The first 5 male animals of test groups 0 - 4 were assigned to exposure group 1. The remaining 5 male animals were assigned to exposure group 3. Likewise, the first five and the remaining five females of test groups 0 to 4 were assigned to exposure groups 2 and 4. By this it was ensured that the examinations of all test groups were performed on the same study day.

3. Aerosol generation and analysis

A head-nose inhalation system INA 60 (stinless-steel construction, BASF Aktiengesellschaft, volume V ≈ 90 l) was used. The animals were restrained in glass tubes and their snouts projected into the inhalation system.

A liquid aerosol was generated. The test substance was diluted 1:9 with acetone. The aerosol was produced by continuously pumping the test-substance solution to a two-component atomizer by means of a metering (test group 1) or an infusion pump (test groups 2 to 4). Using compressed air, the aerosol was generated which was produced inside the exposure system.

A positive pressure was maintained inside the exposure systems by adjusting the air flow of the exhaust air system. This ensured that the aerosol in the breathing zones of the animals was not diluted by laboratory air.
The concentrations of the inhalation atmospheres were analyzed by gravimetry in test group 2 - 4. This analytical method is judged to be valid, because pyraclostrobin does not possess an appreciable vapor pressure. Daily means were calculated based on two measured samples per concentration and exposure.
The sampling for determination of the **actual aerosol concentration** was performed with a filtration equipment using a sampling probe (diameter 7 mm). For this pre-weighed filters were placed into the filtration equipment. By means of the vacuum pump metered volumes of the liquid aerosol were drawn through the filter.

- Filter: MN 85/90 BF (d = 47 mm)
- Sampling position: immediately adjacent to the animals' noses
- Sampling flow: 3 l/min
- Sampling velocity: 1.25 m/s
- Sampling frequency: 4 samples at about hourly intervals
- Sample volume: Test group 2: 450 l; Test group 3: 90 l; Test goup 4: 9 l; The sampling volumes were adjusted to achieve suitable amounts of test substance for analysis
- Sampling frequency: two samples per exposure and concentration group

The volatile solvent acetone was analyzed by gas chromatography in test groups 1 and 4 based on one sample per exposure. The samples were withdrawn immediately adjacent to the animals' noses by means of a 100 µl gas tight Hamilton syringes. The entire sample was injected. The following equipment and analysis conditions were used:

- Gas comatograph: Hewlett-Packard 5840 A
- Column: glass
- Length: 3 m
- Internal diameter: 2 mm
- Separation phase: 10%Carbowax 20M
- Support: Supelcpoprt 80/100 mesh
- Carrier gas: He
- Carrier gas flow rate: 20 ml/min
- Hydrogen: 30 ml/min
- Air: 240 ml/min
- Oven temperature: 150°C/min
- Detector: FID
- Detector temperature: 220°C
- Injector temperature: 220°C/min
- Calibr. retention time: approx. 1.40 min.

The particle size analysis was done using a Stack Sampler Martple 298 (Sierra) and a vacuum pump (Millipore). The sampling probe had an internal diameter 7 mm. Before sampling, the impactor was assembled with pre-weighed glass-fiber collecting disks and equipped with a backup particle filter. The impactor was connected to the vacuum pump and for each test group samples were taken from the breathing zone of the animals. Samples were withrawn at a velocity of 1.25 m/sec. Depending on the nominal atmosphere concentrations the sample volumes were 1800, 60 and 6 L for Test groups 2 to 4, respectively. Each two samples were taken per concentration level.
After sampling the impactor was disassembled. The impactor stages and the backup particle filter were freed of acetone and re-weighed.

4. Statistics:

Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to following table:

Parameter	Statistical test	References
Food consumption, body weight, body weight gains; food efficiency	Simultaneous comparison of all test groups with the vehicle control group using the DUNNETT-test (twosided) for the hypothesis of equal means	DUNNETT, C.W. (1955): A multiple comparison procedure for comparing several treatments with a control. JASA, Vol. 50, 1096 – 1121 DUNNETT, C.W. (1964). New tables for multiple comparisons with a control. Biometrics, Vol. 20, 482 – 491
	A comparison of group 1 with group 0 was performed using the Welch t-test (two sided) for the hypothesis of equal means	Welch B.L. (1947): WELCH, B.L (1947).The generalization of Student´s problem when several different population valiances are involved. Biometrika, 34, 28-35
Feces, rearing, grip strength forelimbs, grip strength hindlimbs, landing foot-splay test, motor activity & Clinical pathology parameters, except reticulocytes and differential blood count	Non-parametric one-way analysis using KRUSKALWALLIS test (two-sided). C. METHODS

1. Clinical examinations:

The animals were examined for evident signs of toxicity or mortality twice daily on working days and once daily on weekends and public holidays.
The clinical condition of the test animals was recorded once on preflow and on post-exposure observation days and at least 3 times (before, during and after exposure) on exposure days. During exposure only a limited examination was possible because of the animals' location in the exposure tubes.
Detailed clinical observations of all animals were performed in a standard arena prior to the administration period and weekly thereafter. The standard arena had a size of 50 x 37.5 cm with walls of 25 cm height. If applicable the findings were ranked according to the degree of severity. The following parameters were examined:

1. abnormal behavior during handling
2. fur
3. skin
4. posture
5. salivation
6. respiration
7. activity/arousal level
8. tremors
9. convulsions
10. abnormal movements
11. impairment of gait
12. lacrimation
13. palpebral closure
14. exophthalmus
15. feces (appearance/consistency)
16. urine
17. pupil size

2. Body weight:

The body weight of the animals was determined on day –7, at the start of the preflow, at the start of the exposure period and then, as a rule, once a week as well as one day prior to gross necropsy.
As a rule, the animals were weighed at the same time of the day.

3. Food consumption, food efficiency and compound intake:
Food consumption was determined parallel to body eight and calculated as mean food consumption in grams per animal and day.
Food efficiency (group means) was calculated based upon individual values for body weight and food consumption:

$$\text{Food efficiency for day x} = \frac{BW_x - BW_Y}{FC_{y\ to\ x}} \times 100$$

- BW_x and BW_y body weight [g] at day x and day y (last weighing date before day x)
- $FC_{y\ to\ x}$ is the mean food consumption from day y to x calculated as mean daily food consumption [g] on day x, multiplied by the number of days from day y to day x.

4. Ophtalmoscopy:
Before the start of the exposure period the eyes of all animals, and towards the end of the study (study day 22) the eyes of the animals of air control group, the acetone control group and high concentration group were subjected to ophthalmocopic examination.

5. Functional observation battery (FOB) and Motor activity:
A functional observational battery was performed in all animals towards the end of the administration period. At the day of examination, the respective groups animals were not exposed to the inhalation atmospheres. The FOB started with passive observations without disturbing the animals; followed by removal from the home cage, open field observations in a standard arena and sensorimotor tests as well as reflex tests. The findings were ranked according to the degree of severity, if applicable. The observations were performed at random.

The parameters determined are given in the table below. Detailed descriptions of the investigations are given in the report.

Home cage observations	Open field observations	Sensorimotor Tests/Reflexes:
1. posture	1. behaviour when removed from cage	1. approach response
2. tremor	2. fur	2. touch response
3. convulsions	3. skin	3. vision ("visual placing response")
4. abnormal movements	4. salivation	4. pupillary reflex
5. impairment of gait	5. nose discharge	5. pinna reflex
6. other findings	6. lacrimation	6. audition ("startle response")
	7. eyes / pupil size	7. coordination of movements ("righting response")
	8. posture	8. behaviour during "handling"
	9. palpebral closure	9. vocalisation
	10. respiration	10. pain perception ("tail pinch")
	11. tremors	11. grip strength of forelimbs
	12. convulsions	12. grip strength of hindlimbs
	13. abnormal movements	13. landing foot-splay test
	14. impairment of gait	14. other findings
	15. activity / arousal level	
	16. feces (number of fecal pellets / appearance / consistency) within two minutes	
	17. urine (appearance / quantity) within two minutes	
	18. number of rearings within two minutes	

Motor activity was measured on the same day as the FOB was performed. The measurement was performed in the dark using Polycarbonate cages with absorbent material and 4 infrared beams per cage. The number of beam interrupts were counted over 12 intervals, each lasting 5 minutes. The measurement was ended exactly 60 minutes after the first interuption of an infrared beam. During the measurements the animals received no food and no water.

6. Hematology and clinical chemistry:

Blood was collected from the retroorbital venous plexus in the morning from over-night fasted animals under isoflurane anaesthesia. The blood sampling procedure and the subsequent analysis of the blood and serum samples were carried out in a randomized sequence. The following parameters were determined.

Hematology:					
	Red blood cells		*White blood cells*		*Clotting Potential*
✓	Erythrocyte count (RBC)	✓	Total leukocyte count	✓	Prothrombine time
✓	Hemoglobin (Hb)	✓	Neutrophils (differential)	✓	Thrombocyte count
✓	Hematocrit (Hct)	✓	Eosinophils (differential)

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

1. Clinical signs of toxicity

There were no treatment-related clinical signs of systemic toxicity in the air and aceton control groups as well as at the low (1 mg/m³) and mid (30 mg/m³) concentration levels.

At the high concentration level (300 mg/m³) treatment related clinical observations consisted of:

- slightly visually increased respiration during exposure in both sexes from study day 7 up to the end of the study,
- urinous odour in 4 males from day 27 to the end of the study and 7 females from study day 22 to the end of the study,
- piloerection in three females from day 19 up to day 24,
- injury on the head in one female from study day 15 up to day 27, and
- moderate labored respiration in 1 male on study day 21.

The animals that died developed visually increased respiration, urinous odour and piloerection before death.

2. Mortality

Four males and 3 females of the high concentration group (300 mg/m³) died during the study. Deaths were observed at days 10, 12, 21 and 22 in males and at days 7, 11 and 24 in females. Despite of the clinical signs mentioned above, there were no clinical biochemistry of histopathological findings indicating the cause of death.

3. Detailed clinical observations

The detailed clinical observations did not reveal any abnormalities in any of the groups, which were not described previously in the daily clinical observation.

4. FOB and Motor activity

No treatment-related findings were observed during the Functional Observation Battery examinations. These included the home cage and open field observations, the sensorimotor tests and reflexes as well as the quantitative observations (feces, rearing, grip strength, landing foot-splay).

Likewise, overall motor activity measurements did not reveal any statistically significant difference between controls and treated groups. If single 5-minute intervalls are considered there as a statistically significant increase of the activity in males exposed to the mid concentration during the 4th interval. Due to the single affected interval and in absence of a dose-response relationship this was considered to be incidental.

5. Ophthalmoscopy

No treatment-related ophthalmoscopical findings were noted in this study.

B. BODY WEIGHT

Body weight development was impaired in males at the high concentration (300 mg/m³) (see Figure 5.3.3-1). This was evident from significantly lower body weights at day 21 (-6.6%) and from significantly lower body weight gains throughout the study when compared to the acetone control group males. Overall body weight gain of high concentration males was decreased by 43%.

Differences between males at ≤ 30 mg/m³ as well as all treated females groups and acetone control groups did not attain statistical significance. Likewise, there were no significant differences between air and acetone control groups.

C. FOOD CONSUMPTION AND FOOD EFFICIENCY

There were no statistically significant differences between food consumption of acetone and treated groups except at day 7 in both sexes at 300 mg/m³. The overall average daily food intake of high concentration males tended to be slightly lower which is in line with the observed body weight effects in this group of animals (see Table 5.3.3-1).

Figure 5.3.3-1: Body weight development of rats exposed to pyraclostrobin by inhalation for 28 days on a 5 days/week basis

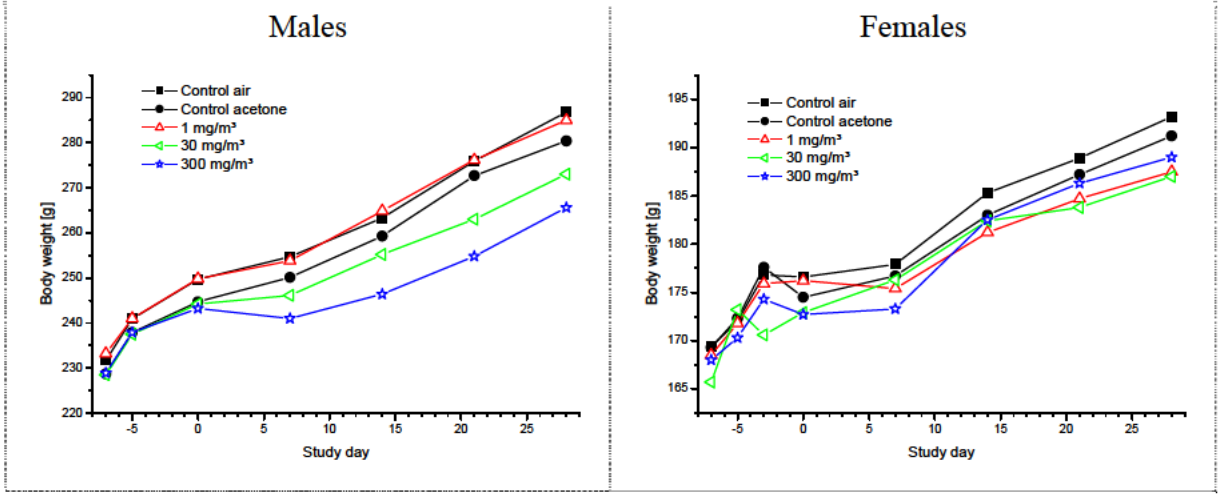

Table 5.3.3-1: Mean body weight and food consumption data of rats exposed to pyraclostrobin by inhalation for 28 days on a 5 days/week basis

- average week 1-4§	15.3	14.8	14.3	14.9	14.6
Δ% (compared to control)			-3.7	+0.5	-1.2

* $p \leq 0.05$ (Dunnett's test, two sided); § calculated from the weekly means

No statistically significant differences of weekly food efficiency between the acetone control and treated groups were observed except for day 21 in mid concentration males (30 mg/m³) and for days 7 and 21 in high concentration males.

D. BLOOD ANALYSIS

1. Hematological findings

Hematology examinations revealed a slight, but not statistically significant increase of white blood cell counts in high concentration males and females when compared to the acetone control groups. This correlated to increased polymorphonuclear neutrophil counts in the differential blood count (see Table 5.3.3-2). No treatment-related changes were seen in the other hematological parameters of both sexes. The only statistically significant differences were a slight increase in mean corpuscular volume (MCV) in females and a decrease of mean corpuscular hemoglobin concentration (MCHC), which in absence of effects on other red blood cell parameters is considered to be of no toxicological relevance.

Table 5.3.3-2: Selected hematology findings of rats exposed to pyraclostrobin by inhalation for 28 days on a 5 days/week basis

Platelets [10^{12}/L]	934	± 83	855$^+$	±133	934	± 95	865	±113	871	±100

comparison acetone control - treated groups: * $p \leq 0.05$; ** $p \leq 0.01$ (Kruskal-Wallis / iWilcoxon-test, two sided)
comparison air and acetone control: $^+$ $p \leq 0.05$ (Kruskal-Wallis / Wilcoxon-test, two sided)

No significant differences in hematology parameters were found between the air control and the vehicle control of the males. In female rats slight, but statistically significantly decreased red blood cell (RBC) and platelet counts and increased MCV and mean corpuscular hemoglobin (MCH) values were found in the peripheral blood of the animals exposed to the vehicle.

2. Clinical chemistry findings

No treatment-related differences were observed between treated and the acetone control groups. In absence of other treatment related changes the marginal, but statistically significant increase of alkaline phosphatase (ALP) in high concentration females was considered to be of no toxicological relevance (see Table 5.3.3-3).

There were a number of statistically significant differences between the air and acetone control. These consisted of decreased potassium, alanine and aspartate aminotransferase activities in female an of increased total bilirubin and total protein concentration in males of the acetone control. or lacked a dose-response relationship (increased total protein in low concentration females).

E. NECROPSY

Statistically significant differences of organ weights between the acetone control groups and treated groups were observed for thymus (absolute) and kidney, liver, lung, spleen and thymus (relative). For details see Table 5.3.3-4.
In absence of relevant morphologic findings, the significantly decreased mean absolute and relative thymus weights in high concentration females were not considered to be toxicologically relevant. The effect on thymus weight in females may be an indirect effect, as animals in this group had remarkable findings in the nasal cavity (atrophy/necrosis, see below). This might have caused stress to the animals which led to a decrease in the thymic absolute and relative weights.
Likewise, all other changes were considered to be incidental since they were not corroborated by any histopathological changes and the changes were not dose-related (relative lung weights in females and relative liver and lung weights in males). Especially, the statistically higher relative lung weights in females were probably due to very low lung weights in the acetone control group when compared to those in the respective air control.

In addition, absolute lung and relative liver and lung weights of aceton control males displayed a statistically significant difference when compared to the air control. These changes were not accompanied by any histopathological changes and were considered to be incidental.

2. Gross and histopathology

The only treatment-related gross pathological findings consisted of discolored lung lobes in 2 males and 3 females which died prematurely.
There were a few additional gross lesions which were observed with single incidences in the air and acetone control groups as well as in treated male and female groups. Neither the type nor distribution indicated a relation to treatment.

Histopatholog identified the respiratory tract, i.e. the nasal cavity, the larynx and the lungs as well as the duodenum as target organs at the two higer dose levels. The histopathological findings in these organs are listed in Table 5.3.3-5.

Table 5.3.3-5: Incidence and severity of selected histopathological lesions in rats exposed to pyraclostrobin by inhalation for 28 days on a 5 days/week basis

$ [ ] mean severity grading; histopathological findings were graded minimal (Grade 1), slight (Grade 2), moderate (Grade 3), marked (Grade 4) and massive/severe (Grade 5). The mean severity is the sum of the gradings divided by the incidence

[ ] The grading of mucosal hyperplasia was assessed by a quantitative mucosal area measurement performed by analySIS Doku 3.0. The following gradings were used: until an area of 6 mm² = grade 0, > 6-8 mm² = grade 1, >8-10 mm² = grade 2, >10-12 mm² = grade 3, > 12 mm² = grade 4.

& [p] finding present, no grading performed

A mild to moderate destruction of the olfactory epithelium in the nasal cavity was observed. These changes were characterized by (multi)focal atrophy and/or necrosis, (multi)focal reactive inflammation and signs of repair and regeneration as irregular architecture of the epithelium or gland-like structures, and karyomegaly of the sustentacular cells. These findings are histomorphological correlates of different stages and intensities of the compound-related irritant effect.
The changes in the respiratory epithelium were not as severe as those in the olfactory epithelium. There was minimal to moderate (multi)focal hyperplasia, especially in level I.
The minimal to slight hyperplasia of the larynx respiratory epithelium observed in three high concentration males was considered to be treatment-related, too.
In the lungs of all groups a minimal to slight perivascular infiltration of inflammatory cells was observed. As the severity was slightly higher in the high concentration females this was considered to be treatment-related. In addition, the number of histiocytes (severity) in the alveoli in was slightly higher at the high concentration males whereas the incidence was elevated females at the mid and high concentration.
Finally, a treatment related increase in the incidence and severity of diffuse mucosal hyperplasia in the duodenum was observed.

F. ATMOSPHERE ANALYSIS

The exposure conditions are summarized in Table 5.3.3-6.

Table 5.3.3-6: Exposure contitions

Test group	Supply air (conditioned) [m³/h]	Supply air (compressed) [m³/h]	Exhaust air [m³/h]	Atomizer pressure [bar]	Pump rate[1] [ml/h]	Acetone pump rate [ml/h]
0	6.0	-	5.4			
1	5.0	1.0	5.4	0.8 - 1.2		23 - 46
2	5.0	1.0	5.4	0.8 - 1.2	8 - 12.8	
3	5.0	1.0	5.4	0.8 - 1.2	184 - 368	
4	5.0	1.0	5.4	0.8 - 1.2	1840 - 3680	

[1] diluted test substance;
Conditioned supply air is activated charcoal filtered air conditioned to about 50% ± 20% relative humidity and 22°C ± 2°C;
Compressed air is filtered air pressurized to about 6 bar

The results of the atmosphere concentration analysis are depicted in Table 5.3.3-7.

Table 5.3.3-7: Measurement of pyraclostrobin and acetone concentrations

Test group	Target concentration [mg/m³]	Measured concentration (Pyraclostobin) [mg/m³]	Measured concentration (Acetone) [mg/m³]
0	Air control		
1	Aceton control		2.63 ± 0.94
2	1	1.17 ± 0.3	
3	30	30.4 ± 1.2	
4	300	299 ± 15	2.44 ± 0.23

The measured MMAD values for the pyraclostrobin containing aerosols are given in Table 5.3.3-8.

Table 5.3.3-8: Particle size measurement

Test group	MMAD [µm]	Geometric standard deviation	< 3 µm [%]
2	1.6 ± 0.3	4.0 ± 0.2	67.8 ± 3
3	1.9 ± 0.1	2.6 ± 0.1	70.3 ± 2
4	1.9 ± 0.1	2.5 ± 0.2	70.7 ± 2

III. CONCLUSIONS

Six hour subacute inhalatory exposure of rats to an aerosol of pyraclostrobin dissolved in acetone for 28-day on a 5 days per week basis resulted in the death of 4 male and 3 female rats at the high concentration of 300 mg/m³ (0.3 mg/L). This concentration is close to the acute 4h LC_{50} of 0.58 mg/L observed for a pyraclostrobin aerosol when dissolved in acetone. The respiratory tract (nasal cavity, larynx and lungs) and the duodenum were identified as target organs as indicated by dose dependent atrophy/necrosis and regeneration/repair of the olfactory epithelium, hyperplasia of the respiratory epithelium of nasal cavity and the larynx, perivascular inflammation of the lungs as well as hyperplasia of the duodenal mucosal. The low dose of 1 mg/m³ was identified as NOAEC.

Report:	CA 5.3.3/2 [redacted]2014a Bas 500 F (Pyraclostrobin) - Repeated dose 28-day inhalation toxicity study with recovery period in Wistar rats, aerosol exposure 2014/1003946
Guidelines:	OECD 413, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. L 142, EPA 870.3465
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a 28-day inhalation toxicity study, four groups of Wistar rats (10/sex) were exposed to liquid aerosols of pyraclostrobin (COD-001236, purity 99.02%) dissolved in acetone at nominal concentrations of 3, 10 and 30 mg/m³ for 6 hours daily on a 5 applications per week basis. The control group was exposed to acetone. The study included a recovery group of 10 animals/sex treated either with acetone (vehicle control) or 30 mg/m³ for 28 day followed by a 4 weeks treatment-free recovery period.
No mortality was observed in any dose group. Fluctuations of body weight (body weight loss during inhalation exposure, body weight gain during the treatment free weekends) was observed in all groups including controls. The overall body weights and body weight gains did not display statistically significant differences. No treatment related clinical biochemistry findings were noted in treated groups. A weight increase of the duodenum in the mid and high dose groups was considered to be treatment-related, but an adaptive and not adverse effect, as no histopathological correlate was observed, which could explain the weight increase. Histopathology did not reveal any indication of systemic toxicity. However, a minimal to slight atrophy/necrosis of the olfactory epithelium in high concentration males and females indicated local irritant effects, which were reversible within the 4-week recovery period.
Based on the results of this study the 'No Observed Adverse Effect Concentration' (NOAEC) for systemic toxicity was 30 mg/m³, whereas based on the effects in the upper respiratory tract the NOAEC for local effect in nasal cavity was 10 mg/m^3.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Pyraclostrobin (BAS 500 F)

Description:	Solid melt / red-brown
Lot/Batch #:	COD-001236
Purity/content:	99.02%
Stability of test compound:	Stable; Expiry date: 01.10.2015

2. Vehicle and/or positive control: Acetone

3. Test animals:

Species:	Rat
Strain:	Wistar Crl:WI(Han)
Sex:	males and females
Age at dosing:	about 7 weeks
Weight at dosing:	260.0 ± 11.1 g (males), 178.7 ± 10.6 g (females)
Source:	Charles River Laboratories, Research Models and Services, Germany GmbH; 97633 Sulzfeld
Acclimation period:	at least one week In order to accustom the animals to exposure they were treated with supply air for 6 hours under conditions comparable to exposure on 2 days before start of exposure (pre-exposure period).
Diet:	milled mouse/rat laboratory diet "GLP", Provimi Kliba SA, Kaiseraugst, Switzerland, ad libitum except during exposure and motor activity measurements
Water:	Tap water ad libitum except during exposure and motor activity measurements
Housing:	five animals per cage in Polysulfon cages H-Temp (PSU) (Tecniplast, Hohenpeißenberg, Germany), floor area approx. 2065 cm².
Environmental conditions:	
Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	Fully air-conditioned rooms; 15 air changes per hour
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN

1. Dates of work: 21-Jan-2014 to12-Jun-2014
(in-life dates: 21-Jan-2014 to 04-Apr-2014)

2. Animal assignment and treatment

Groups of 10 male and 10 female Wistar rats per test group were exposed in a head-nose inhalation system to atmospheres containing aerosols of BAS 500 F for 6 hours per working day for about 28 days on a 5 days/week basis (20 exposures). For generation of the aerosols the test substance (non volatile solid melt) was dissolved in acetone. The target concentrations were 0, 3, 10 and 30 mg/m³. Additionally, one group of male and female rats each was exposed to the vehicle acetone.

Test group	Target concentration [mg/m³]	No. of animals per sex	Males Animal No.	Females Animal No.
0	Acetone control	10	1-10	41-50
1	3	10	11-20	51-60
2	10	10	21-30	61-70
3	30	10	31-40	71-80

In order to check for any reversibility, progression or delay of toxic effects the following post-exposure observation groups were used. These animals were observed for about 4 weeks after the exposure period.

Test group	Target concentration [mg/m³]	No. of animals per sex	Males Animal No.	Females Animal No.
0	Acetone control	10	81-90	101-110
3	30	10	91-100	111-120

The animals were allocated to the treatment groups according to weight using suitable randomization software. The variation of individual weights of the animals used did not exceed 20% of the mean weight of each sex.

3. Aerosol generation and analysis

A head-nose inhalation system INA 60 (stainless-steel construction, BASF Aktiengesellschaft, volume V ≈ 90 L) was used. The animals were restrained in glass tubes and their snouts projected into the inhalation system.

A liquid aerosol was generated. The test substance was diluted 1:9 with acetone. The aerosol was produced by continuously pumping the test-substance solution to a two-component atomizer by means of a metering pump. Using compressed air, the aerosol was generated which was produced inside the exposure system. From study day 4 to day 15 the atmosphere generation procedure was changed for the low dose group due to variability of the test atmosphere concentration. In principle, a higher concentrated aerosol was generated, which was diluted with additional air to achieve the desired concentration of 3 mg/m³. Due to technical reasons, the initial generation setup for the low concentration group was restored from study day 18 onwards. This did not negatively affect the pyraclostrobin concentration in the inhalation atmosphere. In the control group, acetone was sprayed at the pump rate used for the high concentration group.

A positive pressure was maintained inside the exposure systems by adjusting the air flow of the exhaust air system. This ensured that the aerosol in the breathing zones of the animals was not diluted by laboratory air.

The concentrations of the inhalation atmospheres were analysed by gravimetry This analytical method is judged to be valid, because pyraclostrobin does not possess an appreciable vapour pressure. Daily means were calculated based on three samples for the mid and high concentration group. Due to the longer sampling time for the low concentration, two samples per day were analyzed only. For this a filtration equipment with a sampling probe of 7 mm diameter was used. Through pre-weight filters metered volumes of the aerosol drawn by means of a vacuum pump.

- Filter: MN 85/90 BF (d = 47 mm)
- Sampling position: immediately adjacent to the animals' noses
- Sampling flow: 3 L/min
- Sampling velocity: 1.25 m/s
- Sample volume: 360 L, 120 L and 45 L at target concentrations of 3, 10 and 30 mg/m³

The volatile solvent acetone was analyzed by gas chromatography in the control group based on one sample per exposure. Like for the treated groups the samples were withdrawn immediately adjacent to the animals' noses. The sampling probe had an inner diameter of 4 mm. Fifteen liter samples were withdrawn at a sampling velocity of 1.25 m/s and a flow rate of 1 L/min. The samples were drawn through 3 absorption vessels connected in series, each of which was filled with 2-propanol as absorption solvent. After the sampling, the content of the probe and the first 2 absorption vessels was eluted and pooled into a 50 mL graduated flask for individual analysis. The last absorption vessel served as control for absorbing efficiency during sampling.

The particle size analysis was done using a Stack Sampler Marple 298 (New Star Environmental) and a vacuum pump (Millipore). The sampling probe had an internal diameter 7 mm. Before sampling, the impactor was assembled with pre-weighed metal collecting discs and equipped with a backup particle filter. The impactor was connected to the vacuum pump and for each test group samples were taken from the breathing zone of the animals. Samples were withdrawn at a velocity of 1.25 m/sec and a volume of 3 L/min. Depending on the nominal atmosphere concentrations the sample volumes were 360, 120 and 45 L for test groups 1 to 3, respectively. After sampling the impactor was disassembled. The impactor stages and the backup particle filter were freed of acetone and re-weighed. Each four samples were taken per concentration level during the 4 weeks exposure period.

4. Statistics:
Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to following table:

Parameter	Statistical test	References
body weight, body weight change (during exposure period)	Comparison of each group with the control group was performed using DUNNETT test (two-sided) for the hypothesis of equal means.	DUNNETT, C.W. (1955): A multiple comparison procedure for comparing several treatments with a control. JASA, Vol. 50, 1096 – 1121 DUNNETT, C.W. (1964). New tables for multiple comparisons with a control. Biometrics, Vol. 20, 482 – 491
body weight, body weight change (recovery group during post-exposure period) and Food consumption (recovery group)	Comparison of the dose group with the control group was performed using the STUDENT'S t-test (two-sided) for the hypothesis of equal means.	WINER, B.J. (1971): Statistical principles in experimental design. McGraw-Hill, New York, 2nd edition
Blood parameters	For parameters with bidirectional changes: Non-parametric one-way analysis using KRUSKAL-WALLIS test. If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using WILCOXON-test (two-sided) for the hypothesis of equal medians For parameters with unidirectional changes: Pairwise comparison of each dose group with the control group using the WILCOXON-test (one-sided) with Bonferroni-Holm adjustment for the hypothesis of equal medians	SIEGEL, S. (1956): Non-parametric statistics for the behavioural sciences. McGraw-Hill New York Holm (1979): A Simple Sequentially Rejective Multiple Test Procedure. Scand. J. Statist. 6, 65-70
Blood parameters (recovery group animals)	For parameters with bidirectional changes: WILCOXON-test (two-sided) for the hypothesis of equal medians For parameters with unidirectional changes: Pairwise WILCOXON-test (one-sided) for the hypothesis of equal medians	SIEGEL, S. (1956): Non-parametric statistics for the behavioural sciences. McGraw-Hill New York
weight parameters (pathology)	Non-parametric one-way analysis using KRUSKALWALLIS test (two-sided). If the resulting p-value was equal or less than 0.05, a pair wise comparison of each concentration group with the control group was performed using the WILCOXON test for the hypothesis of equal medians	HETTMANNSPERGER, T.P. (1984): Statistical Inference based on Ranks, John Wiley & Sons New York, 132-140. International Mathematical and Statistical Libraries, Inc., 2500 Park West Tower One, Houston, Texas 77042-3020, USA, nakl-1 - nakl-3 MILLER, R.G. (1981): Simultaneous Statistical Inference Springer-Verlag New York Inc., 165-167 NIJENHUIS, A. and S.W. WILF (1978): Combinatorial Algorithms, Academic Press,New York, 32-33

C. METHODS

1. Clinical examinations:
The animals were examined for evident signs of toxicity or mortality twice daily on working days and once daily on weekends and public holidays.
The clinical condition of the test animals was recorded once on pre-exposure and on post-exposure observation days and at least 3 times (before, during and after exposure) on exposure days. During exposure only a group wise examination was possible.

2. Body weight:
The body weight of the animals was determined on start of the pre-exposure, at the start of the exposure period and then, as a rule, twice a week (Monday and Friday) as well as prior to gross necropsy. As a rule, the animals were weighed at the same time of the day.

3. Food consumption, food efficiency and compound intake:
Food consumption was determined weekly and calculated as mean food consumption in grams per animal and day.
The animals were maintained in social-housing cages, with 5 animals per cage, during the whole study period. Therefore, the food consumption was determined cage-wise. The food consumption per animal and day was calculated by dividing food consumption of the day of a respective cage by the 5 animals per cage. For test groups 1 and 2, the animals of each test group were housed in only two cages per sex, no statistical evaluation of food consumption is possible. Due to recovery group animals of test group 3 and control group statistical evaluation were done during exposure period, but not for the post-exposure observation period for the same reason mentioned above.

4. Ophtalmoscopy:
Before the start of the exposure period the eyes of all animals, and towards the end of the study (study day 27/26) the eyes of the animals of the acetone control group and high concentration group were subjected to ophthalmocopic examination. At the end of the observation period (day 56/55) the eyes of the animals of control group and test group 3 (high concentration) were examined, additionally.

5. Functional observation battery (FOB) and Motor activity:
Not performed in this study.

6. Hematology and clinical chemistry:
Blood was collected from the retroorbital venous plexus in the morning from over-night fasted animals under isoflurane anaesthesia. The blood sampling procedure and the subsequent analysis of the blood and serum samples were carried out in a randomized sequence. The following parameters were determined.

Hematology:					
	Red blood cells		*White blood cells*		*Clotting Potential*
✓	Erythrocyte count (RBC)	✓	Total leukocyte count	✓	Platelet count
✓	Hemoglobin (Hb)	✓	Neutrophils (differential)	✓	Prothrombin time

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

1. Clinical signs of toxicity

There were no treatment-related clinical signs of systemic toxicity in the aceton control groups as well as at the low (3 mg/m³) and mid (10 mg/m³) and high (30 mg/m³) concentration levels.

2. Mortality

No deaths occurred throughout the study.

3. Ophthalmoscopy

No treatment-related ophthalmoscopical findings were noted in this study.

B. BODY WEIGHT

Body weight development in all dose groups during exposure was not statistically significantly different from the control group (see Figure 5.3.3-1 and Table 5.3.3-9). This holds true for the high dose recovery group at days 27 (end of exposure) and 55/56 (end of recovery period).
Fluctuations of body weights were observed during the exposure period. These were more pronounced in males than females. These fluctuations were considered to be due to the stress associated with the exposure conditions as these fluctuations were observed in all groups independent of dose and occurred already after the first, pre-treatment exposures to air in the inhalation apparatus during the acclimatization period. Additionally, a recovery of body weights was generally observed during the treatment-free weekends.

In the report body weight gains were only calculated for the treatment periods; treatment-free weekends were not considered. Sporadically, statistically significant changes of body weight gain were observed, which were considered incidental due to a lack of a dose response (low dose females for the day 10 to 14 interval) or temporal inconsistency (recovery group males for the intervals day -3 to 0 and 0 to 1, recovery group females for the day 38 to 42 interval).

Considering the entire treatment period, respectively the treatment and recovery period for the recovery animals, a numerically, but not statistically significant effect on body weight gain was observed in high concentration males (see Table 5.3.3-9).
The overall body weight change (day 0 to 56) of high concentration males was decreased by 19.3%.

Figure 5.3.3-2: Body weight development of rats exposed to pyraclostrobin by inhalation for 28 days on a 5 days/week basis

* $p \leq 0.05$ (Dunnett's test, two sided); [$] calculated from the weekly means; R = Recovery group; [#] average week 1-8
Values may not calculate exactly due to rounding of figures

C. FOOD CONSUMPTION AND FOOD EFFICIENCY

There were no statistically significant differences between food consumption of acetone and treated groups. The overall average daily food intake was well comparable between the test and the control groups (see Table 5.3.3-9).

D. BLOOD ANALYSIS

1. Hematological findings

No treatment-related changes of hematological parameters were observed (see Table 5.3.3-10). In mid and high concentration females (10 and 30 mg/m³) a slight decrease in hemoglobin values was observed, which is considered incidental and not treatment-related because the group means were within historical control range (7.8 to 9.5 mmol/L). Slight changes in absolute and relative neutrophil cell counts and relative lymphocyte counts in 30 mg/m³ females were within historical control range and thus not considered to be affected by treatment. The control ranges were 0.37-0.88 Giga/L absolute neutrophil and 11.1-26.6% for relative neutrophil counts as well as 66.7-83.9% for relative lymphocyte counts.

Table 5.3.3-10: Selected hematology findings of rats exposed to pyraclostrobin by inhalation for 28 days on a 5 days/week basis

Sodium [mmol/L]	141.5 ±1.1	141.6 ±0.9	140.3 ±1.0*	141.4 ±1.0	141.5 ±1.2	141.1 ±1.0

* $p \leq 0.05$, ** $p \leq 0.01$ (Kruskal-Wallis / Wilcoxon-test, two sided)
R Recovery group, values measured on day 56

No treatment-related differences were observed between treated and the acetone control groups. In absence of dose a dependency the statistically significant changes of creatinine sodium levels and alanine aminotransferase (ALT) values were considered to be of incidental nature and not related to treatment (see Table 5.3.3-11). The latter values were additionally within the historical control range (0.43-0.80 µkat/L).

E. NECROPSY

1. Organ weight

Statistically significant differences of organ weights were restricted to the duodenum and spleen (see Table 5.3.3-12). In absence of a histopathological correlate the increase of absolute and relative duodenum weight at ≥ 10 mg/m³ se group was regarded as a treatment-related, but adaptive, non-adverse change.

In absence of corroborative histopathological changes, the increase of absolute spleen weights in high concentration females was not considered to be treatment-related.

Table 5.3.3-12: Selected absolute and relative organ weights of rats exposed to pyraclostrobin by inhalation for 28 days on a 5 days/week basis

Sex		Males				Females			
	Concen-tration [mg/m³]	Absolute weight [mg]	Δ%	Relative weight [% of b.w.]	Δ%	Absolute weight [mg]	Δ%	Relative weight [% of b.w.]	Δ%

	3	258.32	(2)			174.79	(0)		
	10	261.12	(3)			174.92	(0)		
	30	257.44	(2)			181.45	(0)		
Duodenum [g]	0	0.371		0.147		0.364		0.209	
	3	0.393	(6)	0.152	(4)	0.363	(0)	0.207	(-1)
	10	**0.425****	**(15)**	**0.163****	**(11)**	**0.440****	**(21)**	**0.252****	**(21)**
	30	**0.502****	**(35)**	**0.195****	**(33)**	**0.508****	**(40)**	**0.281****	**(34)**
Spleen [g]	0	0.471		0.186		0.373		0.214	
	3	0.490	(4)	0.190	(2)	0.403	(8)	0.231	(8)
	10	0.519	(10)	0.199	(7)	0.381	(2)	0.218	(2)
	30	0.518	(10)	0.201	(8)	0.442*	(18)	0.243	(14)

* $p \leq 0.05$; ** $p \leq 0.01$ (Kruskal-Wallis / Wilcoxon-test, two sided)

No altered organ weights were noted at the end of the recovery period.

2. Gross and histopathology

All macroscopic findings occurred either individually or were equally distributed between control and treatment groups. They were considered to be incidental or of spontaneous origin.

Histopathology identified the respiratory tract, i.e. the nasal cavity and the larynx as target organs. A minimal to slight (multi)focal loss and/or destruction (atrophy/necrosis) of the olfactory epithelium in the nasal cavity was observed at 30 mg/m³ (see Table 5.3.3-13). These histopathological changes were reversible within the 4 weeks recovery period.
In some treated and one control animal at the base of the epiglottis a small focal area was covered by flattened epithelium, which differed from the normal cuboidal to columnar laryngeal epithelium. This finding was still observed in recovery group in two control animals and two treated animals (see Table 5.3.3-14). This minimal and focal change was regarded to be an adaptive, non-adverse response to the inhalation procedure and occurs also in controls. No dysfunction of the larynx is to be expected (Kaufmann et al., 1st International ESTP Expert Workshop: ‘‘Larynx squamous metaplasia’’. A re-consideration of morphology and diagnostic approaches in rodent studies and its relevance for human risk assessment, ExpToxicol Pathol 61: 591-603, 2009).

Concentration [mg/m³]		0	30	0	30
Animals in selected group		10	10	10	10
Larynx, level II	**exam**	10	0	10	10
Epithelial alteration		1 [1.0]$	2 [1.0]	1 [1.0]	0

$ [ ] mean severity grading; histopathological findings were graded minimal (Grade 1), slight (Grade 2), moderate (Grade 3), marked (Grade 4) and massive/severe (Grade 5). The mean severity is the sum of the gradings divided by the incidence

In the testes of each five control animals and high concentration group animals, tubular degeneration was observed. This finding was characterized by randomly affected (not stage specific) tubules with sloughed spermatogenic cells, vacuolation of the spermatogenic epithelium or missing germ cell layers. This effect in testis is known if rats are kept in tubes and try to evade. The equal incidence of this finding in control and treated animals indicates that this effect is not treatment-related. The histopathological changes observed in the epididymides (focal cibriform change, inflammatory cell or lymphoid infiltration, edema, oligospermia and debris) were regarded to be secondary to the above mentioned changes in the testes.

All other findings occurred either individually or were biologically equally distributed between control and treated groups and thus considered to be of incidental or spontaneous origin without any relation to treatment.

F. ATMOSPHERE ANALYSIS

The exposure conditions are summarized in Table 5.3.3-15.

Table 5.3.3-15: Exposure conditions

Test group	Supply air 1 (conditioned) [m³/h]	Supply air (compressed) [m³/h]	Supply air 2 (conditioned) [m³/h]	Exhaust Air 1 [m³/h]	Exhaust Air 2 [m³/h]	Acetone concentration [mg/m³]
0	4.5 ± 0.0	1.5-± 0.0		5.4		485.4 ± 181.5
1	5.0 ± 0.6	1.0 ± 0.6	4.0 ± 6.0*	5.4	4.0 ± 0.0*	
2	5.0 ± 0.6	1.0 ± 0.6		5.4		
3	5.0 ± 0.6	1.0 ± 0.6		5.4		

* from study day 4 to day 15;
Conditioned supply air is activated charcoal filtered air conditioned to about 30% to 70% relative humidity and 22°C ± 2°C;
Compressed air is filtered air pressurized to about 6 bar

The results of the atmosphere concentration analysis are depicted in Table 5.3.3-16.

Table 5.3.3-16: Measurement of pyraclostrobin and acetone concentrations

Test group	Target concentration [mg/m³]	Measured concentration (pyraclostobin) [mg/m³]	Measured concentration (Acetone) [mg/m³]
0	Aceton control		485.4 ±181.5
1	3	3.01 ± 0.8	n.d.
2	10	10.1 ± 1.5	n.d.
3	30	29.1 ± 2.9	n.d.

The measured MMAD values for the pyraclostrobin containing aerosols are given in Table 5.3.3-17.

Table 5.3.3-17: Particle size measurement

Test group	MMAD [µm]	Geometric standard deviation	< 3 µm [%]
1	0.6 – 2.3	2.8 – 6.0	56.3 – 95.0
2	0.9 – 3.8	2.7 – 5.2	44.6 - 89.3
3	0.8 – 3.1	2.7 – 4.5	49.3 - 89.9

The aerosols were highly respirable for rats and a very high proportion of the aerosol particles reached the lungs. The remaining fractions may have reached the upper respiratory tract and been deposited there.

III. CONCLUSIONS

Six hour subacute inhalatory exposure of rats to an aerosol of pyraclostrobin dissolved in acetone for 28-day on a 5 days per week basis did not result in any adverse effects indicating systemic toxicity. The respiratory tract (nasal cavity) was identified as target organ as indicated by atrophy/necrosis of the olfactory epithelium in the group treated with the highest concentration of 30 mg/m³. This change was reversible. Therefore, the 'No Observed Adverse Effect Concentration' (NOAEC) for systemic toxicity was 30 mg/m³ under the conditions of this study, whereas the NOAEC for local effect in nasal cavity was 10 mg/m^3.

Overall conclusion on subchronic inhalation toxicity

Regarding classification, the above described inhalation studies provide supportive evidence for the proposed classification of pyraclostrobin with STOT SE Category 3 (H335, May cause respiratory irritation). In absence of validated animal models that deal specifically with respiratory tract irritation, classification with STOT SE Cat. 3 is primarily based on human data. As discussed in MCA 5.9.3 there is evidence from direct observation that single exposure of humans to aerial spray mist of pyraclostrobin containing formulations can cause upper respiratory tract pain or irritation. The data of the subchronic inhalation studies provide supportive evidence for this classification. The observed inflammatory reactions of the (upper) respiratory tract (lung, nasal cavity and larynx at higher concentrations (first study), nasal cavity and larynx (second study)) are considered to represent local effects as similar effects in the respiratory tract were not observed in feeding or gavage studies. Reversibility of the observed irritant effects to the respiratory tract was observed in humans and in rats. In the occupational poisoning cases the severity was graded as being of low severity, which according to the US NIOSH (National Institute of Occupational Safety and Health) typically include illness or injury that resolves without treatment. Reversibility respiratory irritation was also demonstrated in the second 28-day inhalation study in rats as the atrophy / necrosis of the olfactory epithelium observed in the nasal cavity at the end of the treatment period was no longer detectable at the end of the 28-day recovery period.

The systemic effects observed in the inhalation studies do not justify a classification for STOT Repeated Exposure for the following reasons: The observed mortality at 0.3 mg/L (300 mg/m³) after repeated exposure for 6 hours is very close to the acute, 4h inhalation LC_{50} of 0.58 mg/L. In both cases for aerosol generation pyraclostrobin was dissolved in acetone. As pyraclostrobin is already classified as ‘toxic by inhalation’, a classification for the same end point after repeated exposure is not appropriate. The increases of white blood cell and neutrophil counts at 300 mg/m³ are considered to be unspecific responses to the local inflammation of the respiratory tract. Finally, in absence of signs of anemia, the minimal to moderate hyperplasia of the duodenal epithelium at $\geq$ 30 mg/m³ in the first subchronic inhalation study, respectively the increase of absolute and relative duodenal weight at $\geq$ 10 mg/m³ in the second subchronic inhalation study is not considered to represent an adverse finding.

CA 5.4 Genotoxicity Testing

Studies evaluated in the draft monograph of Rapporteur Member State Germany of August 1, 2001:
A sufficient data-package of in vitro genotoxicity studies in bacterial and mammalian cell systems and of in vivo genotoxicity studies conducted with pyraclostrobin is available. These studies as listed in Table 5.4.1-1 and Table 5.4.2-1 below have been evaluated by European authorities and Germany as Rapporteur Member State (European Commission Peer Review Program) and were considered to be acceptable. For the convenience of the reviewer, these studies are summarized below as extracted from the monograph.

Submission of not yet per-reviewed studies in this dossier:
No additional data on genotoxicity of pyraclostrobin was generated.

Pyraclostrobin has been tested both in vitro and in vivo in a series of mutagenic and genetic toxicity tests using bacterial and mammalian cells and whole animals to assess its potential to induce mutations and to damage chromosomes and DNA. All of these tests were clearly negative.

In summary the available data on genotoxicity of pyraclostrobin does not indicated a genotoxic potential.

Thus, the conclusion for relevant endpoints for the current re-registration remains as follows:

In vitro studies	Weight of evidence suggests no genotoxic concern
In vivo studies	Weight of evidence suggests no genotoxic concern
In vivo studies in germ cells	No data, not required

CA 5.4.1 In vitro studies

A summary of the in vitro genotoxicity studies evaluated for Annex I inclusion of pyraclostrobin is summarized in Table 5.4.1-1 below.

Table 5.4.1-1: In vitro mutagenicity studies with pyraclostrobin

Study type	Test System	With S-9 mix	Result	Reference (BASF DocID)
In vitro Mutagenicity in bacterial cells (Ames test)	*Salmonella thyphimurium* (TA 1535, 100, 1537, 98); *Escherichia coli* (WP2 uvrA); Concentration up to 5000 µg/plate	No Yes	Negative Negative	1997/10973
In vitro Mutagenicity in mammalian cells	CHO/HGPRT; Concentrations up to 20 µg/mL	No Yes	Negative Negative	1998/11422
In vitro Cytogenicity	Chromosome aberration in Chinese hamster V79 cells; Wide range of concentrations up to 25 µg/mL	No Yes	Negative Negative	1999/11403
In vitro DNA damage and repair	UDS, rat primary hepatocytes; Dose range: 0 – 1.0 µg/mL	No	Negative	1998/11421

CA 5.4.2 In vivo studies in somatic cells

A summary of the *in vivo* genotoxicity studies evaluated for Annex I inclusion of pyraclostrobin is summarized in Table 5.4.2-1 below.

Table 5.4.2-1: *In vivo* mutagenicity studies with pyraclostrobin

Study type	Test System	With S-9 mix	Result	Reference (BASF DocID)
In vivo Cytogenicity	Mouse Micronucleus test (0, 75, 150, 300 mg/kg bw); Oral gavage	Not applicable	Negative	1998/10460

A report amendment to the mouse micronucleus test was prepared, providing the results of the range finding toxicity test for the setting of the dose levels in the main study. In the following the data included in this report amendment are discussed.

Report:	CA 5.4.2/1 [redacted] 2016 a Amendment No 1: Cytogenetic study in vivo with BAS 500 F in the mouse micronucleus test. Single oral administration 2016/1309356
Guidelines:	OECD 474, EEC 92/69 B 12, EPA/TSCA 798.5395
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Administration of BAS 500 F (pyraclostrobin; batch: CP 026063; purity: 98.2%) to NMRI mice at dose levels of 125, 250, 300, 400, 500, 1000 and 2000 mg/kg bw resulted in dose dependent mortality at dose levels ≥ 400 mg/kg. In this study pyraclostrobin was dissolved in olive oil. Based on the mortality data, a LD_{50} of > 400 mg/kg bw, but < 500 mg/kg bw can be derived.

A. MATERIALS (as given in the main study, BASF DocID 1998/10460)

1.	**Test Material:**	BAS 500 F (pyraclostrobin)
	Description:	Red-brown melt
	Lot/Batch #:	CP 026063
	Purity:	98.2%
	Stability of test compound:	not explicitly indicated in the report
2.	**Vehicle and/or positive control:**	Olive oil
3.	**Test animals:**	
	Species:	Mice
	Strain:	NMRI
	Sex:	Male and female
	Age:	not indicated in the report
	Weight at dosing:	mean weight of males and female mice: 27.1 g
	Source:	Charles River GmbH, WIGA, Sulzfeld, Germany
	Acclimation period:	about 1 week
	Diet:	Kliba Haltungsdiät, Klingentalmühle, Kaiseraugst, Switzerland, ad libitum
	Water:	Drinking water from water bottles, ad libitum

Housing:	Group housing during acclimatization, single housing during the mutagenicity test in Makrolon M1 cages

Environmental conditions:

Temperature:	20 - 24°C (central air-conditioning)
Humidity:	30 - 70% (central air-conditioning)
Air changes:	not indicated in the report
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN

1. Dates of experimental work: Not explicitly indicated in the report. According to the raw data, the in-life part of the study and the evaluation of the bone marrow was performed in July and August 1997.

2. Animal assignment and treatment:

In the range finding toxicity test either 2 animals/sex (2000 mg/kg bw) or 4 animals/sex/dose (500 and 1000 mg/kg bw) or 5 animals/sex/dose (125, 250, 300 and 400 mg/kg bw) were dosed and observed for mortality and clinical signs up to 5 days (information provided in the report amendment).

For the main study groups, 5 male and 5 female mice were administered BAS 500 F at dose levels of 75, 150, and 300 mg/kg bw. Additional groups of the same size were administered either the vehicle (olive oil) or the positive controls cyclophosphamide or vincristine. The animals were assigned to the treatment groups by means of a computer generated randomization list. The animals were killed either 24 or 48 hours after administration for the evaluation of the bone marrow.

3. Test item preparation:

Pyraclostrobin (BAS 500 F) was dissolved in olive oil. While the preparation of the solution was not described in detail in the study report, information in the study protocol and the raw data indicate that the test-item was dissolved by heating the vehicle to about 60 °C for 5 minutes.

II. RESULTS AND DISCUSSION (data of the range finding toxicity test only)

A. Observations

1. Clinical signs of toxicity

Dose-related clinical signs of systemic toxicity were noted at dose levels ≥ 250 mg/kg and consisted of reduced general state, irregular respiration, lateral position, piloerection, salutatory spasm and hunched posture. No clinical signs of toxicity were recorded for animals which died within 15 minutes. The duration of the clinical signs is likewise indicated in Table 5.4.2-2.

2. Mortality

A dose-related mortality was noted at dose levels ≥ 400 mg/kg bw. Mortality was observed as early as 15 minutes after administration up to 1 day [see Table 5.4.2-2].

Table 5.4.2-2: Results of the range finding toxicity test in mice for dose setting in the mouse micronucleus assay with BAS 500 F (pyraclostrobin)

Dose (mg/kg)	Toxicological results*	Time of death	Duration of signs#	Recovery of survivors	Type of signs [code]
Males					
2000	2/0/2	h 0.25	not observed	all dead	not observed
1000	4/3/4	h 0.25 to d 1	h 0.25 to d 1	all dead	3, 4, 8, 38

4 irregular respiration
8 lateral position
10 piloerection
25 saltatory spasm
38 hunched posture

3. Dose selection for the main study

Based on the data of the range finding toxicity study, dose levels of 75, 150 and 300 mg/kg bw were selected for the main study. The highest dose of 300 represents 2/3 of the LD_{50} (see below).

4. Derivation of a LD_{50} in mice

Even though not designed as a study to determine a LD_{50} in mice, the mortality data are suitable to derive an acute oral toxicity value.
Based on the mortality data in Table 5.4.2-2 it is obvious that the LD_{50} of pyraclostrobin dissolved in olive oil is > 400 mg/kg, but < 500 mg/kg.

Including the mortality data generated in the course of the main study (no mortality in each 5 ♂ and 5 ♀ at 75 and 150 mg/kg; 1 case of mortality in 10 ♂ (24h und 48h groups) and no mortality in 10 ♀ at 300 mg/kg) acute LD_{50} values of 449, 453 and 451 mg/kg bw can be calculated for male mice, female mice and combined sexes, respectively. This calculation used the Probit analysis according to Finney (Finney, D.J. (1971): "Probit Analysis" Cambridge University Press, pp. 1 – 50) using SAS 9.3.

III. CONCLUSIONS

Based on the data of the preliminary toxicity test in NMRI mice dose levels of 75, 150 and 300 mg/kg were selected for the main part of the in-vivo mouse micronucleus assay with BAS 500 F (pyraclostrobin). The mortality data allow the calculation of a LD_{50} of 451 mg/kg bw for NMRI mice when data of male and female animals were combined. The calculated LD_{50} values for the individual sexes were 449 mg/kg bw for males and 453 mg/kg bw for females.

In order to prove the exposure of the target organ in the mouse micronucleus assay, i.e. the bone marrow, a study with radioactive pyraclostrobin was conducted in mice using the same vehicle as in the micronucleus assay.

Report:	CA 5.4.2/2 [redacted] 2016 c 14C-BAS 500 F- Study on the kinetics in mice 2016/1225931
Guidelines:	OECD 417, EPA 870.7485, Commission Regulation (EC) No 440/2008, JMAFF
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

^{14}C-BAS 500 F was administered once orally to four male mice at a target dose level of 300 mg/kg bw and an actual nominal dose of 296.7 mg/kg bw. Two hours after dosing, mice were sacrificed under isoflurane anaesthesia and defined organs and tissues (e.g. blood cells, plasma, bone marrow, liver) were prepared and worked up for the detection of the radioactive residues to demonstrate that the test substance and/or its metabolites reached the systemic circulation including organs/tissues. Corresponding samples of untreated mice from a parallel running study served as controls (see BASF DocID 2016/1225930).
The mean total radioactive residues (TRR) 2 h post dosing were 6.38 µg Eq/g in plasma and 6.54 µg Eq/g in bone marrow. In liver and blood cells, mean total radioactive residues of 44.63 and 1.81 µg Eq/g were found, respectively. Taken together, the data demonstrate that ^{14}C-BAS 500 F and/or its metabolites reach the systemic circulation including bone marrow and liver after single oral administration of the test substance at a target dose of 300 mg/kg bw.

(BASF DocID 2016/1225931)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material (labelled):	^{14}C-BAS 500 F
Lot/Batch #:	566-6101
Purity (radiochemical):	>95%
Purity (chemical):	98.1% (the CoA provided indicates a radiochemical purity of 98.9%)
Specific activity of AI:	5.59 MBq/mg
Stability of test compound:	The stability was verified within the current study.

2. Test Material (non-labelled):	BAS 500 F
Description:	Solidified melt
Lot/Batch #:	COD-001236
Purity:	99.02%
Stability of test compound:	The stability was guaranteed by the sponsor (expiry date: 01 Feb 2020).
3. Vehicle:	Olive oil
4. Test animals:	
Species:	Mouse
Strain:	Crl:NMRI
Sex:	Male
Age:	4 weeks
Weight at dosing:	33.0 ± 2.6 g
Source:	Charles River Laboratories, Research Models and Services, Germany GmbH, Sulzfeld, Germany
Acclimation period:	At least 5 days
Diet:	Kliba lab diet (mouse / rat "GLP") pellets, Provimi Kliba SA, Kaiseraugst, Basel, Switzerland, ad libitum
Water:	Tap water, ad libitum
Housing:	During acclimatization: Individual housing in Polycarbonate Cages (Type III)
	During the experiment: Individual housing in Polycarbonate Cages (1291H; PC, 820 cm^2, Tecniplast) with steel wire mesh ground (7 x 7 mm mesh wire).
Environmental conditions:	
Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	15 per h
Photo period:	Alternating 12 hour light and dark cycles, artificial light from 6 am to 6 pm

B. STUDY DESIGN AND METHODS

1. Dates of work: 19-July-2016 to 01-Aug-2016

2. Test substance preparation:

In order to achieve a homogenous test substance preparation (nominal concentration: 6.63 mg/g), a suspension of non-labelled test substance was prepared in olive oil. The preparation was stirred vigorously for about 2 h, sonicated at about 50°C for 15 min and afterwards stirred and sonicated at about 50°C to yield a homogenous preparation. In order to achieve the required specific activity, an appropriate amount of the radio-labelled test substance was taken, the solvent was evaporated to dryness under a stream of nitrogen and the residue was mixed with a defined weight of the previously prepared non-labelled test substance in olive oil. The preparation was homogenized by stirring with a magnetic stirrer for about 1 ½ hours, additional ultrasonication for about 15 minutes and repeating this homogenization process procedure once. On the administration day, the preparation was stirred for at least one hour before samples were taken.

Before start and at the end of the administration, samples were taken to determine the specific activity of the test substance in the preparation and to demonstrate the correct concentration of the test substance, its homogeneity and stability as well as its radiochemical purity.

Based on the current data, the nominal concentration of the test substance preparation was 32.9 mg/g, corresponding to 30.0 mg/mL and its nominal specific activity was 36.6 MBq/mL. The dosed amount of radioactivity per animal was between 10.9 and 13.4 MBq.

3. Homogeneity/Concentration and stability control:

The amounts of radioactivity, the amounts of ^{14}C-BAS 500 F and the total amount of BAS 500 F (sum of ^{14}C and non-radioactive) in the test substance preparation was determined by LSC, Radio-HPLC as well as HPLC-UV in samples that were taken before and after administration of the test substance preparation to the animals. The samples were prepared for analysis using conventional methods described in standard operating procedures. The analyses of these samples allow to demonstrate the homogeneity, correctness of the concentration and the stability of the test substance in the test substance preparation.

4. Study design and test groups:

The study was designed to obtain data to demonstrate that the test substance reaches the systemic circulation and defined organs / tissues. For this purpose, blood cells, plasma, bone marrow from the two femora, and the liver were collected.
Treated animals were sacrificed 2 hours after administration. Data from four untreated control animals, derived from another, parallel running study (BASF DocID 2016/1225930, see M-CA 5.8 of this dossier), were used for calculation of background levels.

The experiments were performed according to the following scheme:

Experiment 0 (BASF DocID 2016/1225930)	
Animals:	4 males
Radioactivity per animal:	untreated control
Dosing:	untreated
Analysis:	total radioactivity (for determination of the detection limit)
Experiment 1 (this study)	
Animals:	4 males
Radioactivity per animal:	about 10 MBq
Dosing:	1 oral dose, 300 mg/kg bw
Analysis:	total radioactivity

5. Experimental procedure and observations:

The animals were dosed at a volume of 10 mL/kg body weight by oral gavage.
A check for moribund and dead animals was conducted at least once daily. A cage side examination was conducted at least once daily for any signs of morbidity, pertinent behavioral changes and signs of overt toxicity.
The body weight was determined on the day of administration prior to dosing for the animals of experiment 1. The animals of experiment 0 were weighed in the parallel running study (BASF DocID 2016/1225930).

6. Sample work up and measurement:

Whole blood samples were inverted several times to ensure homogeneity and then separated into plasma and blood cells by centrifugation.
After weighing, aliquots of plasma were mixed with scintillation cocktail (Hionic Fluor, Perkin Elmer) and analyzed for radioactivity without any additional treatment.
The liver was homogenized. Subsequently 1 mL Soluene®-350 was added to aliquots of the suspensions and incubated over night at about 37°C and isopropanol was added afterwards. Bleaching was performed with 1 mL 30% H_2O_2 followed by incubation at room temperature at least over night. Hionic Fluor was added before measurement of radioactivity by LSC.
Blood cells were dissolved in Soluene®-350 and processed as described above. Bone marrow from the two femora was removed with a cotton ball, which transferred into a scintillation vial. After addition of Soluene®-350 the samples were processed as described for the liver.
All values given in the project and in the report are background corrected. The background values of LSC analyses were 10 to 170 cpm (see BASF DocID 2016/1225930). The quantification limit (LOQ) for LSC measurement was set twice the background. For further calculations (e.g. mean values and standard deviations) samples < LOQ were set to 0.

II. RESULTS AND DISCUSSION

A. ANALYTICS

Concentration control analysis confirmed the nominal concentration with means between 90 and 110 % related to the nominal value (109.1 ± 3.5; Mean ± RSD). The relative standard deviation below 5% demonstrates the homogenous distribution of the test substance in its preparation.
The measured specific activity of the test substance preparation compared to its target value is assessed to be acceptable within the precision of the method (36.7 and 41.2 MBq/mL for target and measured specific activity, respectively). Radio-HPLC analyses confirmed the stability of the radio-labelled test substance over the administration period by radiochemical purities of ^{14}C-BAS 500 F > 95%.

B. CLINICAL OBSERVATIONS AND MORTALITY

No mortality occurred during the study period. No test substance related relevant findings were observed.

C. BODY WEIGHT

As to be expected for a short-term experiment (2 h), no effects on body weight were noted.

D. BIOKINETICS

After a single administration of ^{14}C-BAS 500 F to male mice at a target dose level 300 mg/kg bw, the mean actual nominal dose level was 296.7 ± 5.9 mg/kg bw (see Table 5.4.2-3).
Mean radioactive residues resulted in 1.81 ± 0.56 µg Eq/g for blood cells and 6.38 ± 2.13 µg Eq/g for plasma. The mean radioactive residues in bone marrow and liver were 6.54 ± 3.57 and 44.63 ± 18.15 µg/g, respectively (see Table 5.4.2-3). Variability of the single animal data reflect inter-individual biological variability that are in a normal range for kinetic studies. Based on the current data, radioactivity was clearly detectable in blood cells, plasma, bone marrow and liver of all orally dosed animals.
Blood cells, plasma, bone marrow and liver from four untreated mice (untreated control, 30.9 – 36.1 g bw) were collected and measured for total radioactivity (background levels). Taking the specific activity of administered ^{14}C-BAS 500 F and the measured sample weights into account, double background levels corresponded to < 0.05 µg Eq/g for plasma, < 0.2 µg Eq/g for blood cells, < 4 µg Eq/g for bone marrow and < 4 µg Eq/g for liver, respectively.
These data demonstrate that the detected residue levels in blood cells, plasma, bone marrow and liver in mice dosed with ^{14}C-BAS 500 F at a dose level of 300 mg/kg bw were significantly above background.

Table 5.4.2-3: Radioactive residues (µg Eq/g) in plasma, blood cells, bone marrow and liver of male mice treated with ^{14}C-BAS 500 F at a target dose level of 300 mg/kg bw (2 hours post dosing)

Parameter	Animal No.	1	2	3	4	Mean	SD
Body weight	[g]	34.4	35.5	32.4	29.5	33.0	2.6
Specific activity	[MBq/g]	-	-	-	-	1252.5	-
Dose	[mg/kg bw]	289.5	301.5	301.7	294.1	296.7	5.9
Radioactive Dose	[MBq/animal]	12.47	13.40	12.24	10.87	12.25	1.05
Blood cells	[µg Eq/g]	1.98	1.58	1.18	2.49	1.81	0.56
Plasma	[µg Eq/g]	8.68	4.70	4.45	7.71	6.38	2.13
Bone marrow	[µg Eq/g]	3.84	3.75	7.26	11.29	6.54	3.57
Liver	[µg Eq/g]	31.50	53.67	27.61	65.72	44.63	18.15

It is worth to note that the mean plasma levels determined in mice two hours after administration of a dose of 300 mg/kg bw (6.38 µg/Eq/g plasma) are in good agreement to the plasma levels in rats at the same point in time after administration of 50 mg/kg bw (1.33 µg Eq/g plasma; see BASF DocID 1998/10997). Plasma levels in mice at a 6-fold higher dose were 4.8-fold higher.

III. CONCLUSION

The current study demonstrated that radioactive residues of ^{14}C-BAS 500 F are present in the systemic circulation, in bone marrow and in liver of mice, two hours after single oral administration of the test substance at a target dose level of 300 mg/kg bw.

CA 5.4.3 In vivo studies in germ cells

This is no data requirement and consequently no studies have been conducted, however, the following literature data was evaluated:

Report: CA 5.4.3/1
Cayir A. et al., 2012b
Micronuclei, nucleoplasmic bridges, and nuclear buds induced in human lymphocytes by the fungicide Signum and its active ingredients (Boscalid and Pyraclostrobin)
2012/1366624
Guidelines: none
GLP: no (literature study)

Executive Summary

Pyraclostrobin and the pyraclostrobin containing formulation Signum as well as the active substance boscalid were tested for their ability to induce micronuclei, nucleoplasmic bridges, and nuclear buds in human lymphocytes in vitro. The method used was similar to OECD guideline 487, but used the additional endpoints nucleoplasmic bridges, and nuclear buds, that are also indicative for a genotoxic effect. Both active ingredients used for the assays were of >99% purity and the formulation Signum was a commercial formulation containing 26.7% w/w boscalid and 6.7 % w/w pyraclostrobin.
Heparinized blood was obtained from 2 young donors that reported to be healthy but were not tested for their health status. 2 parallel cultures were tested for each test concentration and culture condition in the absence of metabolic activation only. In a G_0 phase protocol blood was treated with the test concentrations for 24 hours without phytohemagglutinin (PHA), then the test item was removed and PHA was added to the culture medium. After 44 hours cytochalasin B was added and cultures were harvested 72 hours after initiation. In the second protocol proliferating lymphocytes were treated with PHA for 44 hours before the test items were added. Cytochalasin B was added 48 hours after initiation and cells were harvested 72 hours after start. Signum and Boscalid were tested in 8 concentrations in both G_0 Phase and proliferating lymphocytes while pyraclostrobin was tested in 7 concentrations in G_0 Phase lymphocytes and only 3 concentrations in proliferating lymphocytes. Cells were fixed and slides stained with Giemsa before microscopic evaluation. 1000 binucleated cells were scored for each culture resulting in a total of 4000 binucleated cells per concentration. Parameters evaluated were micronuclei, nuclear buds and nucleoplasmic bridges as a measure of genotoxicity and cytokinesis-block proliferation index (CBPI) and %cytostasis as a measure of cytotoxicity. Mitomycin C served as a positive control and yielded a statistically significant increase in micronuclei in all experiments.

For all 3 test items an increase in micronuclei compared to the concurrent vehicle control was observed both in G_0 and proliferating cells. This increase was not dose dependent for both boscalid and Signum with only single concentrations reaching statistical significance. The study authors attribute the missing dose response for micronucleus induction to the increasing level of %cytostasis, nevertheless all concentrations tested were well below the cytostasis limit of 55%. For pyraclostrobin a more pronounced effect on micronucleus formation was noted that was dose-related even though levels of cytostasis were enhanced compared to Signum and boscalid. The authors do not indicate their historical control data for the study design employed. On this basis it is difficult to assess the biological relevance of the effects observed. Nevertheless, it can be concluded that under the conditions described, boscalid, pyraclostrobin and the formulated product Signum induce clastogenic or aneugenic effects in vitro.

This is not considered relevant information since for both, pyraclostrobin and boscalid, comprehensive in vitro and in vivo data for genotoxicity are already available and have been evaluated for Annex I inclusion. The relevant follow up assay for a positive in vitro micronucleus assay in either mammalian cell lines or human lymphocytes is a rodent bone marrow micronucleus assay addressing both aneugenic and clastogenic effects. This study has been performed for boscalid and was clearly negative (BASF DocID 1999/11048). For pyraclostrobin a chromosomal aberration assay in mice was likewise negative (see above). The author`s recommendation to perform a Comet assay in vivo is not considered useful since this assay addresses clastogenic and mutagenic but not aneugenic effects and would not lead to a better understanding of the genotoxic profile.

Genotoxicity testing of formulated products is not a data requirement in the EU and is in general not considered useful since testing of the undiluted active substance for a genotoxic hazard is considered more appropriate. Therefore, no in vivo studies on the formulation Signum (BAS 516 07 F) are available. Nevertheless, for product registrations in Brazil in vivo micronucleus tests in mouse bone marrow have been performed with altogether 12 different formulations containing pyraclostrobin and with one formulation containing boscalid. **All these studies were negative, thus proving that the presence of formulation auxiliaries does not alter the genotoxic profile of the active substances.** Table 5.4.3-1 shows a list of in vivo micronucleus studies available for formulated products containing either pyraclostrobin or boscalid.

Table 5.4.3-1: In vivo micronucleus assays with formulated products containing pyraclostrobin or boscalid

Study type	Test System	Formulation tested	Result	Reference*
In vivo Cytogenicity	Mouse Micronucleus test (0, 312.5, 625, 1250 mg/kg bw); Oral gavage	WG-type 6.7g/kg pyraclostrobin	Negative	2010/1141998 ** &2013/1403103 **
In vivo Cytogenicity	Mouse Micronucleus test (0, 200, 400, 800 mg/kg bw); Oral gavage	TK-type 40% pyraclostrobin	Negative	2005/1006741
In vivo Cytogenicity	Mouse Micronucleus test (0, 75, 150, 300 mg/kg bw); Oral gavage	DS-type 50g/L pyraclostrobin	Negative	2006/1015913

In vivo Cytogenicity	Mouse Micronucleus test (0, 93.75-750 mg/kg bw); Oral gavage	WG-type 200 g/L boscalid	Negative	2008/1037578

* study reports available on request
** study summaries are given below

Based on negative genotoxicity datasets for both, pyraclostrobin and boscalid, and a large number of negative in vivo micronucleus assays in mice with different formulated products, the in vitro findings reported by Cayir et al. are not considered to have any relevance in vivo.

Category: Supplemental information

The formulation listed first in Table 5.4.3-1 (BAS 536 02 F) has a composition which very similar to the composition of Signum (BAS 516 07 F). The content of pyraclostrobin is identical and with the exception of the second active substance (dimethomorph instead of boscalid) both formulations differ only in the type of carrier used. A comparison of the composition of both formulations (BAS 516 07 F and BAS 536 02 F) is provided in the confidential Document JCP of BAS 516 07 F.
In the following the mutagenicity studies available for the formulation BAS 536 02 F are presented. These are considered as further strong evidence that BAS 516 07 F does not have any mutagenic potential in vivo.

Report:	CA 5.4.3/2 Schulz M., Landsiedel R., 2010 a BAS 536 02 F - Salmonella typhimurium / Escherichia coli reverse mutation assay (standard plate test and preincubation test) 2010/1059892
Guidelines:	OECD 471 (1997), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.13 No. L 142, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.14 No. L 142, EPA 870.5100
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

S. typhimurium (strains TA98, TA 100, TA 1535 and TA 1537) and E. coli strain WP2 uvrA were exposed to BAS 536 02 F; batch: 3481; containing 12.2% dimethomorph and 7.0% pyraclostrobin) using DMSO as a solvent in the presence and absence of metabolic activation in two independent experiments. Triplicate plates were used per dose and per test condition. Vehicle and positive controls were included in each experiment.

The test substance was tested in concentrations between 33 and 5000 µg/plate. A weak bacteriotoxic effect was observed in the preincubation assay at 5000 µg/plate. No precipitation of the test substance was found with and without S9 mix.

No biologically relevant increase in the number of revertant colonies was observed in any of the strains tested in presence or absence of metabolic activation in any of the experiments. The positive controls induced the appropriate response in the corresponding strains, thus demonstrating the sensitivity of the test system.

The test substance BAS 536 02 F is not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions of the study.

(BASF DocID 2010/1059892)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 536 02 F

Description:	Solid, brown
Lot/Batch #:	3481
Purity:	Formulation, contents of active ingredients BAS 550 F (Dimethomorph): 12.2% BAS 500 F (Pyraclostrobin): 7.0%
Stability of test compound:	The test substance was stable over the study period under the storage conditions and guaranteed until 01 Jan 2012.
	The homogeneity of the test substance was ensured by mixing prior to preparation of test substance solutions.
Solvent used:	DMSO

2. Control Materials:

Negative control:	In parallel to each experiment, negative control experiments were carried out in order to check for possible contaminants (sterility control) and to determine the spontaneous mutation rate (vehicle control).
Vehicle control:	The vehicle control with and without S9 mix only contained the vehicle used for the test substance at the same concentration and volume for all tester strains.
Solvent/final concentration:	100 µL/plate

Positive control compounds tested without addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1535	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1537	9-Aminoacridine (AAC)	DMSO	100 µg/plate
TA 98	4-nitro-o-phenylendiamine (NOPD)	DMSO	10 µg/plate
WP2 uvrA	4-nitroquinoline-N-oxide (4-NQO)	DMSO	5 µg/plate

Positive control compounds tested with addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1535	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1537	2-aminoanthracene	DMSO	2.5 µg/plate
TA 98	2-aminoanthracene	DMSO	2.5 µg/plate
WP2 uvrA	2-aminoanthracene	DMSO	60 µg/plate

To demonstrate the efficacy of the S9 mix in this assay, the S9 batch was further characterized with benoz(a)pyrene in the strains TA 100 and TA 98 as required in OECD 471.

3. Activation:

S9 was produced from the livers of induced male Wistar rats. The rats received on three consecutive days intraperitoneal injections of 80 mg phenobarbital and 80 mg β-naphthoflavone orally per kg body weight. 24 hours after the last administration the animals were sacrificed. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction is thawed at room temperature and 1 volume of S9-fraction is mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9 mix, was kept on ice until used.

The S9 mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4. Test organisms:

S. typhimurium strains: TA98, TA100, TA1535, TA1537
E. coli: WP2 uvrA
The Salmonella strains are checked for the following characteristics at regular intervals: deep rough character (rfa); UV sensitivity (uvrB); ampicillin resistance (R factor plasmid). E. coli WP2 uvrA is checked for UV sensitivity.
Histidine and tryptophan auxotrophy is automatically proven in each experiment via the spontaneous rate.

5. Test concentrations:

Plate incorporation assay:	In the first experiment triplicate plates were prepared for each concentration (neg. control; 33, 100, 333, 1000, 2500 and 5000 µg/plate and positive controls at the concentrations indicated above) and conditions (i.e. with and without S9) for all tester strains indicated above.
Pre-incubation assay:	In the second experiment the test article / vehicle / positive control substance, bacterial and S9 mix or phosphate buffer were incubated at 37°C for the duration of about 20 minutes. Triplicate plates were prepared for each concentration (neg. control; 33, 100, 333, 1000, 2500 and 5000 µg/plate and positive controls at the concentrations indicated above) and condition (i.e. with and without S9) for all tester strains.

B. TEST PERFORMANCE:

1. Dates of experimental work: 20-Apr-2010 to 29-Apr-2010

2. Plate incorporation assay:

To test tubes containing 2 mL portions of warm soft agar (containing 0.5 mM histidine + 0.5 mM biotin), 0.1 mL test solution or vehicle, 0.1 mL fresh bacterial culture, 0.5 mL S9-mix (in tests with metabolic activation) or 0.5 mL phosphate buffer (in tests without metabolic activation) were added in the given order. After mixing, the samples are poured onto Vogel-Bonner agar plates (minimal glucose agar plates). In the experiments with E. coli the warm soft agar contains 0.5 mM tryptophan instead of histidine + biotin.

3. Pre-incubation assay:

100 µL of test solution or vehicle, 0.1 mL bacterial suspension and 0.5 mL S9 mix or phosphate buffer were incubated at 37°C for about 20 minutes. Subsequently, 2 mL of soft agar was added and, after mixing, the samples are poured onto the agar plates.
After incubation in the dark for 48 to 72 hours at 37°C each plate was checked for precipitates and status of the background lawn. Revertant colonies were counted. Means and standard deviations were calculated.

4. Titer determination:

In order to assess bacteriotoxic effects, the titer was additionally determined in experimental parts with S9 mix using the vehicle control and the two highest doses. The procedure followed in both experiments (plate incorporation and pre-incubation) was the same as described above for the individual experiments with the exception that the soft agar used contained maximal amino acid solution (5 mM tryptophan or 5 mM histidine + 0.5 mM biotin). After the incubation in the dark for 48 to 72 hours at 37°C the number of bacterial colonies was determined.

5. Statistics:

No special statistical tests were performed.

6. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A dose-related and reproducible increase in the number of revertant colonies, i.e. about doubling of the spontaneous mutation rate in at least one tester strain either without S9 mix or after adding a metabolizing system.

A test substance is generally considered non-mutagenic in this test if:

- The number of revertants for all tester strains was within the historical negative control range under all experimental conditions in at least two experiments carried out independently of each other.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The test substance was stable in the vehicle DMSO and in water over a period of 4 hours.

B. TOXICITY

No bacteriotoxic effect (reduced his^- or trp^- background growth, decrease in the number of his^+ or trp^+ revertants, reduction of titer) was observed in the standard plate test up to the highest concentration tested.

In the preincubation assay bacteriotoxicity (reduced his^+ or trp^+ background growth, decrease in the number of his^+ or trp^+ revertants, reduction in the titer) was observed depending on the strain and test conditions from about 5000 µg/plate onwards.

C. MUTATION ASSAYS

Neither in the plate incorporation nor in the preincubation experiment with and without metabolic activation a biologically relevant increase in number of revertants was observed in any strain tested [see Table 5.4.3-2]. The positive controls yielded revertant numbers in a range expected for the respective strains and thus demonstrated the sensitivity of the test system.

No test substance precipitation was observed with and without S9 mix.

III. CONCLUSION

According to the results of the present study the test substance BAS 536 02 F is not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions chosen here.

Report:	CA 5.4.3/3 [redacted] 2010 a BAS 536 02 F - Micronucleus test in bone marrow cells of the mouse 2010/1141998
Guidelines:	OECD 474, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.12, EPA 870.5395

Report:	CA 5.4.3/4 [redacted] 2014 a Amendment No. 1 to the report - BAS 536 02 F - Micronucleus test in bone marrow cells of the mouse 2013/1403103
Guidelines:	OECD 474, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.12, EPA 870.5395
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Please note: The Amendment provides detailed information on the clinical observation made in the preliminary dose range finding study.

Executive Summary

BAS 536 02 F (batch: 3481, containing 12.2% dimethomorph and 7.0% pyraclostrobin) was tested for chromosomal damage (clastogenicity) and for the ability to induce spindle poison effects (aneugenic activity) in NMRI mice using the micronucleus test method. For this purpose, the test substance was administered once orally to groups of 5 male mice at dose levels of 312.5, 625 and 1250 mg/kg body weight. The vehicle (deionized water) served as negative and cyclophosphamide and vincristine sulfate as positive controls. The animals were sacrificed 24 or 48 (additional high dose and vehicle group) hours after the administration and the bone marrow was prepared and investigated for micronuclei.

The oral administration of BAS 536 02 F did not lead to any biologically relevant increase in the number of polychromatic erythrocytes containing either small or large micronuclei. The rate of micronuclei was mostly close to the concurrent negative control and was within the range of the historical control data. Inhibition of erythropoiesis, determined from the ratio of polychromatic to normochromatic erythrocytes, did not occur.

Both of the positive control chemicals, i.e. cyclophosphamide for clastogenic effects and vincristine for induction of spindle poison effects, led to the expected increase in the rate of polychromatic erythrocytes containing small (cyclophosphamide) or small and large (vincristine sulphate) micronuclei, thus demonstrating the sensitivity of the test system.

BAS 536 02 F does not induce the formation of micronuclei in mouse polychromatic erythrocytes under the conditions of the study, i.e. is devoid of clastogenic or aneugenic activity in vivo.

(BASF DocID 2010/1141998)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 536 02 F

Description:	Solid, brown
Lot/Batch #:	3481
Purity:	Formulation, contents of active ingredient BAS 550 F (dimethomorph): 12.2% BAS 500 F (pyraclostrobin): 7.0%
Stability of test compound:	The stability of the test substance under storage conditions throughout the study period was guaranteed until 01 Jan 2012 as indicated by the sponsor. Homogeneity of the test substance was guaranteed on account of the high purity and was ensured by mixing before test substance preparation.
Vehicle used:	Deionized water

2. Control Materials:

Negative:	No negative control was employed in this study.
Vehicle control:	Deionized water
Positive control:	Cyclophosphamide (CPP) 20 mg/kg for the determination of clastogenic effects Vincristine sulphate (VCR) 0.15 mg/kg for the determination of aneugenic effects

3. Test animals:

Species:	Albino mice
Strain:	Crl:NMRI
Sex:	Male for the main study; male and female for the range finding study
Age:	5 - 8 weeks
Mean body weight at dosing:	29.78 g
Source:	Charles River Laboratories Germany GmbH
Number of animals per dose:	
Range finding study:	3 males and female/dose
Micronucleus assay:	5 males/dose
Acclimation period:	At least 5 days
Diet:	Standardized pelleted feed (Maus/Ratte Haltung "GLP", Provimi Kliba SA, Kaiseraugst, Switzerland)
Water:	Drinking water in bottles, ad libitum
Housing:	During the study the mice were housed individually in Makrolon cages, type MII.

4. Environmental conditions:

Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	frequency not indicated (fully air-conditioned rooms)
Photo period:	12-hour light-dark cycle (06:00 - 18:00, 18:00 - 06:00)

5. Test compound doses:

Range finding test:	1000, 1500 and 2000 mg/kg
Micronucleus assay:	312.5, 625 and 1250 mg/kg The test substance was administered once by oral gavage using an application volume of 10 mL/kg.

B. TEST PERFORMANCE

1. Dates of experimental work: 12-Jul-2010 to 06-Oct-2010

2. Preliminary range finding test:

Groups of 3 male and 3 female NMRI mice were treated once by oral gavage with a test substance at dose levels of 1000, 1500 or 2000 mg/kg bw.

3. Micronucleus test:

Treatment and sampling:	Groups of 5 male mice were treated once with either the vehicle or 312.5, 625 or 1250 mg test substance/kg bw by oral gavage. Additional test groups treated with the vehicle control and the high dose were used for the second sampling period. The application volume was 10 mL/kg bw and the volume to be applied was calculated based on actual weight on the day of administration. The positive control substances CPP and VCR were administered once by oral gavage (CPP) or i.p. injection (VCR). The animals were observed for evident clinical signs of toxicity throughout the study. Twenty-four hours after the administration the mice were sacrificed and the two femora were prepared free of all soft tissue. After cutting the epiphyses the bone marrow was flushed out in a centrifugation tube with fetal calf serum and subsequently centrifuged at 300xg for 5 minutes. The supernatant was discharged and the pellet re-suspended in about 50 µl fresh FCS. The sampling of the femora from the additional high dose and vehicle control group was performed as described above 48 h after the treatment.
Slide preparation:	One drop of the suspension was applied on a clean microscopic slide and smears were prepared. After air drying the smears were stained with May-Grünwald solution, rinsed, and finally stained with Giemsa solution (7.5%). After rinsing and clarifying in xylene, the preparations were mounted. The slides were coded prior to microscopic evaluation.
Slide evaluation:	In general, 2000 polychromatic erythrocytes (PCEs) from each male animal of every test group were evaluated and investigated for micronuclei (MN). The normochromatic erythrocytes (NCEs) that occurred were also scored. The increase in the number of micronuclei in polychromatic erythrocytes of treated animals as compared to the vehicle control group provides an index of a chromosome-breaking (clastogenic) effect or of a spindle activity (aneugenic) of the substance tested.

In addition, the number of small micronuclei (d < D/4) and of large micronuclei (d ≥ D/4) (d = diameter of micronucleus, D = cell diameter) was determined: The size of micronuclei may indicate the possible mode of action of the test substance, i.e. a clastogenic or a spindle poison effect.

The ratio of polychromatic to normochromatic erythrocytes was calculated. An alteration of this ratio indicates a toxic effect on erythropoieses and thus, that the test substance actually reached the target organ.

4. Statistics:

The number of polychromatic erythrocytes with micronuclei was analyzed by comparing the dose groups with the vehicle control using the Mann-Whitney U-test (modified rank test according to Wilcoxon). Here, the relative frequencies of cells with micronuclei of each animal were used.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A dose-related and significant increase in the number of micronucleated polychromatic erythrocytes was observed.
- The proportion of cells containing micronuclei exceeded both the values of the concurrent vehicle control range and the vehicle historical control range.

A test substance is generally considered negative in this test system if:

- There was no significant increase in the number of micronucleated polychromatic erythrocytes at any dose above concurrent control frequencies.
- The frequencies of cells containing micronuclei were within the historical control range.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance in the vehicle was verified analytically. The homogeneity of the test substance in the vehicle was guaranteed by constant stirring during the removal and administration of the test substance formulation and by analytical determination of 3 individual samples of each concentration. The mean test substance concentrations were determined as 33.75, 71.31 and 139.69 mg/mL at nominal concentrations of 31.25, 62.50, and 125.00 mg/mL, respectively. These values correspond to 108 to 114.1% of the nominal concentration. The recovery rates of the mid and high dose group (114.1 and 111.7%) was slightly higher than the expected range (90-110%). However, these recovery rates are well within the internationally accepted range of 80 - 120%.
The homogeneity of the test substance in the vehicle was guaranteed by constant stirring during the removal and administration of the test substance formulation and indirectly by analytical determination of 3 individual samples of each concentration.

B. PRELIMINARY RANGE FINDING TEST

In the pretest in males and females, deaths were observed down to 1500 mg/kg bw. At 1000 mg/kg bw, all animals survived displaying piloerection and hunched posture as signs of general toxicity up to the end of the observation period of 2 days. There were no distinct differences between male and female animals. Thus, only male animals were used for the main experiment. Based on the mortality down to 1500 mg/kg bw and the clinical signs observed throughout the observation period of 2 days at 1000 mg/kg bw, the dose of 1250 mg/kg bw was considered as maximum tolerated dose (MTD) for the main study.

C. MICRONUCLEUS ASSAY

Treatment of mice with BAS 536 02 F did not lead to a biologically relevant increase in the rate of micronuclei (see Table 5.4.3-3). Micronucleus frequencies of treated animals were near to the concurrent vehicle control values and within the historical control range (0.4 to 3.0% for the vehicle water). The number of normochromatic or polychromatic erythrocytes containing small or large micronuclei did not deviate from the vehicle control value and was within the historical control range.

The PCE/NCE ratio was not affected by treatment with the test substance. Thus, there was no indication that erythropoiesis was inhibited.

The clastogenic activity of the positive control substance cyclophosphamide was evident by the increase in the number of PCE containing almost exclusively small micronuclei (21.7‰). The administration of the spindle poison vincristine resulted in an incidence of micronuclei in polychromatic erythrocytes of 75.8‰. This included 22.7‰ of PCE with large micronuclei. The positive controls thus demonstrated the sensitivity of the test system.

The administration of the test substance led to distinct clinical signs of toxicity. At 625 mg/kg body weight, all animals displayed piloerection from 1 to 4 h after injection. At 1250 mg/kg all animals from the 24 hour and 48 hour treatment groups displayed piloerection and hunched posture at the 1, 2 and 4 h observation intervals.

No signs of systemic toxicity were observed in any of the animals treated with the positive control substances or the vehicle.

Table 5.4.3-3: Micronucleus test in mice administered BAS 536 02 F by oral gavage

Test group	Sacrifice interval [h]	Animal No.	Micronuclei in PCE		Number of NCE[c]
			total[a] [‰]	large[b] [‰]	
Vehicle control deionized water	24	5	1.2	0.0	2734
Test substance 312.5 mg/kg bw	24	5	1.7	0.0	2386
Test substance 625 mg/kg bw	24	5	1.5	0.1	2424
Test substance 1250 mg/kg bw	24	5	1.1	0.0	2520

Positive control Vincristine sulfate 0.15 mg/kg bw	24	5	75.8**	22.7**	4888
Vehicle control deionized water	48	5	2.0	0.0	3603
Test substance 1250 mg/kg bw	48	5	1.1	0.0	2592

** $p \leq 0.01$ (Wilcoxon Test; one sided)
PCE: polychromatic erythrocytes; NCE: normochromatic erythrocytes
[a] sum of small and large micronuclei
[b] large micronuclei (indication of spindle poison)
[c] number of NCEs observed when scoring 10 000 PCEs

The exposure of the target organ, i.e. bone marrow was not determined in this study. However, as demonstrated in a separate study, radioactive pyraclostrobin administered to mice by oral gavage was detected at quantifiable concentrations in bone marrow and plasma (see BASF DocID 2016/1225931). Despite of the use of different vehicles (olive oil vs. a mixture of Pluriol E 200 (= polyethylene glycol) and 0.5% aqueous Tylose®) and dose levels (300 mg/kg bw vs. 50 mg/kg bw) plasma levels were in good agreement in mice and rats (see BASF DocID 1998/10997), respectively. Based on this independence of vehicle (and strain) used, it can be reasonably assumed that pyraclostrobin formulated in BAS 536 02 F likewise reached the blood circulation and the highly blood perfused bone marrow.

III. CONCLUSION

Based on the result of this study BAS 536 02 F does not induce the formation of micronuclei in mouse polychromatic erythrocytes under the conditions of the study, i.e. is devoid of clastogenic or aneugenic activity in vivo.

CA 5.5 Long-Term Toxicity and Carcinogenicity

Studies evaluated in the draft monograph of Rapporteur Member State Germany of August 1, 2001:

A chronic toxicity study in rats and two carcinogenicity studies in rats and mice have been evaluated by European authorities and Germany as Rapporteur Member State and were considered to be acceptable. For the convenience of the reviewer, these studies are summarized below as extracted from the monograph. The results are summarized in Table 5.5-1.

Table 5.5-1: Summary of long-term toxicity/carcinogenicity studies conducted with pyraclostrobin

Study	Dosages (mg/kg bw/d)	NOAEL (mg/kg bw/d)	LOAEL (mg/kg bw/d)	Main adverse effect	Reference (BASF DocID)
24-month chronic toxicity Wistar rats	M: 1.1, 3.4 and 9.0 F: 1.5, 4.6 and 12.3 [0, 25, 75, 200 ppm]	3.4/4.6 m/f [75 ppm]	9.0/12.3 m/f [200 ppm]	Systemic toxicity: Reduced body weight Oncogenicity: No increase in tumour incidences	1999/11672 *2002/100511 3*[#]
24-month carcinogenicity Wistar rats	M: 1.2, 3.4 and 9.2 F: 1.5, 4.7 and 12.6 [0, 25, 75, 200 ppm]	3.4/4.7 m/f [75 ppm]	9.2/12.6 m/f [200 ppm]	Systemic toxicity: Reduced body weight, reduced food consumption (m), liver cell necrosis (m) Oncogenicity: No evidence of carcinogenictity	1999/11868 *2002/1005114* [#]
18-month carcinogenicity B6C3F1 mice	M: 1.4, 4.1 and 17.2 F: 1.6, 4.8, 20.5 and 32.8 [0, 10, 30, 120 ppm (m, f), 180 ppm (f)]	4.1/4.8 m/f [30 ppm]	17.2/20.5 m/f [120 ppm] & 32.8 f [180 ppm]	Systemic toxicity: Reduced body weight Oncogenicity: No evidence of carcinogenictity	1999/11871

[#] References (BASF DocIDs) in italic are submitted the first time in this supplemental dossier. As these report amendment do not affect the outcome and interpretation of the studies they are listed in this table.

The results of the chronic toxicity study in rats (24 months) indicated that a maximum tolerated dose was met at the high dose of 200 ppm (ca. 9.0 mg/kg bw/day for males and 12.3 mg/kg bw/day for females). This is demonstrated by a body weight gain depression in the second part of the study. No further substance related adverse effects were observed. There was no evidence of treatment related increase in neoplasms.

A carcinogenicity study in rats was conducted up to 200 ppm, which represents the maximum tolerated dose as evidenced by significant body weight gain depression in males and females, which was accompanied by reduced food consumption in males only. Furthermore, liver cell necrosis occurred in males. Nevertheless, there was no evidence of a pyraclostrobin related carcinogenic response.

A carcinogenicity study in mice was conducted up to 180 ppm for females and 120 ppm for males, which represents the maximum tolerated dose as evidenced by significant body weight gain depression. No further substance related effects were observed in this study. There was no evidence of a treatment related increase in neoplasms.

In summary, long-term feeding studies with pyraclostrobin in rats and mice demonstrated that the primary toxic treatment-related effect is body weight decrease. No evidence of a carcinogenic potential could be established.

Based on the available studies, the following endpoints were determined in the Annex I listing of pyraclostrobin.

Target/critical effect:	Reduced body weight; (rat & mouse); liver cell necrosis (rat)
Lowest relevant NOAEL	24-months, rat/mouse: 75/30 ppm (4 mg/kg bw/d)
Carcinogenicity:	No evidence of carcinogenicity

Submission of not yet per-reviewed studies in this dossier:
In this dossier amendments to the already submitted long-term studies as well as supplementary long term studies are submitted.

The amendments to the chronic and carcinogenicity studies in rats further evaluated the histopathology of mid and low dose animals previously not completely examined. These examinations were performed on request of US EPA in order to potentially detect additional histiocytic sarcoma or systemic infiltrations of these tumors. But these additional evaluations revealed no further cases of histiocytic sarcoma. The examination of the full set of preserved organs of additional, previously not completely examined low and mid dose male rats revealed a low incidence of additional neoplastic and non-neoplastic lesions. These additional findings did not affect the original interpretation of the rat chronic and carcinogenicity studies.

The supplementary studies using higher dose levels were mostly conducted in parallel to the main long-term feedings studies. An exception is one carcinogenicity study in female B6C3F1 mice, which was performed on request of US EPA in 2004/2005. In essence, all studies confirmed that the main studies were dosed up to the Maximum Tolerated Dose (MTD). Accordingly, the studies were terminated pre-term and the examination and reporting was restricted to in-life parameters (clinical observations, body weight and food consumption, if appropriate clinical biochemistry investigations). No histopathological examinations were performed.

Thus, the conclusion for relevant endpoints for the current re-registration remains as follows:

Target/critical effect	Reduced body weight (rat & mouse); liver cell necrosis (rats) No classification required
Lowest relevant NOAEL / NOEL	24-months, rat/mouse: 75/30 ppm (4 mg/kg bw/d)
Carcinogenicity	No evidence for carcinogenicity No classification required

Note: The rat chronic toxicity and carcinogenicity study reports (CA 5.5/1 and CA 5.5/3) were already submitted and reviewed in the course of the initial registration of pyraclostrobin. These studies are submitted for completeness as the basis for the assessment of report amendments submitted under CA 5.5/2 and CA 5.5/4. Both amendments provide the results of additional histopathological evaluations on the low and mid dose animals to specifically determine the incidence of histiocytic sarcomas. In addition, all tumors as well as any significant non-neoplastic findings observed in the intermediate dose groups were recorded. Taking into account that the majority of the data were already reviewed, the following study summary will be more comprehensive than for other studies already reviewed, but will be less detailed than the summary of new studies.

Report:	CA 5.5/1 [redacted] 1999d BAS 500 F - Chronic toxicity study in Wistar rats. Administration in the diet for 24 months 1999/11672
Guidelines:	EEC 87/302, OECD 452, EPA 83-1, JMAFF
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Report:	CA 5.5/2 [redacted] 2002a Amendment No. 1 to the report: BAS 500 F - Chronic toxicity study in Wistar rats. Administration in the diet for 24 months 2002/1005113
Guidelines:	EEC 87/302, OECD 452, EPA 83-1, JMAFF
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Material and Methods:
Pyraclostrobin was administered to groups of 20 male and 20 female Wistar rats at dietary concentrations of 0, 25, 75 and 200 ppm for 24 months. Food consumption and body weight were determined once a week during the first 13 weeks, thereafter at 4-week intervals. The animals were examined for signs of toxicity or mortality at least once a day; moreover, comprehensive clinical examinations and palpations of the animals were performed once a week. Ophthalmological examinations were carried out prior to the start and towards the end of dosing. Urinalysis, clinico-chemical and hematological examinations were carried out 3, 6, 12, 18 and 24 months after start of the administration period. The animals were subjected to gross pathological assessment, followed by histopathological examinations.

Findings:
The stability of the test substance itself and the homogeneous distribution, stability and correct concentration of the test substance in the diet were confirmed by analysis.

There was no test substance related increase in mortality or clinical signs of toxicity in this study. No relevant effects on food consumption were observed at any dose level (see Table 5.5-2). In females, there were isolated statistically significant deviations (increased or decreased values) in all dose groups. Due to the isolated occurrence and the lack of a dose-response relationship, these deviations were assessed as being incidental and not related to treatment.

§ Calculated from the weekly means- Time weighted average.

In both sexes, the terminal body weight was somewhat lower than in the control group. During the course of the study, the maximum differences between the control and the high dose group achieved values of 10% (males) and 9% (females). Body weight gain was also reduced in top dose males and females, mainly in the second part of the study. Maximum differences in body weight change between the control and high dose group achieved 11% (males) or 14% (females). However, statistical significance (ANOVA and Dunnett´s test) was reached in males only occasionally (i.e. on study days 7 and 539) and in females only on study day 483 (see Figure 5.5-1and Table 5.5-2).

Clinico-chemical investigations demonstrated, at the high dose level only, a statistically significant decrease in alkaline phosphatase activity in both sexes, and alanine aminotransferase activity in the males (see Table 5.5-3). The slight, but not statistically significant decrease in protein and globulin values in high dose males mentioned in the DAR was marginal. In addition, some statistically significant differences of clinical chemistry parameters were noted. These were not dose dependent and/or not consistent over time and thus not considered to be related to treatment.

# Values may be not calculated exactly due to rounding of figures

The pathological investigations did not demonstrate any test substance related adverse effect. A slight, not statistically significant increase of absolute and relative testis weights, and kidney weights in females at 200 ppm were regarded as toxicologically not significant (see Table 5.5-4). The increase of relative kidney weights was due to female #553, which displayed a mass of 18 mm diameter at the kidney, which later was identified as a metastasis of an uterus adeno-carcinoma.
In males, there were higher, but not dose-related incidences of tubular degeneration (1/7/7/6) and tubular mineralization (1/4/6/4) in the testes of all treated groups. However, these findings were often associated with tubular atrophy (9/5/5/6) and Leydig cell tumours (9/12/11/8), and they are hence not regarded as treatment-related findings, but being secondary events to atrophy and/or Leydig cell tumours.

There were no test substance related effects at dietary dose levels of 75 and 25 ppm.

By request of the US EPA, detailed histopathological evaluations of all male animals of the low and mid dose groups, which were killed scheduled at study termination and which exhibited no gross lesions in any of the organs with lymphoma infiltrates during necropsy, were performed specifically to determine the incidence of occult histiocytic sarcomas. This request was based on an apparent increase of histiocytic sarcoma of the hemolymphoreticular system in high dose males of the carcinogenicity study (see BASF DocID 1999/11868). In addition, all neoplastic and non-neoplastic findings in previously not histopathologically investigated organs of intermediate dose level males were recorded. The results of this additional analysis are presented in the Report Amendment No. 1.

The pathological investigations to determine histiocytic sarcomas revealed no additional malignant systemic tumors related to pyraclostrobin treatment in any group. Likewise, no 'sarcoma infiltrates' indicating the presence of a histiocytic sarcoma were observed in any organ investigated. The detailed histopathological evaluation of male animals of the low and mid dose groups identified only a marginal amount of additional neoplastic findings (see Table 5.5-5) which either displayed no dose-response relationship (e.g. mesenteric lymph node hemangioma in mid dose males) or were observed in comparable incidences in all groups. Thus these neoplasms were considered to be of incidental nature. Likewise, the total incidence of neoplastic findings was not altered in a way indicative for a treatment-related effect on carcinogenicity (see Table 5.5-6).

Conclusion:

The no observed adverse effect level (NOAEL) in this 24-month chronic toxicity study in rats was 75 ppm (3.4 mg/kg bw/d in males and 4.6 mg/kg bw/d in females), based on a slight decrease in body weight at 200 ppm. There was no indication of a carcinogenic potential in rats.

Report:	CA 5.5/3 [redacted] 1999e BAS 500 F - Carcinogenicity study in Wistar rats. Administration in the diet for 24 months 1999/11868
Guidelines:	EEC 87/302, OECD 451, EPA 83-2, JMAFF
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Report:	CA 5.5/4 [redacted] 2002b Amendment No. 1 to the report: BAS 500 F - Carcinogenicity study in Wistar rats. Administration in the diet for 24 months 2002/1005114
Guidelines:	EEC 87/302, OECD 451, EPA 83-2, JMAFF
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Material and Methods:
Pyraclostrobin was administered to groups of 50 male and 50 female Wistar rats at dietary concentrations of 0, 25, 75 and 200 ppm for 24 months. Food consumption and body weight were determined once a week during the first 13 weeks, thereafter at 4-week intervals. The animals were examined for signs of toxicity or mortality at least once a day; moreover, comprehensive clinical examinations and palpations of the animals were performed once a week. Differential blood counts were determined for all surviving animals at the end of the study and also from all animals sacrificed moribund during the study. After about 24 months, the animals were subjected to gross-pathological assessment, followed by histopathological examinations.

Statistical analysis of the results was based on the Dunnett's test (two-sided), the F-test (ANOVA, two-sided), the Kruskal-Wallis test (two-sided) and the Wilcoxon test.

Findings:
The stability of the test substance itself and the homogeneous distribution, stability and correct concentration of the test substance in the diet were confirmed by analysis.

There was no test substance related increase in mortality or clinical signs of toxicity in this study.

Impaired body weight development was observed in male and female rats at 200 ppm (see Figure 5.5-2). Body weights were significantly decreased in males from day 7 throughout day 567 and in females from study day 147 onwards. Decreases of cumulative body weight gain approached 10% in males and 22% in females (see Table 5.5-7).

Values may not calculate exactly due to rounding of mean values
§ Calculated from the weekly means (time weighted).

Statistically significant reductions of food consumption were frequently observed in males during the first three month of treatment (see Table 5.5-7). Additionally, isolated cases of statistically significant altered food consumption were observed in all treated groups, which due to their sporadic occurrence were considered to be incidental.

Relative kidney weights were increased in males at 200 ppm and in females at the high (200 ppm) and the mid (75 ppm) dose level (see Table 5.5-8). Restricted to the high dose group, histopathological investigation of the kidneys revealed higher incidences of tubular casts and tubular atrophy in males and tubular atrophy in females. However, these findings show high spontaneous incidences. Additionally, lower incidences in kidney findings were observed, concerning pyelitis and chronic nephropathy in high dose males.

Absolute liver weights were decreased in females at the high dose level. Histopathological investigations revealed an increased incidence of liver cell necrosis (1/2/2/10) in males. Furthermore, at 200 ppm, lower incidences of adrenal cortex hyperplasia in males (37/34/31/19) and ovarial pigment deposition in females (33/26/32/17) were noted.

Based on an apparent increase of histiocytic sarcoma of the hemolymphoreticular system observed in high dose males, US EPA requested detailed histopathological evaluations of all male animals of the low and mid dose groups to determine the significance of these tumors. In addition, all neoplastic and non-neoplastic findings in previously not histopathologically investigated organs of intermediate dose level males were recorded. The results of this additional analysis are presented in the Report Amendment No. 1.

The pathological investigations to determine histiocytic sarcomas revealed no additional malignant systemic tumors related to BAS 500 F treatment in any group. The detailed histopathological evaluation of intermediate dose males identified a low incidence of additional neoplastic findings (see Table 5.5-9) which did not affect the overall tumor incidence (see Table 5.5-10).

[a] Values in brackets indicate incidences of the histopathological investigation of the main report if different from those in the report amendment.

Overall, there were no test substance related effects at 75 and 25 ppm. Likewise, there was no evidence of a carcinogenic response at any dose level.

Conclusion:

The no observed adverse effect level (NOAEL) in this 24-month carcinogenicity study in rats was 75 ppm (3.4 mg/kg bw/d for males and 4.7 mg/kg bw/d for females), based on decreased body weights in both sexes and increased incidence of liver cell necrosis in males at 200 ppm. There was no indication of carcinogenic potential in rats.

In the following the supplementary chronic toxicity and carcinogenicity studies in rats conducted in parallel to the main studies are summarized. These studies were previously not submitted.

Report:	CA 5.5/5 [redacted] 2002c BAS 500 F - First supplementary chronic toxicity study in Wistar rats - Administration in the diet for 24 months 2002/1004125
Guidelines:	EEC 87/302 B, OECD 452, EPA 83-1, JMAFF
GLP:	yes (partially) (during the in-life phase up to the pre-term termination regular QAU audits were performed for this GLP study. However, the report was not QAU audited and thus the study has no full GLP status)

Executive Summary

This supplementary study was conducted in parallel to the chronic feeding study in male and female Wistar rats (see BASF DocID 1999/11672). BAS 500 F (pyraclostrobin) was administered to groups of 20 male and 20 female Wistar rats at dietary concentrations of 0 and 400 ppm. Since in the main study the maximum tolerated dose (MTD) was obtained at 200 ppm, the study was terminated after 405 study days without any further examinations. During the study period no animal died. A number of clinical chemistry parameters were altered, several of them were similar to effects already seen in the shorter-term studies at higher dose levels. Due to pre-term termination of the study, no organs were preserved.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 F

Description:	viscous melt / reddish-brown, clear
Lot/Batch #:	J. No. 27882/191/c (Tox. III/part 1)
Purity:	97.09%
Stability of test compound:	Stable until May 1997 (The same batch of test material was used in the main study (see BASF DocID 1999/11672). This material was reanalyzed after end of the in-life phase of the latter study and found to be stable.)

2. Vehicle and/or positive control: Rodent diet

3. Test animals:

Species:	Rat
Strain:	Wistar, Chbb:THOM (SPF)
Sex:	Male and female
Age:	42 days
Weight at dosing:	mean males: ca. 194 g; mean females: ca. 146 g
Source:	Dr. Karl Thomae GmbH, Biberach a. d. Riss, Germany
Acclimation period:	9 days
Diet:	Kliba maintenance diet rat-mouse-hamster 343 meal, Klingentalmühle AG, Kaiseraugst, Switzerland, ad libitum
Water:	Drinking water, ad libitum
Housing:	Group housing (1 animals/cage) housed in wire cages, type DK-III, Becker & Co. (Castrop-Rauxel, Germany)
Environmental conditions:	
Temperature:	20 - 24°C (central air-conditioning)
Humidity:	30 - 70% (central air-conditioning)
Air changes:	not reported
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN

1. Dates of experimental work: 24-Feb-1997 to 14-Apr-1998
(Inlife dates: 5-Mar-1997 (start of administration) - 14-Apr-1998 (necropsy of last female animals)

2. Animal assignment and treatment:
BAS 500 F was administered to groups of 20 male and 20 female Wistar rats at dietary concentrations of 0 and 400 ppm for 405 days. The animals were assigned to the treatment groups by means of a computer generated randomization list based on body weights. At day 405 all animals were sacrificed without any further examination.

3. Test substance preparation and analysis:
The containers of test substance required for the feed mixtures in each case were cooled to approx. -20°C in the freezer so that they can be treated mechanically. Subsequently, the test substance was comminuted mechanically and stored at -20°C, unlike the usual storage conditions, to prevent it from becoming conglutinated again. For preparation of the feed mixes an acetone solution was prepared with the weighed test substance in the specific concentration. This solution was sprayed onto approx. 3.0 kg feed in a rotary evaporator (Büchi, Rotapor R 153) under partial vacuum. Subsequently, the solvent was removed under suction while heating to approx. 40°C for at least 30 minutes. Then, the premix was adjusted to the concentration desired with the appropriate amount of feed and mixed in a laboratory mixer of GEBR. LÖDIGE for approx. 10 minutes. The preparation frequencies were selected to ensure the stability of the test substance concentrations in the diet.

The stability of the test substance in the diet over 43 days at room temperature was verified analytically in the study 08B0376/956006 (analytical report (Amendment No. 1) of Jul. 5, 1996). Analyses to detect the homogeneous test substance distribution in the diet were carried out in samples of the parallel carcinogenicity studies (8250494/96086 (see BASF DocID 1999/11672) and 8250494/96096 (see BASF DocID 2002/1004124). For the concentration control analysis of the test substance preparations, samples were sent to the analytical laboratory at the beginning of the study, then at approx. 3-month intervals and approx. 4 weeks before the end of the study.

4. Statistics:

Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to following tables:

Statistics of clinical examinations

Parameter	Statistical test
food consumption, body weight, body weight change, food efficiency	Student's t-test (two-sided) for the hypothesis of equal means

Statistics of clinical chemistry

Parameter	Statistical test
hematological examinations	Mann-Whitney u-test (two-sided)
urinalysis	Fisher's exact test (one- and two-sided)

C. METHODS

1. Observations:

The animals were examined for morbidity or mortality once daily.
A general cage side observation of the animals with regard to their outer appearance and behavior was carried out at least once daily. In addition to the general daily observation, each animal was subjected to an exact clinical check (including palpation).

2. Body weight:

The body weight of the animals was determined once weekly up to the 13th week of administration, then at 4-week intervals.

3. Food consumption, food efficiency and compound intake:

Food consumption was determined weekly during the first 13 weeks of administration, thereafter at 4-week intervals.
Even though not mentioned in report it is assumed that the food efficiency and substance intake was calculated as in the main study (see BASF DocID 1999/11672).
Food efficiency was calculated based upon individual values for body weight and food consumption:

$$Food\ efficiency\ at\ day\ x = \frac{BW_x - BW_y}{FC_{y\ to\ x}} x\,100$$

with BW_x and BW_y body weight (g) on day x and day y (last weighing date before day x), $FC_{y\ to\ x}$ as the mean food consumption (in g) from day y to day x, calculated as mean daily food consumption on day x multiplied with the number of days from day y to day x.

The mean daily intake of test substance (group means) was calculated based upon individual values for body weight and food consumption.

$$Substance\ intake\ for\ day\ x = \frac{FC_x \times C}{BW_x}$$

with FC_x as the mean daily food consumption (in g/day) on day x, C as the concentration in food on day x (mg/kg = ppm) and BW_x as body weight on day x of the study (g).

4. Water consumption:

No water consumption values were recorded.

5. Ophthalmoscopy:

On day 13 after the beginning of administration period, the eyes of all animals were examined with an ophthalmoscope (HEINE OPTOTECHNIK HERRSCHING, Germany) after administration of a mydriatic (Pharma Stulln). The ophthalmoscopy planned to be performed in all animals before the beginning of administration was inadvertently not carried out until day 13 of the study. The shift of the date has no adverse effect on the results of the study as the eye findings of the animals did not show any abnormalities on day 13.

6. Hematology and clinical chemistry:

Blood was taken in the morning from non-fasted animals from the retro-orbital venous plexus. The blood sampling procedure and the subsequent analysis of the blood and serum samples were carried out in a randomized sequence.
The following hematological and clinical chemistry parameters were determined after 3, 6 and 12 months of the administration period:

Hematology:					
	Red blood cells		*White blood cells*		*Clotting Potential*
✓	Erythrocyte count (RBC)	✓	Total leukocyte count (WBC)	✓	Prothrombin time (Hepato Quick's test – HQT)
✓	Hemoglobin (HGB)	✓	Neutrophils (differential)		
✓	Hematocrit (HCT)	✓	Eosinophils (differential)		
✓	Mean corp. volume (MCV)	✓	Basophils (differential)		
✓	Mean corp. hemoglobin (MCH)	✓	Lymphocytes (differential)		
✓	Mean corp. Hb. conc. (MCHC)	✓	Monocytes (differential)		
✓	Platelets (PLT)				
✓	Reticulocytes	✓	Large unstained cells		

Clinical chemistry:					
	Electrolytes		*Metabolites and Proteins*		*Enzymes:*
✓	Calcium	✓	Albumin	✓	Alanine aminotransferase (ALT)
✓	Chloride	✓	Bilirubin (total)	✓	Aspartate aminotransferase (AST)
✓	Magnesium	✓	Cholesterol	✓	Alkaline phosphatase (ALP)
✓	Phosphorus (inorganic)	✓	Creatinine	✓	γ-glutamyl transferase (SGGT)
✓	Potassium	✓	Globulin	✓	Serum Cholinesterase (SCHE)
✓	Sodium	✓	Glucose		
		✓	Protein (total)		
		✓	Triglycerides		
		✓	Urea		

7. Urinalysis:

For urinalysis the individual animals were transferred to metabolism cages and urine was collected overnight. No food or water was supplied during urine collection. The samples were analyzed in a randomized order.
The following parameters were determined after 3, 6 and 12 months of the administration period:

Urinalysis					
	Quantitative parameters:		*Semiquantitative parameters*		
✓	Urine volume	✓	Bilirubin	✓	Protein
✓	Specific gravity	✓	Blood	✓	pH-value
		✓	Color and turbidity	✓	Urobilinogen
		✓	Glucose	✓	Sediment (microscopical exam.)
		✓	Ketones		

8. Sacrifice and pathology:

No gross or histopathological examinations were performed as the study was terminated pre-term on study day 405.

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

1. Clinical signs of toxicity

No treatment related clinical signs of toxicity were observed in treated rats (see Table 5.5-12). All clinical observations were either observed in single animals only or displayed no dose-response relationship. Thus, they were not considered to be related to treatment.

Table 5.5-12: Clinical observations in rats administered pyraclostrobin for about 405 days – First supplemental chronic toxicity study

Sex	Male		Female	
Dose [ppm]	0	400	0	400
Animals in group	20	20	20	20
Hindlimb(s) swelling	2	0	-	-
Eyelid, crusts	1	0	0	1
Cataract	2	0	-	-
Vagina, discharge, red	-	-	0	1
Skin, palpable mass	-	-	0	1
Anogenital region smeared, red	-	-	0	1
Abdomen, palpable mass	-	-	0	1
paleness	-	-	0	1
Feces, discolored	-	-	0	1

2. Mortality

No mortality was observed during the study period.

3. Ophthalmoscopy

No treatment-related ophthalmoscopical findings were noted.

B. BODY WEIGHT AND BODY WEIGHT GAIN

Body weight development was impaired in dosed males as indicated by statistically significant lower body weights from study day 7 onwards. Body weight development of females was impaired when administered test substance as indicated by statistically significant lower body weights from study day 21 onwards (see Table 5.5-13 and Figure 5.5-3). Cumulative body weight gain was significantly lower throughout the major part of the study for males and females and was decreased by 18.4% in males and 21.4% in females at study day 399.

Figure 5.5-3: Body weight development of rats administered pyraclostrobin for 405 days –First supplemental chronic toxicity study

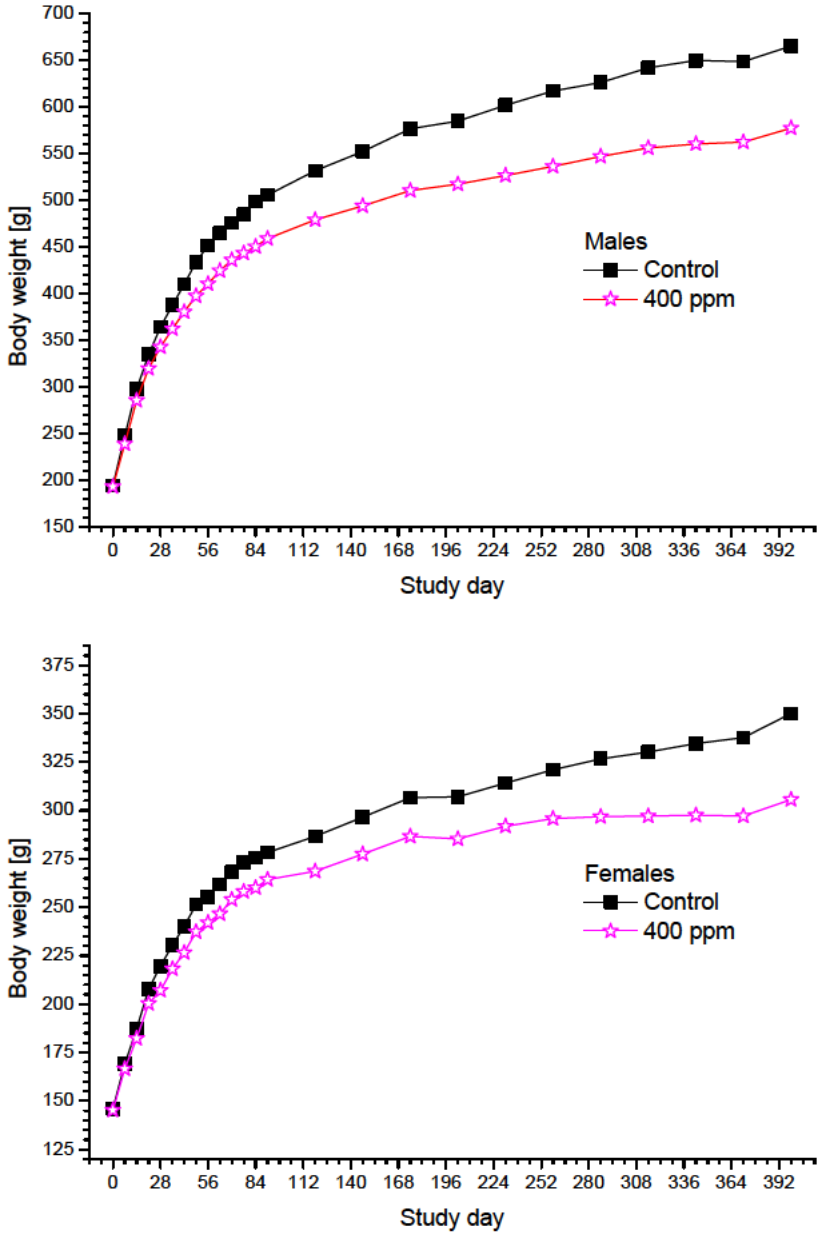

Table 5.5-13: Mean body weight of rats administered pyraclostrobin for 405 days – First supplemental chronic toxicity study

* $p \leq 0.05$; ** $p \leq 0.01$; *** $p \leq 0.001$ (Student's t-test. two sided)

C. FOOD AND COMPOUND INTAKE

For treated males and females lower mean daily food intakes were observed frequently throughout the study period (see Figure 5.5-4 and ,Table 5.5-14). This was statistically significant in males and females at 19/24 and 15/24 determinations, respectively.

Figure 5.5-4: Mean daily food intake of rats administered pyraclostrobin for 405 days – First supplemental chronic toxicity study

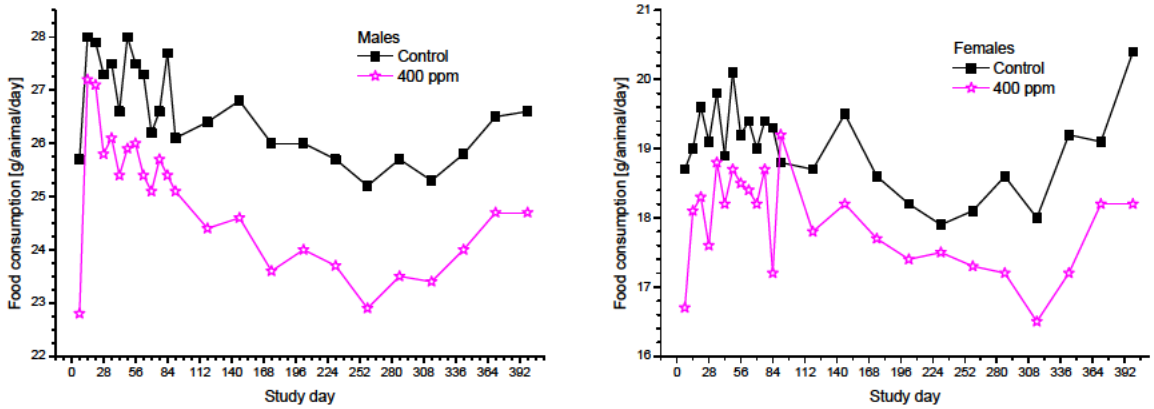

Table 5.5-14: Average daily food consumption of rats administered pyraclostrobin for 405 days – First supplemental chronic toxicity study

	Males		Females	
Dose level [ppm]	0	400	0	400
Average daily food consumption [g/animal]				
Day 0 to 90#	27.1	25.6	19.3	18.2
Δ% (compared to control)		-5.5		-5.5
Day 0 to 399[a]	26.3	24.3	18.9	17.7
Δ% (compared to control)#		-7.3		-6.1

Values were calculated based on weekly means. Values may not calculate exactly due to rounding of mean values

[a] Time weighted average

The time weighted mean daily test substance intake was calculated to have been 20.3 and 26.1 mg/kg bw/day in males and females, respectively.

D. BLOOD ANALYSIS

1. Hematological findings

A number of statistically significant differences to controls were observed. Most of these changes were not seen to all time points and were of marginal degree and thus were considered to be of incidental nature. These included increased MCV, WBC and prothrombin time and decreased MCHC values in females. In males only an increased prothrombin time was observed on day 187 (see Table 5.5-15).

Table 5.5-15: Selected hematology findings in rats administered pyraclostrobin for 405 days – first supplemental chronic toxicity study

	Study day	MCV [fL]	MCHC [mmol/L]	WBC [giga/L]	HQT [sec.]

* $p \leq 0.05$; ** $p \leq 0.02$; *** $p \leq 0.002$ (Mann-Whitney u-test, two sided)

2. Clinical chemistry findings

A number of statistically significant and treatment-related clinical chemistry findings were observed (see Table 5.5-16). Some of the changes were similar to those seen in the 28-day and 90-day studies (e.g. decreased ALT, AL(A)T, serum cholinesterase, cholesterol, glucose) and may be related to the impaired nutritional state of the animals.

Table 5.5-16: Selected clinical chemistry findings in rats administered pyraclostrobin for 405 days (group means) – First supplemental chronic toxicity study

3. Urinalysis

No treatment related changes of urinary parameters were observed.

III. CONCLUSIONS

Dietary administration of pyraclostrobin to rats at dietary dose levels of 0 and 400 ppm for 405 days resulted in an impairment of body weight development in males and females fed with 400 ppm test substance.
Treatment with pyraclostrobin did not affect the survival of rats. A number of treatment-related clinical chemistry parameters were altered, similar to those observed in shorter-term studies. As the study was terminated pre-term after a MTD was obtained in the main study no histological examination of the animals was performed.

Report:	CA 5.5/6 [redacted] 2002d BAS 500 F - Second supplementary chronic toxicity study in female Wistar rats - Administration in the diet for 24 months 2002/1004126
Guidelines:	EEC 87/302 B, OECD 452, EPA 83-1, JMAFF
GLP:	yes (partially) (during the in-life phase up to the pre-term termination regular QAU audits were performed for this GLP study. However, the report was not QAU audited and thus the study has no full GLP status)

Executive Summary

This 2nd supplementary study was conducted in parallel to the chronic feeding study female Wistar rats (see BASF DocID 1999/11672). BAS 500 F (pyraclostrobin) was administered to groups of 20 female Wistar rats at dietary concentration of 600 ppm. Control animal data were taken from the parallel conducted main study (see BASF DocID 1999/11672). Since in the main study the maximum tolerated dose (MTD) was obtained at 200 ppm, the study was terminated after 433 study days without any further examinations.
Treatment neither affected the survival of rats nor elicited clinical signs. Treatment–related changes of leukocyte counts were observed throughout the study. Even though other hematology parameters were changed in a way consistent to the changes seen in short-term studies at higher concentrations, these changes were either not consistent over time or – despite of their statistical significance – of marginal degree. Thus their toxicological significance remains unclear. Conversely, a number of clinical chemistry changes were consistent with previous studies and probably treatment-related.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 F

Description:	viscous melt / reddish-brown, clear
Lot/Batch #:	J. No. 27882/191/c (Tox. III/part 1)
Purity:	97.09%
Stability of test compound:	Stable until May 1997. (The same batch of test material was used in the main study (see BASF DocID 1999/11672). This material was reanalyzed after end of the in-life phase of the latter study and found to be stable.)

2. Vehicle and/or positive control: Rodent diet

3. Test animals:

Species:	Rat
Strain:	Wistar, Chbb:THOM (SPF)
Sex:	Female
Age:	42 days ± 1 day
Weight at dosing:	mean females: ca. 144 g
Source:	Dr. Karl Thomae GmbH, Biberach a. d. Riss, Germany
Acclimation period:	9 days
Diet:	Kliba maintenance diet rat-mouse-hamster 343 meal, Klingentalmühle AG, Kaiseraugst, Switzerland, ad libitum
Water:	Drinking water, ad libitum
Housing:	Group housing (1 animals/cage) housed in wire cages, type DK-III, Becker & Co. (Castrop-Rauxel, Germany)
Environmental conditions:	
Temperature:	20 - 24°C (central air-conditioning)
Humidity:	30 - 70% (central air-conditioning)
Air changes:	not reported
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN

1. Dates of experimental work: 10-Feb-1997 to 14-Apr-1998
Inlife dates: 19-Feb-1997 (start of administration) to 14-Apr-1998 (sacrifice of animals)

2. Animal assignment and treatment:
BAS 500 F was administered to a group of 20 female Wistar rats at dietary concentration 600 ppm for 433 days. The animals were assigned to the treatment groups by means of a computer generated randomization list based on body weights. At day 433 all animals were sacrificed without any further examination. The data of control animals were taken from the parallel conducted main study (see BASF DocID 1999/11672).

3. Test substance preparation and analysis:
The containers of test substance required for the feed mixtures in each case were cooled to approx. -20°C in the freezer so that they can be treated mechanically. Subsequently, the test substance was comminuted mechanically and stored at -20°C, unlike the usual storage conditions, to prevent it from becoming conglutinated again. For preparation of the feed mixes an acetone solution was prepared with the weighed test substance in the specific concentration. This solution was sprayed onto approx. 3.0 kg feed in a rotary evaporator (Büchi, Rotapor R 153) under partial vacuum. Subsequently, the solvent was removed under suction while heating to approx. 40°C for at least 30 minutes. Then, the premix was adjusted to the concentration desired with the appropriate amount of feed and mixed in a laboratory mixer of GEBR. LÖDIGE for approx. 10 minutes. The preparation frequencies were selected to ensure the stability of the test substance concentrations in the diet.

The stability of the test substance in the diet over 43 days at room temperature was verified analytically in the study 08B0376/956006 (analytical report (Amendment No. 1) of Jul. 5, 1996). Analyses to detect the homogeneous test substance distribution in the diet were carried out in samples of the parallel carcinogenicity studies (8250494/96086 (see BASF DocID 1999/11672) and 8250494/96096 (see BASF DocID 2002/1004124). For the concentration control analysis of the test substance preparations, samples were sent to the analytical laboratory at the beginning of the study, then at approx. 3-month intervals and approx. 4 weeks before the end of the study.

4. Statistics:
Means and standard deviations of each test group were calculated for several parameters. The data of control animals were taken from the parallel study (see BASF DocID 2002/1004125). Further statistical analyses were performed according to following tables:

Statistics of clinical examinations

Parameter	Statistical test
food consumption, body weight, body weight change, food efficiency	Student's t-test (two-sided) for the hypothesis of equal means

Statistics of clinical chemistry

Parameter	Statistical test
hematological examinations	Wilcoxon test (two-sided)
Urinalysis	Fisher's exact test (one- and two-sided)

C. METHODS

1. Observations:

The animals were examined for morbidity or mortality once daily. A general cage side observation of the animals with regard to their outer appearance and behavior was carried out at least once daily. In addition to the general daily observation, each animal was subjected to an exact clinical check (including palpation).

2. Body weight:

The body weight of the animals was determined once weekly up to the 13th week of administration, then at 4-week intervals.

3. Food consumption, food efficiency and compound intake:

Food consumption was determined weekly during the first 13 weeks of administration, thereafter at 4-week intervals.
Even though not mentioned in report it is assumed that the food efficiency and substance intake was calculated as in the main study (see BASF DocID 1999/11672). Food efficiency was calculated based upon individual values for body weight and food consumption:

$$\text{Food efficiency at day x} = \frac{BW_x - BW_y}{FC_{y\ to\ x}} \text{ x } 100$$

with BW_x and BW_y body weight (g) on day x and day y (last weighing date before day x), $FC_{y\ to\ x}$ as the mean food consumption (in g) from day y to day x, calculated as mean daily food consumption on day x multiplied with the number of days from day y to day x.

The mean daily intake of test substance (group means) was calculated based upon individual values for body weight and food consumption.

$$\text{Substance intake for day x} = \frac{FC_x \times C}{BW_x}$$

with FC_x as the mean daily food consumption (in g/day) on day x, C as the concentration in food on day x (mg/kg = ppm) and BW_x as body weight on day x of the study (g).

4. Water consumption:

No water consumption values were recorded.

5. Ophthalmoscopy:

Before the beginning of administration period, the eyes of all animals were examined with an ophthalmoscope after administration of a mydriatic (Pharma Stulln).

6. Hematology and clinical chemistry:

Blood was taken in the morning from non-fasted animals from the retro-orbital venous plexus. The blood sampling procedure and the subsequent analysis of the blood and serum samples were carried out in a randomized sequence.
The following hematological and clinical chemistry parameters were determined after 3, 6 and 12 months of the administration period:

Hematology:					
	Red blood cells		*White blood cells*		*Clotting Potential*
✓	Erythrocyte count (RBC)	✓	Total leukocyte count (WBC)	✓	Prothrombin time (HQT)
✓	Hemoglobin (HGB)	✓	Neutrophils (differential)		
✓	Hematocrit (HCT)	✓	Eosinophils (differential)		
✓	Mean corp. volume (MCV)	✓	Basophils (differential)		
✓	Mean corp. hemoglobin (MCH)	✓	Lymphocytes (differential)		
✓	Mean corp. Hb. conc. (MCHC)	✓	Large unstained cells		
✓	Platelets (PLT)	✓	Monocytes (differential)		
✓	Reticulocytes				
Clinical chemistry:					
	Electrolytes		*Metabolites and Proteins*		*Enzymes:*
✓	Calcium	✓	Albumin	✓	Alanine aminotransferase (ALT)
✓	Chloride	✓	Bilirubin (total)	✓	Aspartate aminotransferase (AST)
✓	Magnesium	✓	Cholesterol	✓	Alkaline phosphatase (ALP)
✓	Phosphorus (inorganic)	✓	Creatinine	✓	γ-glutamyl transferase (SGGT)
✓	Potassium	✓	Globulin	✓	Serum Cholinesterase (SCHE)
✓	Sodium	✓	Glucose		
		✓	Protein (total)		
		✓	Triglycerides		
		✓	Urea		

7. Urinalysis:

For urinalysis the individual animals were transferred to metabolism cages and urine was collected overnight. No food or water was supplied during urine collection. The samples were analyzed in a randomized order.
The following parameters were determined after 3, 6 and 12 months of the administration period:

Urinalysis					
	Quantitative parameters:		*Semiquantitative parameters*		
✓	Urine volume	✓	Bilirubin	✓	Protein
✓	Specific gravity	✓	Blood	✓	pH-value
		✓	Color and turbidity	✓	Urobilinogen
		✓	Glucose	✓	Sediment (microscopical exam.)
		✓	Ketones		

8. Sacrifice and pathology:

No pathology was done since the study was terminated on day 433.

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

1. Clinical signs of toxicity

No treatment related clinical signs of toxicity were observed in treated rats.

2. Mortality

No mortality was observed during the study period.

3. Ophthalmoscopy

No data given in the report concerning ophthalmoscopy.

B. BODY WEIGHT AND BODY WEIGHT GAIN

Body weight development was impaired in dosed females as indicated by statistically significant lower body weights from day 28, 56, 77, 84 and 147 onwards (see Figure 5.5-5 and Table 5.5-17).
Cumulative body weight gain was significantly lower throughout the major part of the study for females.

Figure 5.5-5: Body weight development of female rats administered pyraclostrobin for 433 days – Second supplemental chronic toxicity study

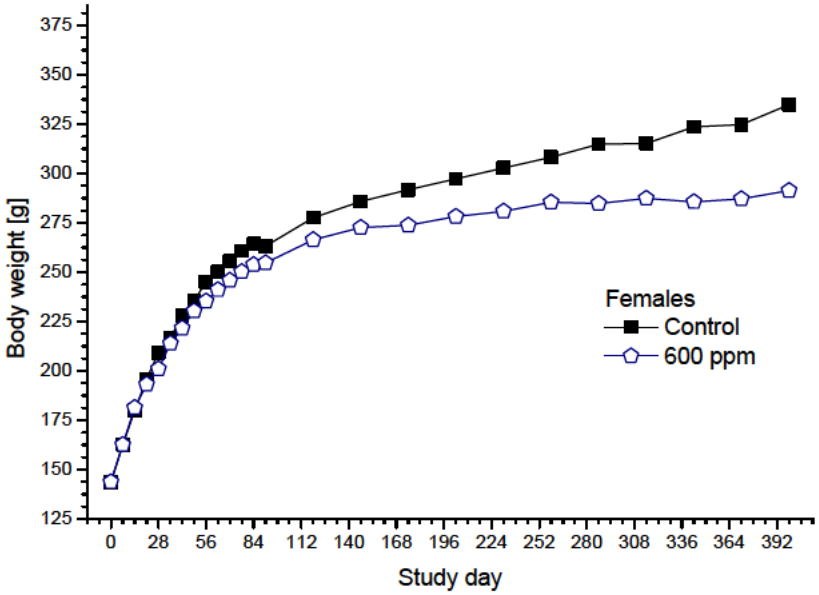

Table 5.5-17: Mean body weight of female rats administered pyraclostrobin for 433 days- Second supplemental chronic toxicity study

	Females	
Dose level [ppm]	0	600
Body weight [g]		
- Day 0	143.6 ± 5.4	143.8 ± 4.8
- Day 91	263.2 ± 19.1	254.7 ± 12.7
Δ% (compared to control)		-3.2
- Day 231	302.8 ± 26.2	**280.8 ± 15.5****
Δ% (compared to control)		**-7.3**
- Day 399	344.9 ± 31.4	**291.3 ± 14.9****
Δ% (compared to control)		**-13.0**
Overall body weight gain [g]		
- Day 91	119.6 ± 16.7	110.9 ± 10.9
Δ% (compared to control)		-7.3
- Day 231	159.1 ± 23.5	**137.0 ± 12.9****
Δ% (compared to control)		**-13.9**
- Day 399	191.3 ± 30.7	**147.5 ± 13.0****
Δ% (compared to control)		**-22.9**

* $p \leq 0.05$; ** $p \leq 0.01$ (Student's t-test. two sided)

C. FOOD & WATER CONSUMPTION AND COMPOUND INTAKE

For treated females statistically lower mean daily food intakes were observed frequently throughout the study period (see Figure 5.5-6 and Table 5.5-18). This was statistically significant at 12/24 determinations.

Figure 5.5-6: Food consumption of female rats administered pyraclostrobin for 433 days – Second supplemental chronic toxicity study

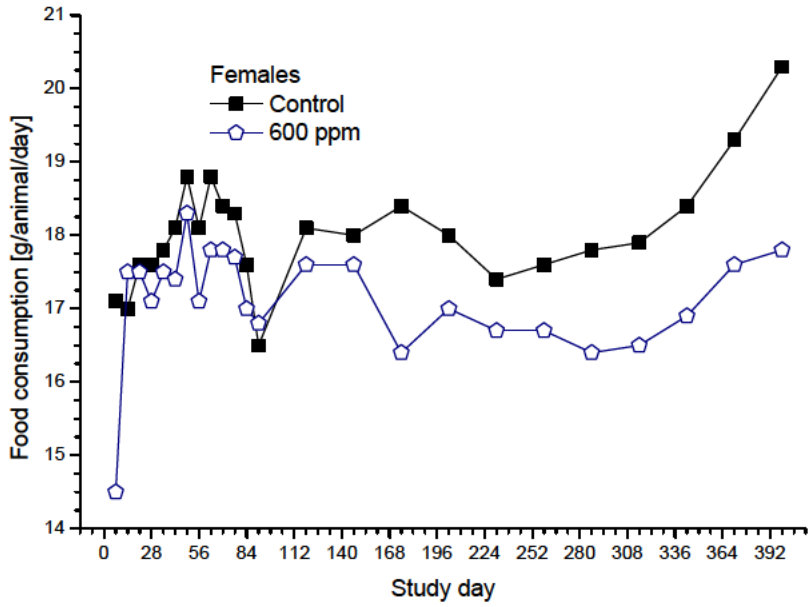

Table 5.5-18: Food consumption of rats administered pyraclostrobin for 433 days – Second supplemental chronic toxicity study

	Females	
Dose level [ppm]	0	600
Mean food consumption [g/animal]		
Day 0 to 90#	17.82	17.23
Δ% (compared to control)#		-3.3
Day 0 to 399	18.18	17.07
Δ% (compared to control)#		-6.1

Values were calculated based on mean individual daily food. Values may not calculate exactly due to rounding of mean values

The mean daily test substance intake was calculated to be 38.8 mg/kg bw/day in females at a dietary dose level of 600 ppm.

D. BLOOD ANALYSIS

* $p \leq 0.05$; ** $p \leq 0.01$ (Wilcoxon-test. two sided)

The increased leucocytes counts (WBC) at all time-points are considered to be treatment-related (see Table 5.5-19). These are consistent with the changes seen in the 1st supplemental study (see BASF DocID 2002/1004125) and the 90-day study in rats at higher dose levels (see BASF DocID 1999/10195). A number of additional parameters displayed statistically significant differences. Most of these changes were not consistent over time and partially of marginal degree. Thus they are considered to be of incidental nature rather than related to treatment.

2. Clinical chemistry findings

A number of statistically significant and treatment-related clinical chemistry findings were observed (see Table 5.5-20). Some of the changes were similar to those seen in the 28-day and 90-day studies (e.g. decreased ALT, AL(A)T, serum cholinesterase, cholesterol, glucose), are consistent to those observed at 400 ppm in the first supplemental chronic toxicity study (see BASF DocID 2002/1004125) and may be related to the impaired nutritional state of the animals.

3. Urinalysis

No treatment related changes of urinary parameters were observed.

III. CONCLUSIONS

Dietary administration of pyraclostrobin to female rats at dietary dose levels of 600 ppm for 433 days resulted in an impairment of body weight development in females fed with 600 ppm test substance. Treatment neither affected the survival of rats nor elicited clinical signs. Treatment–related changes of leukocyte counts were observed throughout the study. Even though other hematology parameters were changed in a way consistent to the changes seen in short-term studies at higher concentrations, these changes were either not consistent over time or – despite of their statistical significance – of marginal degree. Conversely, a number of clinical chemistry changes were consistent with previous studies and probably treatment-related.
Since the study was terminated pre-term, no histopathological examination was performed.
Based on the design of the study it was not intended to determine a NOAEL.

Report:	CA 5.5/7 [redacted] 2002e BAS 500 F - First supplementary carcinogenicity study in Wistar rats - Administration in the diet for 24 months 2002/1004123
Guidelines:	EEC 87/302 B, OECD 451, EPA 83-2, JMAFF
GLP:	yes (partially) (during the in-life phase up to the pre-term termination regular QAU audits were performed for this GLP study. However, the report was not QAU audited and thus the study has no full GLP status)

Executive Summary

This supplementary study was conducted in parallel to the carcinogenicity study in male and female Wistar rats (see BASF DocID 1999/11868). Pyraclostrobin (BAS 500 F) was administered to groups of 50 male and 50 female Wistar rats at dietary concentrations of 0 and 400 ppm. Since in the main study the maximum tolerated dose (MTD) was obtained at 200 ppm, the study was terminated after 399 study days without any further examinations. During the study period one male animal died in the treated group and 2 females and 1 female died in the control or treated group, respectively. These deaths are not assumed to be treatment related. No relevant clinical signs were observed. Due to termination of the study, no organs were preserved.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 F

Source:	Dr. Karl Thomae GmbH, Biberach a. d. Riss, Germany
Acclimation period:	8 days
Diet:	Kliba maintenance diet rat-mouse-hamster 343 meal, Klingentalmühle AG, Kaiseraugst, Switzerland, ad libitum
Water:	Drinking water, ad libitum
Housing:	Group housing (1 animals/cage) housed in wire cages, type DK-III, Becker & Co. (Castrop-Rauxel, Germany)
Environmental conditions:	
Temperature:	20 - 24°C (central air-conditioning)
Humidity:	30 - 70% (central air-conditioning)
Air changes:	not reported
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN

1. Dates of experimental work: 03-Mar-1997 to 14-Apr-1998
(Inlife dates: 11-Mar-1997 (start of administration) to 14-Apr-1998

2. Animal assignment and treatment:
BAS 500 F was administered to groups of 50 male and 50 female Wistar rats at dietary concentrations of 0 and 400 ppm for 399 days. The animals were assigned to the treatment groups by means of a computer generated randomization list based on body weights. At day 399 all animals were sacrificed without any further examination.

3. Test substance preparation and analysis:
The containers of test substance required for the feed mixtures in each case were cooled to approx. -20°C in the freezer so that they can be treated mechanically. Subsequently, the test substance was comminuted mechanically and stored at -20°C, unlike the usual storage conditions, to prevent it from becoming conglutinated again. For preparation of the feed mixes an acetone solution was prepared with the weighed test substance in the specific concentration. This solution was sprayed onto approx. 3.0 kg feed in a rotary evaporator (Büchi, Rotapor R 153) under partial vacuum. Subsequently, the solvent was removed under suction while heating to approx. 40°C for at least 30 minutes. Then, the premix was adjusted to the concentration desired with the appropriate amount of feed and mixed in a laboratory mixer of GEBR. LÖDIGE for approx. 10 minutes. The preparation frequencies were selected to ensure the stability of the test substance concentrations in the diet.

The stability of the test substance in the diet over 43 days at room temperature was verified analytically in the study 08B0376/956006 (analytical report (Amendment No. 1) of Jul. 5, 1996). Analyses to detect the homogeneous test substance distribution in the diet were carried out in samples of the parallel carcinogenicity studies (8250494/96086 (see BASF DocID 1999/11672)) and 8250494/96096 (see BASF DocID 2002/1004124)). For the concentration control analysis of the test substance preparations, samples were sent to the analytical laboratory at the beginning of the study, then at approx. 3-month intervals and approx. 4 weeks before the end of the study.

4. Statistics:
Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to following tables:

Statistics of clinical examinations

Parameter	Statistical test
mortality	Fisher's exact test (two-sided)
food consumption, body weight, body weight change, food efficiency	Student's t-test (two-sided) for the hypothesis of equal means

C. METHODS

1. Observations:

The animals were examined for morbidity or mortality once daily.
A general cage side observation of the animals with regard to their outer appearance and behavior was carried out at least once daily. In addition to the general daily observation, each animal was subjected to an exact clinical check (including palpation).

2. Body weight:

The body weight of the animals was determined once weekly up to the 13th week of administration, then at 4-week intervals.

3. Food consumption, food efficiency and compound intake:

Food consumption was determined weekly during the first 13 weeks of administration, thereafter at 4-week intervals.
Even though not mentioned in report it is assumed that the food efficiency and substance intake was calculated as in the main study (see BASF DocID 1999/11868).
Food efficiency was calculated based upon individual values for body weight and food consumption:

$$\text{Food efficiency at day x} = \frac{BW_x - BW_y}{FC_{y\ to\ x}} \times 100$$

with BW_x and BW_y body weight (g) on day x and day y (last weighing date before day x), $FC_{y\ to\ x}$ as the mean food consumption (in g) from day y to day x, calculated as mean daily food consumption on day x multiplied with the number of days from day y to day x.

The mean daily intake of test substance (group means) was calculated based upon individual values for body weight and food consumption.

$$\text{Substance intake for day x} = \frac{FC_x \times C}{BW_x}$$

with FC_x as the mean daily food consumption (in g/day) on day x, C as the concentration in food on day x (mg/kg = ppm) and BW_x as body weight on day x of the study (g).

4. Water consumption:

No water consumption values were recorded.

5. Ophthalmoscopy:

No ophthalmoscopy was performed in this study.

6. Hematology and clinical chemistry:

In this study, no blood smears were prepared.

7. Urinalysis:

No urinalysis was performed in this study.

8. Sacrifice and pathology:

No pathology was done since the study was terminated on day 399.

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

1. Clinical signs of toxicity

No treatment related clinical signs of toxicity were observed in treated rats (see Table 5.5-21). All clinical observations were either observed in single animals only and displayed no dose-response relationship.

Table 5.5-21: Clinical observations in rats administered pyraclostrobin for 399 days – First supplemental carcinogenicity study

Sex	Male		Female	
Dose [ppm]	0	400	0	400
Animals in group	50	50	50	50
Sacrificed moribund	0	1	2	1

paleness	-	-	1	0
hypothermia	-	-	1	0
Urine, discolored	-	-	1	1
Feces, discolored	-	-	1	0

2. Mortality

The low incidence of mortality (one 400 ppm male and 2 and 1 females at 0 and 400 ppm, respectively) was not indicative of a treatment-related effect.

B. BODY WEIGHT AND BODY WEIGHT GAIN

Body weight development was impaired in dosed males as indicated by statistically significant lower body weights from study day 7 onwards. Likewise, body weight development of females was impaired, however body weights were significantly lower from study day 70 onwards only (see Table 5.5-22 and Figure 5.5-7). Cumulative body weight gain was significantly lower throughout the major part of the study for males and females (see Table 5.5-22).

Figure 5.5-7: Body weight development of rats administered pyraclostrobin for 399 days – First supplemental carcinogenicitiy study

C. FOOD & WATER CONSUMPTION AND COMPOUND INTAKE

Consistently lower food consumption was observed for males throughout and for females during major parts of the study. This was statistically significant for males at all and for females at 15/23 determinations (see Figure 5.5-8 and Table 5.5-23).

Figure 5.5-8: Mean daily food consumption in rats administered pyraclostobin for 399 days – First supplemental carcinogenicity study

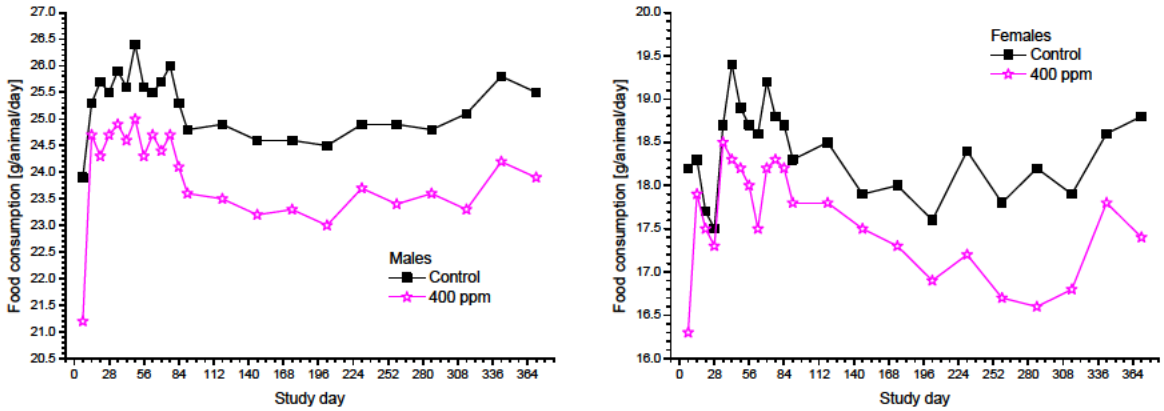

Table 5.5-23: Average food consumption of rats administered pyraclostrobin for 399 days – First supplemental carcinogenicity study

	Males		Females	
Dose level [ppm]	0	400	0	400
Food consumption [g/animal]				
Day 0 to 90#	25.5	24.2	18.5	17.8
Δ% (compared to control) #		-4.8		-3.7
Day 0 to 371#	25.1	23.7	18.3	17.4
Δ% (compared to control) a		-5.6		-4.9

Values were calculated based on mean individual daily food. Values may not calculate exactly due to rounding of mean values

a Time weighted

The time weighted mean daily test substance intake was determined to have been 19.7 and 25.0 mg/kg bw/day for males and females, respectively.

III. CONCLUSIONS

Dietary administration of pyraclostrobin to rats at dietary dose levels of 0 and 400 ppm for 399 days resulted in an impairment of body weight development in males and females. Treatment did not affect the survival of rats and no relevant clinical signs were observed. Based on the study design it was not intended to determine a NOAEL.

Report:	CA 5.5/8 [redacted] 2002f BAS 500 F - Second supplementary carcinogenicity study in female Wistar rats - Administration in the diet for 24 months 2002/1004124
Guidelines:	EEC 87/302 B, OECD 451, EPA 83-2, JMAFF
GLP:	yes (partially) (during the in-life phase up to the pre-term termination regular QAU audits were performed for this GLP study. However, the report was not QAU audited and thus the study has no full GLP status)

Executive Summary

This supplementary study was conducted in parallel to a carcinogenic feeding study in male and female Wistar rats (see BASF DocID 1999/11672). Pyraclostrobin (BAS 500 F) was administered to groups of 50 female Wistar rats at a dietary concentration of 600 ppm. Control animal data were taken from the parallel conducted main study (see BASF DocID 1999/11672). Since in the main study the maximum tolerated dose (MTD) was obtained at 200 ppm, the study was terminated after 426 study days without any further examinations.

No mortality or relevant clinical signs were observed during the study. Food consumption and body weight development was impaired throughout the study.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 F

Description:	viscous melt / reddish-brown, clear
Lot/Batch #:	J. No. 27882/191/c (Tox. III/part 1)
Purity:	97.09%
Stability of test compound:	Stable until May 1997. (The same batch of test material was used in the main study (see BASF DocID 1999/11672). This material was reanalyzed after end of the in-life phase of the latter study and found to be stable.)

2. Vehicle and/or positive control: Rodent diet

3. Test animals:

Species:	Rat
Strain:	Wistar, Chbb:THOM (SPF)
Sex:	Female
Age:	43 days ± 1 day
Weight at dosing:	mean females: ca. 164 g
Source:	Dr. Karl Thomae GmbH, Biberach a. d. Riss, Germany
Acclimation period:	8 days
Diet:	Kliba maintenance diet rat-mouse-hamster 343 meal, Klingentalmühle AG, Kaiseraugst, Switzerland, ad libitum
Water:	Drinking water, ad libitum
Housing:	Group housing (1 animals/cage) housed in wire cages, type DK-III, Becker & Co. (Castrop-Rauxel, Germany)
Environmental conditions:	
Temperature:	20 - 24°C (central air-conditioning)
Humidity:	30 - 70% (central air-conditioning)
Air changes:	not reported
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN

1. Dates of experimental work: 03-Feb-1997 to 14-Apr-1998
Inlife dates: 12-Feb-1997 (start of administration) to 14-Apr-1998 (necropsy of last female animals)

2. Animal assignment and treatment:
BAS 500 F was administered to a group 50 female Wistar rats at a dietary concentrations 600 ppm for 426 days. The animals were assigned to the treatment groups by means of a computer generated randomization list based on body weights. At day 426 all animals were sacrificed without any further examination. The data of control animals were taken from the parallel study with the Doc ID 1999/11868.

3. Test substance preparation and analysis:
The containers of test substance required for the feed mixtures in each case were cooled to approx. -20°C in the freezer so that they can be treated mechanically. Subsequently, the test substance was comminuted mechanically and stored at -20°C, unlike the usual storage conditions, to prevent it from becoming conglutinated again. For preparation of the feed mixes an acetone solution was prepared with the weighed test substance in the specific concentration. This solution was sprayed onto approx. 3.0 kg feed in a rotary evaporator (Büchi, Rotapor R 153) under partial vacuum. Subsequently, the solvent was removed under suction while heating to approx. 40°C for at least 30 minutes. Then, the premix was adjusted to the concentration desired with the appropriate amount of feed and mixed in a laboratory mixer of GEBR. LÖDIGE for approx. 10 minutes. The preparation frequencies were selected to ensure the stability of the test substance concentrations in the diet.

The stability of the test substance in the diet over 43 days at room temperature was verified analytically in the study 08B0376/956006 (analytical report (Amendment No. 1) of Jul. 5, 1996). Analyses to detect the homogeneous test substance distribution in the diet were carried out in samples of the parallel carcinogenicity studies (see BASF DocID 1999/11672 and BASF DocID 2002/1004124). For the concentration control analysis of the test substance preparations, samples were sent to the analytical laboratory at the beginning of the study, then at approx. 3-month intervals and approx. 4 weeks before the end of the study.

4. Statistics:
The data of control animals were taken from the main study (see BASF DocID 1999/11672). Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to following tables:

Statistics of clinical examinations

Parameter	Statistical test
food consumption, body weight, body weight change, food efficiency	Student's t-test (two-sided) for the hypothesis of equal means

C. METHODS

1. Observations:

The animals were examined for morbidity or mortality once daily.
A general cage side observation of the animals with regard to their outer appearance and behavior was carried out at least once daily. In addition to the general daily observation, each animal was subjected to an exact clinical check (including palpation).

2. Body weight:

The body weight of the animals was determined once weekly up to the 13th week of administration, then at 4-week intervals.

3. Food consumption, food efficiency and compound intake:

Food consumption was determined weekly during the first 13 weeks of administration, thereafter at 4-week intervals.
Even though not mentioned in report it is assumed that the food efficiency and substance intake was calculated as in the main study (see BASF DocID 1999/11672).
Food efficiency was calculated based upon individual values for body weight and food consumption:

$$\text{Food efficiency at day x} = \frac{BW_x - BW_y}{FC_{y\ to\ x}} \times 100$$

with BW_x and BW_y body weight (g) on day x and day y (last weighing date before day x), $FC_{y\ to\ x}$ as the mean food consumption (in g) from day y to day x, calculated as mean daily food consumption on day x multiplied with the number of days from day y to day x.

The mean daily intake of test substance (group means) was calculated based upon individual values for body weight and food consumption.

$$\text{Substance intake for day x} = \frac{FC_x \times C}{BW_x}$$

with FC_x as the mean daily food consumption (in g/day) on day x, C as the concentration in food on day x (mg/kg = ppm) and BW_x as body weight on day x of the study (g).

4. Water consumption:

No water consumption values were recorded.

5. Ophthalmoscopy:

No ophthalmoscopy was performed in this study.

6. Hematology and clinical chemistry:

In this study, no blood smears were prepared.

7. Urinalysis:

No urinalysis was performed in this study.

8. Sacrifice and pathology:

No pathology was done since the study was terminated on day 426.

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

1. Clinical signs of toxicity

No treatment related clinical signs of toxicity were observed in treated rats (see Table 5.5-24). All clinical observations were observed in single animals only.

Table 5.5-24: Clinical observations in rats administered pyraclostrobin for 426 days – Second supplemental carcinogenicity study

Sex	Female
Dose [ppm]	600 pmm
Animals in group	50
Oblique head posture	1
Skin, palpable mass	2
Forelimb(s), injury	1
Loss	1
Mamma, induration	2
Piloerection	2
Mydriasis	1
Cataract	1
Eyelid, crusts, red	1
Reduced general state	1

2. Mortality

No mortality was observed during the study period.

B. BODY WEIGHT AND BODY WEIGHT GAIN

Body weight development was impaired in dosed females as indicated by statistically significant lower body weights from study day 35 onwards. (see Figure 5.5-9 and Table 5.5-25).
Cumulative body weight gain was significantly lower throughout the major part of the study for females.

Figure 5.5-9: Body weight development of rats administered pyraclostrobin for 426 days – Second supplemental carcinogenicity study

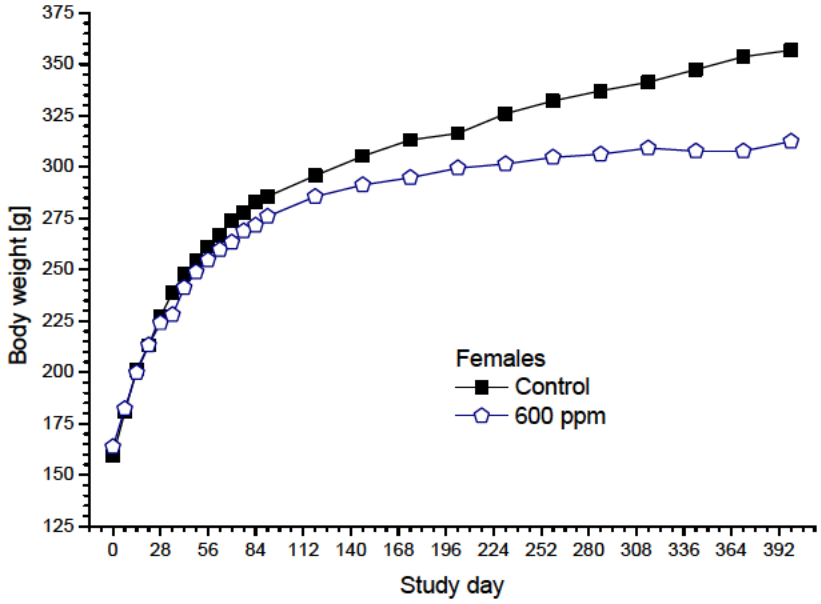

Table 5.5-25: Mean body weight of rats administered pyraclostrobin for 426 days – Second supplemental carcinogenicity study

	Females	
Dose level [ppm]	0	600
Body weight [g]		
- Day 0	159.2 ± 6.6	163.7 ± 4.8**

- Day 399	197.7 ± 31.9	**148.8 ± 20.4****
Δ% (compared to control)		**-24.7**

* $p \leq 0.05$; ** $p \leq 0.01$ (Student's t-test. two sided)

C. FOOD & WATER CONSUMPTION AND COMPOUND INTAKE

Food consumption of treated females was statistically lower almost throughout the entire study (see Figure 5.5-10 and Table 5.5-26).

Figure 5.5-10: Food consumption of female rats administered pyraclostrobin for 426 days – Second supplemental carcinogenicity study

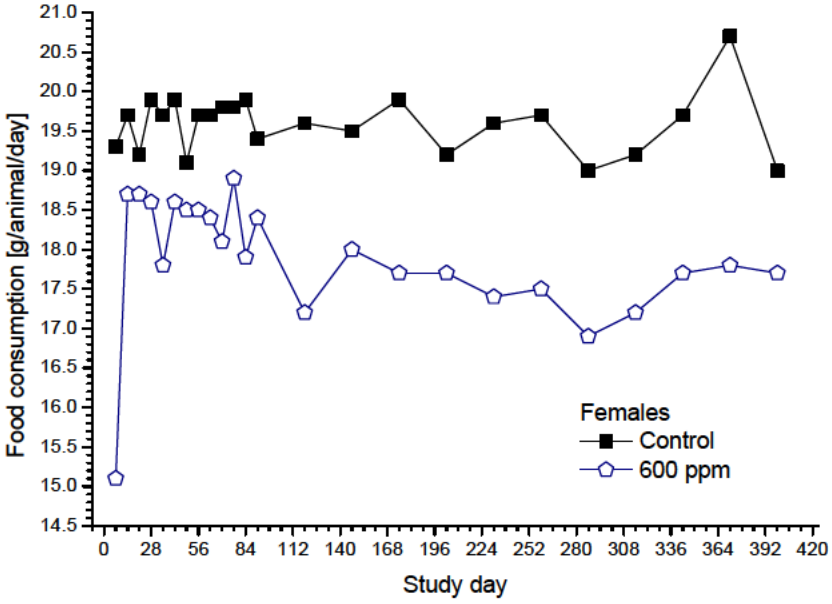

Table 5.5-26: Mean food consumption of rats administered pyraclostrobin for 426 days

	Females	
Dose level [ppm]	0	600
Food consumption [g/animal]		
Day 0 to 90[#]	19.6	18.2
		-7.4
Day 0 to 399	19.6	17.7
Δ% (compared to control)[#]		-9.7

[#] Values were calculated based on mean individual daily food. Values may not calculate exactly due to rounding of mean values

The time weighted mean daily test substance intake was calculated to have been 37.4 mg/kg bw/day in females at the dietary dose level of 600 ppm.

III. CONCLUSIONS

Dietary administration of pyraclostrobin to female rats at dietary dose levels of 600 ppm for 426 days resulted in lower food consumption and an impairment of body weight development Treatment neither affected survival nor elicited relevant clinical signs. Based on the design of the study it was not intended to determine a NOAEL.

For convenience of the reviewer a brief summary of the mouse carcinogenicity study as extracted from the monograph is provided below.

Pyraclostrobin, mouse – carcinogenicity study (original dossier BASF DocID 1999/11871)

Pyraclostrobin was administered to groups of 50 male and 50 female B6C3F1 mice at dietary concentrations of 0, 10, 30 and 120 ppm and additionally 180 ppm (females only) for 18 months.
There was no test substance related increase in mortality or clinical signs of toxicity in this study.
After 90 days, body weight and body weight change were significantly reduced at 120 ppm in males only. After one year, this effect was observed at 120 ppm in males and 180 ppm in females.
In the second year, body weight and body weight change were significantly reduced at all dose levels in males on days 455-546 and at 10 ppm, 120 ppm and 180 ppm in females on days 539 and 546. At the high dose levels, body weight was 13% lower than controls in both sexes and body weight development was reduced by 27 and 29% in males and females, respectively. However, the reduced body weights at the end of the treatment period were without any dose-response relationship. Occasionally, food consumption was decreased in the treated groups, in particular in females, without showing any dose-response relationship.
Blood smears did not indicate any substance-related effect. Histopathological investigations did not reveal any test substance related adverse effect. There was no evidence of a carcinogenic response.

Conclusion:
The no observed adverse effect level (NOAEL) in this 18-month carcinogenicity study in mice was 30 ppm (4.1 mg/kg bw/d for males), based on reduction of body weights in males at 120 ppm during the first year of the study.
During the last 6 months of the study, food consumption, body weight and body weight change were significantly reduced at all dose levels. However, these effects at the end of the treatment period were without any dose-response relationship and not regarded as treatment-related. There was no indication of a carcinogenic potential of pyraclostrobin in mice.

In the following the additional carcinogenicity study in mice requested by US-EPA is summarized. This study was previously not submitted.

Report:	CA 5.5/9 [redacted] 2005a BAS 500 F: Terminated carcinogenicity study in female B6C3F1 mice; administration in the diet for 7 months 2005/1026477
Guidelines:	EPA 870.4200, EEC 87/302 B, OECD 451, MAFF Testing Guideline for Toxicology Studies (1985)
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

Pyraclostrobin (BAS 500 F) was administered to groups of 50 female B6C3F1 mice at dietary concentration of 360 ppm for a period of 7 months. The study was conducted upon request of US-EPA as the authority considered that the maximum tolerated dose (MTD) was not met in females in the main study. After about 7 months a marked impairment of body weight development was noted at 360 ppm as indicated by a decrease of mean absolute body weights by 31.5% and of cumulative body weight gain by 40.2% when compared to the control. Secondary to the 30% lower (exsanguinated) terminal body weight, a number of absolute organ weights were decreased whereas relative organ weights were increased. The only treatment-related gross necropsy finding was a slight increase in the incidence of glandular stomach erosion/ulceration.
The marked impairment of body weight development indicated that the MTD was exceeded in females administered pyraclostrobin at a dietary concentration of 360 ppm. Thus – after consultation with US EPA - the study was terminated at seven months without histopathological evaluation of the preserved organs.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 F

Description:	Solid / crystalline / yellowish
Lot/Batch #:	LJ 27882/199/b (ToxCharge III/Teil 2)
Purity:	98.7%
Stability of test compound:	Stable until March 28, 2008.

2. Vehicle and/or positive control: Rodent diet

3. Test animals:

Species:	Mouse
Strain:	B6C3F1/Crl
Sex:	Female
Age:	41 ± 1 days
Weight at dosing (Day 0):	mean: 19.5 g
Source:	Charles River, Sulzfeld, Germany
Acclimation period:	6 days
Diet:	Kliba maintenance diet for mouse/rats “GLP”, Provimi Kliba SA, Kaiseraugst, Switzerland, ad libitum
Water:	Tap water in bottles, ad libitum
Housing:	Single housing in polycarbonate cages, type M I with wire cover from Becker & Co., Castrop-Rauxel, Germany.
Environmental conditions:	
Temperature:	20 - 24 °C
Humidity:	30 - 70 %
Air changes:	not reported
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 07-Sep-2004 to 01-Aug-2005
In life dates: 13-Sep-2004 (start of administration) to 14-Apr-2005 (necropsy)

2. Animal assignment and treatment:

BAS 500 F was administered to groups of 50 female mice at dietary concentrations of 0 and 360 ppm for 7 months. The animals were assigned to the treatment groups by means of computer generated randomization lists based on body weights.

3. Test substance preparation and analysis:

Appropriate amounts of the test item were dissolved in acetone and subsequently srayed on about 3 kg powdered diet in a rotation vaporizer (Büchi, Rotavapor R 153) under partial vacuum. Acetone was removed by heating up to about 40°C for about 1 hour. Thereafter this premix was adjusted to the desired concentration with appropriate amounts of powdered diet and mixed for about 10 minutes in a laboratory mixer. Details of the mixers used are retained with the raw data. The test substance preparation usually was mixed every 5 weeks.
The stability of the test substance in the diet over a period of 43 days at room temperature was proven prior to the conduct of the study.
Homogeneity and concentration analyses of the diet preparations were performed at the beginning of administration, after 3 and 4 months. For this three samples were randomly taken and analyzed for test-item content.
No test-article was determined in control diets. Relative standard deviations of the homogeneity samples in the range of 0.6 to 2.9% indicate the homogenous distribution of pyraclostrobin in the diet preparations. The individual sample test-substance concentrations were in the range of 91.1 to 103.3% of the nominal concentrations with an overall mean of 99.7% ± 4.9 of the nominal concentration. The group average dietary concentrations and % of nominal values are given in the following table.

Analysis of diet preparations for homogeneity and test-item content

Dose level [mg/kg]	Sampling	Analysis	Concentration[#] [mg/kg] Mean ± SD	Mean % of nominal concentration
360	09.09.04	10.09.04	369.7 ± 2.1	102.7 ± 0.6
	24.12.04	13.01.05	338.7 ± 9.7	94.1 ± 2.7
	28.02.05	11.03.05	368.3 ± 2.3	102.3 ± 0.6
average			**358.9 ± 17.5**	**99.7 ± 4.9**

[#] based on mean values of the three individual samples (homogeneity samples)
Values may not calculate exactly due to rounding of figures.

4. Statistics:

Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to following tables:

Statistics of clinical examinations

Parameter	Statistical test
food consumption, body weight, body weight change, food efficiency	A comparison of dose group with the control group was performed using the Welch t-test (two sided) for the hypothesis of equal means.

Statistics of pathology

Parameter	Statistical test
Weight parameters	Non-parametric one-way analysis using KRUSKALWALLIS test (two-sided). If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using the WILCOXON test for the hypothesis of equal medians

C. METHODS

1. Observations:

The animals were examined for morbidity or mortality as well as for signs of toxicity twice daily on working days and once daily on weekends and public holidays.
Detailed clinical observations were performed in all animals prior to the start of the administration period and weekly thereafter. For this the animals were transferred to a standard arena (50 x 37.5 cm with sides of 25 cm high). The findings were ranked according to the degree of severity, if applicable. The following parameters were examined:

1. abnormal behavior during handling	10. abnormal movements
2. fur	11. impairment of gait
3. skin	12. lacrimation
4. body posture	13. palpebral closure
5. salivation	14. exophthalmus
6. respiration	15. feces (appearance/consistency)
7. activity/arousal level	16. urine
8. tremors	17. pupil size
9. convulsions	

2. Body weight:

The body weight of the animals was determined before the start of the administration period (in order to randomize the animals), at the start of the treatment (day 0), once weekly for the first 13 weeks, thereafter at 4-week intervals and at the end of the study.

3. Food consumption, food efficiency and compound intake:

Individual food consumption was determined once a week during the first 13 weeks, at 4-week intervals thereafter and prior to the start of necropsy. Food consumption was calculated as mean food consumption in grams per animal and day.

Food efficiency (group means) was calculated based upon individual values for body weight and food consumption:

$$\text{Food efficiency at day x} = \frac{BW_x - BW_y}{FC_{y\ to\ x}} \text{ x } 100$$

with BW_x and BW_y body weight [g] at day x and day y (last weighing date before day x), $FC_{y\ to\ x}$ as the mean food consumption (in g) from day y to day x, calculated as mean daily food consumption on day x multiplied with the number of days from day y to day x.

The mean daily intake of test substance (group means) was calculated based upon individual values for body weight and food consumption.

$$\text{Substance intake for day x} = \frac{FC_x \times C}{BW_x}$$

with FC_x as the mean daily food consumption (in g/day) on day x, C as the dose in ppm and BW_x as body weight on day x of the study (in g).

4. Water consumption:

Water consumption was observed daily by visual inspection of the water bottles for any overt changes in volume.

5. Ophthalmoscopy:

Not performed in this study.

6. Hematology and clinical chemistry:

Due to the termination of the study after 7 months of the test substance administration, no hematology analyses were carried out.

7. Urinalysis:

Not performed in this study.

8. Sacrifice and pathology:

Surviving animals were sacrificed by decapitation under CO_2 anesthesia. The exsanguinated animals were necropsied and assessed by gross pathologically.

The following organs were sampled, weighed and preserved in neutral buffered 4% formaldehyde solution:

Pathology:

The following organs were collected (column C), weighed (W) and examined histopathologically (H).

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

1. Clinical signs of toxicity

One female from the dose group showed loss of tail end. This single occurrence was assessed as being incidental and not related to the test substance treatment.

2. Mortality

No animal died prematurely in this study.

3. Ophthalmoscopy

Not performed in this study.

B. BODY WEIGHT AND BODY WEIGHT GAIN

Body weight in animals treated with 360 ppm of BAS 500 F was statistically significantly decreased from the beginning of the treatment (study day 7, -4%) to the termination of the study (study day 210, -21%). The maximum impairment of body weight was up to 24% below control on study day 147. Body weight change reflected the effects on body weight in the dosed group even more clearly. Body weight change in animals treated with 360 ppm of BAS 500 F was statistically significantly decreased from the beginning of the treatment (study day 7, -177%) to the termination of the study (study day 210, -40%). The maximum impairment of body weight gain, after at least three months of test substance treatment, was up to 52% below control on study day 147. The above-mentioned findings were considered related to the test substance treatment (see Figure 5.5-11 and Table 5.5-27).

Figure 5.5-11: Body weight development of female B6C3F1 mice administered pyraclostrobin for about 7 month

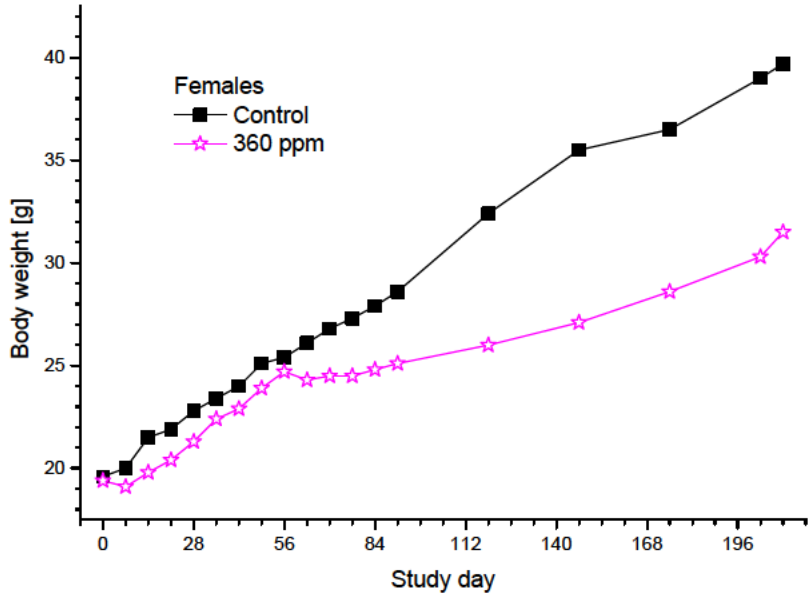

Table 5.5-27: Mean body weights of female mice administered pyraclostrobin about 7 months

Dose level [ppm]	Females 0	Females 360

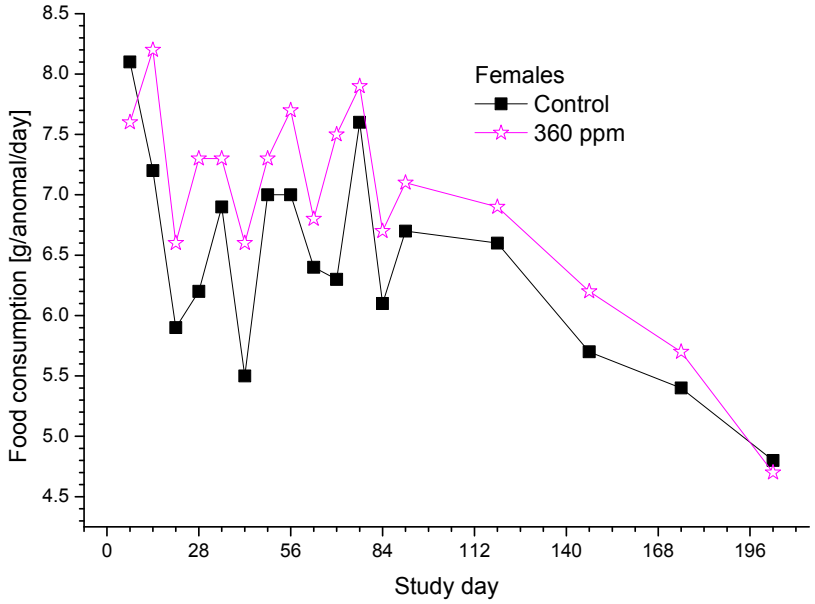
[#] Values may not calculate exactly due to rounding of mean figures

C. FOOD & WATER CONSUMPTION AND COMPOUND INTAKE

1. Food consumption:

During the early phase of the study, statistically significant increases of food consumption (days 14, 21, 28, 42, 56, 70 and 84) were observed (Figure 5.5-12). In view of the significant impairment of body weight development observed in this study period and taking into account the usual food spilling by mice this was assessed as being not biologically relevant.

Figure 5.5-12: Mean daily food consumption of female B6C3F1 mice administered pyraclostrobin for about 7 month



Remark: Food spillage was sporadically observed in all group including controls. The values therefore may not give exact food consumption.

The mean daily test substance intake in 360 ppm females was calculated to be 106.5 mg/kg bw/day. The time weighted test substance intake was 94 mg/kg bw/day.

2. Water consumption:
There were no overt deviations in volume between treated group and control animals.

D. BLOOD ANALYSIS

Due to the termination of the study after 7 months of the test substance administration, no further analyses were carried out.

E. NECROPSY

1. Organ weight

The mean terminal body weights and the absolute weights of the adrenal glands, kidneys and liver were significantly decreased (see Table 5.5-28). Secondary to the decreased terminal body weight relative weights of the adrenal glands, brain, heart, kidneys, liver, ovaries, spleen and uterus were significantly increased (see Table 5.5-28). These significantly increased organ weights are related to the decreased terminal body weights and do not express a direct effect on the single organs.

Table 5.5-28: Selected mean absolute and relative organ weights of mice administered pyraclostrobin for about 7 months

Sex		Females

values may not calculate exactly due to rounding of figures
* $p \leq 0.05$; ** $p \leq 0.01$ (Kruskal-Wallis and Wilcoxon-test, two sided)

2. Gross pathology

Four treated females displayed "erosion/ulcer" of the glandular stomach. This was considered to be treatment-related. All other gross necropsy findings occurred in single cases only and were regarded to be of incidental nature (see Table 5.5-29).

Table 5.5-29: Incidence of selected gross pathological findings in mice administered pyraclostrobin for about 7 months

Sex		Female	
Dose [ppm]		0	360
Animals in group		50	50

3. Histopathology

No histopathological examinations were performed in this study.

III. CONCLUSIONS

Dietary administration of pyraclostrobin to mice at a dose level of 360 ppm for 7 months resulted in a significant reduction in body weight and body weight gain. Due to the severity of the body weight effects the study was terminated in agreement with US EPA after about 7 months of treatment.

The following statistical evaluation was done to address questions of US-EPA and Canada PMRA regarding the adequate dosing in the rat and mouse long-term studies.

Report: CA 5.5/10
[redacted]., 2002a
Chronic and oncogenicity studies with BAS 500 F: Further evaluations of body weight, food consumption and food efficiency
2002/5002875
Guidelines: none
GLP: no

Executive Summary

The oncongenic potential of pyraclostrobin (BAS 500 F) was investigated in oncogenicity studies in rats and mice and a chronic toxicity study in rats. The original reports concluded significant decreases in body weight and body weight gain that were considered to have met EPA maximum tolerated dose (MTD) requirements. However, the Joint Review of the data by US EPA and the Canada PMRA concluded that the toxicity observed in the highest dose tested (particularly in females of both species) did not meet MTD requirements. Therefore, this report contains further analyses of body weight and food consumption data from the rodent carcinogenicity and chronic toxicity studies with pyraclostrobin that address the concerns noted in the Joint Review meeting.
The decreased body weights and body weight gains observed at the high doses in both sexes of both species were treatment-related toxic effects that were not due to decreases in food consumption, as it would occur if palatability of the test diets were an issue. Food consumption was only slightly decreased in rats and not affected at all in mice. Food efficiency, however, was decreased along with body weight gain, therefore a toxic effect other than decreased food consumption was the reason for the observed body weight effect. These findings provide clear evidence of treatment-related toxicity. The decrements in body weight and body weight gain reached levels of 10% or greater in both sexes of both species. The effect on body weight and body weight gain became more severe over time indicating a cumulative toxicity. Collectively, these data, specifically the body weight gain decrements of 10 % or more, indicate that the MTD was reached in male and female rats (200 ppm) and in male (120 ppm) and in female mice (180 ppm) that received pyraclostrobin in the diet for a chronic exposure.

I. MATERIAL AND METHODS

A. MATERIALS

This report contains the results of statistical analyses conducted on the rat and mice animal data from the chronic and carcinogenicity studies on BAS 500 F (BASF DocIDs 1999/11672, 1999/11868 and 1999/11871). This analysis also considered the supplemental chronic toxicity and carcinogenicity studies submitted in this supplemental dossier (see BASF DocIDs 2002/1004125, 2002/1004126, 2002/1004123 and 2002/1004124).

B. STUDY DESIGN AND METHODS

1. Dates of work: 04/22/2002 (completion date)

2. Method

Because the chronic toxicity study in rats and the carcinogenicity study in rats were conducted at the same time using similar protocols, the data for these studies were combined for this analysis. For this analysis the data were grouped into intervals. These intervals were used to capture potential treatment-related effects that might occur over time or at certain points during the course of the study. To capture any treatment-related effects and to lessen the effect of minor variations over a weekly period, within study intervals were calculated. For the within study intervals during the growth phase, data was pooled using two week or monthly intervals. In the maintenance phase where the data is only reported monthly, data was pooled using three month intervals. In addition, to see the overall treatment-related effects, data were pooled into across study intervals which started at the beginning of the study. These intervals would tend to smooth out fluctuations at any time period during the interval and show the overall effect from the beginning of the study up to the end of the interval. For these across study intervals, data was pooled over the first two weeks, the first month, and the first 91 days. After the growth period, the next three study intervals increased in length by approximately a month through the first 175 days and the remainder of study intervals increased in length by approximately 90 days each through the end of study.

Therefore, for this analysis, two different types of intervals were used. The across study intervals all start with the first day of the study and include all the information through the end of the interval (e.g., day 0-14, day 0-28, day 0-91, day 0-119, day 0-147, day 0-175, day 0-259, day 0-371, day 0-455, day 0-539 and day 0-728 for rats and day 0-546 for mice). The across study intervals show the overall treatment effect through the last day of the study interval.

Within study intervals are used and each interval starts were the preceding one stops (e.g., day 0-14, day 15-28, day 29-63, day 64-91, day 92-175, day 176-259, day 260-343, day 344-427, day 428-511, and day 512-595, day 596-679 and day 679-728 for rats with day 512-546 for mice). For the within study intervals, the period of time that has the most overall effect on the across study intervals can be seen.

In both the across study intervals and the within study intervals, the five values reported in the tables were calculated on individual animal data. Means, standard deviations and sample sizes for these statistics were calculated and statistical analysis of the data was done.
Since food consumption may be affected by body weight and body weight is affected by food consumption, comparing just food consumption or just body weight across treatments can be misleading. Therefore, two statistics are computed that evaluate the body weight gain relative to the food consumed and the food consumption relative to the overall body weight.
The individual interval values calculated for each animal were then used in an analysis of variance test (ANOVA) to see if the variation between treatment groups was significantly different from the variation within treatment groups. If there was a significant difference in the ANOVA at the $\alpha = 0.05$ level, a two-tailed Dunnett's test was performed to compare the means, standard deviations and sample sizes (N) for each group in each interval. The % value reported is the percent deviation of the treated group mean from the control group mean.
For the rat studies, the ANOVA and pair wise comparison were done in two stages. First, the original control, 25 ppm, 75 ppm, 200 ppm and, for the females only, the 600 ppm groups were analyzed. Then, the concurrent control for the 400 ppm group and the 400 ppm group were analyzed separately.

II. RESULTS AND DISCUSSION

The dose-response patterns observed for the parameters measured in mice and rats administered pyraclostrobin are consistent not only across sexes within a species but across species as well. These findings can be summarized as follows:

Body weight and body weight gain decrements
In female rats, body weight gain in 200 ppm dose group was decreased compared to the control and persisted throughout the study. With continued dosing, significant decreases in body weight gain were noted in the 200 ppm group beginning with a 6% decrease in the 0 to 147 day interval and progressing to 10% after 259 days, 13% after 371 days, 15% after 539 days and 19% by the end of the study at 728 day (see Table 5.5-30). In the 25 and 75 ppm groups, body weight gain was equal to or slightly greater than that in the controls up to the 0 to 175 day interval. Similar trends but with less severity than that with the 200 ppm group were noted for female rats in the 25 and 75 ppm dose groups at later time points. The final body weight gain decrements compared to control were 6, 8, and 19% in the 25, 75, and 200 ppm dose groups, respectively.
A similar pattern was noted in the 400 and 600 ppm female rats dosed for one year. Body weight gain deficit was significant at all time-points but remained about 10% up to the 0 to 175 time-period and then increased to 15 and 25% by the end of day 371. Across all dose groups at day 371, the deficits were 2, 1, 13, 15 and 25% for the 25, 75, 200, 400, and 600 ppm dose groups, respectively.

A pattern similar to the pattern in female rats was observed in male rats. The body weight gain deficits in the 200 ppm male rats progressed reaching 8% at 91 days and 10% after 539 days (see Table 5.5-30). By 728 days, body weight gain in the 200 ppm male rats was 5% less than the controls. However, the control male rats lost weight at the end of the study. Consequently, the magnitude of the difference in body weight gain between the control male rats and the 200 ppm male rats was diminished.
A pattern of progressive decreases in body weight gain was observed in the 400 ppm male rats as well. Body weight gain deficits in the 400 ppm male rats was 9% below the controls in the early portion of the study and was 16% lower than the controls by day 371.
A similar pattern was noted in both male and female mice (see Table 5.5-31). Initially in all dose groups and both sexes, body weight gain in the first two weeks was reduced relative to controls. In female mice, the decrease was 12, 10, 10, and 44% in the 10, 30, 120, 180 ppm groups, while in males the decrease was 3, 16 and 21%, in the 10, 30, and 120 ppm dose groups. Following the initial 14 days, the body weight gain in the lower dose groups was less affected for most of the study, fluctuating between 1 and 10%. However, the effect in high dose animals was greater fluctuating between 15 and 20% until the 0 to 455 interval. After day 455, body weight gains began to be decreased in the lower dosed animals. By the end of the study the body weight gain decrease relative to control was 17, 12, 20 and 26% in the female dose groups and 23, 18 and 28% in the male dose groups. However, the severity of the effect in the lower dose groups is mostly due to an initial decrease during the first 14 days and a decrease compared to controls much later in the study. In contrast the effect on body weight gain on high dose males and females was more severe and more consistent over the course of the study. The only time interval when the body weight gain was less than 15% in the females in the high dose group was in the 0 to 91 day interval. The intervals surrounding that time point (days 0 to 28 and 0 to 119) had decreases of 20 and 15%, respectively, suggesting that the 10% decrease in that time interval may represent variability rather than a true value given the small differences. Body weight gain in high dose males was consistently decreased over the course of the study by at least 15% reaching 28% at the end.
These data strongly suggest that the toxic effects of BAS 500 F are cumulative over time. The animals later in life are less able to handle the toxicity of the chemical. As the animal matures these effects become manifested more strongly than when the animal is younger.

Decreased body weights and body weight gains were not due to decreases in food consumption

There were no consistent and sustained significant decreases in food consumption in either male or female rats dosed up to 200 ppm (see Table 5.5-32). Further, there were no indications of a dose-response either across time or dose-groups found in the food consumption values. In female rats in the 200 ppm group, food consumption was within 2 to 3% of the control group throughout the study. By the end of the study, food consumption was reduced by only 3%, but body weight gain was reduced 19%. In male rats, food consumption was initially significantly reduced below controls values but was only approximately 3 to 4% less than controls up to day 175. After that these differences were no longer significantly different from controls and the differences at the end of the study were 1% less than control.
There were no consistent and sustained significant decreases in food consumption in male and female mice dosed up to 120 and 180 ppm, respectively. Food consumption in the high dose female mouse was consistently higher than the control until day 539 and only 3% lower than control at the end of the study (see Table 5.5-33). In male mice, food consumption was also initially higher than in controls, and remained between 1 to 2% less than controls throughout the study rising only to about 5% less at the end of the study. Food spillage was noted occasionally in the study, but this occurred only in a few animals, did not have a dose-related pattern and when noted, animals with significant food spillage were not included in food consumption calculations for that interval. So, food spillage does not affect the data on food consumption. While there were slight decreases in food consumption, these decreases were not large enough to explain or be responsible for the magnitude of the body weight differences.

Food Efficiency was consistently decreased

Food efficiency in both sexes and species was consistently reduced and these reductions were sustained throughout the study. In female rats, and in male and female mice, the decreases in food efficiency decreased consistently with increased time on treatment. By the end of the study, food efficiency was decreased 17% in female rats (see Table 5.5-32), 23% in female mice and 26% in male mice (see Table 5.5-33). These data indicate that less of the food intake was being converted to body mass in the treated animals than in control, indicative of a toxic effect. In the male rat, food efficiency was lower for the 200 ppm group at all time-points, when compared with the food efficiency for the controls, with many of the time points significantly lower. Food efficiency was decreased by approximately 5% by day 91 and progressed to a 6.5% decrease by day 399. For the entire study period (day 0-728), food efficiency was decreased by approximately 3% for the 200 ppm males, when compared with the controls. However, the control male rats lost weight at the end of the study, which would diminish the difference in food efficiency between the control and 200 ppm male rats.

CONCLUSION

The decreased body weights and body weight gains observed at the high doses in both sexes of both species were treatment-related toxic effects that were not due to decreases in food consumption, as would occur if palatability of the test diets were an issue. Food consumption was only slightly decreased in rats and not affected at all in mice. Food efficiency, however, was decreased along with body weight gain indicating a toxic effect other than decreased food consumption was the cause for the body weight effect. These findings provide clear evidence of treatment-related toxicity. The decrements in body weight gain reached levels of 10% or greater in both sexes of both species. The effect on body weight and body weight gain became more severe over time indicating a cumulative toxicity. Collectively, these data, specifically the body weight gain decrements of 10% or more, indicate that the MTD was reached in male and female rats (200 ppm) and in male (120 ppm) and female mice (180 ppm) that received BAS 500 F in the diet for a chronic exposure.

CA 5.6 Reproductive Toxicity

The pyraclostrobin studies evaluated in the draft monograph of the Rapporteur Member State Germany (August 01, 2001) consisted of a two-generation study in rats and developmental toxicity studies in rats and rabbits. Further evaluations of the developmental studies were made in the 2nd and 4th Amendment to the DAR. These studies have been evaluated by European authorities and Germany as Rapporteur Member State (European Commission Peer Review Program) and were considered to be acceptable. For the convenience of the reviewer, these are summarized below as extracted from the monograph.

Table 5.6-1: Summary of reproduction toxicity studies conducted with pyraclostrobin

Study	Dosages (mg/kg bw/d)	NOAEL (mg/kg bw/d)	LOAEL (mg/kg bw/d)	Main adverse effect	Reference (BASF DocID)
2-Generation, oral, feed, Wistar rats (constant diet concentrations: 0, 25, 75 and 300 ppm)	2.7, 8.2 and 32.6 (mean)	Parental toxicity: ca. 8.2 [75 ppm] Reproductive toxicity: ca.8.2 [75 ppm]	Parental toxicity: ca. 32.6 [300 ppm] Repro-ductive toxicity: ca. 32.6 [300 ppm]	Parental toxicity: Reduced food consumption and body weight gain Reproductive toxicity: Reduced pup body weight gain, organ weight changes and a delay in vaginal opening (F_1 females only). No adverse effects on fertility.	1999/11869
Developmental toxicity, gavage (days 6-9), Wistar rats	0, 10, 25 and 50	Maternal toxicity: 10 Developmental toxicity: 25	Maternal toxicity: 25 Develop-mental toxicity:50	Maternal toxicity: Reduced food consumption and body weight gain Developmental toxicity: Increased variations	1999/11511
Developmental toxicity, gavage (days 7-28), Himalayan rabbits (1st study)	0, 5, 10 and 20	Maternal toxicity: <5 Developmental toxicity: 5	Maternal toxicity: 5 Develop-mental toxicity: 10	Maternal toxicity: Reduced food consumption, reduced body weight gain Developmental toxicity: Increased skeletal malformations, at 20 mg/kg bw/d increased resorption and post-implantation losses, reduced number of live fetuses.	1999/11512
Developmental toxicity, gavage (days 7-28), Himalayan rabbits (2nd study with special regard to maternal effects)	0, 1, 3 and 5	Maternal toxicity: 3 Developmental toxicity: 5	Maternal toxicity: 5 Develop-mental toxicity: 10	Maternal toxicity: Reduced food consumption, reduced body weight gain Developmental toxicity: No evidence of developmental toxicity (limited range of parameters investigated).	2001/1003803

In the 2-generation study, the NOAEL for reproductive toxicity was 75 ppm (8.2 mg/kg bw/d), based on impairments in body weight/body weight gain in F_1 and F_2 pups and a slight delay in vaginal opening in F_1 female rats at 300 ppm (32.6 mg/kg bw/d). There were no treatment-related effects on fertility. The NOAEL for parental toxicity was 75 ppm (8.2 mg/kg bw/d) based on the signs of systemic toxicity in male and female animals occurring in both parental generations at 300 ppm (32.6 mg/kg bw/d). Toxicity was characterised by decreased food consumption and impairments in body weight and body weight gain.

In the teratogenicity study done with rats the NOAEL for maternal toxicity was 10 mg/kg bw/d, based on reduced food consumption and reductions in corrected body weight gain.
Under the conditions of this prenatal developmental toxicity study, pyraclostrobin was not teratogenic in rats. The NOAEL for developmental toxicity was 25 mg/kg bw/d, based on increased incidences of several soft tissue and skeletal variations inside the range of the historical control values.

In the teratogenicity study done with rabbits, pyraclostrobin was embryotoxic at dose levels with severe maternal toxicity.
The NOAEL for maternal toxicity was <5 mg/kg bw/d, suggesting a higher susceptibility of this species as compared to the rat at least when the test compound is administered during gestation. The NOAEL for developmental toxicity was 5 mg/kg bw/d, based on increased incidences of skeletal malformations at 10 and 20 mg/kg bw/d, which was just outside the historical control range of this laboratory at the time the study report was written. More complete historical control data including also studies performed at a later time showed that the incidences were within the historical control range. These data were discussed in the 4th Addendum to the DAR. At the highest dose level of 20 mg/kg bw/d, elevated postimplantation losses (mainly due to increased early resorptions) and a subsequent reduction in the mean number of live fetuses/doe were observed. As discussed in the 4th Addendum the "developmental toxicity occurred only at dose levels which were associated with maternal toxicity, and the embryotoxic effects (increased post-implantation losses) were likely to be secondary to the marked nutritional deficit in the dams at a critical time in gestation."
On request of the Rapporteur, a second prenatal developmental toxicity study in rabbits was performed with the main objective to establish a clear NOAEL for maternal toxicity.

In this additional prenatal developmental toxicity study in rabbits, a weak adverse effect on maternal food consumption and body weight gain was observed at a dose level of 5 mg/kg bw/d. The next lower dose of 3 mg/kg bw/d is considered the NOAEL for maternal toxicity since the occasionally reduced food intake at this dose level was not accompanied by an impaired food utilisation or a statistically significantly compromised body weight gain. Even though the applicant argued that the minor effects at the highest dose level (5 mg/kg bw/d) were not related to compound administration the NOAEL of 3 mg/kg bw/d was finally concluded in the EU review.
The gestational parameters were not affected and no evidence of developmental toxicity was obtained up to the highest dose of 5 mg/kg bw/d, however, the range of fetal parameters investigated was rather limited.

Based on the available data, the following endpoints were determined during the last Annex I listing of pyraclostrobin:

Reproductive toxicity (SANCO/1420/2001)

Target / critical effect - Reproduction:	Pup body weight gain reduced in the presence of parental toxicity
Lowest relevant reproductive NOAEL / NOEL:	Rat: 8.2 mg/kg bw/d (75 ppm)
Target / critical effect - Developmental toxicity:	Developmental effects in rats and embryotoxicity in rabbits at maternally toxic doses
Lowest relevant developmental NOAEL / NOEL:	Rabbit: 5 mg/kg bw/day
Lowest relevant maternal NOAEL / NOEL:	Rabbit 3 mg/kg bw/d

There are no new studies available with pyraclostrobin that could affect the overall evaluation for reproduction and developmental toxicity. Thus, the conclusion for relevant endpoints for the current renewal remains as follows:

Reproduction target / critical effect	Reduced pup body weight gain in the presence of parental toxicity No classification required
Lowest relevant reproductive NOAEL / NOEL	Rat: 75 ppm (8.2 mg/kg bw/d)
Developmental target / critical effect	Developmental effects in rats and embryotoxicity (including malformations) in rabbits at maternally toxic doses No classification required
Lowest relevant developmental NOAEL / NOEL	Rabbit: 5 mg/kg bw/d
Lowest relevant maternal NOAEL / NOEL	Rabbit: 3 mg/kg bw/d

The classification and labelling was discussed at ECB in January 2003 (ECBI 52/03 Add.1 Rev. 1) and concluded in September 2004. No classification for reproductive or developmental toxicity was considered necessary. A more detailed discussion can be found below.

For convenience of the reviewer brief summaries of the respective studies as extracted from the monograph are provided under the respective chapters.

Furthermore, a complete study summary of the not yet peer reviewed one-generation range finding reproduction toxicity study can be found below. Based on the results of this study dose levels of 25, 75 and 300 ppm were selected for the 2-generation study.

CA 5.6.1 Generational studies

Report:	CA 5.6.1/1 [redacted] 2002 a BAS 500 F - One generation range-finding reproduction toxicity study in Wistar rats; continuous dietary administration 2002/1004187
Guidelines:	EEC 87/302 B, OECD 415
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

In a one-generation range finding reproduction toxicity study, BAS 500 F (pyraclostrobin; batch: J.-No. 27882/191/c (Tox. III/part 1); purity 97.09%) was administered as a constant homogeneous addition to the diet to groups of 10 male and 10 female Wistar rats at dietary concentrations of 0, 200, 400 and 600 ppm (corresponding to a mean, 6-week pre-mating period substance intake of approximately 20.5, 39.9, 59.1 and 21.3, 42.5, 60.4 mg/kg bw/day in males and females, respectively).

No treatment-related mortality was observed throughout the study. Signs of systemic toxicity were observed in all treated F_0 parental rats. Food consumption and body weight/body weight gain was impaired at all dose levels. Indication of a hypochromic anemia were noted in males at 400 and 600 ppm in males and at 600 ppm in females. Thickening of the duodenal wall occurred in high dose males.
Signs of developmental toxicity were observed in F_1 pups as indicated by impairment of body weight development. No other pup parameters were affected by treatment.
Treatment had no effects on reproductive performance and fertility up to and including 600 ppm.

Based on the systemic toxicity observed in parental animals and the developmental toxicity in the pups up to the highest dose level, a NOAEL could not be determined in this study. In absence of any effects on fertility and reproductive performance the NOAEL for reproductive performance and fertility was at least 600 ppm (59.1 mg/ kg bw/day).

Based on the results of this study dose levels of 25, 75 and 300 ppm were selected for the 2-generation study.

(BASF DocID 2002/1004187)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 F

Description:	solidified melt / red-brown, clear
Lot/Batch #:	J.-No. 27882/191/c (Tox.III/part 1)
Purity:	97.09%
Stability of test compound:	The test substance was stable over the study period; proven by re-analysis.

2. Vehicle and/or positive control: Rodent diet

3. Test animals:

Species:	Rat, Wistar
Strain:	Chbb = THOM (SPF)
Sex:	Male and female
Age:	27 ± 1 days at delivery; 36 ± 1 days at beginning of treatment
Weight at dosing:	♂: 162.5g (147.5-176.5 g), ♀: 127.3g (113.0-139.1 g)
Source:	Boehringer Ingelheim, Pharma KG, Biberach/Riss, Germany
Acclimation period:	about 9 days
Diet:	Kliba maintenance diet rat/mouse/hamster, Provimi Kliba SA, Kaiseraugst, Switzerland, ad libitum
Water:	drinking water from water bottles, ad libitum
Housing:	individual housing in type DK III stainless steel wire mesh cages supplied by Becker & Co., Castrop-Rauxel, Germany (floor area of about 800 cm²), with the following exceptions: • pregnant animals and their litters were housed together from day 18 of gestation until day 14 after birth in Makrolon type M III cages supplied by Becker & Co. pregnant females were provided with nesting material (cellulose wadding) toward the end of gestation bedding: SSNIFF (type 3/4) supplied by SSNIFF Spezialdiaeten GmbH, Soest, Germany
Environmental conditions:	
Temperature:	20 - 24°C (central air-conditioned rooms)
Humidity:	30 - 70% (central air-conditioned rooms)
Air changes:	number of air changes not indicated in report
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 24-Feb-1997 to Jun-17-1997
In-life dates: 05-Mar-1997 (start of administration of F_0 parental animals) to 17-Jun-1997 (sacrifice of last parental animals)

2. Animal assignment and treatment:

BAS 500 F was administered in the diet to groups of 10 male and 10 female rats at nominal dose levels of 0, 200, 400, and 600 ppm. The animals used as F_0 parental animals were derived from different litters according to a written statement from the breeder. By this, sibling mating was avoided. The animals were randomly assigned to the test groups by means of a computer generated randomization list based on body weights before the beginning of the administration period (day -1).
After the acclimatization period F_0 parental animals continuously received the test substance throughout the entire study. About 16 hours prior to sacrifice food was withdrawn.
At least 45 days after beginning of treatment, male and female rats of the same dose groups were mated at a ratio of 1:1. Females were allowed to litter and rear their pups (F_1 generation pups) until PND 4 (standardization, see below) or day 21 after parturition. After weaning of F_1 pups the F_0 generation parental animals were sacrificed.
All surviving F_1 pups were sacrificed by means of CO_2 after standardization or weaning.

Mating procedure: Males and females were mated overnight at a 1:1 ratio for a maximum of 3 weeks. Throughout the mating period, each female was paired with a predetermined male from the same dose group. The animals were paired by placing the female in the cage of the male mating partner from about 4.00 pm until 7.00 - 9.00 am of the following morning. Deviations from the specified times were possible on weekends and public holidays, and were reported in the raw data.
A vaginal smear was prepared after each mating and examined for the presence of sperm. If sperm was detected, pairing of the animals was discontinued. The day on which sperm were detected was denoted "gestation day (GD) 0" and the following day "gestation day (GD) 1".

Standardization of litters: On PND 4, the individual litters were standardized in such a way that, where possible, each litter contained 4 male and 4 female pups (always the first 4 pups/sex and litter were taken for further rearing). If individual litters did not have 4 pups/sex it was proceeded in such a way that the most evenly distributed 8 pups per litter were taken for further rearing (e.g., 5 male and 3 female pups). Standardization of litters was not performed in litters with ≤ 8 pups.

3. Test substance preparation and analysis:

The test item was frozen and mechanically crushed and appropriate concentrated solutions of the test item in acetone were prepared. The diets were prepared by spraying these acetonic solutions onto about 3 kg food in a rotation vaporizer under partial vacuum. Acetone was removed by heating up to about 40°C for about 30 minutes. Subsequently, appropriate amounts of food were added to obtain the intended dietary concentrations and mixed for approx. 10 minutes in a laboratory mixer. Diet preparations were performed at intervals, which guaranteed that the test substance in the diet remained stable throughout the feeding period.

Analyses of the dietary test substance preparations performed with a comparable batch (27882/37/a) prior to the start of the administration period revealed that the test substance was stable in the diet up to 43 days at room temperature.

The above described method for diet preparation was shown to yield in homogenous distribution of the test item in the diet as was demonstrated in the course of the pyraclostrobin 2-year carcinogenicity study in rats (Project No. 82S0494/96086; see BASF DocID 1999/11868). In this study, relative standard deviations of the homogeneity samples in the range of 1.5 to 2.0% indicate the homogenous distribution of pyraclostrobin in the diet preparations at concentrations of 25 and 200ppm.

Concentration control analyses were performed in the course of the 1-generation study. Analyses were carried out at the beginning of the administration period, thereafter in intervals of about 6 weeks during the study, and before study termination.

The actual test article concentrations were in the range of 90.5 to 104.2% of nominal concentration. The means were in the range of 98.0 to 99.4% of nominal concentrations.

Analyses of the test item preparations for stability and test item content (current study: project no. 15R0494/96131)

Dose level [mg/kg] = [ppm]	Sampling	Concentration [mg/kg]	% of Nominal
200	March 5, 1997	206	103.0
	April 16, 1997	181	90.5
	May 21, 1997	201	100.5
Average		**196.0 ± 13.2**	**98.0 ± 6.6**
400	March 5, 1997	415	103.8
	April 16, 1997	365	91.3
	May 21, 1997	408	102.0
Average		**396.0 ± 27.1**	**99.0 ± 6.8**
600	March 5, 1997	625	104.2
	April 16, 1997	557	92.8
	May 21, 1997	607	101.2
Average		**596.3 ± 35.2**	**99.4 ± 5.9**

4. Statistics:

Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to the following tables:

Statistics of clinical examinations

Parameter	Statistical test
Food consumption (parental animals), body weight and body weight change (parental animals and pups; for the pup weights, the litter means were used), number of mating days, duration of gestation, number of pups delivered per litter	Simultaneous comparison of all dose groups with the control group using the DUNNETT-test (two-sided) for the hypothesis of equal means
Male and female mating indices, male and female fertility indices, gestation index, females with liveborn pups, females with stillborn pups, females with all stillborn pups, live birth index, pups stillborn, pups died, pups cannibalized, pups sacrificed moribund, viability index, lactation index, number of litters with affected pups at necropsy	Pairwise comparison of each dose group with the control group using FISHER'S EXACT test for the hypothesis of equal proportions
Proportions of affected pups per litter with necropsy observations	Pairwise comparison of each dose group with the control group using the WILCOXON-test (one-sided) for the hypothesis of equal medians

Statistics of pathology and clinical pathology

Weight parameters	Non-parametric one-way analysis using KRUSKAL-WALLIS test (two-sided). If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using the WILCOXON test for the hypothesis of equal medians.
Clinical pathology parameters, except differential blood count	Non-parametric one-way analysis using KRUSKAL-WALLIS test (two-sided). If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using MANN-WHITNEY U- test (two-sided) for the equal medians.

C. METHODS

1. Observations:

The animals, i.e. parental animals and pups, were examined for mortality at least once daily. If animals were in a moribund state, they were sacrificed and necropsied. Observations for clinical evident signs of toxicity were performed once daily.
The nesting, littering, and lactation behavior of the dams was generally evaluated in the mornings in combination with the daily clinical inspection of the dams. Only special findings (e.g. disability to deliver) were documented on an individual dam basis.
The littering behavior of the dams was also inspected on weekdays (except holidays) in the afternoons in addition to the evaluations in the mornings.

2. Body weight:

Body weight of **parental** animals was determined once a week at the same time of the day (in the morning). The body weight change of the animals was calculated from these results. The following exceptions are notable for female parental animals:

a. During the mating period the F_0 generation parental females were weighed on the day of positive evidence of sperm (GD 0) and on GD 7, 14, and 20.
b. Females were not weighed during mating until there was a positive evidence of sperm in vaginal smears.
c. Females with litter were weighed on the day after parturition (PND 1) and on PND 4, 7, 14, and 21.
d. Females without litter were not weighed during the lactation phase.

Pup body weights were determined on the day after birth (PND 1) and on PND 4 (before standardization), 7, 14, and 21 at the same time of the day (in the morning) and on PND4 immediately before standardization of the litters. Pup body weight change was calculated from these results.

3. Food consumption, food efficiency and compound intake:

During the premating period of the F_0 generation parental animals, food consumption was determined once a week (for a period of 7 days) and calculated as mean food consumption in grams per animal and day.

Food consumption of the F_0 parental females during pregnancy (animals with evidence of sperm) was determined weekly on GD 0, 7, 14, 20. During the lactation period food consumption of the females was determined on PND 1, 4, 7 and 14.

No food consumption was determined between PND 14 and 21, as required in the test guidelines, since during this time pups will begin to consume considerable amounts of solid food offered, and therefore there was no point in such a measured.

No food consumption was determined after week 6 in F_0 parental males, during the mating period and for females without positive evidence of sperm during the programmed gestation phase and in females without litters during the lactation phase.

The mean daily intake of test substance (group means in mg/kg bw/d) was calculated based upon individual values for body weight and food consumption:

$$\text{Substance intake for day x} = \frac{FC_x \times C}{BW_y}$$

FC_x = daily food consumption on day x in grams; C = concentration in ppm; BW_y = body weight on day y in grams (last weighing before day x)

4. Ophtalmoscopy:

Not performed in this study

5. Hematology and clinical chemistry:

The following hematological and clinical chemistry parameters were determined for all animals per test group and sex:

Hematology:					
	Red blood cells		*White blood cells*		*Clotting Potential*
✓	Erythrocyte count (RBC)	✓	Total leukocyte count (WBC)	✓	Platelet count
✓	Hemoglobin (Hb)	✓	Differential blood count		Prothrombin time
✓	Hematocrit (Hct)				
✓	Mean corp. volume (MCV)				
✓	Mean corp. hemoglobin (MCH)				
✓	Mean corp. Hb. conc. (MCHC)				
✓	Reticulocytes				
Clinical chemistry:					
	Electrolytes		*Metabolites and Proteins*		*Enzymes:*
✓	Calcium	✓	Albumin	✓	Alanine aminotransferase (ALT)
✓	Chloride		Bile acids	✓	Aspartate aminotransferase (AST)
✓	Phosphorus (inorganic)	✓	Bilirubin (total)	✓	Alkaline phosphatase (ALP)
✓	Potassium	✓	Cholesterol	✓	γ-glutamyl transpeptidase (γ-GT)
✓	Sodium	✓	Creatinine	✓	serum cholinesterase (SCHE)
✓	Magnesium	✓	Globulin (by calculation)		
		✓	Glucose		
		✓	Protein (total)		
		✓	Triglycerides		
		✓	Urea		

Furthermore, differential blood smears and smears for reticulocyte counts were prepared and stained according to Wright without being evaluated.

6. Estrous cycle determination:

Not performed in this study.

7. Male reproduction data

For males, mating and fertility indices were calculated for F_1 litters according to the following equations:

$$\text{Male mating index [\%]} = \frac{\text{number of males with confirmed mating *}}{\text{number of males placed with females}} \times 100$$

* defined by a female with vaginal sperm or with implants in utero

$$\textit{Male fertility index [\%]} = \frac{\textit{number of males proving their fertility *}}{\textit{number of males placed with females}} \times 100$$

** defined by a female giving birth to a litter with pups / fetuses in utero*

8. Sperm parameters

Not performed in this study.

9. Female reproduction and delivery data

For females, mating, fertility and gestation indices were calculated for F_1 litters according to the following equations:

$$\textit{Female mating index [\%]} = \frac{\textit{number of females mated *}}{\textit{number of females placed with males}} \times 100$$

* defined as the number of females with vaginal sperm or that gave birth to a litter or with fetuses in utero

$$\textit{Female fertility index [\%]} = \frac{\textit{number of females pregnant *}}{\textit{number of females mated **}} \times 100$$

* defined as the number of females that gave birth to a litter or with fetuses in utero

*** defined as the number of females with vaginal sperm or with implants in utero*

$$\textit{Female gestation index [\%]} = \frac{\textit{number of females with live pups on the day of birth}}{\textit{number of females pregnant *}} \times 100$$

* defined as the number of females that gave birth to a litter or with fetuses in utero

The total number of pups delivered and the number of liveborn and stillborn pups were noted, and the live birth index was calculated for F_1 litters:

$$\text{Live birth index [\%]} = \frac{\text{number of liveborn pups at birth}}{\text{total number of pups born}} \times 100$$

10. Litter data

All F_1 pups were examined as soon as possible on the day of birth to determine the total number of pups and the number of liveborn and stillborn members of each litter. Pups, which died before the first examination on the day of birth, were designated as stillborn pups.

The number and percentage of dead pups on the day of birth (PND 0) and of pups dying between days 1-4, 5-7, 8-14 and 15-21 of the lactation period were determined.

The number of live pups/litter was calculated on the day after birth, and on lactation days 4, 7, 14, and 21. Furthermore, viability and lactation indices were calculated as follows:

$$\text{Viability index [\%]} = \frac{\text{number of live pups on day 4* after birth}}{\text{number of live pups on the day of birth}} \times 100$$

* before standardization of litters (i.e. before culling)

$$\text{Lactation index [\%]} = \frac{\text{number of live pups on day 21 after birth}}{\text{number of live pups on day 4* after birth}} \times 100$$

* after standardization of litters (i.e. after culling)

On the day of birth (PND 0) the sex of the pups was determined by determination of the anogenital distance. Subsequently the sex of the pups was assessed by the external appearance of the anogenital region and/or the mammary line. The sex of the animals was finally confirmed at necropsy. The sex ratio was calculated at PND 0 and PND 21 after birth using the following equation:

$$\text{Sex ratio [\%]} = \frac{\text{number of live male or female pups on day 0 / 21}}{\text{number of live male and female pups on day 0 / 21}} \times 100$$

11. Sacrifice and pathology:

The **parental animals** were sacrificed by decapitation under CO_2 anesthesia. The exsanguinated animals were necropsied and assessed by gross pathology. Animals that were sacrificed in a moribund state were necropsied as soon as possible after death and assessed by gross pathology. The organs were sampled and weighed as indicated in the table below. No histopathological examinations were performed.

Pathology:
The following organs were collected (column C), weighed (W) and examined histopathologically (H, ✓: all groups, #: control and top dose).

C	W	H		C	W	H		C	W	H	
✓			adrenals	✓			larynx	✓			skin
✓			aorta	✓	✓		liver	✓			spinal cord (3 levels)@
✓			bone marrow§	✓			lung	✓			spleen
✓			brain	✓			lymph nodes#	✓			sternum w. marrow
✓			caecum	✓			mammary gland (♀)	✓			stomach (fore- & glandular)
✓			colon	✓			muscle, skeletal	✓	✓		testes
✓			duodenum	✓			nerve, peripheral (sciatic n.)	✓			thymus

✓			jejunum	✓			rectum				
✓	✓		kidneys	✓			salivary glands				
✓			lacrimal glands%	✓			seminal vesicles~				

§ from femur; # axillary and mesenteric; @ cervical, thoracic, lumbar; *mandibular and sublingual.; % extraorbital, ‡

All **pups** with scheduled sacrifice (i.e. pups, which were culled on PND 4 and pups, which were sacrificed on PND 21 or subsequent days) were killed by means of CO_2.These pups were examined externally and eviscerated, their organs were assessed macroscopically and their duodeni were retained by litter in 4% formaldehyde solution. All stillborn pups and all pups that died up to weaning were examined externally, eviscerated, and their organs assessed macroscopically and their duodeni were retained by litter in 4% formaldehyde solution. All pups without any notable findings or abnormalities were discarded after their macroscopic evaluation.

II. RESULTS AND DISCUSSION

A. TEST SUBSTANCE ANALYSES

See section B 3 above.

B. OBSERVATIONS

1. Clinical signs of toxicity

No treatment-related clinical observations were noted in the male and female F_0 parental animals in any group during the administration period.

The isolated occurrence and the absence of a dose-response relationship of the following observations indicated a spontaneous origin of these findings:

- During the gestation period one dam (#133) of the high dose group (600 ppm) showed insufficient nesting activity around the expected day of parturition for F_1 litter.
- One low dose (200 ppm) dam (#113) and one mid dose (400 ppm) dam (#125) were sperm-positive but did not deliver any pups.
- During lactation of F_1 one control dam (#105) did not cut all umbilical cords and did not consume all placentae of its litter after delivery.
- One dam (#130) of the mid- dose group (400 ppm) had only one pup which was stillborn or died on the day of birth, thus this dam had no live pups.

2. Mortality

No mortality was observed in any of the male and female F_0 parental animals throughout the study.

C. PARENTAL BODY WEIGHT AND BODY WEIGHT GAIN

Treatment-related effects on body weight and body weight changes were found in mid and high dose F_0 males and females.

Mean body weights of the mid dose (400 ppm) F_0 males were statistically significantly reduced from study week 4 until termination at week 14 (-10%).
Statistically lower mean body weights in the high dose males were already recorded from study week 1 onwards (-14% at week 14). Concomitantly, mean body weight gains of mid and high dose males were statistically significantly lower for weeks 0-14 (-15% and -20%, respectively) [Figure 5.6.1-1].

In high dose (600 ppm) F_0 females mean body weights were slightly but non-significantly lower during premating (-6%), and statistically significantly lower during gestation (GD20: -11%) and lactation (-9% at weaning). As compared with controls body weight gains were impaired in 600 ppm females during premating (-14% for weeks 0-6) and gestation (GD 0-20: -15%), but not during lactation. During lactation days 1 and 14 body weights were decreased in the mid dose (400 ppm) females. Occasionally, body weight gains were impaired in mid dose females during gestation (GD0-20: -18%), but not during lactation [see Figure 5.6.1-1 and Figure 5.6.1-2].

Most of the adverse effects on body weight data were associated with concurrent reductions in food consumption (see below).

Figure 5.6.1-1: Body weight development of F_0 male (left) and female (right) rats during premating

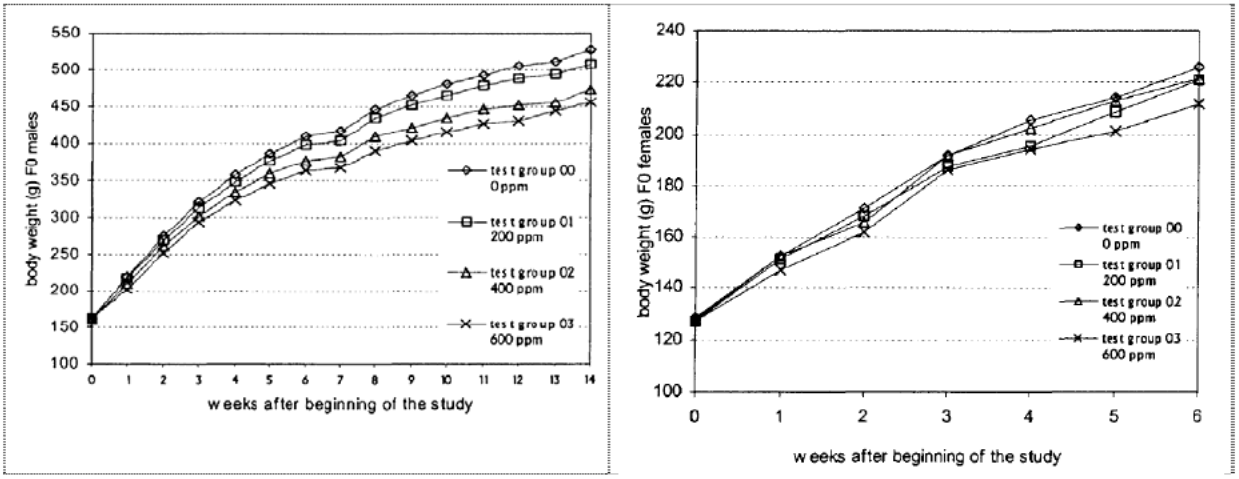

Figure 5.6.1-2: Body weight development of F_0 females during gestation (left) and during lactation (right) of F_1 pups

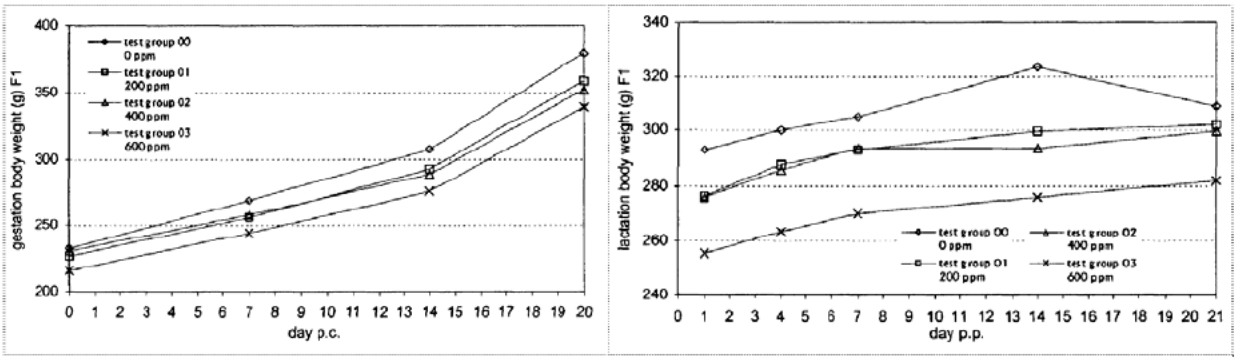

D. PARENTAL FOOD CONSUMPTION AND COMPOUND INTAKE

During the premating period treatment-related effects on food consumption were seen in mid and high dose (400 and 600 ppm) F_0 parental males and were restricted to high dose females. During gestation and lactation substance-related reduced food consumption was observed in F_0 females at all dose levels, i.e. 200,400, and 600 ppm (gestation) and at the mid and high dose levels (lactation).

A statistically significant reduction of food consumption in F_0 parental males by approx. 8 and 10% in the 400 and 600 ppm dose group, respectively, was observed during the entire premating period (weeks 0-6) [see Figure 5.6.1-3]. Food consumption values of the low dose (200 ppm) males were similar to the concurrent control animals during the pre-mating phase.

A treatment-related decrease in food consumption by up to 10% was observed in high dose F_0 females during the whole premating period, reaching statistical significance for all except one interval (week 5-6). Food consumption values of the low and mid dose group females were not affected by treatment during premating.

During gestation food consumption was statistically significantly lower in all dose groups compared to controls (GD 0-20: -7%, -11%, and -15% at 200, 400, and 600 ppm, respectively, compared to -4%). During lactation days 1-14, the food uptake was reduced by 18% and 23% at 400 and 600 ppm, respectively [see Figure 5.6.1-4].

Figure 5.6.1-3: Food consumption of F_0 male (left) and female (right) rats during premating

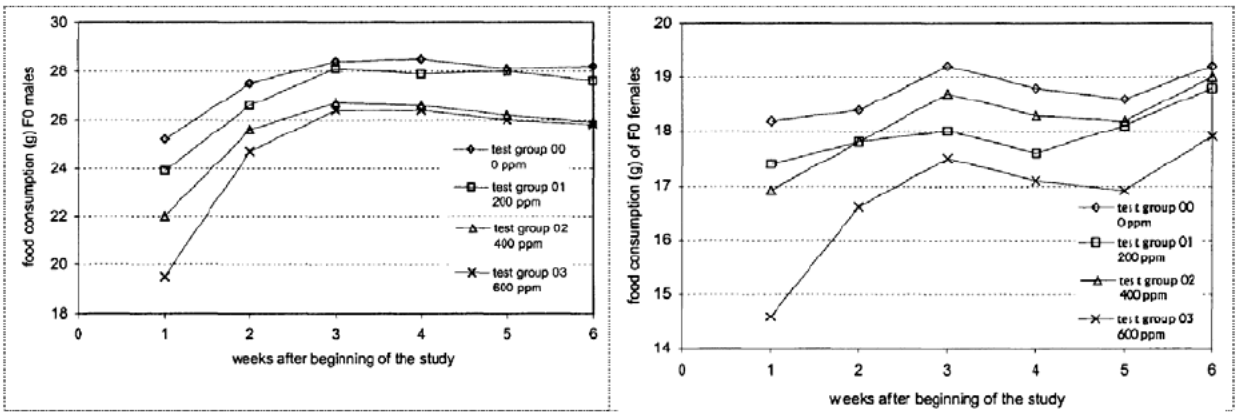

Figure 5.6.1-4: Food consumption of F_0 females during gestation (left) and during lactation (right) of F_1 pups

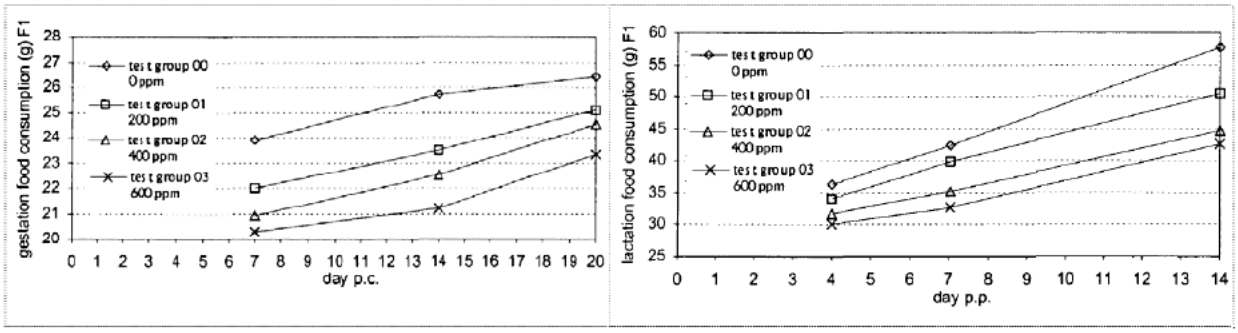

E. COMPOUND INTAKE

Average compound intakes during the different phases of the 1-generation range-finding study are provided in Table 5.6.1-1. Compound intakes in females tended to be slightly lower during gestation, but were roughly 30% higher during the lactation period when compared to the premating period.

Table 5.6.1-1: Average compound intake in F_0 and F_1 parental animals [mg/kg bw/day]

Parental generation	F_0		
Dose [ppm]	200	400	600
Males	20.5	39.9	59.1
Females			
- premating	21.3	42.5	60.4
- gestation	18.3	35.0	53.2
- lactation (PND 1-14)	29.0	51.9	80.2

F. ESTROUS CYCLE DETERMINATIONS

Not determined in this study.

G. MATING AND GESTATION DATA

1. Male reproductive performance

Male reproductive performance was not affected by treatment [see Table 5.6.1-2]. For all F_0 males which were placed with females to generate F_1 pups, mating was confirmed, thus the male mating index was 100% in all dose groups. For nearly all F_0 parental males, fertility was confirmed within the scheduled mating interval. The male fertility index varied between 90% and 100% without showing a dose-response relationship. Each one male of the low dose (male #13 mated with female #113) and the mid dose group (male #25 mated with female #125) did not generate F_1 progeny. In the absence of a dose-response relationship and gross macroscopic findings these changes in single animals are regarded to be spontaneous in nature and not associated with treatment.

Table 5.6.1-2: Reproduction parameters of male rats treated with BAS 500 F

Parental generation	F_0			
Dose [ppm]	0	200	400	600
Animals per dose	10	10	10	10
Male fertility				
- placed with females	10	10	10	10
- mated [n]	10	10	10	10
- mating index [%]	**100**	**100**	**100**	**100**
- pregnant [n]	10	9	9	10
- Fertility index [%]	**100**	**90**	**90**	**100**

2. Sperm analysis

Not performed in this study.

3. Female reproductive performance

Female reproductive performance was not affected by treatment. The female mating index was calculated to be 100% for all dose groups.

All F_0 females that were mated became pregnant except for one female in the low dose group (female #113) and one female in the mid dose group (female #125). Therefore, the fertility index varied between 90% (at 200 and 400 ppm) and 100% (in the control group and high dose 600 ppm group). Due to the lack of a dose-response relationship and in the absence of gross pathology findings, these changes are assessed to be incidental.

The mean duration until sperm was detected (GD 0; pre coital interval) ranged between 1.4 and 2.6 days, without a relation to treatment.

No treatment related effects on gestational parameters were noted. Gestation length was essentially identical in control and treated groups. The gestation index in F_0 females was 100% for the control, low and high dose groups, indicating that all pregnant females of these groups delivered live F_1 pups. One mid dose dam (#130) had only one dead pup on the day of delivery, leading to a lower gestation index of 89% in this 400 ppm dose group. The single incidence and the lack of a dose-response relationship indicated an incidental occurrence of this finding.
Mean number of F_1 pups delivered per dam, the number of liveborn and stillborn pups and the live birth index were not affected by treatment considering the normal biological variation.

Table 5.6.1-3: Reproduction and gestational parameters of female rats treated with BAS 500 F

Parental generation		F_0			
Dose	[ppm]	0	200	400	600
Animals per dose		10	10	10	10

- **Live birth index**	[%]	97	98	98	94

H. PUP DATA

1. Survival

Survival of F_1 pups was not affected by treatment. The viability index (survival days 0 to 4 pre cull) ranged between 96 and 100% in F_1 offspring [see Table 5.6.1-4]. Pup survival from PND 4-21 (Lactation index) ranged from 97% (in the high dose group) and 100% in all the other dose groups including the control group.

2. Sex ratio

The sex ratios of F_1 pups on day 0 (day of birth) and 21 (weaning) were not affected by treatment [see Table 5.6.1-4].

3. Pup clinical observations

No clinical observations were recorded in **F_1** pups up to weaning which could be attributed to treatment.

Table 5.6.1-4: Pup survival, sex-ratio and body weights

Statistics: *: p≤0.05, **: p≤0.01

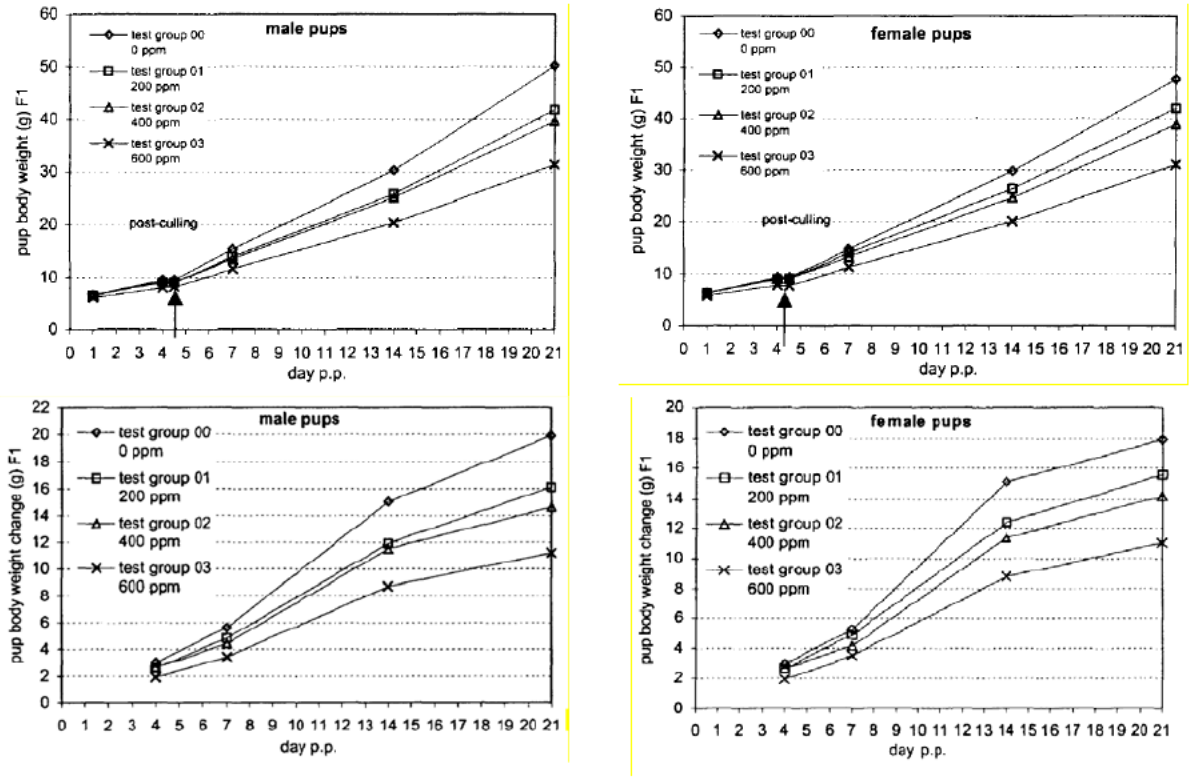
4. Body weight

F_1 male and female pup body development displayed a dose- and time related and statistically significant impairment [see Table 5.6.1-4 and Figure 5.6.1-5].

5. Organ weights

Not performed in this study.

Figure 5.6.1-5: Food consumption of F_0 females during gestation (left) and during lactation (right) of F_1 pups



6. Pup necropsy findings

No treatment-related gross necropsy findings were observed in F_1 pups. The macroscopic examination of stillborn pups, pups that died intercurrently, culled and surplus pups of F_1 litters did not reveal any differences between the test groups neither in the type nor in the number of pup necropsy observations.

Table 5.6.1-5: Incidence of gross necropsy observations in F_1 pups

Dose [ppm]	0	200	400	600
	F_1 pups			
Litters evaluated	10	10	10	10
Pups evaluated	144	125	105	137
- Live	140	123	103	129
- Stillborn	4	2	2	8
Post mortem autolysis	4(4)	0	0	1 (1)
Anasarca	0	1 (1)	0	0
Incisors sloped	0	2 (2)	1 (1)	0
Dilated renal pelvis	1 (1)	0	3 (1)	0
Total pup necropsy observations	5 (5)	3 (3)	4 (2)	1 (1)
- % affected pups/litter	3.4 ± 3.64	2.1 ± 3.24	3.5 ± 7.85	2.0 ± 6.32

( ) values in brackets give litter incidence

A few spontaneous gross necropsy findings were observed in F_1 pups of all groups including the controls. The individual findings, such as anasarca, incisors sloped, dilated renal pelvis, and post mortem autolysis were observed in a low incidence and displayed no dose response [see Table 5.6.1-5].
All findings were therefore considered to be spontaneous and not related to treatment.

7. Sexual maturation

Not performed in this range-finding study.

H. HEMATOLOGY AND CLINICAL CHEMISTRY

At the end of the administration period significantly increased white blood cell (WBC) counts were observed in all treated F_0 male groups and in high dose F_0 females.
In the differential blood counts of the males the increase in leukocytes was associated with an increase in lymphocytes in all treatment groups and with a higher number of polymorphonuclear neutrophils in the mid and high dose animals.
A slight but statistically significant decrease in hemoglobin concentration was found in mid and high dose males.
In parental females white blood cells and polymorphonuclear neutrophils were increased in the high dose animals. Significantly decreased hemoglobin, mean corpuscular hemoglobin (MCH) and mean corpuscular hemoglobin concentration (MCHC) as well as prolonged prothrombin times were found in mid and high dose females [see Table 5.6.1-6].

Table 5.6.1-6: Hematology findings of rats administered BAS 500 F during premating until PND 21

Clinical chemistry investigation in F_0 parents revealed statistically significant decreases in alkaline phosphatase (ALP) in all and alanine aminotransferase (ALT) in mid and high dose males. High dose females displayed a significant drop in cholinesterase activity (SCHE).

Blood chemistry investigations revealed a number of dose-dependent and statistically significant changes [see Table 5.6.1-7]. These treatment-related changes were printed in bold typeface. The marginally and not dose dependent decrease of calcium levels in low dose males was not considered to be treatment-related.

Table 5.6.1-7: Clinical chemistry findings of rat administered BAS 500 F during premating until PND 21

I. Parental terminal investigations

1. Organ weights

A significant and treatment-related decrease of parental terminal body weights was noted in males in the mid and high dose and in females in the low and high dose [see Table 5.6.1-8]. Organ weight determination in F_0 parental animals revealed significant changes of absolute and/or relative organ weights in males but not in females.

The statistically significant decrease of absolute liver and kidney weights as well as the statistically significant increases of relative testes and epididymis weights were not accompanied by respective changes of either relative (liver and kidney) or absolute (testes and epididymis) weights and thus considered secondary to the decrease of terminal body weights in mid and high dose males. The alterations of absolute and/or relative organ weights in parental males were not accompanied by any gross lesions (see below).

Table 5.6.1-8: Organ weights of F_1 male and female parental animals

Sex		F_0 Males				F_0 Females			
	Dose [ppm]	Absolute weight	Δ%	Relative weight [% of b.w.]	Δ%	Absolute weight	Δ%	Relative weight [% of b.w.]	Δ%

* $p \leq 0.05$, ** $p \leq 0.01$
( ) Percent difference values calculated on means

2. Macroscopic lesions

The only gross pathology finding was a thickening of the wall of the duodenum in all males of the high dose group.

3. Histopathology

Histopathology was not performed.

4. Differential ovarian follicle count

Not performed in this range-finding study.

III. CONCLUSIONS

Administration of BAS 500 F (pyraclostrobin) to rats at dietary dose levels of 0, 200, 400, and 600 ppm resulted in signs of general, systemic toxicity at all dose levels as indicated by impaired body weight development, which was partially accompanied by decreased food consumption. In mid and/or high dose levels a slight anemia was noted as indicated by decreased hemoglobin concentrations and changes of mean corpuscular hemoglobin and mean corpuscular hemoglobin concentration. A number of clinical chemistry changes were noted in addition.
Indications of developmental toxicity consisted of impaired body weight development of pups at all dose levels. No effects on fertility and reproductive performance were observed up to the highest dose tested. Therefore, under the conditions of the present range finding study no NOAEL was identified.

2-generation study, rat

Pyraclostrobin (batch No. 27882/199/b; purity: 98.7%) was administered to groups of 25 male and 25 female sexually immature Wistar rats (F0 parental generation) in the diet at concentrations of 0, 25, 75 or 300 ppm. At least 74 days after the beginning of treatment, F0 animals were mated to produce a litter (F1). Groups of 25 males and 25 females selected from F1 pups as the F1 parental generation were offered diets containing 0; 25; 75 or 300 ppm of the test substance post weaning, and the breeding program was repeated to produce an F2 litter. The study was terminated with the sacrifice of the F2 weanlings and F1 adult animals.
There were no overt clinical signs of toxicity in F0 and F1 parental animals. One high dose F0 dam died on the first day of lactation following complete delivery, which is considered to be not treatment-related since it was an isolated case without any gross or histopathological findings. The following effects were observed in animals dosed with 300 ppm pyraclostrobin: Significantly decreased food consumption was observed in the male rats during the first weeks of the premating phase (F0 up to 5%, F1 up to 12%) and in the females during the premating (F0 up to 8%, F1 up to 9%) and gestation period (F1 only, up to 7%). Significantly reduced mean body weights were noted in F0 females during gestation (up to 5%) and lactation (up to 4%) in several weeks. In the F1 generation, a lower body weight than in the control group was determined in the male animals during certain phases of treatment period (weeks 4-11, week 14: up to 7%) and in the females during the first weeks after weaning (up to 9%). A reduction in body weight gain attaining statistical significance was observed during the premating period in high dose F0 females (1st week after initiation of treatment: up to 12%) as well as occasionally in F0 males (weeks 9 –10: about 25%).
Organ weight determination as well as gross or histopathology did not reveal any evidence of compound-related changes.
There were no adverse effects on reproductive performance including sperm and ovarian parameters as well as the estrus cycle of the rats of both generations. A lower mean number of implantation sites in mid and high dose F0 dams, although statistically significant, did not show a clear dose response. Mainly because of a lower postimplantation loss in the high dose group, this difference did not result in a significant decrease in the mean number of pups delivered or the number of live born pups and, thus, did not affect the reproductive success. Furthermore, the number or implantation sites in F0 mid and high dose groups was virtually identical to that in F1 control females (14.5 ± 3.91 and 14.4 ± 2.18 versus 14.5 ± 3.27, respectively).

Finally, in the F1 generation no changes in mean implantation site number were seen. Actually, the mean number of implantations at the high dose level was higher (15.4 ± 2.74) compared to the control. This confirms that the slightly lower number of implantation sites is an expression of biological variability rather than indicative for an effect of compound administration.
Pup birth weight and pup viability were not affected by treatment.

Reduced mean body weights and body weight gains became apparent in F1 and F2 pups from day 4 *post partum* up to weaning at the highest dose levels. At the highest dose also reduced mean absolute weight of thymus (F1 about -18%; F2 about -17%), spleen (F1 about -16%; F2 about -17%) and brain (F2 about -4%) and increased mean relative brain weights (F1 about 13%; F2 about 11%) were observed. These findings were attributed to the reduction in pup body weight (gain). A delay in vaginal opening in the F1 female pups was observed at the highest dose, which was considered to be secondary to a slight delay in physical development due to the observed body weight effects rather than a specific effect of treatment. As a matter of fact, there was no high dose female with vaginal opening later than in the latest control female. Furthermore, statistically significant differences in vaginal opening were only observed for PND 30 to 32, i.e. at an early point in time. This confirms that this effect is rather related to the reduced body weight development than providing evidence of a selective effect of the test substance (for a more detailed discussion see M-CA 5.8.3).

Conclusion:
Fertility was not affected up to the highest dose level of 300 ppm (ca 32.6 mg/kg bw/d). The NOAEL concerning parental toxicity in this study was 75 ppm (approximately 8.2 mg/kg bw/d) for F0 and F1 animals, and this was also the NOAEL for reproductive toxicity in the F1 and F2 litters. Offspring effects were confined to reduced body weight gain and associated changes of organ weights. A single developmental landmark (vaginal opening) was delayed in F1 pups at 300 ppm suggesting a possible (slight) retardation in female pup development due to impaired body weight development.

CA 5.6.2 Developmental toxicity studies

Developmental toxicity, rat

Pyraclostrobin (batch No. CP028719; purity: 98.9%) was tested for its prenatal toxicity in Wistar rats. The test substance was administered as an aqueous suspension to 25 mated female rats/group by stomach tube at dosages of 0, 10, 25 and 50 mg/kg bw on days 6–19 *post coitum* (p.c.).
No mortalities, abortions or premature deliveries occurred during the study. The oral administration of pyraclostrobin elicited overt maternal toxicity at 50 mg/kg bw/d and was still toxic to the dams at 25 mg/kg bw/d. Maternal toxicity was substantiated by reduced food consumption, impairments in body weight gain (high dose only) and reductions in corrected body weight gain.
There was no evidence of an increase in the incidence of malformations up to and including the highest dose level of 50 mg/kg bw/d. However, the incidence of several soft tissue and skeletal variations was increased at 50 mg/kg bw/d. Although all increased incidences were inside the range of the historical control values, a treatment related increase at the highest dose level was not completely excluded in the DAR. At the lowest dose level, the slight increased incidence of dilated ureter, closely related to the finding dilated renal pelvis, appeared without a clear relation to dosing. It should be also noticed that dilatation of the renal pelvis is a very common finding in the offspring of this rat strain.

Conclusion:
In the prenatal toxicity study in rats, developmental toxicity was observed at the highest dose tested (50 mg/kg bw/d), based on increased incidences of several soft tissue and skeletal variations inside the range of the historical control values. This dose level was clearly toxic to the dams, as demonstrated by a 16% reduction in body weight gain. Thus, the NOAEL for maternal toxicity was established at 10 mg/kg bw/d, and the developmental NOAEL was 25 mg/kg bw/d.

Developmental toxicity, rabbit (1st study)

The teratogenic potential and developmental toxicity of pyraclostrobin (batch No. CP028719; purity: 98.9%) was studied in Himalayan rabbits. Groups of 24 or 25 pregnant female rabbits were administered the test substance as an aqueous suspension at dose levels of 0, 5, 10 or 20 mg/kg bw/d by gavage from days 7–28 post insemination (p.i.).
Two accidental deaths occurred in the control and mid dose group, respectively. Furthermore, two mid dose females were not pregnant at termination.
The oral administration of pyraclostrobin to pregnant Himalayan rabbits elicited pronounced maternal toxicity at 20 mg/kg bw/d and was still toxic to the does at 10 and 5 mg/kg bw/d. Maternal toxicity was substantiated by dose-related reduced food consumption (down to 11% of control group) with subsequent impairments in body weight gain at all dose levels and decreased defecation occurring in up to ten does, days 10-14 p.i. and one doe, day 10 p.i. at 20 and 10 mg/kg bw/d, respectively.

The corrected body weight gain (i.e., terminal body weight minus gravid uterus weight) was not affected, but additional adverse clinical findings (blood in bedding, observed in 4 does, days 16-29 p.i. and 2 does, days 16-24 p.i. at 20 and 10 mg/kg bw/d, respectively) and reductions in mean gravid uterus weight were observed, which are well in line with the embryotoxic or fetotoxic effects of the test compound at maternally toxic doses. Necropsy of the does did not reveal indications of a treatment-related effect.
There was a dose-related impact on some gestational parameters reaching statistical significance at the top dose level. Postimplantation losses were elevated mainly due to an increase in early resorptions and (consequently) the mean number of live fetuses/doe was reduced. These are not unusual findings in prenatal developmental toxicity studies in rabbits at dose levels which are clearly toxic to the does.
The incidence of external or soft tissue malformations or variations of any type was not affected by treatment, but there was an apparent but not statistically significant increase in the occurrence of skeletal malformations, consisting mainly of misshapen or absent vertebra. While the absolute number of affected fetuses was increased at the highest dose (6, 4, 5 and 9 at 0, 5, 10 and 20 mg/kg bw/d, respectively), the number of affected fetuses per litter was increased at ≥ 10 mg/kg bw/day (3.8 ± 7.0, 2.2 ± 5.1, 5.3 ± 13.2 and 12.1 ± 24.51). The percentage of affected fetuses was just outside the historical control range of this laboratory and strain. BASF submitted additional historical control data which were discussed in detail in the 4th addendum to the DAR. In essence, the total number of misshapen or absent vertebra was within the historical range.

Conclusion:

In the rabbit developmental toxicity study, maternal toxicity was proven by clear reduction of body weight gain and a lower food consumption at 5 mg/kg bw/d and above. Thus, the NOAEL for maternal toxicity was <5 mg/kg bw/d suggesting a higher susceptibility of this species as compared to the rat at least when the test compound is administered during gestation. Prenatal toxicity was substantiated by embryolethality resulting in elevated postimplantation losses and an according reduction in the mean number of live fetuses/doe at 20 mg/kg bw/d. An increased incidence of vertebral malformations was observed at 10 and 20 mg/kg bw/d, which was just inside the historical control range of this laboratory and this strain. It must be emphasised that developmental toxicity was observed only in the presence of severe maternal toxicity. The NOAEL for developmental toxicity was 5 mg/kg bw/d.
A further rabbit study was required by the Rapporteur to establish a clear NO(A)EL for maternal toxicity.

Developmental toxicity, rabbit (2nd study)

Pyraclostrobin (batch No. CP028719; purity: 98.9%) was tested for its maternal toxicity in Himalayan rabbits. The test substance was administered as an aqueous suspension to 25 inseminated females/group by stomach tube at doses of 0, 1, 3 and 5 mg/kg bw/d on day 7 through day 28 post insemination (p.i.).
There was no unscheduled mortality in this study. No abnormal clinical signs occurred in any of the groups. 24 (low dose group only) or 25 does/group became pregnant.
A dose-related decrease in food consumption was observed at the medium and upper dose levels of 3 and 5 mg/kg bw/d throughout the administration period. As compared to the control group, the difference remained statistically significant up to study day 17 at least in the high dose group, but was apparently more pronounced during the first days of treatment. Food utilisation was impaired at the highest dose level only. The lower food consumption did not result in a significant reduction in body weight. Initially, body weight gain was affected, but this effect reached statistical significance only for the first days of exposure and in the group receiving 5 mg/kg bw/d.
Necropsy of the does did not reveal treatment-related findings.
The gestational parameters were not altered. There was no impact of test substance administration up to the highest dose of 5 mg/kg bw/d on the number or the mean body weight of the fetuses. The marginally lower mean placental weight in the highest dose group (4.2 g as compared 4.6 g in all the other groups) is considered a consequence of the incidentally higher number of live fetuses/doe in this group (7.3 live fetuses/doe at 5 mg/kg bw/d versus 6.8 in the control).

Conclusion:

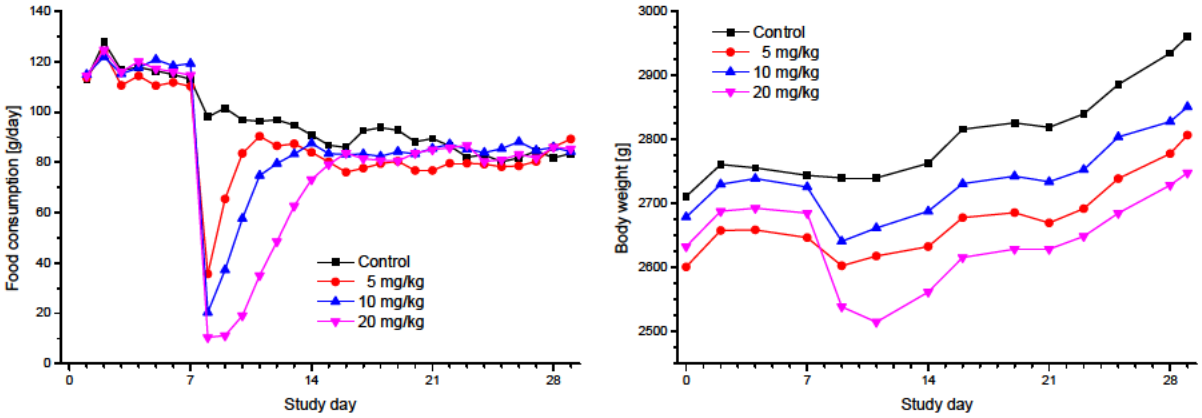
In this second study, a reduction in food consumption at the highest dose of 5 mg/kg bw/d as observed in the 1st experiment was confirmed. Again, body weight gain was reduced at this dose level, however, as compared to the control group, the difference reached statistical significance during the first three days of the exposure period only. In the mid dose group receiving a daily dose of 3 mg/kg bw from gestation days 7 through 28, food consumption was still decreased due to a significant lower food intake on days 7 and 8. In contrast to the top dose level, this effect was not accompanied by an impaired food utilisation and there was no statistically significant impact on the body weight. Thus, 3 mg/kg bw/d is considered the NOAEL for maternal toxicity.
No evidence of developmental toxicity was obtained in this additional study but the range of parameters investigated was rather limited since the foetuses were counted and weighed only.

Overall discussion

Regarding classification for developmental toxicity, the applicant considers a classification of pyraclostrobin not to be justified. For the rat the percentage of affected fetuses per litter for dilated renal pelvis (19%) was well within the historical control range (8.3 to 29.8%). The incidence of dilated ureter displayed no dose response relation-ship (0.0, 2.7. 0.6 and 3.0% at 0, 10, 25 and 50 mg/kg). Likewise, the incidence of incomplete ossified sternebra of 32.7% was within the historical control range (0 – 33.9%). Thus there is no basis for a classification.

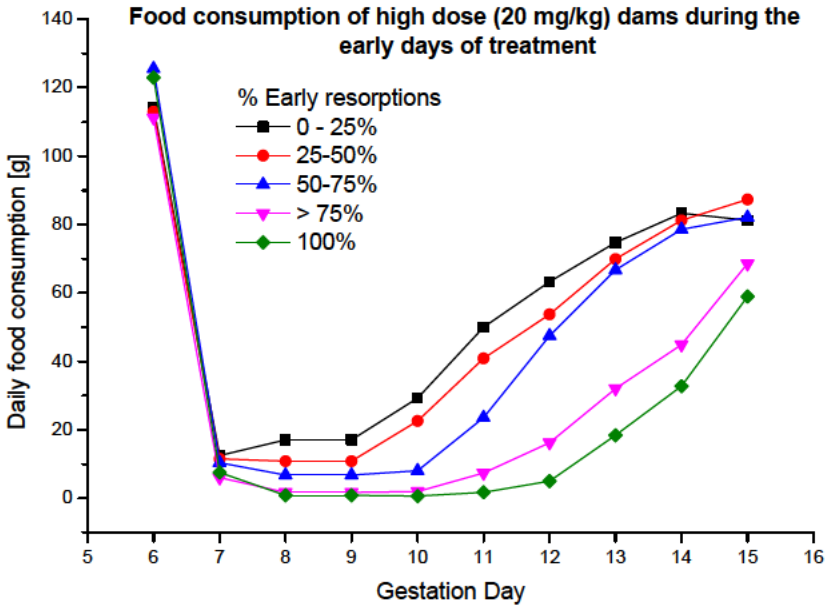
In the rabbit developmental toxicity study severe maternal toxicity as indicated by markedly reduced food consumption, body weight loss (see Figure 5.6.2-1) and clinical signs was observed. The extent and duration of the decreased food consumption was dose dependent. The mean food consumption at 20 mg/kg was decreased down to 11% of the control at days 7 and 8. The decreased food consumption resulted in a substantial body weight loss during the early phase of the pregnancy (-146.3g at 20 mg/kg bw/day vs. -3.8g in the control; days 7 to 11).

Figure 5.6.2-1: Body weight and food consumption of pregnant rabbits administered pyraclostrobin during days 7 to 28 of pregnancy



Secondary to the substantial decrease of food consumption during and shortly after implantation, embryotoxicity was increased at the high dose level (post implantation loss 38.6% ($p \leq 0.01$) at 20 mg/kg bw/day vs. 6.2% in control does). This was mainly due to an increased number of early resorptions. The relation between the extent of food consumption reduction and early resorptions becomes evident when the food consumption of does having 0 – 25%, 25 – 50%, 50 – 75% and > 75% early resorptions is grouped and plotted over time (Figure 5.6.2-2).

Figure 5.6.2-2: Correlation of decreased food consumption during and shortly after implantation and early resoprtions



Does with the highest rate of early resorption had the lowest food consumption over the longest period of time. This is especially evident from does having 100% early resorptions: the average food consumption of the three females affected was 3.2 ± 0.7 g compared to 98.0 ± 27.4 g in controls, i.e. food consumption was reduced to 3.3% of the control value. These animals also displayed a much higher day 7 to 11 body weight loss of 315.7 ± 41.6 g when compared to the high dose group mean (146.3 ± 51.7 g).

There is evidence in the literature that a reduction of food consumption causes hematology and clinical chemistry changes including alterations of progesterone levels (Matsuoka T. et al., J. Toxicol. Sci., 34(1), 129-137, 2009; J. Toxicol. Sci., 37(1), 207-14, 2012). However, the extent of reduction of food consumption in these studies was less pronounced (usually down to 10 to 15% of the control), but for a longer period of time, resulting rather in abortions at ≥ 19 days than early resorptions occurring up to day 12 of pregnancy (Matsuzawa T. et al., Toxicology, 22, 255-259, 1981; Matsuoka T. et al., J. Toxicol. Sci., 31(2), 169-175, 2006).

While all literature studies cited above were conducted in New Zealand White rabbits, the study with pyraclostrobin was conducted in Himalayan (Russian) rabbits. There is evidence from a maternal stress study that Himalayan rabbits respond to stress with an increased number of early resorptions (Schneider S. et al., Abstract 1087v, The Toxicologist, Supplement to Toxicological Sciences, 138(1), 2014, BASF DocID 2014/1177661). In this study groups of 25 pregnant rabbits were either restrained (15 min) or restrained (15 min) and dressed with stretchable bandages for 6 hours during days 6 – 28 of pregnancy. All findings were assessed against an untreated control. While neither 'treatment' resulted in changes to food consumption, maternal body weight development, any clinical signs or any fetal effects (weight, incidence of external, visceral or skeletal malformations or variations), 4 does aborted and a post-implantation loss of 50 ± 40.7% (47.1 ± 42.1% early resorptions) was observed in rabbits exposed to both stressors (restraint and wrapping). No such effects were noted in animals which were only subject to restraint.

Changes to clinical condition and a dramatic drop of food consumption are likely to result in stress in pregnant Himalayan rabbits comparable to the restraint and wrapping treatment in this study. It is likely that the dramatic drop of food consumption probably resulted in perturbations of the homeostasis of the severely affected rabbits, though this was not determined.

Therefore, the increased post-implantation loss is not considered to be a specific substance-related effect but secondary to the severe maternal toxicity. Furthermore, the Himalayan rabbit may be more susceptible than New Zealand White rabbits to perturbations of the normal homeostasis during or shortly after implantation.

The second finding discussed in the DAR and its amendments was an apparent, but not statistically significant increase of skeletal malformations (fetal incidence: 6, 4, 5, and 9; litter incidence: 6, 4, 4, 7; % affected fetuses per litter: 3.8 ± 7.0, 2.2 ± 5.0, 5.3 ± 13.22 and 12.1 ± 24.51 at 0, 5, 10, and 20 mg/kg bw/d, respectively). These malformations mainly pertained to the vertebrae, 'absent/missing lumbar vertebra' was the most common finding. While the total number of vertebral malformations was outside the historical control at the time of reporting, additional historical control data, which included studies performed later, demonstrated that the incidence was actually within the historical control range. These data were discussed in the 4th Addendum to the DAR and are depicted in Figure 5.6.2-3.

As evident from Figure 5.6.2-3, vertebral malformations are relatively common and mostly evenly distributed between controls and treated groups. There are two exceptions – the pyraclostrobin (BAS 500 F) study and study 92082. In both cases the incidence of vertebral malformations at the high dose was considerably higher than in the concurrent controls. However, the incidences are still within the spontaneous occurrence of this finding as indicated by the second of the 2001 studies, which likewise had 7 malformed vertebrae in the control group. Study 92082 is interesting for another reason: In study 92100 the same test-item as in study 92082 was used and the apparent increase of vertebral malformations could not be reproduced even though the rabbits were dosed with 1200 mg/kg bw/day, whereas in study 92082 dose levels of 0, 100, 400 and 1000 mg/kg bw/day were used. This demonstrates that the incidence of vertebral malformations is highly variable and observable in all groups, controls and treated, without obvious relation to treatment.

Figure 5.6.2-3: Incidence for vertebral malformations in 23 studies conducted between 1991 and 2001

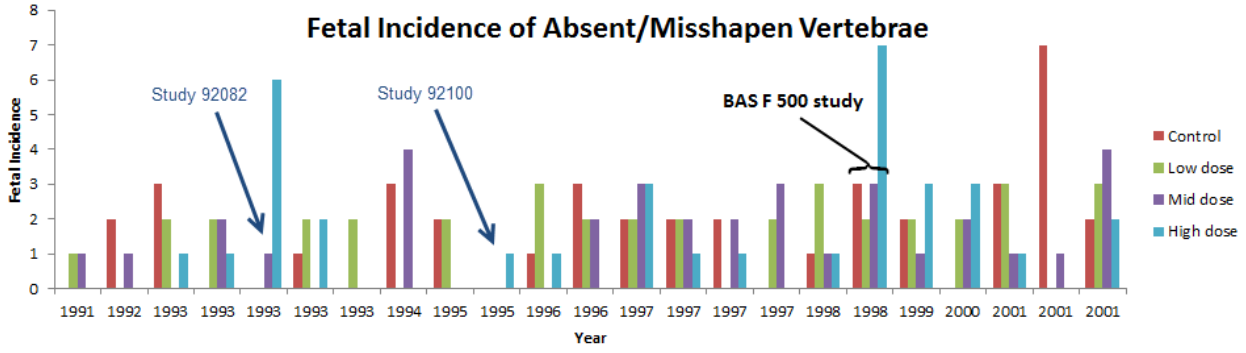


Figure 5.6.2-4: Incidence for lumbar vertebral malformations in 23 studies conducted between 1991 and 2001

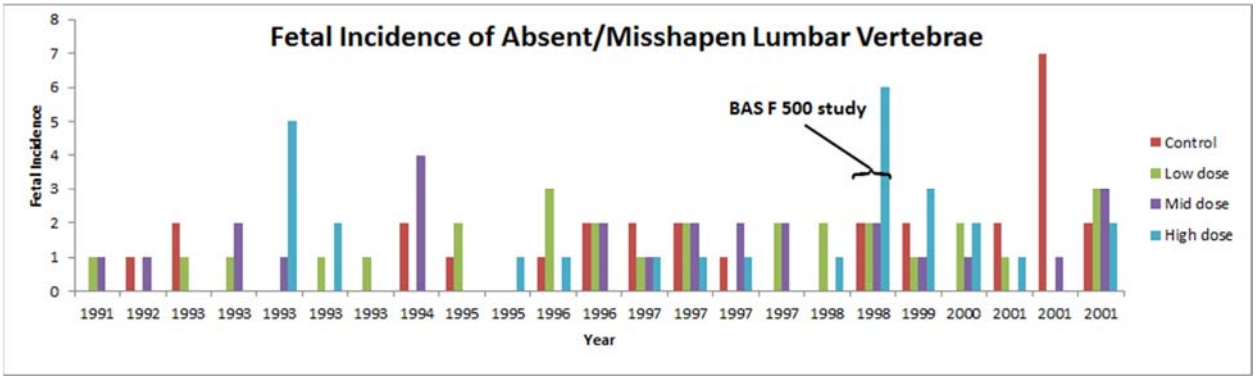


The incidences given in Figure 5.6.2-4 depict the incidence lumbar malformations. It is interesting to note that 110 of the 145 cases, i.e. 75.9% of vertebral malformations pertained lumbar vertebrae, i.e. lumbar vertebral malformations are quite common in Himalayan rabbits.

At the time of these studies, the lab assumed 12 thoracic and 7 lumbar vertebrae to be the "typical" pattern of the vertebral column in rabbits. If only 6 lumbar vertebrae were counted without having additional thoracic or sacral vertebrae, this was called a "missing lumbar vertebra" and classified as a malformation. However, there is evidence from the literature that, in contrast to what is observed in rodents, the thoracolumbar border and the number of presacral vertebrae generally is highly variable in rabbits. Variants in the number of vertebrae are quite common in this species. In addition to the historical data presented above, Greenaway et al. (J. Am Anim Hosp Assoc, 37, 27-34, 2001, BASF DocID 2001/1031903) found the "typical" 12/7 lumbosacral vertebral configuration in only 43.8% of the investigated rabbits. Viertel and Trieb (Laboratory Animals, 37, 19–36, 2003; BASF DocID 2003/1034159) showed that "missing lumbar vertebrae" is among the most often seen spontaneous malformations in the Himalayan rabbit breeding line used in the presented studies.
Thus the significance of extra or missing lumbar vertebrae in developmental toxicity is unclear. The lack of concordance of vertebral variation between animal species (i.e. rabbits vs. rodents) suggest that these findings might just reflect species-specific anatomic variation, without indication of a detrimental effect on health.

CA 5.7 Neurotoxicity Studies

Studies evaluated in the draft monograph of Rapporteur Member State Germany of August 01, 2001:

An acute and a short-term neurotoxicity study in rats are available for pyraclostrobin. These studies have been evaluated by European authorities and Germany as Rapporteur Member State (European Commission Peer Review Program) and were considered to be acceptable. For the convenience of the reviewer, these are summarized below as extracted from the monograph.

Table 5.7-1: Summary of neurotoxicity studies with pyraclostrobin

Study Dose levels (Batch / purity)	sex	NOAEL mg/kg bw/d	LOAEL mg/kg bw/d	Adverse effects at LOAEL	Reference (BASF DocID)
Acute neurotoxicity study Wistar rat, 0, 100, 300 and 1000 mg/kg bw/d	M	1000	not obtained	no signs of neurotoxicity observed	1999/11111
	F	1000	not obtained	no signs of neurotoxicity observed	
Subchronic (3 months) neurotoxicity study Wistar rat, 0, 50, 250 and 750 (males only) and 1500 ppm (females only)	M	49.9 (750 ppm)	not obtained	no signs of neurotoxicity observed	1999/11329
	F	111.9 (1500 ppm)	not obtained	no signs of neurotoxicity observed	

In the acute neurotoxicity study the unspecific signs of toxicity were attributed rather to acute systemic toxicity and/or local effects on the digestive tract than indicative of a specific neurotoxic potential. The NOEL for neurotoxicity under the conditions of this study was 1000 mg/kg bw in both sexes, i.e. the highest dose tested.

Oral administration of pyraclostrobin to rats over three months revealed no adverse neurobehavioral effects and did not show any alterations in neuropathology investigations. The NOELs for neurotoxicity were 1500 ppm (111.9 mg/kg bw/d) in females and 750 ppm (49.9 mg/kg bw/d) in males, the highest dosages applied. As already seen in subchronic studies with pyraclostrobin, the test substance caused signs of general toxicity at 1500 ppm in females and 750 and 250 ppm in males. The no observed effect level (NOEL) for systemic effects was 250 ppm (20.4 mg/kg bw/d) in female rats and 50 ppm (3.5 mg/kg bw/d) in males.

Based on the available data, the following endpoint was determined during the previous Annex I listing process of pyraclostrobin concerning neurotoxicity/delayed neurotoxicity:

Neurotoxicity / Delayed neurotoxicity (SANCO/1420/2001)

	No neurotoxic potential (rat, acute and 13 week studies)

There are no new studies available with pyraclostrobin that could affect the overall evaluation for neurotoxicity and delayed neurotoxicity. Thus, the conclusion for relevant endpoints for the current renewal remains as follows:

Acute neurotoxicity	Not neurotoxic **No classification required**
Subchronic neurotoxicity	Not neurotoxic **No classification required**

For convenience of the reviewer brief summaries of the respective studies as extracted from the monograph of are provided under the respective chapters.

CA 5.7.1 Neurotoxicity studies in rodents

Acute neurotoxicity study, rat

Pyraclostrobin (Batch CP 029053; Purity 99.0%) was administered to groups of 10 male and 10 female Wistar rats as a single oral administration by gavage at dose levels of 0, 100, 300 and 1000 mg/kg bw.
At the high dose level (1000 mg/kg bw), piloerection was observed in 4 females. Impaired body weight change in males on day 7 was also evident. At this dose level, also diarrhoea was observed in 5 males and 4 females. In animals dosed with 300 mg/kg bw, diarrhoea was observed in 2 males and 1 female. Furthermore, soft faeces were observed in 1 male rat of the 1000 mg/kg bw group, 5 males of the 300 mg/kg bw group, and in 3 males and 1 female of the 100 mg/kg bw group. All clinical findings were observed on day 0 (day of administration) only, and were reversible by day 7 post exposure.
Functional observational batteries and motor activity measurements did not reveal evidence of treatment-related differences between the groups. The histological examination of the central and peripheral nervous system did not reveal any substance-dependent changes in the organs examined.

Conclusion:

Pyraclostrobin did not exhibit neurotoxicity following a single oral administration to rats. The unspecific signs of toxicity recorded in the present study were rather due to acute systemic toxicity and/or local effects on the digestive tract than indicative of a specific neurotoxic potential. The NOEL for neurotoxicity under the conditions of this study was 1000 mg/kg bw in both sexes, i.e. the highest dose tested.

Subchronic neurotoxicity study, rat

Pyraclostrobin was administered to groups of 10 male and 10 female Wistar rats at dietary concentrations of 0, 50, 250 and 750 (males only) or 1500 ppm (females) for 3 months.
Reduced food and water consumption was observed in animals of the high (1500 / 750 ppm) dose level, as well as in males of the mid (250 ppm) dose level. At the high dose level, body weight was reduced in males (11.9%) and females (8.9%). Body weight gain at this dose level was reduced by 17.4% (males) and 18.1% (females).
An impairment of grip strength of forelimbs at the end of the study was noted in high dose animals, but was attributed to the lower body weight. There were no test substance related effects at 50 ppm.
Neurohistopathological investigations did not show any test substance related changes at any dose level.

Conclusion:

Pyraclostrobin caused signs of general toxicity at 1500 ppm in females and 750 and 250 ppm in males. The no observed effect level (NOEL) for systemic effects was 250 ppm (20.4 mg/kg bw/d) in female rats and 50 ppm (3.5 mg/kg bw/d) in males. No signs of selective neurotoxicity were detected under the conditions of this specially designed study. The NOELs for neurotoxicity were 1500 ppm (111.9 mg/kg bw/d) in females and 750 ppm (49.9 mg/kg bw/d) in males, the highest dosages applied.

CA 5.7.2 Delayed polyneuropathy studies

As there was no indication for neurotoxicity and/or neuropathy from any of the studies conducted and as pyraclostrobin does not belong to a chemical class suspected to induce delayed neuropathies, no study is considered to be necessary and thus no further study was conducted.

CA 5.8 Other Toxicological Studies

CA 5.8.1 Toxicity studies of metabolites

Studies evaluated in the draft monograph of rapporteur member state Germany of August 1, 2001: Studies submitted for Annex I listing consisted of 3 Ames tests of water photolysis metabolites BF 500-11 (= Reg.No. 411847 = 500M60), BF 500-13 (= Reg.No. 412785 = 500M62) and BF 500-14 (= Reg.No. 413038 = 500M76). All three tests were negative. For the convenience of the reviewer, these studies are summarized below as extracted from the monograph.

Based on the available data the following assessment was drawn in the Annex I listing of pyraclostrobin:

Other toxicological studies	Three water metabolites (BF500-11, BF500-13, BF500-14) proved negative in the Ames test

Pyraclostrobin is extensively metabolised in all matrices (mammal, plant and soil/water) resulting in numerous metabolites identified. Meanwhile further metabolism studies and studies on metabolites were conducted.

Within the past few years, metabolites in food of plant and animal origin were getting more into focus within the regulatory evaluation process. In 2012, EFSA published a Scientific Opinion on approaches to evaluate the toxicological relevance of metabolites and degradates of pesticides (see: EFSA Journal 2012;10(07): 2799. [187 pp.] doi:10.2903/j.efsa.2012.2799). The opinion identifies the threshold of toxicological concern (TTC) concept as an appropriate screening tool. Pyraclostrobin is intensively metabolized in plants and animals by mainly three key transformation steps:

- N-Desmethoxylation and O-desmethylation of the side chain
- Hydroxylation of the aromatic ring systems
- Cleavage between the ring systems

These reactions followed by subsequent conjugation steps lead to a large number of metabolites. A grouping of plant metabolites into 6 groups was performed according to structure. Details of this grouping can be found mainly in M-CA 5.1 as well as in M-CA 6.7 and M-CA 6.9. An overview of this grouping is given below:

- Group 1: Desmethoxy metabolite 500M07
- **Group 2: Chlorphenyl pyrazole derivatives (500M04 and derivatives)**
- **Group 3: Anthranilic acid derivatives (500M24, 500M49 and 500M51)**
- Group 4: Hydroxylated metabolites (chlorphenyl pyrazole moiety)
- Group 5: Hydroxylated metabolites (tolyl moiety)
- **Group 6: Photo metabolite 500M76**

Due to their presence in significant amounts in the rat metabolism study, the same toxicological endpoints are also applying to the Group 1 metabolite 500M07 (BF 500-3) as well as the Group 4 and the Group 5 metabolites resulting from simple ring hydroxylation reactions (plants: 500M34, 500M54, 500M56, 500M68, 500M70, 500M71; livestock: 500M08, 500M32, 500M39, 500M45, 500M64, 500M66, 500M67). The use of the same ADI value is further corroborated by investigations performed by the Austrian authority AGES (T. Coja et al., presented e.g. at the 10th International Fresenius Conference held in Mainz in February 2012).

Whereas the metabolites in Groups 1, 4 and 5 are covered by the toxicological testing of the parent molecule, the metabolites in **Groups 2, 3 and 6** will be addressed in this section. For details regarding the coverage of metabolites by the toxicological testing of the parent pyraclostrobin see M-CA 5.1 of this dossier. An estimation of the potential and actual exposure through diet is provided in M-CA 6.9.

Additionally, the metabolites **500M02 and 500M106**, which were identified in new metabolism studies (see M-CA 5.1), are addressed.

Finally, the water photolysis metabolites **500M60 and 500M62** are disussed in this section.

Accordingly, the following metabolites have been taken into consideration and their toxicological relevance is addressed in this dossier section.

Table 5.8.1-1: Pyraclostrobin metabolites considered for potential toxicological relevance

Metabolite	Structure	Reason for relevance assessment
Plant and livestock metabolites		
Group 2: Chlorphenyl pyrazole derivatives		
500M04 Reg.No. 298327		Plant metabolite in edible commodities
	Group 3: Anthranilic acid derivatives	
500M24 Reg.No. 5916421		Plant metabolite in edible commodities
500M49 Reg.No. 5916420		Plant and livestock metabolite in edible commodities
500M51 Reg.No. 78810		Livestock animal (goat) metabolite

Table 5.8.1-1: Pyraclostrobin metabolites considered for potential toxicological relevance

Group 6: Chlorphenyl pyrazole derivatives		
500M76 BF 500-14 Reg.No. 413038		Plant metabolite in feed items / Photolysis metabolite in surface water
Metabolites identified in new metabolism studies		
500M02 BF 500-7 Reg.No. 369315		In vitro metabolite
500M106 Reg.No. 399379		In vitro metabolite (also determined in rat plasma)
Water photolysis metabolites		
500M60 BF 500-11 Reg.No. 411847		Water photolysis metabolite
500M62 BF 500-13 Reg.No. 412785		Water photolysis metabolite

Based on the evaluation performed below, the conclusion for relevant future endpoints was drawn as follows:

Other toxicological studies (SANCO/11802 data point 5.8)

Toxicity studies of metabolites	**Plant and livestock metabolites** **Group 2** **500M04** - LD50 oral > 2000 mg/kg bw - not irritating to skin and eye, not a skin sensitizer - 90-day dietary rat study: NOAEL 102 mg/kg bw/day (males), 316 mg/kg bw/day (females), target organs: red-blood cell system, kidney - no evidence for genotoxicity in vitro and in vivo - ADI: 0.52 mg/kg bw/day (200 SF, 90-day rat study) **Conclusion: not toxicologically relevant** **Group 3** **500M24** - no evidence for genotoxicity in vitro and in vivo - ADI: 0.0015 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) - ARfD: 0.005 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) **Conclusion: not toxicologically relevant** **500M49** - no evidence for genotoxicity in vitro - ADI: 0.0015 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) - ARfD: 0.005 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) **Conclusion: not toxicologically relevant** **500M51** - no evidence for genotoxicity in vitro - ADI: 0.0015 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) - ARfD: 0.005 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) **Conclusion: not toxicologically relevant** **Group 6** **500M76** - no evidence for genotoxicity in vitro and in vivo - ADI: 0.0015 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) - ARfD: 0.005 mg/kg bw/day (based on TTC-concept for non-genotoxic compounds) **Conclusion: not toxicologically relevant** **Metabolites (human and rabbit) identified in in vitro comparative metabolism** **500M02** - by weight of evidence no conclusive alert for genotoxicity - not genotoxic in vitro (Ames, Mouse Lymphoma $TK^{+/-}$, micronucleus test) **Conclusion: not toxicologically relevant** **500M106** - 28-day oral gavage study in rats: NOAEL 300 mg/kg bw/day (both sexes) - evidence for genotoxicity in vitro, which was not confirmed in two in vivo genotoxicity studies (in vivo micronucleus test in mice and transgenic rodent assay in Muta™Mice): Overall weight of evidence: not genotoxic

- ADI: 0.5 mg/kg bw/day (600 SF, 28-day rat study)
Conclusion: not toxicologically relevant

Water photolysis metabolites
500M60
- no evidence for genotoxicity in vitro and in vivo
Conclusion: not toxicologically relevant
500M62
- no evidence for genotoxicity in vitro
Conclusion: not toxicologically relevant

The toxicological assessment was performed based on experimental studies and/or QSAR analyses.

QSAR evaluation of metabolites

For all metabolites identified with potential relevance, the presence for potential structural alerts was evaluated with different SAR/QSAR models. Models used, were the OECD toolbox, OASIS TIMES, DEREK (partly) and VEGA. However, the QSAR predictions obtained are limited in reliability as most of the structures evaluated were not in the prediction domain. Thus, given the structural relationship of the metabolites evaluated inter alia and in relation to the parent molecule pyraclostrobin, the predicted alerts were compared to those for the parent and those metabolites were toxicological data were available in order to overcome the limitations of the predictions made.

OECD Toolbox (Profiling module)

The OECD toolbox version 3.2 as downloadable via link of the ECHA webpage [http://www.qsartoolbox.org/download.html] was used for the evaluation. The outcome of the OECD toolbox profiling conducted for the metabolites was exported and collected [see DocID 2014/1172955]. The profiling module provided structural alerts for different endpoints. Of particular interest were the modules dealing with DNA-binding capacity as well as genotoxicity predictions. It should be noted that the profiles just provide structural alerts without consideration on probability that these alerts may become active or inactive due to chemical reactivity and/or sterical hindrance.

OASIS TIMES

OASIS TIMES is a hybrid statistical and knowledge-based model for toxicity prediction. The Tissue Metabolism Simulator (TIMES), developed by LMC (Bourgas University, Bulgaria; http://oasis-lmc.org/) integrates on the same platform a metabolic simulator and QSAR models for predicting toxicity of selected metabolites. The metabolic simulator generates plausible metabolic maps from a comprehensive library of Dettenbiotransformations and abiotic reactions. It allows prioritization of chemicals according to toxicity of their metabolites. Of OASIS TIMES the prediction models for Ames test and in vitro chromosome aberration were considered and therefore predictivity is limited to these test systems only. The reports for the evaluations made are available under DocID 2014/1172952 for Ames mutagenicity and DocID 2014/2014/1172953 for prediction of chromosomal aberration in vitro. Q(SAR) Model Reporting Formats (QMRF) for both endpoints are provided in DocIDs 2013/1414242 and 2013/1414460.

The reactivity model describing interactions of chemicals with DNA is based on an alerting group approach. Only those toxicophores extracted from the training set having clear interpretation for the molecular mechanism causing the ultimate effect are included in the model. The mechanistic interrelation between alerts and related parametric ranges generalizing the effect of the rest of the molecules on the alert, are also considered. The structural component of the model is based on the structural similarity between chemicals in the training set which were correctly predicted by the model. The structural neighborhood of atom-centered fragments is used to determine this similarity. The training set consists of 1514 chemicals for Ames and 808 chemicals for chromosomal aberration.

The derived model is combined with the metabolic simulator TIMES used for predicting metabolic activation of chemicals with the S9 mix. The metabolic simulator is trained to reproduce documented maps for mammalian liver metabolism for 261 chemicals. Parent chemicals and each of the generated metabolites are submitted to a battery of models to screen for a general effect and mutagenicity mechanisms. Thus, chemicals are predicted to be mutagenic as parents only, parents and metabolites, and metabolites only. Mutagenicity could be due to the parent chemical only or as a result of its metabolic activation (i.e., the parent is inactive but it is transformed to a mutagenic metabolite), or both parent structure and metabolites could be mutagenic.

This OASIS QSAR system is also included in the OECD Toolbox (but not in combination with TIMES), in order to make use of (Q)SAR approaches also in the assessment of chemicals under REACH (OECD, 2008). The BASF-internal version has the advantage that it is capable to consider metabolic transformation.

VEGA

Using the VEGA platform, access to a series of QSAR (quantitative structure-activity relationship) models for regulatory purposes was obtained. Of the models offered by VEGA [http://www.vega-qsar.eu/] only the two independent statistical prediction models for mutagenicity (Ames) were selected. The data obtained for pyraclostrobin and its metabolite can be found in DocID 2014/1172954. This report includes both models used (CAESAR and SarPy). CAESAR makes predictions based on the comparison of the structure of interest to the CAESAR database of mutagenicity data of substances in the structure database. A score is provided for the match of the structures, and the mutagenicity data of the closest related substances compared to the structure of interest. Consequently, if a structure is not adequately presented in the database, the prediction is only of very limited validity.

The second algorithm SarPy searches for isolated structural alerts of substructures in the molecule. Again, this is based on the mutagenicity data provided in the structure database. Only predictivity for mutagenicity based on the Ames test was generated.

DEREK

DEREK Nexus (http://www.lhasalimited.org/) is a knowledge-based expert system for the prediction of toxicological hazard. It is designed to assist chemists and toxicologists in predicting toxicological hazards based on an analysis of chemical structure. The DEREK Nexus knowledge base is written and maintained by experts. A collaborative group of major agrochemical, pharmaceutical, chemical and regulatory organisations oversees the development of the DEREK Nexus system and knowledge base.

DEREK Nexus uses a knowledge base, which contains alerts describing structure-toxicity relationships, with an emphasis on the understanding of mechanisms of toxicity and metabolism.

DEREK Nexus identifies any toxophores or substructures associated with toxicity, and highlights these to the user with a brief statement about the hazard it represents. The user can access additional information concerning the structure-toxicity relationship including literature references and supporting examples.

The knowledge base covers a wide variety of important toxicological end points, which include mutagenicity and neurotoxicity.

DEREK analysis for mutagenicity and neurotoxicity were performed for pyraclostrobin and a number of metabolites. The investigated species were given in the report as ‘bacterium, Escherichia coli, Salmonella typhimurium, all mammalien species’ [see BASF DocID 2011/1022602].

CAVEAT on reliability of QSAR modules implied

With regard to the QSAR evaluations as implied in the OECD toolbox, in OECD TIMES and in VEGA it should be noted that for nearly all analysis the algorithm reported an out of structural domain error. Each of this QSAR models is build on a set of chemicals that forms its chemical domain, space or applicability domain. That means that the prediction is best if a structure of interest is represented in the original baseline dataset. Substances outside of the dataset are evaluated in comparison to the chemical space, and only in case that the chemical space adequately covers all structural elements or the querried structure, the prediction is considered to be adequately covered by experimental data. Predictions outside of the applicability domain have far lower predictability. In addition, all mentioned QSAR models check for structural alerts, like those identified by the Benigni-Bossa rules that have been implicated in mutagenic actions.

As a consequence, the predictivity is solely based on the proposed DNA-interaction via the structural alert, not (OECD toolbox and VEGA) or not appropriately (OASIS TIMES) taking into account possible functional group interaction and stereochemical hindrance. It is well established that structure elements have to be evaluated within the context of a structure.

To evaluate the predictivity of each QSAR model, we also tested pyraclostrobin and all metabolites for which experimental data were available. The genotoxic alerts identified in these structures, that did not result in positive experimental genotox results are considered to be false positive.
In general, the predictivity of various QSAR models for genotoxicity equilvalent to the Ames test has been considered to be reasonable accurate. Predictivity rates expressed as accuracy and specificity are usually >80%. This is in particular true, if information from more than one QSAR model is combined.

QSAR models for chromosome aberration however are far less well established. One of the underlying limitations is that typical in vitro assays for chromosome aberration, like chromosome aberration in V79 cells or the in vitro micronucleus assay have false discovery rates of approximately 30%. This means that three out of ten molecules are falsely categorized. In addition, a high number of in vitro positive substances are negative in adequate in vivo assays. The later is often a function of the underlying mode of action and the kinetic behavior of a substance. Both are not adequately covered by QSAR predictions.

Predictions for chromosome damage were performed with OASIS Times and OECD Toolbox. The prediction model used in the OECD toolbox is similar to that of OASIS Times, with the major difference being the different underlying database of reference compounds and the combination with the metabolism generator in OASIS Times.

BASF has tested the valididy of the the OASIS Times predictions for chromosome aberration. For this > 100 chemicals with in vitro experimental data on chromosome aberration were evaluated with OASIS Times. It is important to note that all chemicals from this subset were within the applicability domain of the algorithm. The concordance between the predicted values and the experimental values was below 50%. This was even worse for a second set of chemicals, which was outside of the applicability domain of the QSAR model.

The above is exemplified with the data provided in this chapter (M-CA 5.8.1). Table 5.8.1-2 gives a short summary of the OECD Toolbox predictions and the actual results of the mutagenicity testing of pyraclostrobin and its tested metabolites. There were 4 predictions of a positive (mutagenic) outcome of the Ames test. Three of the positive outcomes were contradicted by negative test results. The fourth prediction (500M106) was not confirmed in the Ames test under the conditions of the actual test, though the in vitro gene mutation test in mammalian cells was positive. However, two in vivo genotoxicity assays (micronucleus assay in mice and a transgenic rodent assay) were clearly negative. Thus, the weight of evidence for 500M106 shows that there is no in vivo genotoxicity potential. In 8 cases the negative Ames test was confirmed by a mutagenicity assay in mammalian cells.

Table 5.8.1-2: Comparison of genotoxicity test results with QSAR predictions made by the OECD Toolbox

Identifier	Ames QSAR	Ames Test	Mam. gene mutation test	CA in vitro QSAR	CA in vitro Test	CA in vivo Test
Pyraclostrobin	negative	negative	negative	positive	negative	negative
500M60 (RegNo 411847)	negative	negative	negative	negative	positive	negative
500M62 (RegNo 412785)	positive	negative		positive	negative	
500M76 (RegNo 413038)	negative	negative	negative	negative	positive	negative
500M49 (RegNo 5916420)	positive	negative	negative	positive	negative	
500M51 (RegNo 78810)	negative	negative	negative	negative	negative	
500M24 (RegNo 5916421)	negative	negative	negative	negative	positive	negative
500M04 (RegNo 298327)	negative	negative	negative	negative	positive	negative
500M106 (RegNo 399379)	positive	negative	positive	positive	negative	negative
500M02 (RegNo 369315)	positive	negative	negative	positive	negative	

In the case of in vitro chromosome aberration 5 out of 10 predictions were positive. Only one of the predictions was actually correct (the one for 500M76 that was predicted and tested to be negative), 5 were false positive and 4 were false negative. It is important to note that in all cases of a positive in vitro CA result, the respective in vivo higher tier study was negative. As a conclusion, in the case of in vitro CA the QSAR predictions are not better than one could expect from tossing a coin.

Table 5.8.1-3: Comparison of genotoxicity test results with QSAR predictions made by OASIS TIMES

Identifier	Ames QSAR	Ames Test	Mam. gene mutation test	CA in vitro QSAR	CA in vitro Test	CA in vivo Test
Pyraclostrobin	negative	negative	negative	positive	negative	negative
500M60 (RegNo 411847)	negative	negative	negative	positive	positive	negative
500M62 (RegNo 412785)	positive	negative		positive	negative	
500M76 (RegNo 413038)	negative	negative	negative	positive	positive	negative
500M49 (RegNo 5916420)	positive	negative	negative	positive	negative	
500M51 (RegNo 78810)	negative	negative	negative	positive	negative	
500M24 (RegNo 5916421)	negative	negative	negative	negative	positive	negative
500M04 (RegNo 298327)	negative	negative	negative	negative	positive	negative
500M106 (RegNo 399379)	positive	negative	positive	positive	negative	negative
500M02 (RegNo 369315)	positive	negative	negative	positive	negative	

Due to the similarity of the algorithms behind OASIS TIMES and the OECD Toolbox, the predictions of OASIS TIMES were comparable to a great extent. The predictions for the Ames test were identical, whereas for the in vitro CA three of the OECD Toolbox negative predicted outcomes were predicted positive by OASIS TIMES [see Table 5.8.1-3]. This time the prediction for in vitro CA was correct in 2 cases, 6 were false positive and 2 were false negative. This is at the end not much better than the prediction of the OEDC Toolbox.

The VEGA system - with the CAESAR and SarPy modules used - only predicts bacterial mutagenicity. CAESAR had 5 positive and 5 negative predictions, i.e. was wrong in at least 4 cases. The fifth positive (500M106) was negative under the actual conditions of the Ames test, but positive in the mammalian cell mutagenicity test (mouse lymphoma assay). However, two in vivo genotoxicity assays (micronucleus assay in mice and a transgenic rodent assay) were clearly negative. Thus, the weight of evidence for 500M106 shows that there is no in vivo genotoxicity potential. The prediction of the SarPy system was positive in all cases, i.e. 90% of the predictions were definitively wrong.

The best prediction was finally obtained from DEREK. For none of the 6 evaluated molecules a genotoxic potential was predicted, which was 100% correct considering the in vivo micronucleus assay as higher tier study to the positive in vitro CA study, leading to the weight of evidence conclusion that the respective molecules are not genotoxic.

The applicant therefore believe that predictions made by the applied QSAR models have to be considered with substantial care and need to be evaluated based on a read across to similar structures (pyraclostrobin parent and metabolites with experimental data) that contain the respective structural elements. At least for pyraclostrobin and its metabolites the chemical space is not sufficiently represented in the databases used by the various QSAR models.

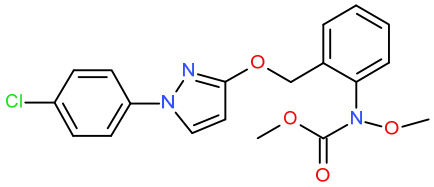
Threshold of toxicological concern concept

A further approach to assess whether chemical structures are of concern for which no or only limited information on the toxicological profile is available, is to consider whether the predicted exposure is above or below a threshold of toxicological concern. The threshold of toxicological concern (TTC) [Cramer et al. 1978a, DocID 1978/1001324; Kroes et al. 2004a, DocID 2004/1036074; Munro et al 1996a, DocID 1996/1005180] has meanwhile been considered in the EU e.g. for the evaluation of chemicals under the REACH regulation [*ECHA (2012) Guidance on information requirements and chemical safety assessment Chapter R.8: Characterisation of dose [concentration]-response for human health*] and has been employed or considered for the evaluation of food flavourings [*EFSA, 2010e. Guidance on the data required for the risk assessment of flavourings to be used in or on foods. European Food Safety Authority. The EFSA Journal 8(6): 1623. Available at: http://www.efsa.europa.eu/en/efsajournal/doc/1623.pdf*] or pesticidal degradation products by EFSA [*EFSA, 2012b. Scientific Opinion: Exploring options for providing preliminary advice about possible human health risks based on the concept of Threshold of Toxicological Concern (TTC). European Food Safety Authority (EFSA) Scientific Committee, Parma, Italy; EFSA Journal, 10(7), 2750 and EFSA, 2012a. Scientific opinion on evaluation of the toxicological relevance of pesticide metabolites for dietary risk assessment. EFSA Panel on Plant Protection Products and their Residues (PPR), European Food Safety Authority (EFSA), Parma, Italy; EFSA Journal, 10(07), 2799*].

The proposed threshold levels are 0.0025 µg/kg bw/day for potentially genotoxic compounds and 1.5 µg/kg bw/day for non-genotoxic Cramer Class III compounds.

The available toxicological database for metabolites will be discussed in the following paragraphs. This starts with an assessment of the QSAR predictions of the parent pyraclostrobin and is followed by the metabolites indicated above.

Pyraclostrobin (other denominators: BAS 500 F, 500M00, Reg.No. 304428, CAS-No. 175013-18-0)



Available experimental genotoxicity information (see M-CA 5.4):

Ames:	negative
In vitro chromosome aberration	negative
In vitro mammalian gene mutation	negative
In vivo chromosome aberration (MNT)	negative

QSAR predictions:

OECD Toolbox (Version: 3.2) [see DocID 2014/1172955]

In the OECD toolbox no DNA alerts for genotoxicity (Ames, MN, CA) and no alerts for DNA or protein binding were observed.

OASIS TIMES (MIX V.2.27.13 TB; Mutagenicity S-9 activated v08.08) [see molecule 1 of report DocID 2014/1172952 and 2014/1172953]

There were no Ames mutagenicity alerts for pyraclostrobin or in-silico generated metabolites. In all cases the structures were out of domain. For in vitro chromosome aberration the prediction for pyraclostrobin was negative (out of domain). Four out of 10 in-silico metabolites were predicted positive (in domain) with the alert info 'phenols'. The remaining in-silico metabolites were negative (out of domain).

Discussion: The in vivo and in vitro data indicates no chromosome damaging potential of pyraclostrobin. Therefore, the positive prediction for CA is not reflecting the toxicological database and is rejected.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 1 of report DocID 2014/1172954; for both VEGA models]

Pyraclostrobin is out of the model applicability domain. The prediction is 'mutagen' with no specific structural alerts. Three of the six most similar molecules had positive experimental data. The other three had the prediction non-mutagen, which was experimentally confirmed. The concordance of the total underlying database was low (0.341) and thus is not very robust. Neither the three positive (similarity 0.593 to 0.614) nor the three negative molecules (similarity 0.583 to 0.611) has a reasonably similar structure to pyraclostrobin. Therefore, the chemical space does not adequately cover the structure of pyraclostrobin.

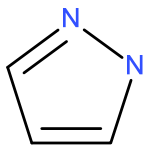
Discussion: Pyraclostrobin did not show genotoxic activity in bacterial or mammalian in vitro assay. Thus, it is apparent, that the positive prediction for genotoxicity does not reflect the experimental evidence. Therefore, the positive prediction is rejected.

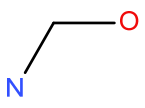
VEGA: Mutagenicity model (SarPy; version 1.0.4-BETA)

Pyraclostrobin is out of the model applicability domain. The prediction is 'mutagen' with the structural alerts SA 96 and SA 98. The prediction for the entire molecule is based on the same 6 molecules, 3 of them positive as for the CAESAR model.

The SA 96 alert (structure see below) is based on 3 molecules in the training data set, two of them were experimentally tested positive. The structure similarity for the three compounds is 0.541, 0.52 and 0.47. Therefore, the compounds are considered to be structurally dissimilar from pyraclostrobin. Pyraclostrobin did not show genotoxic activity in bacterial or mammalian in vitro assay. Thus, it is apparent, that the positive prediction for genotoxicity does not reflect the experimental evidence. Therefore, the positive prediction is rejected.

The same structural element was seen in a number of metabolites for which in vitro bacterial genotoxicity data is available, namely 500M60 (Reg.No. 411847), 500M76 (Reg.No. 413038), 500M62 (Reg.No. 412785), 500M04 (Reg.No. 298327) and 500M02 (Reg.No. 369315). None of them was mutagenic. Together with the data generated for pyraclostrobin, this clearly demonstrates that this chemical structure class has no intrinsic genotoxic potential. Therefore, the positive prediction is rejected.

Structure Alert SA 96	Structure Alert SA 98
	




The SA 98 alert (structure see above) is based on 3 molecules in the training data set, with only one of them experimentally tested positive. The lack of concordance indicates that even for the model's database SA98 is not predictive. The structure similarity for the three compounds is 0.577, 0.571 and 0.57. Therefore, the compounds are considered to be structurally dissimilar from pyraclostrobin. Pyraclostrobin did not show genotoxic activity in bacterial or mammalian in vitro assay. Thus, it is apparent, that the positive prediction for genotoxicity does not reflect the experimental evidence. Therefore, the positive prediction is rejected.
The same structural element was seen in a number of metabolites for which in vitro bacterial genotoxicity data is available, namely 500M60 (Reg.No. 411847), 500M76 (Reg.No. 413038), 500M24 (Reg.No. 4916421), 500M49 (Reg.No. 5916420), 500M51 (Reg.No. 78810), 500M62 (Reg.No. 412785). None of them was mutagenic. Together with the data generated for pyraclostrobin parent, this clearly demonstrates that this chemical structure class has no intrinsic genotoxic potential. Therefore, the positive prediction is rejected.

DEREK (Version 2.0.0.201011301322; Knowledge base version: 11_20_05_2010)
The prediction for genotoxicity and neurotoxicity was negative.

Summary and discussion:

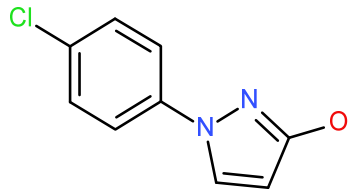
Pyraclostrobin does not induce mutagenic effects in in vitro and in vivo studies (see M-CA 5.4). All QSAR analysis models were out of domain and are thus of low predictivity. Analysis by the OECD Toolbox was negative. OASIS Times predicted no mutagenicity in bacteria (Ames test). The alert for chromosome aberration is not reflected by the available experimental data for pyraclostrobin and metabolites of similar structures and therefore is rejected. The positive prediction for genotoxicity by CAESAR is based on structures with low structural similarity and the concordance of the experimental data in the CAESAR database is only 0.341 and thus considered not to be predictive. The structural alerts SA98 and SA96 were identified via SarPy. Like for the CAESAR model the concordance and similarity was low. Based on the negative experimental results for pyraclostrobin and a number of metabolites containing the same structure elements, predictions based on SA96 or SA98 are rejected. In the following descriptions of the database for the respective metabolites, the structural alerts SA96 and SA98 identified by SarPy will therefore automatically be rejected. Prediction for genotoxicity with DEREK was negative.

This summary demonstrates that the positive association to mutagenicity or chromosome damage identified by the various QSAR algorithms are not reflected by the experimental database of pyraclostrobin.

Plant Metabolites

Group 2: Chlorphenyl pyrazole derivatives

500M04 (other denominators: Reg.No. 298327, BF 500-5, 'Pyrazolon')



500M04 (Reg.No. 298327) is a metabolite found in all compartments, i.e. soil, water, plants, livestock, fish, rat as well as in comparative in vitro metabolism studies using human, rat, rabbit and dog hepatocytes. In addition, a chlor-phenyl hydroxylated and a number of conjugated derivatives of 500M04 (Reg.No. 298327) have been identified.

QSAR Predicitions on 500M04 (Reg.No. 298327, BF 500-5, 'Pyrazolon')

OECD Toolbox (Version: 3.2) [see DocID 2014/1172955]

For 500M04 (Reg.No. 298327) the OECD toolbox did not indicate DNA alerts for genotoxicity (Ames, MN, CA) or alerts for protein binding.

Nonetheless, there is a DNA-binding alert: '*Radical|Radical >> Radical mechanism via ROS formation (indirect)|Radical >> Radical mechanism via ROS formation (indirect) >> Hydrazine Derivatives*'

Discussion: In view of the overall negative mutagenicity data package (as shown under paragraph E: genotoxicity studies) the DNA binding alert is rejected.

OASIS TIMES (MIX V.2.27.13 TB; Mutagenicity S-9 activated v08.08) [see molecule 8 of report DocID 2014/1172952 and 2014/1172953]

There were no Ames mutagenicity alerts for 500M04 (Reg.No. 298327) or in-silico generated metabolites. In all cases the structures were out of domain. The same holds true for the in vitro chromosome aberration.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 8 of report DocID 2014/1172954; for both VEGA models]

500M04 (Reg.No. 298327) is out of model applicability domain. The prediction is 'mutagen' with no specific structural alerts. The prediction is based on 6 molecules, of which only one was a predicted and actual mutagen. The similarity to 500M04 (Reg.No. 298327) of the molecules in the data set is low as indicated by similarity factors of 0.583 to 0.628. Based on the negative Ames test (see CA 5.8.1/9) the positive prediction for genotoxicity does not reflect the experimental evidence. Therefore, the positive prediction is rejected.

VEGA: Mutagenicity model (SarPy; version 1.0.4-BETA)

500M04 (Reg.No. 298327) is out of model applicability domain. The prediction is 'mutagen' with the structural alert SA 96. As discussed above, this alert was also obtained for pyraclostrobin and a number of pyraclostrobin metabolites, which like 500M04 (Reg.No. 298327) were actually tested negative. The predicition is therefore rejected.

DEREK (Version 2.0.0.201011301322; Knowledge base version: 11_20_05_2010)

The prediction for genotoxicity and neurotoxicity is negative.

Acute toxicity studies on 500M04 (Reg.No. 298327, BF 500-5, 'Pyrazolon')

Report:	CA 5.8.1/11 [redacted] 1997a Study on the acute oral toxicity of Pyrazolon in rats 1997/10963
Guidelines:	EEC 92/69, Official Journal of the European Communities L383A (1992)
GLP:	yes (certified by Ministerium fuer Arbeit, Soziales und Gesundheit, Postfach 3180, 55021 Mainz)

Executive Summary

In an acute oral toxicity study 6 Wistar rats (3/sex) were given a single oral dose via gavage of 'Pyrazolon' (synonym to Reg.No. 298327, 500M04, BF 500-5; batch 27967/95) suspended aqueous solution of 0.5% tylose CB 30.000 at a dose level of 200 and 2000 mg/kg bw.

No mortality occurred in both dose groups. Accordingly, the oral LD_{50} was found to be greater than 2000 mg/kg bw for rats.

Rat, oral: LD_{50} > 2,000 mg/kg bw

Signs of toxicity were restricted to male animals of the 2000 mg/kg bw dose group and consisted of impaired or poor general state, dyspnea, apathy and staggering. These symptoms are considered to be unspecific toxicity symptoms. The animals appeared normal two days after application. The expected body weight gain was observed in the course of the study, with the exception of one female animal of the 200 mg/kg bw dose group which showed weight reduction. No abnormalities were noted at necropsy of animals sacrificed at the end of the study.

(BASF DocID 1997/10963)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: 1-(4-chlorphenyl)-1,2-dihydro-3H-pyrazol-3-on (Pyrazolon)

Description:	crystalline powder, light-beige
Lot/Batch #:	27967/95
Purity:	100.5 g/100 g
Stability of test compound:	The stability of the test substance in 0.5% tylose CB 30.000 in aqua bidest. For a time period of 4 hours was confirmed by analysis.
CAS-No.	76205-19-1

2. Vehicle: 0.5% tylose CB 30000 (cleaned natriumcarboxy-methylcellulose in aqua bidest

3. Test animals:

Species:	Rat
Strain:	Wistar (CHBB: THOM (SPF))
Sex:	males and females
Age:	young adults
Weight at dosing (mean):	mean female: 173 g; mean male: 179 g
Source:	Dr. K. Thomae GmbH, Biberach, Germany
Acclimation period:	at least one week
Diet:	Kliba-Labordiaet 343, Klingentalmuehle AG, Kaiseraugust, Switzerland, ad libitum except 16 hours before administration (fasting period)
Water:	tap water ad libitum
Housing:	Single housing in stainless steel wire mesh cages, type DK-III (Becker & Co, Castrop-Rauxel, Germany)
Environmental conditions:	
Temperature:	20 – 24°C
Humidity:	30 – 70%
Air changes:	no data available
Photo period:	12-hour light-dark cycle (06:00 – 18:00, 18:00 – 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work:

30-May-1996 to 09-Jul-1996 (day of first administration and day of last administration + 14 days observation period)

2. Animal assignment and treatment:

6 rats (3 per sex per group) received a single dose of each 200 or 2000 mg/kg bw of test substance in 0.5% aqueous suspension of tylose CB 30.000 by oral gavage. Test substance was given to the animals at a volume of 10 mL/kg bw. The observation period lasted 14 days. Individual body weights were recorded shortly before application (day 0) and weekly thereafter and at the end of the study. Clinical signs and symptoms were recorded several times on the day of administration, at least once each workday for the individual animals. After the observation period a necropsy of all animals with grosspathology followed.

II. RESULTS AND DISCUSSION

A. MORTALITY

No deaths occurred after oral administration of 200 and 2000 mg/kg bw of the test substance.

B. CLINICAL OBSERVATIONS

At a dose of 2000 mg/kg bw p.o. male rats showed an impaired or poor general state, dyspnea, apathy, staggering and staggering on the day of administration whereas female rats did not show any symtpoms. Likewise, no symptoms were noted for males and females at the dose of 200 mg/kg bw.

C. BODY WEIGHT

Normal body weight gain was observed during the 14 days of the observation period with exception of a 200 mg/kg female, which displayed a body weight loss during the second week of observation.

D. NECROPSY

No macroscopic anomaly was noted in the organs examined after oral treatment.

III. CONCLUSION

Under the experimental conditions of this study the oral LD_{50} of 'pyrazolon' (synonym to Reg.No. 298327, 500M04, BF 500-5) in rats was determined to be greater than 2000 mg/kg bw for males and females.

Report: CA 5.8.1/12
[redacted] 1997b
Study on the acute dermal irritation/corrosion of Pyrazolon in the rabbit
1997/10964
Guidelines: OECD 404, EEC 92/69 B 4
GLP: yes
(certified by Ministerium fuer Arbeit, Soziales und Gesundheit, Postfach 3180, 55021 Mainz)

Executive Summary

In a primary dermal irritation study the skin irritation/corrosion potential of pyrazolon (synonym to Reg.No. 298327, 500M04, BF 500-5, Batch No. 27967/95) was tested. The clipped intact skin of three New Zealand White rabbits was exposed to 0.5 g of the test-substance for four hours under semiocclusive dressing. Observation of local reactions was performed 1, 24, 48 and 72 hours after removal of the patch. No erythema or edema of intact skin was noted after 24 to 72 hours in the 3 rabbits treated with pyrazolon. Based on the findings of this study pyrazolon does not show a skin irritation potential.

(BASF DocID 1997/10964)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: 1-(4-chlorphenyl)-1,2-dihydro-3H-pyrazol-3-on (Pyrazolon)

Description:	crystalline powder, light-beige
Lot/Batch #:	27967/95
Purity:	100.5 g/100 g
Stability of test compound:	The stability of the test substance over the study period has been proven by reanalysis.

2. Vehicle: test substance was used unchanged

3. Test animals:

Species:	Rabbit
Strain:	White New Zealand (SPF)
Sex:	2 males and 1 females
Age:	young adults
Weight at dosing (mean):	female: 3.87 kg; mean male: 3.37 kg
Source:	Dr. K. Thomae GmbH, Biberach, Germany
Acclimation period:	at least one week
Diet:	Kliba-Labordiaet 341, Klingentalmuehle AG, Kaiseraugust, Switzerland, about 130 g/day
Water:	about 250 mL/day tap water
Housing:	Single housing in stainless steel wire mesh cages with grating, floor area: 3000 cm²
Environmental conditions:	
Temperature:	20 – 24°C
Humidity:	30 – 70%
Air changes:	no data available
Photo period:	12-hour light-dark cycle (06:00 – 18:00, 18:00 – 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 15-Jul-1996 (day of application)

2. In vitro pre-test: No in vitro pre-test was conducted.

3. Animal assignment and treatment:

The potential of pyrazolon to cause acute dermal irritation or corrosion was assessed by a single topical application of the unchanged test substance (moistened with water) to the clipped intact skin of three New Zealand White rabbits. The test patch (2.5 cm x 2.5 cm) was covered with a dose of 0.5 g of moistened unchanged test substance and applied to the skin (upper third of the back or flank). The patch was secured in position with a semiocclusive dressing (Idealbinde, Pfaelzische Verbandstoff-Fabrik, Kaiserslautern and Fixomull® stretch (adhesive fleece), Beiersdorf AG) for 4 hours. The test substance was removed at the end of the exposure period with Lutrol® (=PEG 400) and Lutrol ®/Water (1:1). Observation of local reactions was performed 1, 24, 48 and 72 hours after removal of the patch. At the beginning of the study the body weights were recored. A check for any dead or moribund animals was made twice each workday and one on Saturdays, Sundays and on public holidays.

II. RESULTS AND DISCUSSION

No erythema or edema of intact skin was noted after 24 to 72 hours in the 3 rabbits treated with pyrazolon Table 5.8.1-4. All animals showed after one hour after removal of the test patch an erythema with a score of 1 which was fully reversible until the next reading time point (24 hours).

III. CONCLUSION

Based on the findings of this study 'pyrazolon' (synonym to Reg.No. 298327, 500M04, BF 500-5) does not show a skin irritation potential under the test conditions chosen.

Report: CA 5.8.1/13
[redacted] 1997c
Study on the acute eye irritation of Pyrazolon in the rabbit
1997/10965
Guidelines: OECD 405, EEC 92/69 B 5
GLP: yes
(certified by Ministerium fuer Arbeit, Soziales und Gesundheit, Postfach 3180, 55021 Mainz)

Executive Summary

In an eye irritation study, the eye irritation/corrosion potential of pyrazolon (synonym to Reg.No. 298327, 500M04, BF 500-5; batch 27967/95) was determined by instillation of 0.1 mL bulk volume (about 72 mg) of the test substance into the conjunctival sac of the right eye of three New Zealand White rabbits.

The ocular reactions were assessed approximately 1, 24, 48 and 72 hours after the administration of the test substance.

No reaction concerning the corneal opacity, iritis and conjunctival chemosis was observed during the observation period. Slight conjunctival redness was observed in two animals during the course of the study. No additional findings were noted in the animals during the observation period. The ocular reactions were fully reversible within 72 hours.

Eye irritation scores (24 to 72 hours) for each animal were 0.0 for corneal opacity, iris and conjuctival discharge and 0.3, 0.7 and 0.0 for conjunctival redness. Consequently, mean average scores for irritation were calculated to be 0.0 for corneal opacity, iris and chemosis and 0.3 for conjunctival redness.

(BASF DocID 1997/10965)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 22-Jul-1996 and 29-Jul-1996 (days of application)

2. In vitro pre-test: No in vitro pre-test was conducted.

3. Animal assignment and treatment:

The potential of pyrazolon to cause acute eye irritation/corrosion was assessed by instillation of 0.1 mL bulk volume (about 72 mg) of the undiluted test substance into the conjunctival sac of the right eye. The left eye, which remained untreated, served as the negative control. About 24 hours after application of the test substance, the treated eye was washed out with tap water.

The application of the test substance was performed in a stepwise procedure starting with one animal and – after no severe eye irritation was observed – completed with the treatment of two additional animals.

The ocular reactions were assessed approximately 1, 24, 48 and 72 hours after the administration of the test substance.

Body weights were measured shortly prior to application. The animals were checked for mortality and morbidity twice on working days and once daily at weekends and on public holidays.

II. RESULTS AND DISCUSSION

No ocular reaction on the cornea and iris were observed. Slight to moderate conjunctival redness and chemosis was observed in all animals at the 1 hour reading point [see Table 5.8.1-5]. Discharge was observed only in one animal. At the 72-hour reading point all effects were fully reversed.

III. CONCLUSION

Based on the findings of this study 'pyrazolon' (synonym to Reg.No. 298327, 500M04, BF 500-5) does not have an eye irritation potential under the test conditions chosen.

Pyrazolon – Maximization test in guinea pigs
1997/10968
Guidelines: EEC 92/69, OECD 406
GLP: yes
(certified by Ministerium fuer Arbeit, Soziales und Gesundheit, Postfach 3180, 55021 Mainz)

Executive Summary

For the determination of potential sensitizing properties of 'pyrazolon' (synonym to Reg.No. 298327, 500M04, BF 500-5; Batch 27967/95) a Maximization test based on the method of Magnusson and Kligman was conducted using a control and a treated group of 5 and 10 female Pirbright White Dunkin Hartley guinea pigs, respectively.

The test-substance concentrations for the main test were selected based on the results of the pretests and the result of the first challenge. The intradermal induction was performed with a 5% test-substance preparation in 1% aqueous tylose CB 30.000 solution or in Freund's complete adjuvant / 0.9% aqueous NaCl-solution (1:1). The epicutaneous induction was conducted with a 25% test-substance preparation in 1% aqueous tylose CB 30.000 solution. Two challenges were performed 14 and 21 days after percutaneous induction.

After the first challenge with a 10% test substance preparation very slight to well defined skin reactions were observed in three test group animals. The second challenge with a 10% substance preparation did not cause any skin reactions.

Based on the results of this study and applying the evaluation criteria, it was concluded that pyrazolon does not have a sensitizing effect on the skin of the guinea pig in the Maximization Test under the test conditions chosen.

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 16-Jul-1996 to 16-Aug-1996

2. Animal assignment and treatment:

The skin sensitizing potential of pyrazolon was assessed using the Guinea Pig Maximization Test. This test consists of a pretest for the determination of suitable induction and challenge concentrations and the Maximization test itself.

For this, female Guinea pigs were allocated to groups according to the randomization instructions of „Nijenhuis, A. and Wilkf, H.S..: Cominatorial Algorithms, Academic Press, New York, San Francisco, London, 1978, pp. 62-64“.

For the intradermal and epicutaneous application, animal fur was clipped at least 2 hours before each test-substance application at the appropriate treatment sites. If necessary, additional hair clipping was performed 2 hours prior to the evaluation of skin reactions.

Evaluations of the skin reactions were performed according to Draize, J.H. (1959): Appraisal of the Safety of Chemicals in Foods, Drugs and Cosmetics. The Association of Food and Drug Officials of the United States Austin, Texas.

Individual body weights were determined on study day 0 and on the last day of observation. Mortality was checked twice daily on working days and once on weekends and public holidays.

A: Preliminary tests

Two animals per test substance concentration received six intradermal injections (see below) in groups of two at the neck region in order to determine a test substance concentration that is well-tolerated locally and systemically for the intradermal induction treatment in the main test. The evaluation of the skin reactions was performed 24 h after application.

Intradermal injections:

(i) front row: 2 injections each of 0.1 mL Freund’s adjuvant without test substance emulsified with 0.9% aqueous NaCl-solution in a ratio of 1:1

(ii) middle row: 2 injections each of 0.1 mL of the test substance formulation

(iii) back row: 2 injections each of 0.1 mL Freund’s adjuvant / 0.9% aqueous NaCl-solution (1:1) with test substance

Additionally, for the dermal induction treatment the highest concentration of the test substance that causes slight to moderate irritation and for the challenge the maximum non-irritant concentration was determined. The test-design took into account the possible influence of a previous intradermal treatment with Freund’s complete adjuvant on irritating effects. For this animals receiving dermal injections of 0.1 mL Freund’s complete adjuvant / 0.9% aqueous NaCl-solution at a ratio of 1:1 (w/w) three weeks prior to the epidermal pretest were used.

Four animals per test substance concentration received the test substance percutaneous at the flank in order to determine the skin reactions. The filter paper strips were coated with an approximately 0.5 mm thick layer of the test substance formulation. The dressing was occlusive and consisted of rubberized linen patches (4 x 4 cm), patches of Idealbinde (5 x 5 cm) and Fixomull® stretch (adhesive fleece). The test substance was applied 2 times for 24 hours within a period of 96 hours in order to detect nonspecific phenomena that are not caused by a sensitization reaction but could possibly be attributed to a shift in the irritation threshold. 24 and 48 hours after removal of the patch evaluations of the skin reactions were performed.

B: Main study – Induction

The intradermal induction consisted of 6 intradermal injections in groups of two per animal into the neck of the animals according to the scheme given above.

Control animals received the same injections (A, B, C) but without test substance, only with the formulated agent.

Skin reactions were assessed 24 hours after injection. The treated and control groups consisted of 10 and 5 females, respectively.

Epidermal induction was performed one week after intradermal induction. For this a 2 x 4 cm filter paper strip containing the test substance formulation were applied to the skin of the shoulder (same area as in the case of the previous intradermal application) under an occlusive dressing. The filter pater strip was soaked in the test substance formulation. The dressing consisted of rubberized linen patches (4 x 6 cm) and Fixomull® stretch (adhesive fleece). The exposure lasted 48 hours and after removal of the patch evaluations of the skin reactions were performed.

C: Challenge

The 1st challenge was carried out 14 days after epidermal induction. A 2nd challenge was performed one week after the first. For this 2 x 2 cm filter paper strip containing the test substance formulation were applied to the skin of the flank under an occlusive dressing. The filter pater strip was soaked in the test substance formulation. The dressing consisted of rubberized linen patches (4 x 4 cm), patches of Idealbinde (5 x 5 cm) and Fixomull® stretch (adhesive fleece). Exposure duration was 24 hours. Skin reactions were determined 24 and 48 hours after removal of the patches.

D: Positive controls:

A positive control (reliability check) with a known sensitizer was not performed in this study. However, positive control studies are performed twice a year in the laboratory. The positive control with alpha-hexylcinnamaldehyde techn. 85% showed that the test system was able to detect sensitizing compounds under the laboratory conditions chosen.

E: Evaluation of results:

The number of animals with skin findings at 24 and/or 48 hours after the removal of the patch was taken into account for the determination of the sensitization rate.

The evaluation "sensitizing" results if at least 30% of the test animals exhibit skin reactions in this adjuvant test.

The evaluation is based on the criteria of the Commission Directive 67/548/EEC and the OECD Harmonized Integrated Classification System that were in place on the date of report signature.

3. Analysis of treatment solutions:

The stability of the test substance in 0.5% tylose CB 30.000 in aqua bidest. For a time period of 4 hours was confirmed by analysis. The homogeneity of the test substance preparations was provided by stirring.

4. Statistics:

Not performed in this study.

II. RESULTS AND DISCUSSION

A. Pre-Test

A first intradermal injection of 5% test substance in 1% aqueous tylose CB 30000 caused moderate erythema and edema [see Table 5.8.1-6].

Table 5.8.1-6: Skin irritation scores 24 hours after intradermal injection – Preliminary test

preliminary intradermal test				
Animal #	Application site	A) Freund's adjuvant / 0.9% aqueous NaCl-solution (1 : 1)	B) 5% test substance preparation in 1% aqueous tylose CB 30.000-solution	C) 5% test substance in A)

2 well defined erythema / slight edema (edges of area well defined by definite raising)

The dermal irritation scores observed 24 and 48 hours after a 48-hour epidermal exposure of 5%, 10%, 25%, 50% dilutions in 1% aqueous tylose CB 30.000 are given in Table 5.8.1-7. Signs of dermal irriation were observed at ≥ 25%.

Based on the data from the pre-test a 5% dilution of pyrazolon in 1% aqueous tylose CB 30.000-solution or in Freund's complete adjuvant / 0.9% aqueous NaCl-solution (1:1) was used for intradermal induction whereas a 25% dilution in 1% aqueous tylose CB 30.000 was used for epidermal induction. As no skin findings were observed 24 and 48 hours after dermal administration of a 10% and 5% aqueous dilution, a 10% dilution was used for the 1st and 2nd challenge.

Grading: 0: no erythema/edema
1: very slight erythema (barely perceptible) / very slight edema (barely perceptible)
2: well-defined erythema / slight edema (edges of area well defined by definite raising)

B. Induction reactions

Intradermal induction of Freund's adjuvant/0.9% aqueous NaCl-solution (1:1) with and without 5% pyrazolon resulted in well-defined erythema and slight edema in all animals. Injections of 5% test substance preparations in tylose CB 30.000, 1% in aqua bidest. Or in Freund's adjuvant/0.9% aqueous NaCl-solution (1:1) caused well-defined erythema and slight edema in all test group animals, whereas injection of the vehicle in control group animals did not show any skin reaction [see Table 5.8.1-8].

After the percutaneous induction with a 25% test substance preparation incrustations, partially open (caused by the intradermal induction), were observed in addition to well-defined erythema and slight edema in all test group animals. Likewise, control groups 1 and 2 animals displayed the same skin reactions when tylose CB 30.000, 1% in aqua bidest, was applied.

Table 5.8.1-8: Skin irritation scores 24 hours after intradermal injection – Main test

Control Animals				
Animal #	Application site	A) Freund's adjuvant / 0.9% aqueous NaCl-solution (1 : 1)	B) 1% aqueous tylose CB 30.000-solution	C) Freund's complete adjuvant / 0.9% aqueous NaCl-solution (1 : 1)
all animals	left	2/2	0/0	2/2
	right	2/2	0/0	2/2
Treated Animals				
Animal #	Application site	A) Freund's adjuvant / 0.9% aqueous NaCl-solution (1 : 1)	B) 5% pyrazolon preparation in 1% aqueous tylose CB 30.000	C) 5% pyrazolon in A)
all animals	left	2/2	2/2	2/2
	right	2/2	2/2	2/2

Grading: 2: well-defined erythema / slight edema (edges of area well defined by definite raising)

C. Challenge

After the first challenge with a 10% test substance preparation 3 out of 10 test group animals showed skin reactions 24 and 48 hours after patch removal [see Table 5.8.1-9]. Two out of these animals additionally showed scaling. Control group 1 animals did not show any skin reaction. Tylose CB 30.000, 1% in aqua bidest., which was applied as a vehicle control to all animals, did not cause any skin reaction. After the 2nd challenge with a 10% test substance preparation no skin reaction was observed in all animals of the test group and control groups 1 and 2 24 and 48 hours after removal of the patches. Tylose CB 30.000, 1% in aqua bidest, which was applied as a vehicle control to all animals, did not cause any skin reations [see Table 5.8.1-9].

Table 5.8.1-9: Challenge skin reaction scores 24 hours after intradermal injection – Main test

	1st challenge		2nd challenge	
	Test substance 10% in 1% aqueous tylose CB 30.000		Test substance 10% in 1% aqueous tylose CB 30.000

- Grade 2	2/10	0/10	0/10	0/10

x/y: number of positive reactions/number of animals tested (reading at 24 h and/or 48 h after the removal of the patch)

D. Observations/Mortality

One animal of control group 1 and one animal of control group 2 died 10 days after the beginning of the study. Macroscopic examination revealed that the animals suffered from pneumonia. The cause of death was not related to the test substance treatment.

E. Body weights

The expected body weight gain was generally observed in the course of the study.

F. Positive control

The sensitivity of Pirbright White, Dunklin Hartely Guinea pigs (Crl℗HA)BR (SPF), Charles River GmbH- Wiga, Kisslegg, Germany) and the reliability of experimental techniques is assessed regularly using a known sensitizer as recommended by the test guidelines.

The study procedures were based on the methods of Magnusson and Kligmann (1969) (Maximization Test) and Buehler, E.V. (1965) (Buehler Test) and test conditions are summarized below:

Name of test substance:	alpha-Hexylcinnamaldehyde, techn. 85%
CAS number:	101-86-0
Substance number:	98/0288-3
Purity:	98.01%
Maximization Test:	
Intradermal induction:	Test substance 5% in olive oil DAB 10 Test substance 5% in Freund's complete adjuvant / 0.9% aqueous NaCl solution (1:1)
Epicutaneous Induction:	Test substance 75% in olive oil DAB 10
Challenge:	Test substance 50% in oil DAB 10

As evident from Table 5.8.1-10 the test system and the used procedures were capable to detect the sensitizing properties of alpha-hexylcinnamaldehyde.

Table 5.8.1-10: Positive control studies – Number of animals with skin findings after the challenge in control studies with the test-substance alpha-hexylcinnamaldehyde (techn. 85%)

				Challenge					
				Test substance in the vehicle			Vehicle		
Project No.	Study type	Date of performance	Group	24 h	48 h	Total	24 h	48 h	Total

			Test group	16/17	11/17	16/17	0/17	0/17	0/17

x/y: number of positive reactions/number of animals tested (reading at 24 h and/or 48 h after the removal of the patch)

III. CONCLUSION

Based on the evaluation criteria the results of this study show that 'pyrazolon' (synonym to Reg.No. 298327, 500M04, BF 500-5) does not have a sensitizing effect on the skin of guinea pig in the Maximization Test under the chosen test conditions.

Short-term toxicity of 500M04 (Reg.No. 298327, BF 500-5, 'Pyrazolon')

Report:	CA 5.8.1/15 [redacted] 2013a Reg.No. 298327 (metabolite of BAS 500 F, Pyraclostrobin) - Repeated dose 90-day oral toxicity study in Wistar rats - Administration via the diet 2013/1042164
Guidelines:	(EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.7 No. L 142, OECD 408, EPA 870.3100, JMAFF No 12 Nosan No 8147
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Administration of Reg.No. 298327 (metabolite of BAS 500 F, pyraclostrobin; batches L84-174; Purity: 99.6%) to Wistar rats target dose levels of 0, 100, 300 and 1000 mg/kg bw/day for 3 months resulted in adverse signs of systemic toxicity at target dose levels ≥ 300 mg/kg bw/day in male and at 1000 mg/kg bw/day in female rats.

Treatment with Reg.No. 298327 did not affect the survival, body weight development or food consumption of rats. High dose (1000 mg/kg bw/day) animals displayed an increased consumption of drinking water, which resulted in an increased discharge of less concentrated urine. In mid and high dose males a massive increase of unknown crystals was noted in the urine sediment. The above changes were in line with the histopathological findings observed in the kidneys (eosinophilic material in the renal pelvis, slightly increased medullar mineralization and chronic progressive nephropathy) and ureter urothelial hyperplasia) at this dose level. However, there was no indication of renal dysfunction as indicated by the absence of respective clinical chemistry alterations.

In high dose males a slight regenerative normochromic-macrocytic anemia was noted. This was accompanied by an adaptive increase of extramedullary hematopoiesis in the spleen of high dose males. Finally, high dose males displayed some changes of clinical chemistry parameters, i.e. decreased total protein and globulin as well as increased triglyceride levels.

Under the conditions of the present study the no observed adverse effect level (NOAEL) in males was 103 mg/kg bw/d (target dose level of 100 mg/kg bw/d) and 316 mg/kg bw/d (target dose level of 300 mg/kg bw/d) in female Wistar rats.

(BASF DocID 2013/1042164)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg.No. 298327 (Metabolite of BAS 500 F, Pyraclostrobin)

Description:	solid / yellow
Lot/Batch #:	L84-174
Purity:	99.6% (tolerance ± 1.0%)
Stability of test compound:	The test substance was stable over the study period until 01 Apr 2020.

2. Vehicle and/or positive control: Rodent diet

3. Test animals:

Species:	Rat
Strain:	Crl:WI (Han)
Sex:	Male and female
Age:	35 ± 1 day at delivery
Weight at dosing:	means: males: 158 g, females: 129 g
Source:	Charles River Laboratories, Sulzfeld, Germany
Acclimation period:	7 days
Diet:	Kliba maintenance diet mouse/rats "GLP", Provimi Kliba SA, Kaiseraugst, Switzerland, ad libitum
Water:	Drinking water from water bottles, ad libitum
Housing:	Group housing (5 animals/cage) housed in H-Temp polysulfonate cages (TECNIPLAST, Hohenpeißenberg, Germany) floor area about 2065°cm²; bedding: wooden dust free bedding; enrichment: wooden gnawing blocks type NGM E-022 (Abedd® Lab. And Vet. Service GmbH, Austria

Environmental conditions:

Temperature:	20 - 24°C (central air-conditioning)
Humidity:	30 - 70% (central air-conditioning)
Air changes:	15 per hour
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN

4. Dates of experimental work: 15-May-2012 to 25-Jan-2013
Inlife dates: 22-May-2012 (start of administration) to 23-Aug-2012 (necropsy of last female animals)

5. Animal assignment and treatment:

Reg.No. 298327 was administered to groups of 10 male and 10 female Wistar rats at target concentrations of 0, 100, 300 and 1000 mg/kg bw/day for three months by the dietary route.

The animals were assigned to the treatment groups by means of a computer generated randomization list based on body weights. At the end of the administration period the animals were sacrificed after a fasting period of at least 16 hours.

6. Test substance preparation and analysis:

The diets were prepared by mixing weighed amounts of test substance with a small amount of food. Subsequently, appropriate amounts of food were added to obtain the intended dietary concentrations and mixed for approx. 10 minutes in a laboratory mixer. In order to meet the target dose levels, the dietary concentrations of the test-item for each test group and sex were adjusted weekly, based on body weight and food consumption measurements from the previous week. For the first week of administration the dietary concentrations were based on historical control data. Accordingly, e.g. nominal dietary concentrations of low dose (100 mg/kg) females varied between 908 and 1583 ppm whereas for example the nominal dietary concentrations in high dose (1000 mg/kg) males varied between 9421 and 17753 ppm.

The stability of Reg.No. 298327 in the diet at room temperature for a period of 33 days was demonstrated before the start of the study (BASF project No. 01Y0615/10Y057; copy of the report included in Volume III of the report).

The homogenous distribution of Reg.No. 298327 in the diet was verified for the highest and lowest concentration (see below) using the first diet preparation. Additionally, the test-item concentrations were determined in all preparations not analyzed for homogeneity. Concentration control analyses were also performed at the end of the administration period with the last diet batches produced.

Analysis of diet preparations for homogeneity and test-item content

Nominal concentration [ppm	Sampling	fed to	Concentration measured [ppm] Mean ± SD#	Relative standard deviation [%]	Mean % of nominal concentration
942	18.05.2012	males	991.1 ± 24.5	2.5	106.1
986	18.05.2012	females	1049		106.5
2826	18.05.2012	males	2682.9		94.9
2957	18.05.2012	females	2897.7		98.0
9421	18.05.2012	males	9786.4		103.9
9857	18.05.2012	females	9296.2 ±457.9	4.9	94.3
1719	22.08.2012§	males	1576.7		102.2
1210	22.08.2012	females	1301.1		107.5
5351	22.08.2012R	males	5703.7		106.6
4051	22.08.2012R	females	4010.2		99.0
16741	22.08.2012	males	15352.6		91.7
12801	22.08.2012	females	11679.4		91.2

R Reserve samples; § Samples prepared 14.08.2012
based on mean values of the three individual samples (homogeneity determinations)
Values may not calculate exactly due to rounding of values

Relative standard deviations of the homogeneity samples in the range of 2.5 to 4.9% indicate the homogenous distribution of Reg.No. 298327 in the diet preparations. The concentration of the test-item in the diet mixtures was in the range of 90.1 to 107.5% and thus in the acceptable range.

4. Statistics:

Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to following tables:

Statistics of clinical examinations

Parameter	Statistical test
Body weight, body weight change	A comparison of each group with the control group was performed using DUNNETT's test (two-sided) for the hypothesis of equal means
Feces, rearing, grip strength forelimbs, grip strength hindlimbs, footsplay test, motor activity	Non-parametric one-way analysis using KRUSKALWALLIS test (two-sided). If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using WILCOXON test (two-sided) for the equal medians

Statistics of clinical pathology

Parameter	Statistical test
Blood parameters	For parameters with bidirectional changes: Non-parametric one-way analysis using KRUSKAL-WALLIS test. If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using WILCOXON-test (two-sided) for the hypothesis of equal medians For parameters with unidirectional changes: Pairwise comparison of each dose group with the control group using the WILCOXON-test (one-sided) with Bonferroni-Holm adjustment for the hypothesis of equal medians
Urinalysis parameters (apart from pH, volume, specific gravity, color and turbidity)	Pairwise comparison of each dose group with the control group using the WILCOXON-test (one-sided) for the hypothesis of equal medians
Urine pH, volume, specific gravity, color and turbidity	Non-parametric one-way analysis using KRUSKAL-WALLIS test. If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using WILCOXON-test (two-sided) for the hypothesis of equal medians. Urine color and turbidity are not evaluated statistically.

Statistics of pathology

Parameter	Statistical test
Weight parameters	Non-parametric one-way analysis using KRUSKAL-WALLIS test (two-sided). If the resulting p-value was equal or less than 0.05, a pair wise comparison of each dose group with the control group was performed using the WILCOXON test (two-sided) for the equal medians

C. METHODS

1. Observations:

The animals were examined for morbidity or mortality twice daily on working days and once daily on weekends and public holidays. If animals were in a moribund state, they were sacrificed and necropsied.

Detailed clinical observations were performed in all animals prior to the start of the administration period and weekly thereafter. For this, the animals were transferred to a standard arena (50 x 37.5 cm; sides 25 cm high). The findings were ranked according to the degree of severity, if applicable. The following parameters were examined:

1. abnormal behavior during handling	10. abnormal movements
2. fur	11. impairment of gait
3. skin	12. lacrimation
4. body posture	13. palpebral closure
5. salivation	14. exophthalmus
6. respiration	15. feces (appearance/consistency)
7. activity/arousal level	16. urine
8. tremors	17. pupil size
9. convulsions	

2. Body weight:

The body weight of the animals was determined before the start of the administration period (in order to randomize the animals), at the start of the treatment (day 0) and at weekly intervals thereafter. The difference between the body weight on the respective day of weighing and the body weight on day 0 was calculated as body weight change.

3. Food consumption and compound intake:

Food consumption was determined weekly over a period of 1 day and calculated as mean food consumption in grams per animal and day.

The mean daily intake of test substance (group means) was calculated based upon individual values for body weight and mean food consumption per cage.

$$D = \frac{FC_x \times PPM_x}{BW_x}$$

with FC_x as the mean daily food consumption (in g) on day x and BW_x as body weight on day x of the study (g) and PPM_x as dietary concentration of the test item at day x.

4. Water consumption:

Drinking water consumption was monitored by daily visual inspection of the water bottles for any changes in volume. According to a personal communication of the study director decreased water consumption was first observed after 5 weeks (35 days) In order to quantify this visual observation water consumption was monitored weekly from day 49 onwards by determining water consumption over a period of 4 days. Water consumption was calculated as mean water consumption in grams per animal and day.

5. Ophthalmoscopy:

The eyes of all animals were examined prior to the start of the administration period. At the end of the administration period, i.e. study day 91, the eyes of animals in test groups 0 (control) and 3 (1000 mg/kg bw/d) were examined for any changes using an ophthalmoscope ophthalmoscope (HEINE OPTOTECHNIK, Herrsching, Germany) after application of a mydriatic (Mydrum, Chauvin ankerpharm GmbH, Rudolstadt, Germany).

6. Functional observation battery (FOB):

A functional observational battery was performed in all animals at the end of the administration period starting at about 10:00 a.m. The FOB started with passive observations without disturbing the animals (home cage observations), followed by removal from the home cage and open field observations in a standard arena. Thereafter, sensorimotor tests and reflex tests were conducted. The examinations were carried out by trained technicians not being aware of the group allocation of the animals. The findings were ranked according to the degree of severity, if applicable.

During the home cage observation special attention was paid to posture, tremors and convulsions, abnormal movements gait abnormalities.

For open field observation the animals were transferred to a standard arena (50 x 50 cm with sides of 25 cm high) and observed for at least 2 minutes. The following parameters were assessed:

1. behavior when removed from cage	10. respiration
2. fur	11. tremors
3. skin	12. convulsions
4. salivation	13. abnormal movements
5. nose discharge	14. impairment of gait
6. lacrimation	15. activity/arousal level
7. eyes/pupil size	16. feces (number of fecal pellets/appearance/ consistency) within two minutes
8. posture	17. urine (appearance/quantity) within two minutes
9. palpebral closure	18. number of rearings within two minutes

For sensorimotor tests and reflexes the animals were removed from the open field. The following tests were performed:

1.	approach response	8.	behavior during "handling"
2.	touch response	9.	vocalization
3.	vision ("visual placing response")	10.	pain perception ("tail pinch")
4.	pupillary reflex	11.	grip strength of forelimbs
5.	pinna reflex	12.	grip strength of hind limbs
6.	audition ("startle response")	13.	landing foot-splay test
7.	coordination of movements ("righting response")	14.	other findings

7. Motor activity measurement:

Motor activity was measured at the same day when the FOB was performed in a randomized order. The measurement was performed in the dark using the TSE Labmaster System (TSE Systems GmbH, Bad Homburg, Germany) with 18 beams per cage. During the measurement the animals were kept in clean Polycarbonate cages with absorbent material. Motor activity measurements were from 2:00 p.m onwards. The number of beam interrupts was counted over twelve 5 minute intervals. Measurement started when the first beam was interrupted by pushing the cage into the rack (staggered start). Measurements ended exactly 60 minutes thereafter. During the measurements the animals received no food and no water.

8. Hematology and clinical chemistry:

Blood was taken in the morning from fasted, isoflurane anesthetized animals from the retro-orbital venous plexus. The blood sampling procedure and the subsequent analysis of the blood and serum samples were carried out in a randomized sequence.

The following hematological and clinical chemistry parameters were determined for 10 animals per test group and sex:

Hematology:					
	Red blood cells		*White blood cells*		*Clotting Potential*
✓	Erythrocyte count (RBC)	✓	Total leukocyte count (WBC)	✓	Platelet count
✓	Hemoglobin (Hb)	✓	Differential blood count	✓	Prothrombin time
✓	Hematocrit (Hct)				
✓	Mean corp. volume (MCV)				
✓	Mean corp. hemoglobin (MCH)				
✓	Mean corp. Hb. conc. (MCHC)				
✓	Reticulocytes				
Clinical chemistry:					
	Electrolytes		*Metabolites and Proteins*		*Enzymes:*
✓	Calcium	✓	Albumin	✓	Alanine aminotransferase (ALT)
✓	Chloride	✓	Bilirubin (total)	✓	Aspartate aminotransferase (AST)
✓	Phosphorus (inorganic)	✓	Cholesterol	✓	Alkaline phosphatase (ALP)
✓	Potassium	✓	Creatinine	✓	γ-glutamyl transpeptidase (γ-GT)
✓	Sodium	✓	Globulin (by calculation)		
		✓	Glucose		
		✓	Protein (total)		
		✓	Triglycerides		
		✓	Urea		

9. Urinalysis:

The dry chemical reactions on test strips (Combur-10-test M, Roche, Mannheim, Germany) used to determine urine constituents semiquantitatively were evaluated with a reflection photometer (Miditron M; Roche, Mannheim, Germany). The following parameters were determined in all animals:

Urinalysis					
	Quantitative parameters:		*Semiquantitative parameters*		
✓	Urine volume	✓	Bilirubin	✓	Protein
✓	Specific gravity	✓	Blood	✓	pH-value
		✓	Color and turbidity	✓	Urobilinogen
		✓	Glucose	✓	Sediment (microscopical exam.)
		✓	Ketones		

10. Sacrifice and pathology:

All animals were sacrificed by decapitation under isoflurane anesthesia. The exsanguinated animals were necropsied and assessed by gross pathology. Special attention was given to the gastrointestinal tract (duodenum). The organs were sampled, weighed, and examined histopathologically as indicated in the table below.

Pathology:
The following organs were collected (column C), weighed (W) and examined histopathologically (H, ✓: all groups, #: control and top dose).

C	W	H		C	W	H		C	W	H

The organs or tissues were fixed in 4% formaldehyde solution or in modified Davidson's solution. The hematoxylin-eosin (HE) stained slides were examined and assessed by light microscopy.

Besides standard HE staining, the following special stains were performed in the kidneys of selected animals:

- Periodic Acid Schiff (PAS) for glycoproteins,
- Mallory-Heidenhain's stain for proteins
- Perl's stain for the detection of ferric iron (Fe^{+++})

The following animals were selected for the special stain:

- Control animals: one male (No. 4) and one female (No. 43)
- Test group 3 (1000 mg/kg bw/d): two males (No. 32 and 34) and two females (No. 71 and 75)

II. RESULTS AND DISCUSSION

A. Observations

1. Clinical signs of toxicity

No test substance-related effects were observed.

2. Mortality

No animal died prematurely in the present study.

3. Ophthalmoscopy

No test substance-related effects were observed. The incidence and distribution of findings was either identical (corneal stiplings) or decreased to lower incidences without any relation to dose (remainders of the pupillary membrane) when comparing the observations at day -1 and day 91.

B. Body weight and body weight gain

No test stubstance-related changes in body weight parameters of both sexes were observed in treated animals when compared to controls. All values represent the normal biological variability typical for animals of this strain and age [see Figure 5.8.1-1 and Table 5.8.1-11].

Figure 5.8.1-1: Body weight development of rats administered Reg.No. 298327 for 91 days

D. Food and water consumption and compound intake

Food consumption was highly variable in all groups including control groups throughout the study [see Figure 5.8.1-2].There was no treatment-related trend when the average daily food consumption was considered [see Table 5.8.1-12].

Table 5.8.1-12: Average food consumption of rats administered Reg.No. 298327 for 91 days

	Males				Females			
Dose level [mg/kg bw/day]	0	100	300	1000	0	100	300	1000
Mean food consumption [g/animal]								
Day 0 to 91#	22.3	22.3	21.5	23.3	16.6	16.9	16.5	17.6
Δ% (compared to control)#		-0.1	-3.5	4.7		1.5	-0.6	5.9

Values were calculated based on weekly mean individual daily food consumption values. Values may not calculate exactly due to rounding of mean values; No statistics was performed because n=2

Figure 5.8.1-2: Mean daily food consumption in rats administered Reg.No 298327 for 91 days

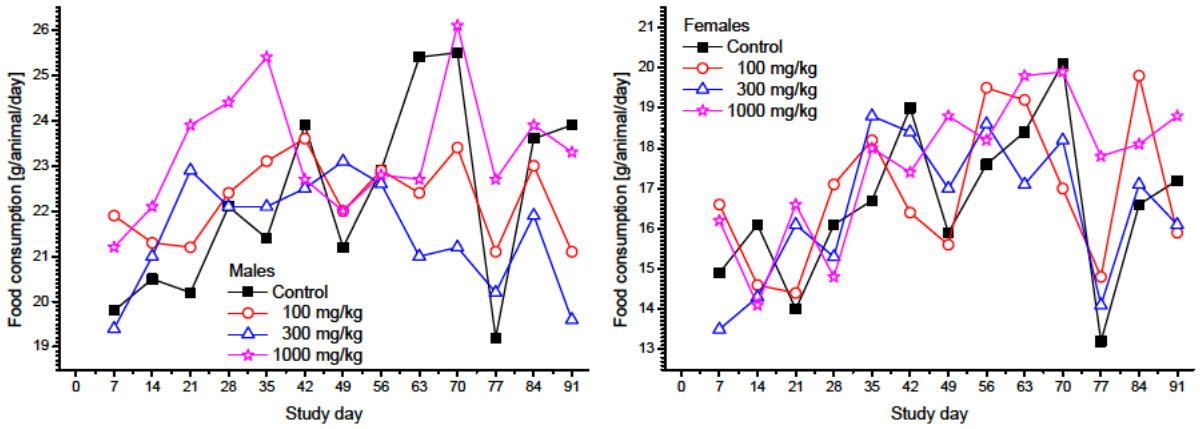

Figure 5.8.1-3: Mean daily water consumption in rats administered Reg.No 298327 for 91 days

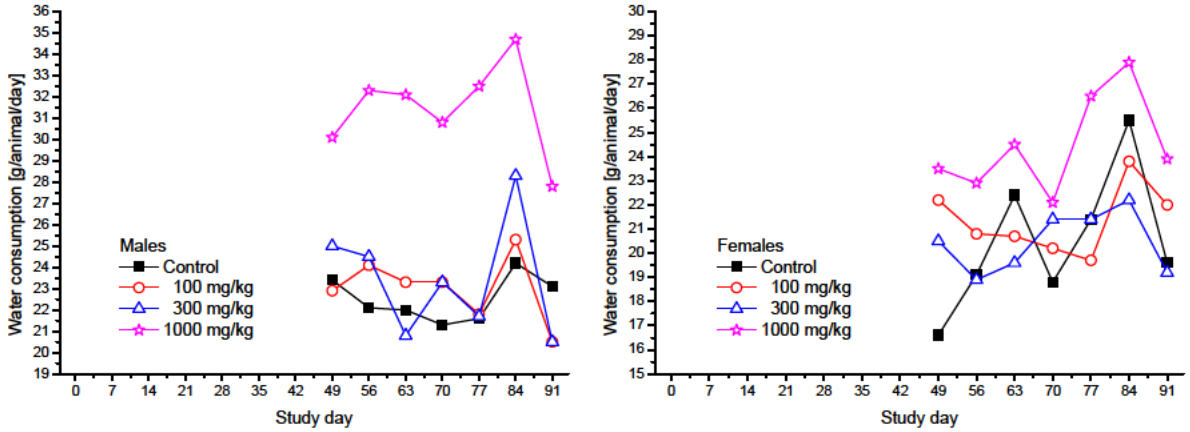

According to a personal communication of the study director decreased water consumption was first observed after 5 weeks (35 days) of treatment as assessed by visual inspection of the water volume in drinking bottles. In order to quantify this visual observation water consumption was monitored from day 49 onwards. Daily drinking water consumption was consistently increased in both sexes at the high dose level (1000 mg/kg bw/d) throughout the observation period [see Figure 5.8.1-3], with males more severely affected than females. The increased water consumption is also evident if the average water consumption between day 49 and 91 is calculated [see Table 5.8.1-13].

The effect on water consumption in mid and low dose animals was neither consistent over time nor dose-dependent and difference of the overall mean water consumption [see Table 5.8.1-13] to the controls was marginal. Thus, only the effect at 1000 mg/kg was considered to be treatment related.

Table 5.8.1-13: Average water consumption of rats administered Reg.No. 298327 for 91 days

	Males				Females			
Dose level [mg/kg bw/day]	0	100	300	1000	0	100	300	1000
Average daily water consumption [g/animal]								
Day 49 to 91[#]	22.5	23.0	23.4	31.5	20.5	21.3	20.5	24.5
Δ% (compared to control)[#]		2.2	4.1	**39.7**		4.2	-0.1	**19.5**

[#] Values were calculated based on mean individual daily food. Values may not calculate exactly due to rounding of mean values; No statistics was performed because n=2

The mean daily test substance intake was calculated as 103, 302, and 1017 mg/kg bw/day in males and 106, 316, and 1066 mg/kg bw/day in females at dietary dose levels of 100, 300 and 1000 mg/gk bw/d, respectively.

E. Functional observation battery and motor activity

1. Functional observational battery

No treatment-related effects were observed during the FOB examinations. There were a few findings, which however were either equally distributed between treated groups and controls, were without a dose response relationship or occurred in single rats only. These observations were considered to be of incidental nature rather than related to treatment.

At the home cage observations and sensorimotor tests/reflexes the animals showed no test substance-related effects. Likewise, the determination of quantitative parameters (feces, rearing, grip strength of fore- and hindlimbs and foot splay test) did not reveal significant changes. During the open field observation period low dose (100 mg/kg) male #13 did not walk. Due to the single occurrence and the lack of a dose response-relationship this finding was considered as incidental and not test substance-related.

2. Motor activity measurement

No test substance-related effects were observed.

F. Blood analysis

1. Hematological findings

Treatment-related hematology changes were restricted to high dose males and consisted of a slight regenerative normochromic-macrocytic anemia indicated by decreased erythrocyte counts (RBC) and hemoglobin values (HGB) and increased mean corpuscular volume (MCV), mean hemoglobin content (MCH) as well as increased relative reticulocyte counts [see Table 5.8.1-14].

Table 5.8.1-14: Selected hematology findings in rats administered Reg.No 298327 for 91 days (Group means ± SD)

	Study day	RBC [10^{12}/L]	HGB [mmol/L]	MCV [fL]	MCH [fmol]	RET [%]	EOSA [10^{12}/L]
Males							
Control	Day 92	8.82 ± 0.48	9.1 ± 0.3	49.7 ± 2.5	1.04 ± 0.06	2.0 ± 0.5	0.10 ± 0.03

Females							
Control	Day 93	7.53 ± 0.31	8.4 ± 0.3	52.4 ± 1.4	1.12 ± 0.03	2.6 ± 0.6	0.08 ± 0.03
100 mg/kg bw/day	Day 93	7.41 ± 0.29	8.3 ± 0.2	52.6 ± 1.5	1.12 ± 0.04	2.9 ± 0.5	0.05 ±0.01*
300 mg/kg bw/day	Day 93	7.58 ± 0.34	8.5 ± 0.4	53.2 ± 1.2	1.12 ± 0.03	2.9 ± 0.5	0.08 ± 0.01
1000 mg/kg bw/day	Day 93	7.54 ± 0.21	8.4 ± 0.2	53.1 ± 1.2	1.12 ± 0.03	2.6 ± 0.5	0.08 ± 0.02

* p ≤ 0.05; ** p ≤ 0.01 (Kruskal-Wallis and Wilcoxon-tests two sided)

The only statistically significant difference observed in females was a lower mean absolute eosinophil count at the low dose of 100 mg/kg bw/d. In absence of a dose-response relationship this alteration was regarded as incidental and not treatment-related.

2. Clinical chemistry findings

Treatment-related clinical chemistry findings were restricted to high dose males and consisted of decreased total protein and globulin values as well as increased triglyceride levels [see Table 5.8.1-15].

Table 5.8.1-15: Selected clinical chemistry findings in rats administered Reg.No. 298327 for 91 days (Group means ± SD)

Dose [mg/kg bw/d]		0	100	300	1000
Males					
ALP	[µkat/L]	1.19 ± 0.18	1.04* ± 0.10	1.24 ± 0.21	1.05 ± 0.21

Triglycerides	[mmol/L]	0.64 ± 0.20	0.49 ± 0.12	0.58 ± 0.25	0.97 ± 0.57
Glucose	[mmol/L]	4.81 ± 0.37	5.84 ± 0.61**	5.13 ± 0.34	5.09 ± 0.39

* p ≤ 0.05; ** p ≤ 0.01 (Kruskal-Wallis and Wilcoxon-test. two sided)

The decreased alkaline phosphatase (ALP) levels in low dose males and the increased glucose levels in low dose females were not dose-dependent and thus considered not to be related to treatment.

3. Urinalysis

Urinalyis revealed increased mean urine volumes which were accompanied by lower specific gravity of the urine in both sexes at 1000 mg/kg [see Table 5.8.1-16]. This is consistent with the higher water consumption noted at this dose level. In addition, more crystals of unknown origin were found in the urine sediment of males at ≥ 300 mg/kg. The aforementioned findings were considered to be treatment-related.

Table 5.8.1-16: Selected urinalysis parameters in rats administered Reg.No. 298327 for 91 days (Group means ± SD)

Dose [mg/kg bw/d]	0	100	300	1000
Males

[#] semi-quantitative parameter: Grade 0 = none, Grade 1 = few, Grade 2 = many, Grade 3 = masses

G. Necropsy

1. Organ weight

No statistically significant absolute or relative organ weight differences were observed.

2. Gross and histopathology

There were no treatment-related gross necropsy findings. All findings were observed in single incidences only.

Treatment-related histopathological findings were observed in the kidney of mid dose males and high dose males and females as well as in the spleen of high dose males [see Table 5.8.1-17].

In the kidney the eosinophilic material was localized in the lumen of the renal pelvis. This material had a heterogeneous structure, characterized by granulated and smooth components. Occasionally, remnants of lytic superficial urothelium (exfoliated cells and slightly mineralized superficial tissue) were admixed in this material. Special stains (PAS, Mallory-Heidenhain, Perl's stain) failed to better characterize the eosinophilic material. The urothelial hyperplasia most probably represented a reactive response to the presence of the eosinophilic material in the renal pelvis. Both findings were considered to be adverse.

The increased mineralization was seen in the inner medulla of males, whereas in females the mineralization was localized at the transition of the outer to the inner medulla. The chronic progressive nephropathy, which showed a slightly increased incidence and severity in both sexes at the high dose level, was characterized by cortical areas with increased tubular basophilia and nuclear crowding associated with minimally thickened basement membranes, dilation of tubules, some of them containing hyaline casts and minimal interstitial fibrosis and mononuclear cellular infiltrates in-between the tubules. Both findings described above are frequently observed in control animals of this age. The slight increase in incidence and/or severity at the high dose levels was considered as a treatment-related exacerbation of spontaneously occurring kidney changes. In absence of changes of clinical chemistry parameters of renaly dysfunction, these observations were considered to be non-adverse.

The papilar ulceration observed in a high dose male was considered to represent an incidental finding due to its single occurrence.

Table 5.8.1-17: Selected histopathological changes in rats administered Reg.No. 298327 for 91 days

Dose [mg/kg bw/d]	0	100	300	1000	0	100	300	1000

Hematopoiesis, extramedullary	6 *[1.0]*	10 *[1.4]*	10 *[1.5]*	10 *[2.0]*	8 *[1.2]*			9 *[1.2]*

[ ] mean severity grading; histopathological findings were graded minimal (Grade 1), slight (Grade 2), moderate (Grade 3), marked (Grade 4) and massive/severe (Grade 5). The mean severity is the sum of the gradings divided by the incidence

The increase in the severity of the extramedullary hematopoiesis in the spleen of high dose males was regarded as treatment-related. The extramedullary hematopoiesis was of erythroid type and, therefore, characterized by foci of cells with markedly basophilic nuclei in the red pulp. The histopathologic finding correlates well to the observed regenerative normochromic-macrocytic anemia in high dose males.

In this study special attention was given to the gastrointestinal tract. No treatment-related findings were observed in the duodenum of high dose male and female animals as a hyperplasia of the duodenal mucosa was observed with the parent molecule pyraclostrobin. However, no treatment-related findings were noted.

There were a number of other histopathological findings which occurred either individually or were biologically equally distributed over control and treatment groups. They were therefore considered to be incidental or spontaneous in origin and without any relation to treatment.

III. CONCLUSIONS

The dietary administration of 500M04 (Reg.No. 298327, metabolite of pyraclostrobin) to male and female Wistar rats for 91-days caused adverse histopathological effects in the kidney of males at ≥ 300 mg/kg bw/day and females at 1000 mg/kg bw/day as well as on the hematological system of high dose males. The effects in the kidney were accompanied by higher water consumption and increased urinary discharge, whereas the anemia in males was accompanied by an increased severity of extramedullary hematopoiesis in the spleen. Additionally, lower total protein and globulin and higher triglyceride levels were observed in high dose males.

Therefore, under the conditions of the present study the no observed adverse effect level (NOAEL) was 103 mg/kg bw/d (target dose level of 100 mg/kg bw/d) in male and 316 mg/kg bw/d (target dose level of 300 mg/kg bw/d) in female Wistar rats, respectively.
Genotoxicity studies of 500M04 (Reg.No. 298327, BF 500-5, 'Pyrazolon')

Report:	CA 5.8.1/16 Woitkowiak C., 2012a Reg.No. 298327 (metabolite of BAS 500 F, Pyraclostrobin) - Salmonella typhimurium / Escherichia coli reverse mutation assay 2012/1220416
Guidelines:	OECD 471 (1997), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.13/B.14 No. L 142, EPA 870.5100
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

S. typhimurium (strains TA98, TA 100, TA 1535 and TA 1537) and E. coli strain WP2 uvrA were exposed to Reg.No. 298327 (Metabolite of BAS 500 F, pyraclostrobin); batch: L83-44-2, purity: 97.6%) using dimethylsulfoxide (DMSO) as a solvent in the presence and absence of metabolic activation in two independent experiments. Triplicate plates were used per dose and per test condition. Vehicle and positive controls were included in each experiment.

The test substance was tested in concentrations between 10 and 5200 µg/plate. A bacteriotoxic effect was observed depending on the strain and test conditions from about 1000 µg/plate onwards. Precipitation of the test substance was found from 2600 µg/plate with and without S9 mix.

A biologically relevant increase in the number of revertant colonies was not noticed in any of the strains tested in presence or absence of metabolic activation in any of the experiments. The positive controls induced the appropriate response in the corresponding strains, thus demonstrating the sensitivity of the test system.

The test substance Reg.No. 298327 (Metabolite of BAS 500 F, pyraclostrobin) is not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions of the study.

(BASF DocID 2012/1220416)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Reg.No. 298327 (Metabolite of BAS 500 F, pyraclostrobin)

Description: Solid, beige
Lot/Batch #: L83-44-2
Purity: 97.6%
Stability of test compound: The test substance was stable over the study period under the storage conditions and guaranteed until 01 Jan 2013. The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 h was verified analytically.
The homogeneity of the test substance was ensured by mixing prior to preparation of test substance solutions.
Solvent used: Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control: In parallel to each experiment, negative control experiments were carried out in order to check for possible contaminants (sterility control) and to determine the spontaneous mutation rate (vehicle control).
Vehicle control: The vehicle control with and without S9 mix only contained the vehicle used for the test substance at the same concentration and volume for all tester strains.
Solvent/final concentration: 100 µL/plate

Positive control compounds tested without addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1535	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1537	9-Aminoacridine (AAC)	DMSO	100 µg/plate
TA 98	4-nitro-o-phenylendiamine (NOPD)	DMSO	10 µg/plate
WP2 uvrA	4-nitroquinoline-N-oxide (4-NQO)	DMSO	5 µg/plate

Positive control compounds tested with addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1535	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1537	2-aminoanthracene	DMSO	2.5 µg/plate
TA 98	2-aminoanthracene	DMSO	2.5 µg/plate
WP2 uvrA	2-aminoanthracene	DMSO	60 µg/plate

To demonstrate the efficacy of the S9 mix in this assay, the S9 batch was further characterized with benoz(a)pyrene in the strains TA 100 and TA 98 as required in OECD 471.

3. Activation:

S9 was produced from the livers of induced male Wistar rats. The rats received on three consecutive days intraperitoneal injections of 80 mg phenobarbital and 80 mg β-naphthoflavone orally per kg body weight. 24 hours after the last administration the animals were sacrificed. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction is thawed at room temperature and 1 volume of S9-fraction is mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9 mix, was kept on ice until used.

The S9 mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4. Test organisms:

S. typhimurium strains: TA98, TA100, TA1535, TA1537
E. coli: WP2 uvrA

Salmonella typhimurium:

The Salmonella strains are checked for the following characteristics at regular intervals: deep rough character (rfa); UV sensitivity (uvrB); ampicillin resistance (R factor plasmid). E. coli WP2 uvrA is checked for UV sensitivity.

Histidine and tryptophan auxotrophy is automatically proven in each experiment via the spontaneous rate.

5. Test concentrations:

Plate incorporation assay:	In the first experiment triplicate plates were prepared for each concentration (neg. control; 33, 100, 333, 1000, 2600 and 5200 µg/plate and positive controls at the concentrations indicated above) and conditions (i.e. with and without S9) for all tester strains indicated above.
Pre-incubation assay:	In the second experiment the test article / vehicle / positive control substance, bacterial and S9 mix or phosphate buffer were incubated at 37°C for the duration of about 20 minutes. Triplicate plates were prepared for each concentration (neg. control; 10, 33, 100, 333, 1000 and 2600 µg/plate and positive controls at the concentrations indicated above) and condition (i.e. with and without S9) for all tester strains.

B. TEST PERFORMANCE:

7. Dates of experimental work: 21-Mar-2012 to 30-Mar-2012

8. Plate incorporation assay:

To test tubes containing 2-mL portions of warm soft agar (containing 0.5 mM histidine + 0.5 mM biotin), 0.1 mL test solution or vehicle, 0.1 mL fresh bacterial culture, 0.5 mL S9-mix (in tests with metabolic activation) or 0.5 mL phosphate buffer (in tests without metabolic activation) were added in the given order. After mixing, the samples are poured onto Vogel-Bonner agar plates (minimal glucose agar plates). In the experiments with E. coli the warm soft agar contains 0.5 mM tryptophan instead of histidine + biotin.

9. Pre-incubation assay:

100 µL of test solution or vehicle, 0.1 mL bacterial suspension and 0.5 mL S9 mix or phosphate buffer were incubated at 37°C for about 20 minutes. Subsequently, 2 mL of soft agar was added and, after mixing, the samples are poured onto the agar plates.

After incubation in the dark for 48 to 72 hours at 37°C each plate was checked for precipitates and status of the background lawn. Revertant colonies were counted. Means and standard deviations were calculated.

10. Titer determination:

In order to assess bacteriotoxic effects, the titer was additionally determined in experimental parts with S9 mix using the vehicle control and the two highest doses. The procedure followed in both experiments (plate incorporation and pre-incubation) was the same as described above for the individual experiments with the exception that the soft agar used contained maximal amino acid solution (5 mM tryptophan or 5 mM histidine + 0.5 mM biotin). After the incubation in the dark for 48 to 72 hours at 37°C the number of bacterial colonies was determined.

11. Statistics:

No special statistical tests were performed.

12. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

A dose-related and reproducible increase in the number of revertant colonies, i.e. about doubling of the spontaneous mutation rate in at least one tester strain either without S9 mix or after adding a metabolizing system.

A test substance is generally considered non-mutagenic in this test if:

The number of revertants for all tester strains was within the historical negative control range under all experimental conditions in two at least two experiments carried out independently of each other.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The test substance was stable over the study period under the storage conditions.

The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically.

B. TOXICITY

A preliminary cytotoxicity assay was not performed in this laboratory. Cytotoxicity was determined in the course of the mutation assay.

A bacteriotoxic effect (decrease in the number of his^+ and trp^+ revertants, reduction in the titer) was observed in the standard plate test depending on the strain and test conditions from about 1000 µg/plate onwards.

In the preincubation assay bacteriotoxicity (reduced his^+ or trp^+ background growth, decrease in the number of his^+ or trp^+ revertants, reduction in the titer) was observed depending on the strain and test conditions from about 1000 µg/plate onwards.

C. MUTATION ASSAYS

Neither in the plate incorporation nor in the preincubation experiment with and without metabolic activation was a biologically relevant increase in number of revertants observed in any strain tested [see Table 5.8.1-18]. The positive controls yielded revertant numbers in a range expected for the respective strains and thus demonstrated the sensitivity of the test system.

Test substance precipitation was found from 2600 µg/plate onwards with and without S9 mix.

III. CONCLUSION

According to the results of the present study the test substance 500M04 (Reg.No. 298327, metabolite of pyraclostrobin) is not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions chosen here.

Report:	CA 5.8.1/17 Schulz M., Landsiedel R., 2012b Reg.No. 298327 (metabolite of BAS 500 F, Pyraclostrobin) - In vitro gene mutation test in CHO cells (HPRT locus assay) 2012/1272482
Guidelines:	(EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.17, EPA 870.5300, OECD 476 (1997)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Reg. No. 298327 (Metabolite of BAS 500 F, pyraclostrobin; batch: L84-174, purity: 99.6%) was tested in vitro for its ability to induce forward mutations in mammalian cells by assessing the mutation of the HPRT locus in Chinese Hamster CHO cells. Two independent experiments were conducted in the presence and absence of metabolic activation with concentrations of up to 1000 µg/mL. The treatment intervals in the absence of metabolic activation were 4 and 24 h in the first and second experiment, respectively. The treatment interval for cultures treated with the test substance in the presence of metabolic activation was 4 h for both experiments. Ethylmethanesulfonate (EMS) and 7,12-Dimethylbenz[a]anthracene (DMBA) served as positive controls in the experiments without and with metabolic activation, respectively.

The test substance did not cause any relevant increase in the mutant frequencies either without S9 mix or after the addition of a metabolizing system in two experiments performed independently of each other.
Based on the results of the study it is concluded that under the conditions of the test Reg.No. 298327 (Metabolite of BAS 500 F, pyraclostrobin) does not induce forward mutations in mammalian cells in vitro.

(BASF DocID 2012/1272482)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

	Reg.No. 298327 (Metabolite of BAS 500 F, pyraclostrobin)
Description:	Solid, yellow
Lot/Batch #:	L84-174
Purity:	99.6% (tolerance ± 1.0%)
Stability of test compound:	The stability of the test substance under storage conditions was guaranteed until 01-Apr-2020 as indicated by the sponsor. The homogeneity of the test substance was guaranteed on account of the high purity and ensured by mixing prior to preparation of test substance solutions. The stability of a comparable batch (L83-44-2) at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically.
Solvent used:	Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control:	A negative control was not employed in this study
Solvent control:	1% (v/v) DMSO in culture medium
Positive control -S9:	Ethyl methanesulfonate (EMS) 300 µg/mL
Positive control +S9:	7.12-Dimethylbenz[a]anthracene (DMBA) 1.25 µg/mL

3. Activation:

S9 was produced from the livers of at least 5 induced male Wistar [Crl:WI(Han)] rats. The rats were administered injections of phenobarbital (80 mg/kg; i.p.) and ß-napthtoflavone (80 mg/kg; per gavage) on three consecutive days. 24 h after the last administration the animals were sacrificed.
The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4. Test organism:	Chinese hamster CHO cells. Stocks of the CHO cell line were maintained at -196°C in liquid nitrogen. Each batch used for mutagenicity testing was checked for mycoplasma contamination. The week prior to treatment, spontaneous HPRT-deficient mutants were eliminated from the stock cultures by growing the cells for 3 to 4 days in pretreatment medium (see below).
5. Culture media:	
Culture medium:	Ham's F12 medium with L-glutamine and hypoxanthine supplemented with 10% (v/v) fetal calf serum (FCS).
Pretreatment medium:	("HAT" medium): FCS-supplemented Ham's F12 medium with L-glutamine containing per mL 13.6 µg hypoxanthine, 0.18 µg aminopterin and 3.88 µg thymidine.
Selection medium:	("TG" medium): L-Glutamine- and FCS-supplemented, hypoxanthine-free Ham's F12 medium with 6-thioguanine at a final concentration of 10 µg/mL All media were supplemented with 1% (v/v) penicillin/streptomycin (10000 IU / 10000 µg/mL) and 1% (v/v) amphotericine B (250 µg/mL) During pulse exposure (4 hours) to the test substance, Ham‘s F12 medium was used without FCS supplementation. In the case of continuous treatment (24 hours) Ham‘s F12 medium with FCS supplementation was used.
6. Locus examined:	hypoxanthine-guanine-phosphoribosyl transferase (H(G)PRT)
7. Test concentrations:	
a) Preliminary toxicity assay:	Nine concentrations ranging from 7.8 to 2000 µg/mL
b) Mutation assay:	
1st experiment:	10.9, 21.9, 43.8, 87.5, 175.0 and 350.0 µg/mL with and 21.9, 43.8, 87.5, 175.0, 350.0 and 700.0 µg/mL without metabolic activation
2nd experiment:	31.3, 62.5, 125.0 and 250.0 µg/mL with and 31.3, 62.5, 125.0, 250.0, 500.0, 1000.0 µg/mL without metabolic activation

B. TEST PERFORMANCE

1. Dates of experimental work: 06-Sep-2012 to 2-Nov-2012

2. Preliminary cytotoxicity assay:

Cytotoxicity was assessed by determination of the cloning efficiency. About 200 cells were incubated in 25-cm² flasks with 9 test substance concentrations in serum-free Ham's F12 medium for about 4 hours (with and without metabolic activation) or 24 hours (only without metabolic activation; serum-supplemented medium) after an attachment period of 20-24 hours. At the end of the exposure period, the cells were washed with Hanks' balanced salt solution (HBSS) or PBS, covered with Ham's F12 and incubated for a further 5 to 8 days. After this incubation period, colonies were fixed, stained and counted. In addition to the cloning efficiency the following parameters were measured: pH, osmolarity and the determination of precipitates (solubility).

3. Mutation Assay:

Pretreatment of Cells: Cells with a passage number ≥ 2 after thawing from the frozen cells stock were seeded into 75 cm^2-flasks and incubated for 3-4 days with "HAT" medium during the week prior to treatment to eliminate spontaneous HPRT-deficient mutants. Afterwards, a passage into culture medium followed and the cells were incubated for further 3-4 days.

Cell treatment: For each test group, about $1x10^6$ cells per flask were seeded into 175 cm^2 flasks containing about 20 mL Ham's F12 medium supplemented with 10% FCS and incubated for about 20 - 24 hours with 5% CO_2 at 37°C and ≥ 90% humidity for cell attachment. Two flasks were used for each test group.

After the cell attachment period the medium was replaced by the treatment medium. In case of experiments without metabolic activation the treatment medium consisted of 18 mL Ham's F12 medium without FCS plus 2 mL positive control substance. For the vehicle control and the test groups, 20 mL of the treatment medium was supplemented with 0.2 mL of the vehicle or test substance preparation. In case of metabolic activation, the treatment medium consisted of 16 mL Ham's F12 medium without FCS, 0.2 mL positive control and 4 mL S9-mix. Analogously, for the vehicle control and test groups, 14 mL of medium was supplemented with 0.2 mL vehicle or test substance preparation and 4 mL S9-mix.

	Concurrent negative and positive controls were tested in parallel. The cells were exposed for 4 hours both with and without S9-mix (or for 24 hours without S9-mix in the second experiment) at 5% CO_2, 37°C and ≥ 90% humidity.
Expression:	After incubation for 4 or 24 hours, respectively, the treatment medium was replaced by at least 20 mL Ham's F12 medium with 10% FCS after having been rinsed several times with Hanks' balanced salt solution (HBSS). The following 1st passage was carried out after an incubation period of about 3 days following the 4 hour exposure or 2 days following the 24 hour exposure period. After an entire expression period of 7 - 9 days the cells were transferred into the selection medium (2nd passage).
Selection:	For the mutant selection, six 75-cm^2 flasks each were seeded with $3x10^5$ cells from each treatment group in selection medium (TG medium) and incubated for about 6 to 7 days. At the end of the selection period, colonies were fixed with methanol, stained with Giemsa and counted.
Determination of Cytotoxicity:	Cloning efficiency 1 (survival): The survival (cloning efficiency 1; CE_1) was determined in parallel to the mutagenicity test. Approximately 200 cells per dose group were seeded into duplicate 25 cm^2 flasks using 5 mL Ham`s F12 medium with 10% FCS. After a 20-24 hour attachment period the cells were incubated with vehicle, test substance or the positive control for 4 or 24 hours as described above. Following exposure, cells were rinsed several times with HBSS. Finally, cells were cultured in 5 mL Ham's F12 medium incl. 10% (v/v) FCS.
Cloning efficiency 2 (viability):	The viability (cloning efficiency 2; CE_2) was determined after the expression period. About 200 cells were separated during the transfer into selection medium and seeded in two flasks (25 cm^2) containing 5 mL Ham's F12 medium incl. 10% (v/v) FCS each. After seeding of the cells, the flasks were incubated for 5 - 8 days to form colonies. These colonies were fixed, stained and counted.

Calculations:

Mutant frequency: Uncorrected mutant frequency:

$$MF_{uncorr} = \frac{\text{total number of mutant colonies}}{\text{number of seeded cells}} \times 10^6$$

Corrected mutant frequency:

$$MF_{corr} = \frac{MF_{uncorr}}{CE_{2\,absolute}} \times 100$$

Cloning efficiency (CE, %) absolute:

$$CE_{absolute} = \frac{total\ number\ of\ colonies\ in\ the\ test\ group}{total\ number\ of\ seeded\ cells\ in\ the\ test\ group} x100$$

relative, in comparison to control:

$$CE_{relative} = \frac{CE_{absolute}\ of\ the\ test\ group}{CE_{absolute}\ of\ the\ vehicle\ control} x100$$

4. Statistics:

An appropriate statistical trend test was performed to assess a dose-related increase of mutant frequencies. The number of mutant colonies obtained for the test substance treated groups was compared with that of the respective vehicle control groups. A trend is judged as statistically significant whenever the p-value (probability value) is below 0.10 and the slope is greater than 0. Both, biological and statistical significance will be considered together.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- Increases of the corrected mutation frequencies ($MF_{corr.}$) both above the concurrent vehicle control values and the historical negative control range.
- Evidence of reproducibility of any increase in mutant frequencies.
- A statistically significant increase in mutant frequencies and the evidence of a dose-response relationship.

Isolated increases of mutant frequencies above the historical negative control range (i.e. 15 mutants per 10^6 clonable cells) or isolated statistically significant increases without a dose-response relationship may indicate a biological effect but are not regarded as sufficient evidence of mutagenicity.

A test substance is generally considered negative in this test system if:

- The corrected mutation frequency ($MF_{corr.}$) in all dose groups is within the historical control range and is not significantly above the concurrent negative control.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance under storage conditions was guaranteed until 20 Apr 2020 as indicated by the Sponsor. The stability of a comparable batch (L83-44-2) at room temperature in the vehicle DMSO and in water over a period of 4 hours was verified analytically.

B. PRELIMINARY CYTOTOXICITY ASSAY

After 4 hours treatment in the absence of S9 mix cytotoxicity indicated by reduced relative cloning efficiency of about or below 20% relative survival was observed at ≥ 500 µg/mL, while no cytotoxicity was observed up to 2000 µg/ml in the presence of metabolic activation. In addition, after 24 hours treatment in the absence of S9 mix strongly reduced relative cloning efficiency of below 20% relative survival was observed at 500 and 1000 µg/mL.

Precipitation of the test substance was macroscopically observed at ≥ 125 µg/mL irrespective of metabolic activation. Microscopically, precipitation wat down to 31.3 µg/ml at the end of the treatment period. No marked effect on osmolarity and pH value was observed.

Based on these data the highest concentration tested in the mutagenicity experiments was up to 1000 µg/mL without and up to 350 µg/mL with metabolic activation.

C. MUTAGENICITY ASSAYS

Cytotoxic effects indicated by clearly reduced cloning efficiencies of about or below 20% of control values were observed in both experiments in the absence of S9 mix at least at the highest applied concentrations [see Table 5.8.1-19 and Table 5.8.1-20]. In contrast, in the experimental parts with S9 mix neither a decrease in the number of colonies nor of the cell densities was observed.

No relevant increase in the number of mutant colonies was observed with or without S9 mix. In both experiments after 4 and 24 hours treatment with the test substance the values for the corrected mutation frequencies (MFcorr.: 0.75 - 6.78 per 106 cells) were close to the respective vehicle control values (MFcorr.: 0.42 - 3.28 per 106 cells) and clearly within the range of historical negative control data (MFcorr.: 0.00 - 16.43 per 106 cells).

In the 2nd experiment with metabolic activation a statistically significant dose-related increase in the mutant frequency was found after 4 hours treatment (MFcorr.: 1.55 - 4.22 per 106 cells) in the trend test. However, the values obtained for the corrected mutation frequency of this experimental part were well within historical negative control data range (MFcorr.: 0.00 - 16.43 per 106 cells). Therefore, this finding has to be regarded as biologically irrelevant (see Table 5.8.1-19 and Table 5.8.1-20).

Treatment with the positive controls EMS and DMBA resulted in a marked increase in the number of mutant colonies as well as of mutant frequencies in all experiments, thus demonstrating the sensitivity of the test.

The pH and osmolarity of the tested concentrations were not altered at the concentrations tested. In the 1st experiment in the absence and presence of S9 mix, test substance precipitation was observed in culture medium 4 hours after start of treatment at 87.5 µg/mL and above. In the 2nd experiment in the absence of S9 mix, test substance precipitation was observed at 250.0 µg/mL and above after 24 hours exposure. Besides in the presence of S9 mix precipitates in culture medium occurred at 125.0 µg/mL and above at the end of 4 hours exposure period.

III. CONCLUSION

Based on the results of the study it is concluded that under the conditions of the test 500M04 (Reg.No. 298327, metabolite of pyraclostrobin) does not induce forward mutations in the HPRT locus in CHO cells in vitro.

Report:	CA 5.8.1/18 Schulz M., Landsiedel R., 2012a Reg.No. 298327 (metabolite of BAS 500 F, Pyraclostrobin) - In vitro chromosome aberration assay in V79 cells 2012/1185707
Guidelines:	OECD 473, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.10, EPA 870.5375

Executive Summary

Reg.No. 298327 (metabolite of BAS 500 F, pyraclostrobin; batch: L83-44-2, purity: 97.6) was tested in vitro for the ability to induce chromosome and numerical aberrations in Chinese Hamster V79 cells in two independent experiments in the presence and absence of metabolic activation. Concentrations of 31.3 µg/mL to 2000 µg/mL were tested for clastogenic effects with and without metabolic activation in experiments with a pulse treatment of 4 hours. The cells were prepared 18 h post treatment-begin. Vehicle (DMSO) and positive controls (cyclophosphamide (CPP) and ethylmethanesulfonate (EMS) for the experiment with and without metabolic activation, respectively) were included to demonstrate the sensitivity of the test system.

The test substance caused a statistically significant and biologically relevant increase in the number of structurally aberrant metaphases only after adding a metabolizing system. This result was seen in two experiments performed independently of each other. No increase in the frequency of cells containing numerical chromosome aberrations was observed.

Based on the results of this study, Reg.No. 298327 is considered to have a chromosome damaging (clastogenic) effect under in vitro conditions in Chinese hamster V79 cells in the presence of metabolic activation.

(BASF DocID 2012/1185707)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg.No. 298327 (Metabolite of BAS 500 F, pyraclostrobin)

Description: Solid, beige
Lot/Batch #: L83-44-2
Purity: 97.6%
Stability of test compound: The stability of the test substance under storage conditions was guaranteed until 01 Jan 2013 by the sponsor. The stability of the test substance at room temperature dissolved in the vehicle DMSO over a period of 4 hours was verified analytically.
The homogeneity of the test substance was ensured by mixing prior to preparation of test substance formulations and on account of the high purity.
Solvent used: Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control: A negative control was not employed in this study.
Solvent control: DMSO
Positive control, -S9: Ethylmethanesulfonate (EMS) 500 µg/mL
Positive control, +S9: Cyclophosphamide (CPP) 0.5 µg/mL

3. Activation: S9 was produced from the livers of 5 induced male Wistar Sprague-Dawley rats. The rats received on three consecutive days intraperitoneal injections of 80 mg phenobarbital and 80 mg β-naphthoflavone orally per kg body weight. 24 hours after the last administration the animals were sacrificed. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction is thawed at room temperature and 1 volume of S9-fraction is mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so called S9 mix, was kept on ice until used.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4. Test organisms: Chinese hamster V79 cells

5. Culture medium: MEM medium with glutamine supplemented with
- 10% (v/v) fetal calf serum (FCS)
- 1% (v/v) penicillin/streptomycin (10000 IU/10000 µg/mL)
- 1% (v/v) amphotericine B (250 µg/mL)
During exposure to the test substance (4-hour treatment), MEM medium was used without FCS supplementation.

6. Test concentrations:

a) Preliminary toxicity assay: Eight concentrations ranging from 15.6 to 2000 µg/mL were used in pretests for dose selection for the main experiments. V79 cells were prepared at a sampling time of 18 hours after 4 and 18 hours exposure time without metabolic activation and after 4 hours exposure time with metabolic activation.

b) Mutation assay:
1st experiment: 31.3, 62.5, 125, 250, 500, 1000 and 2000 µg/mL with and without metabolic activation (18 h preparation interval)
2nd experiment: 50, 100, 150, 200 and 250 µg/mL with metabolic activation (18 h preparation interval)

B. TEST PERFORMANCE:

1. Dates of experimental work: 13-Mar-2012 to 15-Oct-2012

2. Preliminary cytotoxicity assay: A range-finding cytotoxicity test was conducted with V79 cultures exposed for 4 and 18 hours to test substance concentrations of 15.6 - 2000 µg/mL both with and without metabolic activation. At the end of the exposure period, cell count, cell attachment, mitotic index and the quality of metaphases were determined in order to derive appropriate test substance concentrations for the main test.

3. Cytogenicity Assay:

Cell treatment:	Cells were exposed to the test substance, solvent or positive control in pulse treatment experiments for 4 hours with or without metabolic activation. The cells were incubated in Quadriperm® dishes at 37°C, 5% CO_2 and ≥ 90% humidity. Two chambers of a Quadriperm dish were used for each concentration (=duplicate cultures). The preparation interval was 18 h post treatment-begin. For determination of cytotoxicity, additional cell cultures (using 25 cm² plastic flasks) were treated in the same way as in the main experiment. Growth inhibition was estimated by comparing the cell number in the treated groups with the concurrent control.
Spindle inhibition:	100 µL colcemide (stock: 10 µg/mL phosphate buffered saline) was added to the cultures 2 - 3 hours prior to harvesting.
Cell harvest:	At the end of the incubation time the culture medium was completely removed. For hypotonic treatment, 5 mL of a 0.4% KCl solution (37°C) was added for about 20 minutes. The cells were fixed by addition of 5 mL methanol/glacial acetic acid (3:1 v/v). The fixative was changed twice.
Slide preparation:	The slides were removed from the Quadriperm chambers, briefly allowed to drip off and passed through a Bunsen burner flame. After drying, the cells were stained with Giemsa and Titrisol. After rinsing and clarifying in Xylene the cover slips were mounted in Corbit-Balsam.
Metaphase analysis:	Slides were coded prior to analysis. As a rule, the first 100 consecutive well-spread metaphases of each culture were counted for all test groups, and if cells had 20 - 22 chromosomes, they were analyzed for structural chromosome aberrations. Numerical chromosome aberrations were also recorded. If there is a clear increase in chromosomally damaged cells, the number of metaphases to be analyzed is reduced to at least 50 mitoses/ test group. A mitotic index based on 1000 cells per culture was determined for all evaluated test groups in both experiments.

4. Statistics:

The proportion of metaphases with aberrations was calculated for each group.

A comparison of each dose group with the vehicle control group was carried out using Fisher's exact test for the hypothesis of equal proportions. This test was Bonferroni-Holm corrected versus the dose groups separately for each time and was performed one-sided.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A statistically significant, dose-related and reproducible increase in the number of cells with structural chromosome aberrations (excl. gaps).
- The number of aberrant cells (excl. gaps) exceeds both the concurrent negative/vehicle control value and the historical negative control data range.

A test substance is generally considered as “negative” if the following criteria are met:

- The number of cells with structural aberrations (excl. gaps) in the dose groups is not statistically significant increased above the concurrent negative/vehicle control value and is within the historical negative control data range.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS:

The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically.

B. PRELIMINARY CYTOTOXICITY ASSAY:

A preliminary cytotoxicity assay was performed to determine appropriate test substance concentrations for the main test. Dose selection was based on the cell count, cell attachment, mitotic index and the quality of metaphases. 2000 µg/mL with and without metabolic activation was selected as the top dose for the 1st experiment of the main test. 250 µg/mL with metabolic activation was selected as the top doses for the 2nd experiment of the main test.

C. CYTOGENICITY ASSAYS:

In the first experiment after a treatment time of 4 hours no relevant increase in the number of chromosomally damaged cells was observed without S9 mix [see Table 5.8.1-21]. The aberration rates after test substance treatment were within the historical negative control data range (0.0% - 5.5% aberrant metaphases, excl. gaps). In the presence of S9 mix a single, statistically significant increase of structural chromosome aberrations (9% aberrant metaphases, excl. gaps) was observed at the intermediate dose of 125 µg/mL [see Table 5.8.1-22]. This concentration was at the border of test substance solubility in culture medium. To confirm the observation an increased sample of 400 metaphase cells was scored. The aberration rate clearly exceeded historical negative control data range (0.0% - 5.5% aberrant metaphases, excl. gaps). The other two scored dose groups (62.5 and 250 µg/mL) showed aberration rates (5.0 and 5.5% exclusive gaps) being within historical negative control data range.

In the second experiment, a statistically significant increase in the number of chromosomally damaged cells was observed after 4 hours exposure in the presence of a metabolizing system. At 100, 200 and 250 µg/mL the number of aberrant metaphases (9.0, 6.5 and 9.5%, respectively) exceeded the historical negative control data range. The aberration rates at 100 and 250 µg/mL were statistical significanct different from the control [see Table 5.8.1-23].

In both experiments, no indication for an aneugenic effect was observed.

No suppression of the mitotic activity was observed under any of the experimental conditions in both experiments. No growth inhibition was observed under any of the experimental conditions, except in the 2nd experiment at 250 µg/mL (49.1% of control).

The osmolarity and pH values were not influenced by the test substance treatment. Test substance precipitation in culture medium at the end of exposure period was macroscopically observed from 250 µg/mL onwards in both experimental parts in the 1st experiment and from 200 µg/mL in the 2nd experiment.

Vehicle and positive controls were all in a range to ensure the validity of the test.

III. CONCLUSION

Based on the results of the study it is concluded that 500M04 (Reg.No. 298327, metabolite of pyraclostrobin) is a chromosome damaging (clastogenic) substance under in vitro conditions using V79 cells in the presence of metabolic activation. The relevance of this in vitro result was evaluated in a higher tier in vivo study (see below) according to Commission Regulation (EU) No 283/2013, Section 5.4.2.

Report:	CA 5.8.1/19 [redacted] 2013a Reg.No. 298327 (metabolite of BAS 500 F, Pyraclostrobin) - Micronucleus test in bone marrow cells of the mouse 2013/1026779
Guidelines:	OECD 474 (1997), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.12, EPA 870.5395
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Reg.No. 298327 (metabolite of BAS 500 F, pyraclostrobin; batch: L84-174, purity: 99.6%) was tested for chromosomal damage (clastogenicity) and for the ability to induce spindle poison effects (aneugenic activity) in NMRI mice using the micronucleus test method. For this purpose, the test substance was administered once orally to groups of 5 male mice at dose levels of 500, 1000 and 2000 mg/kg body weight. The vehicle served as negative and cyclophosphamide and vincristine sulfate as positive controls. The animals were sacrificed 24 or 48 (additional high dose and vehicle group) hours after the administration and the bone marrow of the two femora was prepared and investigated for micronuclei.

The oral administration of Reg.No. 298327 did not lead to any biologically relevant increase in the number of polychromatic erythrocytes containing either small or large micronuclei. The rate of micronuclei was mostly close to the concurrent negative control and was within the range of the historical control data. Inhibition of erythropoiesis, determined from the ratio of polychromatic to normochromatic erythrocytes, did not occur. Weak signs of systemic toxicity were observed in all dose groups consisting of piloerection and hunched posture.

Both of the positive control chemicals, i.e. cyclophosphamide for clastogenic effects and vincristine for induction of spindle poison effects, led to the expected increase in the rate of polychromatic erythrocytes containing small (cyclophosphamide) or small and large (vincristine sulphate) micronuclei, thus demonstrating the sensitivity of the test system.

In conclusion, under the the experimental conditions of this study, the test substance Reg. No. 298327 (Metabolite of BAS 500 F, pyraclostrobin) does not induce cytogenetic damage in bone marrow cells of NMRI mice in vivo.

(BASF DocID 2013/1026779)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

	Reg.No. 298327 (Metabolite of pyraclostrobin)
Description:	Solid, yellow
Lot/Batch #:	L84-174
Purity:	99.6% (tolerance ± 1.0%)
Stability of test compound:	The stability of the test substance under storage conditions throughout the study period was guaranteed until 01 Apr 2020 as indicated by the sponsor. Homogeneity of the test substance was guaranteed on account of the high purity and was ensured by mixing before test substance preparation.
Vehicle used:	DMSO and subsequent emulsion in corn oil

2. Control Materials:

Negative:	No negative control was employed in this study.
Vehicle control:	DMSO and subsequent emulsion in corn oil
Positive control:	Cyclophosphamide (CCP) 20 mg/kg for the determination of clastogenic effects Vincristine sulphate (VCR) 0.15 mg/kg for the determination aneugenic effects

3. Test animals:

Species:	Albino mice
Strain:	Crl:NMRI
Sex:	Male for the main study; male and female for the range finding study
Age:	5 - 8 weeks
Mean body weight at dosing:	28.8 g
Source:	Charles River Laboratories Germany GmbH
Number of animals per dose:	
Range finding study:	Not indicated in the report
Micronucleus assay:	5 males/dose
Acclimation period:	At least 5 days
Diet:	Standardized pelleted feed (Maus/Ratte Haltung "GLP", Provimi Kliba SA, Kaiseraugst, Switzerland)
Water:	Drinking water in bottles, ad libitum
Housing:	During the study the mice were housed individually in Makrolon cages, type MII

4. Environmental conditions:

Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	frequency not indicated (fully air-conditioned rooms)
Photo period:	12-hour light-dark cycle (06:00 - 18:00, 18:00 - 06:00)

5. Test compound doses:

Range finding test:	2000 mg/kg
Micronucleus assay:	500, 1000 and 2000 mg/kg The test substance was administered once by oral gavage using an application volume of 10 mL/kg.

B. TEST PERFORMANCE

1. Dates of experimental work: 30-Jul-2012 to 10-Jan-2013

2. Preliminary range finding test:

Male and female NMRI mice were treated once by oral gavage with a test substance dose of 2000 mg/kg bw.

3. Micronucleus test:

Treatment and sampling:	Groups of 5 male mice were treated once with either vehicle or 500, 1000 or 2000 mg test substance/kg bw by oral gavage. Additional test groups treated with the vehicle control and the high dose were used for the second sampling period. The application volume was 10 mL/kg bw and the volume to be applied was calculated based on actual weight on the day of administration. The positive control substances CCP and VCR were administered once by oral gavage (CCP) or i.p. injection (VCR). The animals were observed for evident clinical signs of toxicity throughout the study.

Twenty-four hours after the administration the mice were sacrificed and the two femora were prepared free of all soft tissue. After cutting the epiphyses the bone marrow was flushed out in a centrifugation tube with fetal calf serum and subsequently centrifuged at 300xg for 5 minutes. The supernatant was discharged and the pellet resuspended in about 50 µl fresh FCS. The sampling of the femora from the additional high dose and vehicle control group was performed as described above 48 h after the treatment.

Slide preparation:

One drop of the suspension was applied on a clean microscopic slide and smears were prepared. After air drying the smears were stained with May Grünwald solution, rinsed, and finally stained with Giemsa solution (7.5%). After rinsing and clarifying in xylene, the preparations were mounted. The slides were coded prior to microscopic evaluation.

Slide evaluation:

In general, 2000 polychromatic erythrocytes (PCEs) from each male animal of every test group were evaluated and investigated for micronuclei (MN). The normochromatic erythrocytes (NCEs) that occurred were also scored.

The increase in the number of micronuclei in polychrometic erythrocytes of treated animals as compared to the vehicle control group provides an index of a chromosome-breaking (clastogenic) effect or of a spindle activity (aneugenic) of the substance tested.

In addition, the number of small micronuclei ($d < D/4$) and of large micronuclei ($d \geq D/4$) (d = diameter of micronucleus, D = cell diameter) was determined: The size of micronuclei may indicate the possible mode of action of the test substance, i.e. a clastogenic or a spindle poison effect.

The ratio of polychromatic to normochromatic erythrocytes was calculated. An alteration of this ratio indicates a toxic effect on erythropoieses and thus, that the test substance actually reached the target organ.

4. Statistics:

The number of polychromatic erythrocytes with micronuclei was analyzed by comparing the dose groups with the vehicle control using the Mann-Whitney U-test (modified rank test according to Wilcoxon). Here, the relative frequencies of cells with micronuclei of each animal were used.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A dose-related and significant increase in the number of micronucleated polychromatic erythrocytes was observed.
- The proportion of cells containing micronuclei exceeded both the values of the concurrent vehicle control range and the vehicle historical control range.

A test substance is generally considered negative in this test system if:

- There was no significant increase in the number of micronucleated polychromatic erythrocytes at any dose above concurrent control frequencies.
- The frequencies of cells containing micronuclei were within the historical control range.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance in the vehicle was verified analytically. The homogeneity of the test substance in the vehicle was guaranteed by constant stirring during the removal and administration of the test substance formulation and by analytical determination of 3 individual samples of each concentration. The mean test substance concentrations were determined as 53.8, 95.7 and 193.3 mg/mL at nominal concentrations of 50, 100 and 200 mg/mL, respectively. This corresponds to a recovery rate ranging between 96% to 108% and is thus, within the expected range (90-110%).

B. PRELIMINARY RANGE FINDING TEST

In the pretest for the determination of the acute oral toxicity in males and females, the animals were treated with 2000 mg/kg bw. All animals survived with weak signs of toxicity. The clinical signs observed were piloerection and hunched posture. There were no distinct differences between male and female animals. Thus, only male animals were used for the main experiment.

C. MICRONUCLEUS ASSAY

Micronucleus frequencies of the animals treated with the indicated doses of Reg.No. 298327 were near to the concurrent vehicle control values and within the historical control range (see Table 5.8.1-24). A single statistically significant increase in the number of micronucleated polychromatic erythrocytes was obtained at 24-hour sacrifice interval at low dose group (500 mg/kg bw). This micronucleus rate (1.1‰) was within the laboratory's historical vehicle control data range (0.3 - 3.0‰ micronucleated PCEs). Therefore, this observation is considered as biologically irrelevant. Large micronuclei (d > D/4) were neither observed in the negative control group nor in the test substance groups.
The PCE/NCE ratio was not affected by treatment with the test substance and were in the range of the vehicle control values. Thus, there was no indication that erythropoiesis was inhibited. At 2000 mg/kg body weight at 48 hours preparation interval the number of mature normochromatic erythrocytes was slightly reduced compared to the respective vehicle control group as indication of bone marrow toxicity, which is interpreted as indication that the test-item reached its target organ. This interpretation is supported by the results of a toxicokinetics study with Reg.No. 298327 in mice [see below; DocID 2012/1278425].
The clastogenic activity of the positive control substance cyclophosphamide was evident by the increase in the number of PCE containing mainly small micronuclei (24.4**, total 26.3‰). The administration of the spindle poison vincristine resulted in an incidence of micronuclei in polychromatic erythrocytes of 35.0‰. This included 12.5‰ of PCE with large micronuclei. The positive controls thus demonstrated the sensitivity of the test system.
The administration of the test substance was well tolerated by all animals with weak clinical signs of toxicity observed in all dose groups consisting of piloerection and hunched posture. No signs of systemic toxicity were observed in any of the animals treated with the positive control substances or the vehicle.

III. CONCLUSION

Based on the result of this study 500M04 (Reg.No. 298327, metabolite of pyraclostrobin) does not induce the formation of micronuclei in mouse polychromatic erythrocytes under the conditions of the study, i.e. is devoid of clastogenic or aneugenic activity in vivo. A kinetic study demonstrated that the Reg.No. 298327 reached the target organ (bone marrow). Thus, the clastogenicity observed in vitro is not relevant under in vivo conditions.

Studies on Absorption, Distribution, Metabolism and Excretion of 500M04 (Reg.No. 298327, BF 500-5, 'Pyrazolon') in Mammals

Report:	CA 5.8.1/20 [redacted], 2013a 14C-Reg.No. 298327 (metabolite of BAS 500 F, Pyraclostrobin) - Study on the kinetics in mice 2012/1278425
Guidelines:	(EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. L 142, OECD 417, EPA 870.7485, JMAFF Guidelines on the Compiling of Test Results on Toxicity - Tests on In Vivo Fate in Animals (2001)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The distribution of Reg.No. 298327 (Metabolite of pyraclostrobin) in mouse blood cells, plasma and bone marrow after a single oral administration was determined using a test substance formulation containing radiolabelled ^{14}C-Reg.No. 298327 (Metabolite of pyraclostrobin). For this purpose, 5 male mice were treated once orally with a nominal dose of 1000 mg/kg bw. The target quantity of radioactivity was about 10 MBq per animal. After 5 hours the animals were sacrificed and samples of the indicated tissues were analysed for test substance content.

The analysis of the test substance formulation showed that the animals 1 to 4 received an actual dose of 986.2, 1035.1 and 1047.6 and 1082.7 mg/kg bw, respectively. Since in a first experiment the dosing failed for one animal due to technical problems, this animal was excluded from analysis. The mean radioactive dose of the 4 remaining animals was 9.25 MBq/animal. The mean total radioactive residues (TRR) in the bone marrow (25.30 µg Eq/g) after 5 hours were 0.001% of the applied dose, 0.008% in the plasma (29.83 µg Eq/g) and 0.003% in the blood cells (7.62 µg Eq/g).

Therefore, it is concluded that Reg. No. 298327 is systemically bioavailable and its presence in the bone marrow and blood after an oral administration is confirmed.

BASF DocID 2012/1278425

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

	a) ^{14}C-Reg.No. 298327 (Metabolite of BAS 500F)
	b) Reg.No. 298327 (Metabolite of BAS 500F)
Description:	a) Not indicated
	b) Solid, yellow
Lot/Batch #:	a) 724-2102
	b) L84-174
Purity:	a) radiochemical purity: >98%; specific activity: 8.99 MBq/mg
	b) 99.6% (tolerance +/- 1.0%)
Stability of test compound:	a) The stability of ^{14}C-Reg.No. 298327 was demonstrated analytically.
	b) The stability of Reg.No. 298327 was guaranteed by the sponsor (expiry date: 01-Apr-2020).

2. Vehicle: 0.5% CMC in drinking water

3. Test animals:

Species:	Albino mice
Strain:	Crl:NMRI
Number:	5
Sex:	Male
Age:	Not indicated
Weight at dosing:	about 30 - 40 g
Source:	Charles River Laboratories Germany GmbH
Acclimation period:	at least 8 days
Diet:	Kliba lab diet (mouse / rat “GLP”), pelleted (Provimi Kliba SA, Kaiseraugst, Switzerland), ad libitum
Water:	drinking water, ad libitum
Housing:	During acclimatization and prior to the experiment animals were housed individually in Macrolon cages type M III. During the experiments animals were housed individually in steel wire mesh cages.

4. Environmental conditions:

Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	15 / hour
Lighting:	12 hours light / 12 hours darkness

5. Dose selection

A nominal dose of 1000 mg/kg bw was selected for this study based on repeated dose studies with Reg.No. 298327.

6. Preparation of the dosing solutions

In order to administer a target quantity of 10 MBq per animal, a stock solution of ^{14}C-Reg.No. 298327 was prepared in acetone. Reg.No. 298327 was added to this solution with an end nominal concentration of 100 mg/mL. The solvent was then evaporated and the mixture formulated in 0.5% CMC in drinking water.

7. Analyses

The stability, homogeneity and correctness of the concentration of the test substance preparation as well as the purity of ^{14}C-Reg.No. 298327 were determined analytically under the conditions described below:

HPLC (HP1100) analysis

Column:	Ascentis Express C18, 150 x 4.6 mm, 2.7 µm
Eluent:	A) acetonitrile / formic acid (1000 mL+1 mL) B) deionized water / formic acid (1000 mL+1 mL), %B: 60%, isocratic
Flow:	1.0 mL/min
Detection:	UV-Extinction at 274 nm HPLC Radioactivity Monitor LB 509 (Cell: 150)

B. TEST PERFORMANCE.

1. Dates of experimental work: 07-Aug-2012 to 03-Apr-2013

2. Study design:

Overall, 5 males were weighed and treated orally with a single nominal dose of 1000 mg/kg bw of the test substance preparation. The application volume was 10 mL/kg. After 5 hours the animals were sacrificed and samples of blood cells, plasma and the bone marrow were weighed and analyzed for total radioactive residues using a liquid scintillation counter. Since in a first experiment the dosing failed for one animal due to technical problems, the amount of test substance preparation for analysis after administration was insufficient. Therefore, only two animals were investigated (animals 1 and 3) and reanalysis of the test substance preparation after administration was not available. In a second experiment, two additional animals were dosed (animals 2 and 4) and the homogeneity, the correctness of the concentration and of the radiochemical purity was demonstrated at least before and after test substance administration. However, based on the current data, radioactivity was clearly detectable in blood, plasma and bone marrow of orally dosed animals.

3. Calculations:

Depending on the preparation of the samples the appropriate formulas were chosen.

Key of abbreviations		Dimension
DPM	= disintegrations per minute (abs. or per sample)	[DPM]
LSC	= weight of sample, prepared for liquid scintillation counting (LSC)	[g]
SOL	= weight of soluene	[g]
TRR	= total radioactive residues	[µg/g]
FRE	= weight of freeze drying sample	[g]
SAM	= weight of organs/Tissue	[g]
AQU	= weight of double distilled water	[g]
ACT	= specific activity of test article	[DPM/µg]
EQUTIS	= equivalents of test article per tissue weight	[µg/g]
D_{rad}	= dose of radioactivity administered	[DPM]

Formula I

$$\%\ of\ D_{rad} = \frac{\sum_{n=1}^{n} DPM_n / LSC_n}{n} \times \frac{SOL}{FRE} \times (SAM + AQU) \times \frac{100}{D_{rad}}$$

Formula II

$$EQUTIS = \frac{\sum_{n=1}^{n} DPM_n / LSC_n}{n} \times \frac{SAM + AQU}{SAM \times ACT}$$

Formula III

$$DPM = \left(\left(TRR\left[\frac{\mu g}{g}\right] \right) * \left(Spec.activity\left[\frac{MBq}{g}\right] * 60 \right) * Poolsampleweight[g] \right)$$

Formula IV

$$\%Dose = \left(DPM\left(Radioact.dose\left[\frac{MBq}{animal}\right] * 60000000 \right) \right) * 100\%$$

II. RESULTS AND DISCUSSION

STABILITY, HOMOGENEITY AND CONTENT OF THE TEST SUBSTANCE IN THE APPLICATION MEDIUM

The stability, homogeneity of ^{14}C- Reg.No. 298327 in the vehicle was confirmed by analysis. The achieved doses of the test substance in the individual mice were 986.2, 1035.1, 1047.6, 1082.7 and 1037.9 mg/kg bw for mice 1 to 4, respectively.

BIOAVAILABILITY DATA

The data in Table 5.8.1-25 demonstrate that after 5 h various amounts of residual radioactivity were present in blood, plasma and bone marrow.

Table 5.8.1-25: Radioactive residues in various tissues of male mice after a single treatment with ^{14}C-Reg.No. 298327

Animal No.		1	2	3	4	MEAN	SD
Animal weight [g]		37.7	34.7	32.9	32.3	34.4	2.41

III. CONCLUSION

Analysis of the systemic availability of 500M04 (Reg.No. 298327) using a radiolabelled mixture showed that 5 h after a single oral administration the test substance could be detected in all examined tissues (blood cells, plasma and bone marrow). Thus, 500M04 is considered to be bioavailable to these tissues after oral application, i.e. the target tissue investigated in the in vivo micronucleus test was exposed to Reg.No. 298327.

Overall toxicological evaluation of 500M04 (Reg.No. 298327, BF 500-5, 'Pyrazolon')

500M04 was of low acute oral toxicity, was not-irritating to the skin and the eye and was not a skin sensitizer.

In a 90-day rat study 500M04 induced a slight regenerative normochromic-macrocytic anemia in males accompanied by an adaptive increase of extramedullary hematopoiesis in the spleen. Furthermore, high dose animals displayed increased drinking water consumption, which resulted in an increased discharge of less concentrated urine. In mid and high dose males a strong increase of unknown crystals was noted in the urine sediment. These changes were seen in a probable relation to the histopathological lesions observed in the kidneys at this dose level. Thus the NOAEL was 103 mg/kg bw/d (target dose level of 100 mg/kg bw/d) in male and 316 mg/kg bw/d (target dose level of 300 mg/kg bw/d) in female Wistar rats, respectively.

The QSAR evaluations of 500M04 were of low reliability and by weight of evidence there was no conclusive alert for genotoxicity.

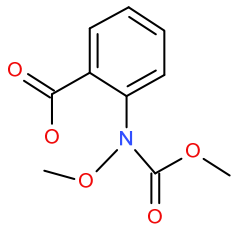
By weight of evidence 500M04 is not genotoxic based on the in vitro and in vivo studies conducted. A mouse kinetic study clearly confirmed that 500M04 is systemically bioavailable and thus present in bone marrow and blood after oral administration.

Compared to the active ingredient pyraclostrobin 500M04 is less toxic. Based on the available toxicological data it is considered to be **not toxicologically relevant** and an **ADI of 0.52 mg/kg bw/day** was established taking into account the NOAEL of 103 of the 90-day rat study and an assessment factor of 200 in order to adopt from a sub-chronic to a live-long exposure period.

The predicted chronic exposure for 500M04 (and its derivatives) does not exceed 0.1% of the proposed ADI of 0.52 mg/kg bw/day.

Group 3: Anthranilic acid derivatives

500M24 (other denominator: Reg.No. 5916421)



500M24 (Reg.No. 5916421) is a metabolite found in the rat as well as in the wheat metabolism studies.

A) QSAR Predicitions on 500M24 (Reg.No. 5916421)

OECD Toolbox (Version: 3.2) [see DocID 2014/1172955]
The OECD Toolbox revealed no DNA alerts for Ames, MN and CA or for DNA or protein binding.

OASIS TIMES (MIX V.2.27.13 TB; Mutagenicity S-9 activated v08.08) [see molecule 7 of report DocID 2014/1172952 and 2014/1172953]

The Ames mutagenicity predicition for 500M24 (Reg.No. 5916421) and its 8 in-silico generated metabolites was negative (out of domain). This holds true for the prediction of in vitro CA mutagenicity.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 7 of report DocID 2014/1172954; for both VEGA models]

The prediction for 500M24 (Reg.No. 5916421) is mutagen (out of model applicability domain). The prediction is based on 6 molecules with the prediction mutagen, which was experimentally confirmed for 4 of them. The similarity indices ranged from 0.657 to 0.739 and thus not very good.

Discussion: The prediction is in contrast to the 500M24 (Reg.No. 5916421) experimental result and thus rejected.

VEGA: Mutagenicity model (SarPy; version 1.0.4-BETA)

500M24 (Reg.No. 5916421) is out of model applicability domain. The prediction is 'mutagen' with the structural alert SA 98. As discussed above, this alert was also obtained for pyraclostrobin and a number of pyraclostrobin metabolites, which like 500M24 (Reg.No. 5916421) were actually tested negative. The predicition is therefore rejected.

DEREK (Version 2.0.0.201011301322; Knowledge base version: 11_20_05_2010)

The prediction for genotoxicity and neurotoxicity is negative.

Genotoxicity studies on 500M24 (Reg.No. 5916421)

Report:	CA 5.8.1/21 Woitkowiak C., 2014a Reg.No. 5916421 (Metabolite of BAS 500 F, Pyraclostrobin) - Salmonella typhimurium/Escherichia coli, reverse mutation test 2013/1323364
Guidelines:	OECD 471 (1997), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.13/B.14 No. L 142, EPA 870.5100
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

S. typhimurium strains TA98, TA100, TA 1535 and TA 1537 and E. coli strain WP2 uvrA were exposed to Reg.No. 5916421 (Metabolite of BAS 500 F, pyraclostrobin); batch: L82-125, purity: 98.8%) using dimethylsulfoxide (DMSO) as a solvent in the presence and absence of metabolic activation in two independent experiments. Vehicle and positive controls were included in each experiment.

In both assays, the plate incorporation assay and the preincubation assay, the test substance was tested in concentrations of 33, 100, 333, 1000, 2500 and 5000 µg/plate. No biologically relevant increase in the number of revertant colonies was noted in any of the strains tested in presence or absence of metabolic activation in any of the experiments. The positive controls induced the appropriate response in the corresponding strains, thus demonstrating the sensitivity of the test system.

A bacteriotoxic effect was occasionally observed in the standard plate test depending on the strain and test conditions from about 1000 µg/plate onwards. No precipitation of the test substance was found up to the highest tested concentration.

The test substance Reg.No. 5916421 (Metabolite of BAS 500 F, pyraclostrobin) is not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions of the study.

(BASF DocID 2013/1323364)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

test substance Reg.No. 5916421 (Metabolite of BAS 500 F, pyraclostrobin)

Description: Solid, brownish
Lot/Batch #: L82-125
Purity: 98.8% (tolerance +/- 1.0%)
Stability of test compound: Stable - expiry date 01-Sep-2015. The homogeneity of the test substance was ensured by mixing prior to preparation of test substance solutions. The stability of the test substance in the vehicle DMSO was verified analytically.
Solvent used: Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control: In parallel to each experiment, negative control experiments were carried out in order to check for possible contaminants (sterility control) and to determine the spontaneous mutation rate (vehicle control).
Vehicle control: The vehicle control with and without S-9 mix only contained the vehicle used for the test substance at the same concentration and volume for all tester strains.
Solvent/final concentration: 100 µL/plate
Positive control compounds tested without addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1535	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1537	9-Aminoacridine (AAC)	DMSO	100 µg/plate
TA 98	4-nitro-o-phenylendiamine (NOPD)	DMSO	10 µg/plate
WP2 uvrA	4-nitroquinoline-N-oxide (4-NQO)	DMSO	5 µg/plate

Positive control compounds tested with addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1535	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1537	2-aminoanthracene	DMSO	2.5 µg/plate
TA 98	2-aminoanthracene	DMSO	2.5 µg/plate
WP2 uvrA	2-aminoanthracene	DMSO	60 µg/plate

3. Activation:

S9 was produced from the livers of induced male Sprague-Dawley rats. The rats received on three consecutive days intraperitoneal injections of 80 mg phenobarbital and 80 mg β-naphthoflavone orally per kg body weight. 24 hours after the last administration the animals were sacrificed. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction is thawed at room temperature and 1 volume of S9-fraction is mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9 mix, was kept on ice until used.

The S9 mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

To demonstrate the efficacy of the S9 mix in this assay, the S9 batch was further characterized with benoz(a)pyrene in the strains TA 100 and TA 98 as required in OECD 471.

4. Test organisms:

S. typhimurium strains: TA98, TA100, TA1535, TA1537
E. coli: WP2 uvrA
Salmonella typhimurium:
The Salmonella strains are checked for the following characteristics at regular intervals: deep rough character (rfa); UV sensitivity (uvrB); ampicillin resistance (R factor plasmid). E. coli WP2 uvrA is checked for UV sensitivity.
Histidine and tryptophan auxotrophy is automatically proven in each experiment via the spontaneous rate.

5. Test concentrations:

Plate incorporation assay: In the first experiment triplicate plates were prepared for each concentration (neg. control; 33, 100, 333, 1000, 2500 and 5000 µg/plate and positive controls at the concentrations indicated above) and conditions (i.e. with and without S9) for all tester strains indicated above.

Pre-incubation assay: In the second experiment the test article / vehicle / positive control substance, bacterial and S-9 mix or phosphate buffer were incubated at 37°C for the duration of about 20 minutes. Triplicate plates were prepared for each concentration (neg. control; 33, 100, 333, 1000, 2500 and 5000 µg/plate and positive controls at the concentrations indicated above) and condition (i.e. with and without S9) for all tester strains.

B. TEST PERFORMANCE:

1. Dates of experimental work: 27-Aug-2013 to 06-Sep-2013

2. Plate incorporation assay:

To test tubes containing 2-mL portions of warm soft agar (containing 0.5 mM histidine + 0.5 mM biotin), 0.1 mL test solution or vehicle, 0.1 mL fresh bacterial culture, 0.5 mL S9-mix (in tests with metabolic activation) or 0.5 mL phosphate buffer (in tests without metabolic activation) were added in the given order. After mixing, the samples are poured onto Merckoplate® plates (minimal glucose agar plates). In the experiments with E. coli the warm soft agar contains 0.5 mM tryptophan instead of histidine + biotin.

3. Pre-incubation assay:

100 µL of test solution or vehicle, 0.1 mL bacterial suspension and 0.5 mL S9 mix or phosphate buffer were incubated at 37°C for about 20 minutes. Subsequently, 2 mL of soft agar was added and, after mixing, the samples are poured onto the agar plates.

After incubation in the dark for 48 to 72 hours at 37°C each plate was checked for precipitates and status of the background lawn. Revertant colonies were counted. Means and standard deviations were calculated.

4. Titer determination:

In order to assess bacteriotoxic effects, the titer was additionally determined in experimental parts with S9 mix using the vehicle control and the two highest doses. The procedure followed in both experiments (plate incorporation and pre-incubation) was the same as described above for the individual experiments with the exception that the soft agar used contained maximal amino acid solution (5 mM tryptophan or 5 mM histidine + 0.5 mM biotin). After the incubation in the dark for 48 to 72 hours at 37°C the number of bacterial colonies was determined.

5. Statistics:

No special statistical tests were performed.

6. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A dose-related and reproducible increase in the number of revertant colonies, i.e. about doubling of the spontaneous mutation rate in at least one tester strain either without S9 mix or after adding a metabolizing system.

A test substance is generally considered non-mutagenic in this test if:

- The number of revertants for all tester strains was within the historical negative control range under all experimental conditions in two experiments carried out independently of each other.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The test substance was stable over the study period under the storage conditions. The stability of the test substance in the vehicle DMSO was verified analytically (BASF study 01Y0173/13Y006).

B. TOXICITY

A preliminary cytotoxicity assay was not performed in this laboratory. Cytotoxicity was determined in the course of the mutation assay.

A weak bacteriotoxic effect as indicated by a slight decrease in the number of his^+ or trp^+ revertants or slight reduction in the titer was occasionally observed in the standard plate test conditions at concentrations ≥1000 µg/plate and in all strains with and without metabolic activation in the preincubation at ≥ 2500 g/plate.

C. MUTATION ASSAYS

Neither in the plate incorporation nor in the preincubation experiment with and without metabolic activation was a biologically relevant increase in number of revertants observed in any strain tested [see Table 5.8.1-26]. The positive controls yielded revertant numbers in a range expected for the respective strains and thus demonstrated the sensitivity of the test system. Precipitation was not observed up to the maximum concentration.

[#] Due to a contamination of TA98 plates in the plate incorporation assay, the repetition of the TA98 experiment was performed as second experiment. Accordingly, the preincubation assay was the 3rd experiment

III. CONCLUSION

According to the results of the present study, the test substance 500M24 (Reg.No. 5916421, metabolite of pyraclostrobin) is not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions chosen.

Report:	CA 5.8.1/22 Schulz M., Landsiedel R., 2014f Reg.No. 5916421 (metabolite of BAS 500 F, Pyraclostrobin) - In vitro gene mutation test in L5178Y mouse lymphoma cells (TK+/- locus assay, microwell version) 2013/1298449
Guidelines:	OECD 476 (1997), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.17, EPA 870.5300
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Reg.No. 5916421 (Metabolite of 500 F; pyraclostrobin; batch: L82-125, purity: 98.8%) was tested in vitro for its ability to induce forward mutations in L5178Y cells by assessing the mutation of the $TK^{+/-}$ locus. Two independent experiments were conducted in the presence and absence of metabolic activation with concentrations from 143.8 to 2300 µg/mL. The treatment intervals were 4 or 24 hours. Methyl methanesulfonate (MMS) and cyclophosphamide (CPP) served as positive controls in the experiments without and with metabolic activation, respectively.

Reg.No. 5916421 did not cause any biologically relevant increase in the mutant frequencies with or without a metabolizing system in two independently performed experiments. The positive control substances induced a marked increase in mutant frequency thus demonstrating the sensitivity of the test system.
Based on the results of the study it is concluded that under the conditions of the test Reg.No. 5916421(Metabolite of BAS 500 F; pyraclostrobin) does not induce forward mutations in mammalian cells in vitro.

(BASF DocID 2013/1298449)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material	Reg.No. 5916421 (Metabolite of 500 F; pyraclostrobin)
Description:	Solid, brownish
Lot/Batch #:	L82-125
Purity:	98.8% (tolerance ± 1.0%)
Stability of test compound:	Stable - Expiry date: 01-Sep-2015. The homogeneity of the test substance was guaranteed on account of the high purity and ensured by mixing prior to preparation of test substance solutions. The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically.
Solvent used:	Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control:	A negative control was not employed in this study
Solvent control:	The vehicle controls with and without S9 mix contained the vehicle selected for the test substance at the same volume and concentration as used in the test cultures.
Positive control -S9:	Methyl methanesulfonate (MMS) 15 µg/mL (4-hour exposure period) and 5 µg/mL (24-hour exposure period)
Positive control +S9:	Cyclophosphamide (CPP) 2.5 µg/mL

3. Activation:

S9 was produced from the livers of at least 5 induced male Wistar [Crl:WI(Han)] rats. The rats were administered injections of phenobarbital (80 mg/kg; i.p.) and ß-napthtoflavone (80 mg/kg; per gavage) on three consecutive days. 24 h after the last administration the animals were sacrificed.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4. Test organism:

Mouse lymphoma L5178Y $TK^{+/-}$ cell line:
This is a cell line with a high proliferation rate (doubling time of about 9 - 10 hours), a high plating efficiency and a stable karyotype with a near diploid number of 40 ± 1 chromosome. Each batch used for mutagenicity testing was checked for mycoplasma contamination.

5. Culture media:

Culture medium:

RPMI 1640 medium including stable glutamine supplemented with:
1% (v/v) penicillin/streptomycin (10000 IU / 10000 µg/mL) and 1% (v/v) sodium pyruvate (10 mM) = RPMI-0
For treatment medium (with S9 mix):
RPMI-0 supplemented with 5% (v/v) fetal calf serum (FCS) = RPMI-5

	For treatment medium (without S9 mix) and subculturing cells: RPMI-0 is supplemented with 10% (v/v) FCS = RPMI-10 For cloning efficiency and selection medium: RPMI-0 supplemented with 20% (v/v) FCS = RPMI-20
Pretreatment medium:	A ("THMG" medium): RPMI-10 supplemented with thymidine (3.0 µg/mL), hypoxanthine (5.0 µg/mL), methotrexate (0.1 µg/mL) and glycine (7.5 µg/mL) B ("THG" medium): RPMI-10 supplemented with thymidine (3.0 µg/mL), hypoxanthine (5.0 µg/mL), and glycine (7.5 µg/mL)
Selection medium:	("TFT" medium): RPMI-20 supplemented with trifluorthymidine (TFT, 4.0 µg/mL)

6. Locus examined: thymidine kinase (TK)

7. Test concentrations:

a) Preliminary toxicity assay: Nine concentrations ranging from 9.0 to 2300 µg/mL
b) Mutation assay:

1st experiment:	287.5, 575, 1150, and 2300 µg/mL with and without metabolic activation (4-hour exposure period)
2nd experiment:	143.8, 287.5, 575, 1150 and 2300 µg/mL without (24-hour exposure period) and 431.3, 862.5, 1725 and 2300 µg/mL with metabolic activation (4-hour exposure period)

B. TEST PERFORMANCE:

1. Dates of experimental work: 24-Jun-2013 to 16-Jan-2014

2. Preliminary

cytotoxicity assay: In the pretest for toxicity based on the purity and the molecular weight of the test substance 2300 µg/mL (approx. 10 mM) Reg.No. 5916421 (Metabolite of BAS 500 F, pyraclostrobin) was used as top concentration both with and without S9 mix at 4 hour exposure time and without S9 mix at 24 hour exposure time.

The pretest was performed following the method described for the main experiment. The relative suspension growth (RSG) was determined as toxicity indicator for dose selection and various parameters were checked for all or at least for some selected doses. Additionally, pH and solubility were determined.

3. Mutation Assay:

Pretreatment of Cells: During the week prior to treatment, spontaneous TK deficient mutants ($TK^{-/-}$) were eliminated from the stock cultures by incubating 3 x 10^5 cells per 75 cm² flask in a total volume of 30 mL for 1 day in "THMG" medium (pretreatment medium A), and for the following 3 days in "THG" medium (pretreatment medium B).

Cell treatment: For each test group, about $1.5x10^7$ cells per flask were seeded into 75 cm^2 flasks containing RPMI-10 for exposures without S9 mix and RPMI-5 medium for exposures with S9 mix and incubated for the respective exposure period (1st experiment: 4-hour exposure with and without S9 mix and 2nd experiment 24 hours without S9 mix and 4 hours with S9 mix) with 5% CO_2 at 37°C and ≥90% humidity for cell attachment. 2 cultures were treated in parallel for each test group.

Expression: At the end of the exposure period, the cells were transferred in tubes, centrifuged for 5 minutes at and were resuspended in RPMI-5 medium. The washing of the cells was repeated at least once. Then the cells were centrifuged and were resuspended in RPMI-10 medium. From each culture a sample of treated cells ($2x10^5$ cells/mL or $6x10^6$ cells/flask) were pipetted in 75 cm² flasks and were incubated for a 2-day expression period. To maintain exponential growth during this phase, each culture was counted daily and the cell numbers were adjusted at each day to $2x10^5$ cells/mL in 30 mL RPMI-10 medium.

Selection: For the mutant selection, the cells were resuspended in selection medium ("TFT" medium) and two 96-well plates per cultures were seeded with 2000 cells/well. After incubation of at least 9 days, both the number of negative wells and the number of wells containing small or large colonies were scored for calculation of the mutant frequency (MF).

Size distribution of the colonies:	The colonies are classified into large colonies (indication of gene mutation) and small colonies (indication of chromosome breakage). Small colonies are defined as less than 1/4 of the diameter of the well. Size is the key factor and morphology (the optical density of the small colonies is considerably higher) should be secondary.
Determination of Cytotoxicity:	Cloning efficiency 1 (survival): The survival (cloning efficiency 1; CE_1) was determined in parallel to the mutagenicity test. At the end of the exposure period, the cells were centrifuged and 400 cells from each culture were resuspended in 50 mL RPMI-20 medium (8 cells/mL). Per culture 200 µL were dispensed in each well of two 96-well plates (1.6 cells/well). After incubation for 9 - 11 days the plates were scored for empty wells.
Cloning efficiency 2 (viability):	The viability (cloning efficiency 2; CE_2) was determined after the expression period. 2 days after end of exposure, the cells were centrifuged and 400 cells from each culture were resuspended in 50 mL RPMI-20 medium (8 cells/mL). Per culture 200 µL were dispensed in each well of two 96-well plates (1.6 cells/well). After incubation for at least 9 days the plates were scored for empty wells. Suspension growth (RSG) and relative total growth (RTG): For calculation of the suspension growth (SG) and the relative total growth (RTG) the cell counts determined within the expression period at 2nd and 3rd passage after exposure in the case of 4-hour exposure and 1st, 2nd and 3rd passage after exposure in the case of 24-hour exposure were used. This measure includes the relative growth in suspension during the expression period (RSG) and the relative cloning efficiency (RCE_2; viability) at the time the mutants are selected. For taking into account any loss of cells during the 4-hour treatment period a relative growth during treatment factor (RGDT, %) was calculated by comparing the growth of each treated culture relative control.

Calculations:

Mutant frequency:
Uncorrected mutant frequency:

$$MF_{uncorr} = \frac{-\ln(\text{total number of empty well s} \div \text{total number of seeded wells (96)})}{\text{number of seeded cells per well (2000)}} \times 10^6$$

Corrected mutant frequency:

$$MF_{corr} = \frac{MF_{uncorr}}{CE_2} \times 100$$

Cloning efficiency (CE, %) absolute:

$$CE_x = \frac{-\ln(\text{total number of empty well s} \div \text{total number of seeded wells (96)})}{\text{number of seeded cells per well (1.6)}} \times 100$$

Cloning efficiency relative, in comparison to control:

$$RCE_x = \frac{CE_x \text{ of the test group}}{CE_x \text{ of the negative / vehicle control}} \times 100$$

Relative total growth:

Relative growth during treatment (RGDT, %)

$$\text{RGDT} = \frac{\text{Cell count after 4 h of the test group}}{\text{Cell count after 4 h of the negative/v ehicle control}} \times 100$$

Total suspension growth (SG) after 4 hour-exposure:

$$SG = \frac{\text{Cell count after 24 h}}{2 \text{ x } 10^5 \text{ cells per mL}^{1,2}} \times \frac{\text{Cell count after 48 h}}{2 \text{ x } 10^5 \text{ cells per mL}^2} \times \frac{\text{RGDT}}{100}$$

Total suspension growth (SG) after 24 hour-exposure:

$$SG = \frac{\text{Cell count after 24 h}}{2 \text{ x } 10^5 \text{ cells per mL}} \times \frac{\text{Cell count after 48 h}}{2 \text{ x } 10^5 \text{ cells per mL}^2} \times \frac{\text{Cell count after 72 h}}{2 \text{ x } 10^5 \text{ cells per mL}^2}$$

$$\text{RSG} = \frac{\text{SG of the test group}}{\text{SG of the negative/vehicle control}} \times 100$$

$$RTG = \frac{RSG \times RCE_2}{100}$$

[1] Cell number seeded following 4-hour treatment
[2] If cell number was lower than 2 x 10^5 cells per mL all remaining cells were seeded

4. Statistics:

An appropriate statistical trend test was performed to assess a dose-related increase of mutant frequencies. The number of mutant colonies obtained for the test substance treated groups was compared with that of the respective vehicle control groups. A trend is judged as statistically significant whenever the one-sided p-value (probability value) is below 0.05 and the slope was greater than 0. Both, biological and statistical significance will be considered together. However, both, biological and statistical significance has been considered together.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- The mutation frequency exceeds a threshold of 126 mutant colonies per 10^6 cells (GEF: Global Evaluation Factor) above the concurrent negative/vehicle control value.

and

- Evidence of reproducibility of any increase in mutant frequencies, means the mutagenic response occurs at least in both parallel cultures of one experiment.

and

- A statistically significant dose-related increase in mutant frequencies using an appropriate statistical trend test.

A test substance is generally considered negative in this test system if:

- The mutation frequency is below a threshold of 126 mutant colonies per 10^6 cells (GEF) above the concurrent negative/vehicle control value.

or

- No evidence of reproducibility of an increase in mutant frequencies is obtained.

or

- No statistically significant dose-related increase in mutant frequencies using an appropriate statistical trend test is observed.

However, in the evaluation of the test results the historical variability of the mutation rates in negative and vehicle controls and the mutation rates of all negative and vehicle controls of this study were taken into consideration. Results of test groups have been rejected if the relative total growth (RTG) and/or the cloning efficiency 1 (CE_1) were less than 10% of the respective vehicle controls. Whenever a test substance is considered mutagenic according to the above mentioned criteria, the ratio of small versus large colonies is used to differentiate point mutations from clastogenic effects. If the increase of the mutation frequency is accompanied by a reproducible and dose-related shift in the ratio of small versus large colonies clastogenic effects are indicated.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically (see BASF study code 01Y0173/13Y006).

B. PRELIMINARY CYTOTOXICITY ASSAY

After 4 hours treatment in the absence and presence of S9 mix no excessive cytotoxicity indicated by reduced relative suspension growth of about or below 20% was observed. After 24 hours treatment in the absence of S9 mix reduced relative suspension growth of 23.9% was observed at 2300 µg/mL.

The pH of the test substance preparation was adjusted by adding small amounts of NaOH. Osmolarity and pH values were not influenced by test substance treatment. In this study no precipitation of Reg.No. 5916421 in the vehicle DMSO or the culture medium was observed.
Based on these data the highest concentration tested in the mutagenicity experiments was 2300 µg/mL without and with metabolic activation.

C. MUTAGENICITY ASSAYS

No relevant increase in the number of mutant colonies was observed with and without metabolic activation after 4 or 24 hours of treatment [see Table 5.8.1-27]. The corrected mutant frequencies obtained for both experiments were always below the calculated threshold taking into consideration the Global Evaluation Factor (GEF). There was no statistically significant dose-related trend in both experiments with and without S9 mix. The mutant frequencies obtained were within the range of the historical negative control data.

In the 24h exposure experiment without metabolic activation the corrected mutant frequency at 2300 µg/mL exceeded the threshold of 164 colonies per 10^6 cells. However, as excessive cytotoxicity was observed at this concentration (relative total growth of 6.8%) this concentration was excluded from evaluation.

		2300.0	+	-	115.3	132.6	36.8	168
		Positive control[4]	+	n.d.	76.2	64.8	411.8	168

* Precipitation in culture medium at the end of exposure period
** For calculation see above in this report
*** Mutant frequency threshold: number of mutant colonies per 10^6 cells of current vehicle control plus 126
n.d. Not determined
[1] DMSO 1% (v/v) [2] MMS 15.0 µg/mL
[3] MMS 5.0 µg/mL [4] CPP 2.5 µg/mL

Treatment with the positive controls MMS and CCP resulted in clearly increased mutant frequencies as expected. The values of the corrected mutant frequencies clearly exceeded the respective calculated thresholds for a mutagenic effect based on the GEF (126 plus the mutant frequency of the respective negative control).

The pH value of the test substance preparation was adjusted by adding small amounts of NaOH. Osmolarity and pH values were not influenced by test substance treatment. No precipitation of Reg.No. 5916421 in the vehicle DMSO or the culture medium was observed.

III. CONCLUSION

Based on the results of the study it is concluded that 500M24 (Reg.No. 5916421, metabolite of pyraclostrobin) does not induce forward mutations in vitro in the mouse lymphoma assay with L5178Y TK$^{+/-}$ cells in the absence and the presence of metabolic activation.

Report:	CA 5.8.1/23 Schulz M., Landsiedel R., 2014e Reg.No. 5916421 (Metabolite of BAS 500 F, Pyraclostrobin) - In vitro micronucleus assay in V79 cells (cytokinesis block method) 2013/1363549
Guidelines:	OECD 487 (2010), Commission Regulation EU No. 640/2012 of 06 July 2012 - B.49: In vitro Mammalian Cell Micronucleus Test
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Reg.No. 5916421 (Metabolite of BAS 500 F, pyraclostrobin) (batch L82-125; purity 98.8%) was tested in vitro for its potential to induce micronuclei in V79 cells of the Chinese hamster in the absence and presence of metabolic activation by S9 mix in three independent experiments with concentrations of 287 to 2300 µg/mL. The exposure periods were either 4 hours or 24 hours (without S9 only) and the preparation intevalls were 24 or 44 hours (with S9 only) after start of treatment. In order to confirm the results of the 2nd experiment in the absence of S9 mix a third experiment was performed.

The test substance induced a statistically significant and biologically relevant increase in the number of micronucleated cells after 24 hours continuous treatment without S9 mix. This observation was confirmed in a second experiment. No increased number of micronucleated cells was observed after the 4 hour treatment with and without metabolic activation.

In all three experiments with and without metabolic activation no cytotoxicity was observed up to the highest applied test substance concentration. Likewise, no test substance precipitation in culture medium was observed.

Vehicle and positive controls revealed the expected results of micronucleated cells thereby ensuring the validity of the test.

Based on the results of this study, Reg.No. 5916421 is considered to have a chromosome-damaging (clastogenic) effect or to induce numerical chromosomal aberrations (aneugenic activity) under in vitro conditions in V79 cells in the absence of metabolic activation.

(BASF DocID 2013/1363549)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg.No. 5916421 (Metabolite of BAS 500 F, pyraclostrobin)

Description:	Solid, brownish
Lot/Batch #:	L82-125
Purity:	98.8% (tolerance ± 1.0%)
Stability of test compound:	Stable - Epxiry date 01-Sep-2015. The homogeneity of the test substance was guaranteed on account of the high purity and ensured by mixing prior to preparation of test substance solutions. The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically.
Solvent used:	Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control:	A negative control was not employed in this study.
Solvent control:	DMSO
Positive control, -S9:	Ethylmethanesulfonate (EMS, 300, 400 and 500 µg/mL, dissolved in MEM without FCS)
Positive control, +S9:	Cyclophosphamide (CPA, 1.0 and 2.5 µg/mL, dissolved in MEM without FCS)

3. Activation: S9 was produced from male Wistar rats. The rats were induced by intraperitoneal applications of 80 mg/kg bw phenobarbital and by oral administrations of 80 mg/kg bw β-naphthoflavone each, on three consecutive days. The livers were prepared 24 hours after the last treatment. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction was thawed at room temperature and 1 volume of S9-fraction was mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9 mix, was kept on ice until used.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4. Test organisms:

Chinese hamster V79 cells
This is a continuous cell line with a high proliferation doubling time of 12-14 hours, a high plating efficiency (≥90%) and a stable karyotype (modal number of 22 chromosomes).

5. Culture medium/conditions:

Culture media:

Minimal essential medium with Earle's salts (MEM) containing a L-glutamine source supplemented with 10% (v/v) fetal calf serum (FCS), 1% (v/v) penicillin/streptomycin (10000 IU / 10000 µg/mL) and 1% (v/v) amphotericine B (250 µg/mL). During exposure to the test substance in the presence of S9 mix MEM medium was used without FCS supplementation.

Cell culture:

Deep-frozen cell stocks were thawed at 37°C in a water bath, and volumes of 0.5 mL were transferred into 25 cm^2 plastic flasks containing about 5 mL MEM supplemented with 10% (v/v) fetal calf serum (FCS). Cells were grown with 5% (v/v) CO2 at 37°C and ≥ 90% humidity and subcultured twice weekly. Cell monolayers were suspended in culture medium after detachment with 0.25% (w/v) trypsin solution.

Cell cycle and harvest time: The cell cycle of the untreated V79 cells lasts for about 12 to 14 hours under the selected culture conditions. Thus, a harvest time of 24 hours is about 2 times the normal cell cycle length. V79 cells are an asynchronous cell population, i.e. at the time of test substance treatment there are different cell stages. Since the effect on these cell stages may vary for different test substances, more than one harvest time after treatment may be appropriate. Furthermore, substance-induced mitotic delay may considerably delay the first post-treatment mitosis. Therefore, delayed harvest times (e.g. 44 hours) and prolonged exposure periods (e.g. 24 hours treatment) were considered.

6. Test concentrations:

a) Preliminary toxicity assay: 17.97 to 2300 µg/mL with and without metabolic activation
Exposure period: 4 hours with and without metabolic activation; 24 hours without metabolic activation
Harvest time: 24 hours

b) Cytogenicity assay:

1st experiment: 287, 575, 1150 and 2300 µg/mL with and without S9 mix (4 hours exposure, 24 hour preparation interval)

2nd experiment: 287, 575, 1150 and 2300 µg/mL with and without metabolic activation (24 and 4 hour exposure, 24- and 44-hour preparation interval)

3rd experiment: 575, 1150, 1725 and 2300 µg/mL without S9 mix (24 hour exposure, 24 hours preparation interval)

B. TEST PERFORMANCE:

1. Dates of experimental work: 24-Jun-2013 to 17-Jan-2014

2. Preliminary cytotoxicity assay:

In the pretest for toxicity based on the purity and the molecular weight of the test substance 2300 µg/mL (approx. 10 mM) Reg.No. 5916421 (Metabolite of BAS 500 F, pyraclostrobin) was used as top concentration. The pretest was performed following the method described for the main experiment. As indication of test substance toxicity relative increase in cell count (RICC) and cell attachment (morphology) were determined for dose selection. pH and solubility were additionally determined.

3. Cytogenicity Assay:

In the beginning two independent experiments were performed. In experiment I, the exposure period was 4 hours with and without S9 mix. In experiment II, the exposure periods were 4 hours with S9 mix and 24 hours without S9 mix. The cells were prepared 24 hours after start of treatment with the test item, except for the 4 hour treatment interval in the presence of metabolic activation (experiment II). In this experimental part cells were harvested after 44 hours to consider possibly occurring mitotic delay. Since statistically significant and biologically relevant increase in the number of micronucleated cells was observed after 24 hours continuous treatment in the absence of a metabolizing system a third corroborate experiment was performed.

Cell seeding / treatment:	Routinely grown cells that did not exceed a max. of 15 passages and reached a confluency of at least 50%, were detached by trypsination and used to prepare a single cell suspension with the required cell count (3-5x10^5 cells per culture, depending on the schedule) in MEM incl. 10% (v/v) FCS. 5 mL cell suspension were transferred into 25 cm² cell culture flasks using a dispenser. Subsequently, the test cultures were incubated. After an attachment period of about 20 - 24 hours, the medium was removed from the flasks and the treatment medium was added. In case of experiments without metabolic activation the treatment medium consisted of 4 mL MEM medium with FCS plus 1 mL positive control or test substance preparation/ vehicle, respectively. In case of metabolic activation, the treatment medium consisted of 3 mL MEM medium without FCS, 1 mL positive control or test substance preparation/ vehicle and 1 mL S9-mix, respectively. The cultures were incubated for the respective exposure period at 37°C, 5% (v/v) CO2 and ≥ 90% humidity. At the end of the exposure period, the medium was removed and the cultures were rinsed twice with 5 mL HBSS (Hanks Balanced Salt Solution). Subsequently, 5 mL MEM incl. 10% FCS supplemented with Cytochalasin B (CytB, final concentration: 3 µg/mL; stock: 0.6 mg/mL in DMSO) was added and incubated for the respective recovery time. In the case of 24-hour continuous exposure, CytB was added to the treatment medium at start of treatment, and cell preparation was started directly at the end of exposure. At 44 hours preparation interval in the presence of S9 mix the supplementation of CytB was 24 hours before preparation of the cultures.

Cell harvest, preparation of slides and staining:	Just before preparation the culture medium was completely removed. Single cell suspensions were prepared from each test group by trypsination. Then, the cell numbers per flask of each single cell suspension were determined using a cell counter. Subsequently, $5x10^4$ cells per slide were centrifuged at 1400 rpm for 7 minutes onto labelled slides using a Cytospin centrifuge. After drying, the slides were fixed in 90% (v/v) methanol for 10 minutes. Before scoring, the slides were stained with a mixture of 4',6-diamidino-2-phenylindole dihydrochloride (DAPI) and propidium iodide (PI) in Fluoroshield™ at a concentration of 0.25 µg/mL each. By the use of the combination of both fluorescence dyes it can be differentiated between DNA (DAPI; excitation: 350 nm, emission: 460 nm) and cytoplasm (PI; excitation: 488 nm, emission: 590 nm).
Analysis of micronuclei and cytotoxicity:	Cytospin slides were scored by fluorescence microscopy. At least 1000 cells per culture, means at least 2000 cells per test group, were evaluated and the number of micronuclei-containing binucleated cells was recorded. Analysis of micronuclei was carried out following the criteria: The diameter of the micronucleus is less than 1/3 of the main nucleus; the micronucleus and main nucleus retain the same color; the micronucleus is not linked to the main nucleus and is located within the cytoplasm of the cell; only cells clearly surrounded by a nuclear membrane were scored. Cultures with few isolated cells were not analyzed for micronuclei.

Relative increase in cell count (RICC):

$$RICC = \frac{(\text{Increase in number of cells in treated cultures (final} - \text{starting}))}{(\text{Increase in number of cells in control cultures (final} - \text{starting}))} \text{ x } 100$$

Thus, a RICC of 53% indicates 47% cytotoxicity/cytostasis.

Proliferation Index (CBPI):

$$CBPI = \frac{\big((\text{No. mononucleated cells}) + (2 \text{ x No. binucleated cells}\big) + (3 \text{ x No. mulitnucleated cells}))}{(\text{Total number of cells})}$$

The CBPI was used to calculate the % cytostasis (relative inhibition of cell growth compared to the respective vehicle control group) - a CBPI of 1 (all cells are mononucleate) is equivalent to 100% cytostasis.

% Cytostasis = $100 - 100 \{(CBPI_T - 1) / (CBPI_C - 1)\}$

(T- test substance treated culture; C = vehicle control)

Replicative Index (RI):

$$RI = \frac{(((\text{No. binucleate cells}) + (2\text{xmultinucleate cells}) \div (\text{Total number of cells}))_T}{(((\text{No. binucleate cells}) + (2\text{xmultinucleate cells}) \div (\text{Total number of cells}))_C} x100$$

(T = test substance treated culture; C = vehicle control culture)

Thus, an RI of 53% means that in comparison to the respective control cultures only 53% of the cells divided in the treated test group (= 47% cytotoxicity/cytostasis).

4. Statistics:

The statistical evaluation of the data was carried out using the MUVIKE program system (BASF SE). The proportion of cells containing micronuclei was calculated for each group. A comparison of each dose group with the concurrent vehicle control group was carried out using Fisher's exact test for the hypothesis of equal proportions. This test is Bonferroni-Holm corrected versus the dose groups separately for each time and was performed one-sided. If the results of this test were statistically significant compared with the respective vehicle control, labels (* $p \leq 0.05$, ** $p \leq 0.01$) have been be printed in the tables.

5. Evaluation criteria:

A test item is considered "positive" in this assay if the following criteria are met:

- A significant, dose-related and reproducible increase in the number of cells containing micronuclei was observed.
- The number of micronucleated cells exceeded both the value of the concurrent vehicle control and the range of our laboratory's recent negative control data.

A test substance is generally considered "negative" in this test system if:

- The number of micronucleated cells in the test groups is not distinctly increased above the concurrent vehicle control and is within our laboratory's recent negative control data range.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS:

The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically (see BASF study code 01Y0173/13Y006).

B. PRELIMINARY CYTOTOXICITY ASSAY:

A preliminary cytotoxicity assay was performed to determine appropriate test substance concentrations for the main test. After 4 hours treatment in the absence and presence of S9 mix no cytotoxicity as indicated by reduced RICC of ≤ 40 - 50% was observed.

C. CYTOGENICITY ASSAYS:

In all experimental parts after 4 hours test substance treatment in the absence and presence of 9 mix the values were close to the concurrent vehicle control values and within historical negative control data range (0.1 - 1.8% micronucleated cells) [see Table 5.8.1-28 and Table 5.8.1-29]. In contrast, a dose dependent and statistically and biologically significant incease in the number of micronucleated cells was observed after 24 hours continuous treatment in the absence of a metabolizing system in two independently performed experiments [see Table 5.8.1-28].

The positive control substances EMS (without S9 mix; 300 and 400 µg/mL) and CPP (with S9 mix; 1.0 µg/mL) induced statistically significant increased micronucleus frequencies in three independently performed experiments.

In all three experiments no growth inhibition was observed up to the highest applied test substance concentrations tested. To the contrary, in both experiments after 24 hours exposure in the absence of S9 mix enhanced cell growth was observed at concentrations ≥ 1150 µg/mL. Cell morphology/ attachment was not adversely influenced at any concentration tested for the occurrence of micronuclei. Osmolarity and pH values were not influenced by test substance treatment. To ensure a constant pH, the pH of the stock solutions was adjusted to a physiological value using small amounts of NaOH as the test-item is acidic. No precipitation of the test substance in culture medium was observed.

Table 5.8.1-28: Summary of results of micronucleus test with Reg.No. 5916421 (Metabolite of BAS 500 F, pyraclostrobin) - without metabolic activation

III. CONCLUSION

Based on the results of the study it is concluded that 500M24 (Reg.No. 5916421, metabolite of pyraclostrobin) has the potential to induce micronuclei (clastogenic and/or aneugenic activity) under the in vitro conditions in V79 cells in the absence of metabolic activation after 24 hours continuous treatment. The relevance of this in vitro result was evaluated in a higher tier in vivo study (see below) according to Commission Regulation (EU) No 283/2013, Section 5.4.2.

Executive Summary

Reg.No. 5916421 (metabolite of BAS 500 F, pyraclostrobin; batch: L82-125, purity: 98.8%) was tested for the potential to induce micronuclei in polychromatic erythrocytes (PCE) in the bone marrow of NMRI mice. For this purpose, the test substance was administered once orally to groups of 7 male mice at dose levels of 500, 1000 and 2000 mg/kg body weight. The vehicle served as negative and cyclophosphamide as positive controls. The animals were sacrificed 24 or 48 (additional high dose and vehicle group) hours after the administration and the bone marrow of the two femora was prepared and investigated for micronuclei.

There was no biologically relevant or statistically significant enhancement in the frequency of micronuclei at any preparation interval after administration of the test item at any dose level. Cyclophosphamide administered orally was used as positive control which showed a substantial increase of induced micronucleus frequency. After treatment with the test item the number of PCEs was not substantially decreased as compared to the mean value of PCEs of the vehicle control thus indicating that Reg.No. 5916421 did not exert any cytotoxic effects in the bone marrow.

No clinical signs were observed in the main experiment in all dose groups. However, analysis of plasma samples taken 24 hours after administration confirmed the presence of Reg.No. 5916421 in blood and thus confirmed that the test-item reaches its target-organ, i.e. the highly blood perfused bone marrow.

In conclusion, it can be stated that under the experimental conditions reported, the test item Reg.No. 5916421 did not induce micronuclei as determined by the micronucleus test with bone marrow cells of the mouse. Therefore, Reg.No. 5916421 (Metabolite of BAS 500 F, pyraclostrobin) is considered to be non-mutagenic in this micronucleus assay.

(BASF DocID 2013/1389659)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg.No. 5916421 (Metabolite of pyraclostrobin)

Description:	Solid, brownish
Lot/Batch #:	L82-125
Purity:	98.8% (tolerance ± 1.0%)
Stability of test compound:	The stability of the test substance under storage conditions throughout the study period was guaranteed until 01 Sep 2015 as indicated by the sponsor.
Vehicle used:	DMSO / PEG 400 (3/7)

2. Control Materials:

Negative:	No negative control was employed in this study.
Vehicle control:	30% Dimethyl suphoxide, 70% Polyethylen glycol 400 (DMSO / PEG 400 (3/7))
Positive control:	Cyclophosphamide (CCP) 40 mg/kg bw

3. Test animals:

Species:	Albino mice
Strain:	NMRI
Sex:	Male for the main study; male and female for the range finding study
Age:	8 - 12 weeks
Mean body weight at dosing:	35.7 ± 1.8 g
Source:	Charles River Laboratories, Research Models and Services Germany GmbH
Number of animals per dose:	
Range finding study:	4 males and 4 females (2/sex for each pre-test)
Micronucleus assay:	7 males/dose
Acclimation period:	At least 5 days
Diet:	pelleted standard diet (certified), ad libitum
Water:	tap water, ad libitum
Housing:	During the study the mice were housed individually in Makrolon cages, type MIII

4. Environmental conditions:

Temperature:	20 - 24°C
Humidity:	45 - 65%
Air changes:	frequency not indicated (fully air-conditioned rooms)
Photo period:	12-hour light-dark cycle (06:00 - 18:00, 18:00 - 06:00)

5. Test compound doses:

Range finding test:	2000 mg/kg
Micronucleus assay:	500, 1000 and 2000 mg/kg The test substance was administered once by oral gavage using an application volume of 10 mL/kg.

B. TEST PERFORMANCE

1. Dates of experimental work: 05-Nov-2013 to 03-Dec-2013

2. Preliminary range finding test:

Male and female NMRI mice were treated once by oral gavage with a test substance dose of 2000 mg/kg bw.

3. Micronucleus test:

Treatment and sampling:	Groups of 5 or 7 male mice were treated once with either vehicle or 500, 1000 or 2000 mg test substance/kg bw by oral gavage. Additional test groups treated with the vehicle control and the high dose were used for the second sampling period. The application volume was 10 mL/kg bw and the volume to be applied was calculated based on actual weight on the day of administration. The positive control substance CCP was administered once by oral gavage (CCP). The animals were observed for evident clinical signs of toxicity throughout the study. Twenty-four after the administration the mice were sacrificed and the two femora were prepared free of all soft tissue. After cutting the epiphyses the bone marrow was flushed out in a centrifugation tube with fetal calf serum and subsequently centrifuged at 390xg for 10 minutes. The supernatant was discarded and the pellet resuspended in about 50 µl fresh FCS. The sampling of the femora from the additional high dose and vehicle control group was performed as described above 48 h after the treatment.
Slide preparation:	One drop of the suspension was applied on a clean microscopic slide and smears were prepared. After air drying the smears were stained with May Grünwald solution, rinsed, and finally stained with Giemsa solution (7.5%). Cover slips were mounted with EUKITT. The slides were coded prior to microscopic evaluation.
Slide evaluation:	In general, 2000 polychromatic erythrocytes (PCEs) from each male animal of every test group were evaluated and investigated for micronuclei (MN). To describe a cytotoxic effect, the ratio between polychromatic and normochromatic erythrocytes was determined in the same sample and expressed in polychromatic erythrocytes per 2000 erythrocytes.

4. Statistics:

Statistical methods (nonparametric Mann-Whitney test) were used as an aid in evaluating the results, if necessary. However, the primary point of consideration is the biological relevance of the results.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A dose-related and significant increase in the number of micronucleated polychromatic erythrocytes was observed.
- The proportion of cells containing micronuclei exceeded both the values of the concurrent vehicle control range and the vehicle historical control range.

A test substance is generally considered negative in this test system if:

- There was no significant increase in the number of micronucleated polychromatic erythrocytes at any dose above concurrent control frequencies.
- The frequencies of cells containing micronuclei were within the historical control range.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance is confirmed indirectly by dose formulation analytics (see report # 04Y0173/13Y053). The actual test-item concentrations were 99.1, 99.5 and 99.7% of the nominal concentrations of 50, 100 and 200 mg/mL.

B. PRELIMINARY RANGE FINDING TEST

In the pretest for the determination of the acute oral toxicity in males and females, the animals were treated with 1000 or 2000 mg/kg bw. All animals survived with weak signs of toxicity (ruffled fur). There were no distinct differences between male and female animals. Thus, only male animals were used for the main experiment.

C. MICRONUCLEUS ASSAY

In comparison to the corresponding vehicle controls there was no statistically significant or biologically relevant enhancement in the frequency of the detected micronuclei at any preparation interval and dose level after administration of the test item. The mean values of micronuclei observed after treatment with Reg.No. 5916421 (Metabolite of BAS 500 F, pyraclostrobin) were below or very close to the value of the vehicle control group [see Table 5.8.1-30]. Moreover, micronucleus values obtained in all dose groups were very well within the historical negative control range (0.112±0.088% micronucleated cells, range: 0-9).

Cyclophosphamide administered orally was used as positive control which showed a statistically significant increase of induced micronucleus frequency.

Table 5.8.1-30: Micronucleus test in mice administered Reg.No. 5916421 by oral gavage

Test group	Dose [mg/kg bw]	Sampling time [h]	PCEs with micronuclei [%]	Range [n]	PCE per 2000 erythrocytes
Vehicle control	0	24	0.120	1-6	1184
Test item	500	24	0.036	0-1	1260
	1000	24	0.043	0-2	1164
	2000	24	0.079	0-4	1197
Positive control	40	24	**1.960****	21-59	1168
Vehicle	0	48	0.040	0-2	1286
Test item	2000	48	0.064	0-3	1282

** $p \leq 0.01$ (nonparametric Mann-Whitney test)
PCE polychromatic erythrocytes

The mean number of polychromatic erythrocytes was not decreased after treatment with the test item as compared to the mean value of PCEs of the vehicle control indicating that Reg.No. 5916421 (Metabolite of BAS 500 F, pyraclostrobin) did not have any cytotoxic properties in the bone marrow. No clinical signs were observed in the main experiment in all dose groups. The analysis of plasma samples taken 24 hours after administration of 2000 mg/kg bw confirmed the presence of the test item in blood in 4 out of 7 high dose mice. Thus, there is proof that Reg.No. 5916421 reached the target organ since the bone marrow is highly blood perfused. The fact that no test-item was detected in the 3 remaining animals does not affect the principal conclusion as the blood samples were only taken at a single sampling time 24 hour after administration.
In a separate study (see below) the plasma levels of Reg.No. 5916421 were determined.

III. CONCLUSION

In conclusion, it can be stated that during the study described and under the experimental conditions reported, the test item 500M24 (Reg.No. 5916421, metabolite of pyraclostrobin) did not induce micronuclei as determined by the micronucleus test in the bone marrow cells of the mouse. The analysis of Reg.No. 5916421 in rat plasma demonstrated that the test item reached the target organ (bone marrow). Thus, the clastogenicity observed in vitro is not relevant under in vivo conditions.

Report:	CA 5.8.1/27 [redacted] et al., 2016 a Reg.No. 5916421 (metabolite of BAS 500 F, Pyraclostrobin) - Investigation of the bioavailability in blood of the mouse 2016/1236540
Guidelines:	OECD 474
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Reg.No. 5916421 (metabolite of BAS 500 F, pyraclostrobin; batch: L82-125, purity: 98.8%) was administered to 2 male and 2 female mice by oral gavage at a dose of 2000 mg/kg bw, using the same vehicle as in the in vivo mouse micronucleus assay. Blood was sampled 24 hours after administration and analyzed for test item plasma concentrations by a validated LC-MS method.
Reg.No. 5916421 (500M24) concentrations of 44.5 to 257.3 ng/mL were determined in plasma. This demonstrates that the highly blood perfused bone marrow as the target organ in the in vivo mouse micronucleus assay was exposed to Reg.No. 5916421.

I. MATERIAL AND METHODS

A. MATERIALS

1.	**Test Material:**	Reg.No. 5916421 (metabolite of pyraclostrobin)
	Description:	Solid, brownish
	Lot/Batch #:	L82-125
	Purity:	98.8% (tolerance ± 1.0%)
	Stability of test compound:	The stability of the test substance under storage conditions throughout the study period was guaranteed until 01 Nov 2017 as indicated by the sponsor (based on a reanalysis in October 2015).
	Vehicle used:	DMSO / PEG 400 (3/7)
2.	**Control Materials:**	
		Due to the special purpose of this study, i.e. the determination of test item plasma levels 24 hours after administration, no control materials were used in this study.

3. Test animals:

Species:	Albino mice
Strain:	NMRI
Sex:	Male and female
Age:	5 - 8 weeks
Mean body weight at dosing:	26.0 ± 2.45 g
Source:	Charles River Laboratories Germany GmbH
Number of animals:	2 male and 2 female mice
Acclimation period:	At least 5 days
Diet:	pelleted standard diet (Maus/Ratte Haltung "GLP", Provimi Kliba SA, Kaiseraugst, Switzerland), ad libitum
Water:	tap water, ad libitum
Housing:	During the study the mice were housed individually in Makrolon cages, type MII

4. Environmental conditions:

Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	frequency not indicated (fully air-conditioned rooms)
Photo period:	12-hour light-dark cycle (06:00 - 18:00, 18:00 - 06:00)

5. Test compound doses: 2000 mg/kg; The test substance was administered once by oral gavage using an application volume of 10 mL/kg.

B. TEST PERFORMANCE

1. Dates of experimental work: 20-Jun-2016 to 07-Sep-2016

2. Treatment of animals:

For the purpose of this study, i.e. to determine the plasma levels of Reg.No. 5916421 24 hours after oral gavage the use of a small number of animals and the highest dose used in the previous mouse micronucleus test (see BASF DocID 2014/1105774) was considered appropriate.

Male and female NMRI mice were treated once by oral gavage with a test substance dose of 2000 mg/kg bw based on actual body weights.

3. Observation of animals:

The animals were checked frequently for signs of systemic toxicity.

4. Sampling of blood:

24 hours administration of the test item the animals were sacrificed by decapitation under isofluorane anaesthesia. Per animal about 500 µL blood were sampled with EDTA as anticoagulant in ready-to-use tubes (Microvette® tubes, Sarstedt, Germany). After centrifugation of 2 minutes at 20000 g at 4°C the plasma was stored in separate tubes at -80°C until analysis.

In order to have plasma control samples of untreated animals (blank samples), about 100 µl blood per animal was taken under isoflurane anesthesia from the vena facialis the day before test substance administration.

5. Sample workup and analysis:

The analysis of the plasma samples for Reg.No. 5916421 was performed by using a validated analytical HPLC-MS method (see M-CA 4, BASF DocID 2016/1327657) with a Limit of Quantification of 50ng/mL plasma.
The samples were extracted by adding 270 µL acetonitrile to 30 µL of plasma (1:10 dilution). After thorough mixing in a 1.5 mL plastic tube and protein precipitation the samples were centrifuged at 13000 rpm for 5 minutes. The clear supernatant was directly used for LC-MS measurements.
The sample extracts were measured in a defined sequence with samples of the extraction solution (acetonitrile), blank matrix solution (extracted control plasma), system suitability samples (independently prepared calibration sample (100 ng/mL)), quality control samples (extracts of spiked control plasma samples containing nominally 14.58, 154.8 and 874.8 ng/mL) and calibration samples (5, 10, 25, 50, 75, 100, 250, 500 and 1000 ng/mL). It is important to note that the concentrations of the system suitability, quality and calibration solutions refer to the concentration in the sample for measurement. The LOQ mentioned above refers to the concentration of Reg.No. 5916421 in plasma, which is 1:10 diluted during extraction.

II. RESULTS AND DISCUSSION

A. Clinical signs of toxicity

No signs of systemic toxicity were noted after a single administration of 2000 mg/kg bw by gavage.

B. Analytical determinations

No analytical determination of the test item concentration in the dosing solution was performed. In the original micronucleus assay (see BASF DocID 2013/1389659 above) the concentrations of the dosing solutions were determined (BASF DocID 2014/1105774). The actual test-item concentrations were 99.1, 99.5 and 99.7% of the nominal concentrations of 50, 100 and 200 mg/mL, demonstrating that the laboratory was able to correctly prepare the dosing solutions. As this study was performed in the same laboratory, the lack of a dosing solution concentration control analysis is not considered to affect the validity of the plasma concentration analysis.

No test item was detected in the (blank) plasma samples retrieved 1 day before administration. The concentrations of Reg.No. 5916421 24 hours after administration of a dose of 2000 mg/kg bw were in the range of 44.5 to 257.3 ng/mL plasma [see Table 5.8.1-31]. The concentration in the plasma of female animal #4 was slightly below the wLOQ.

Table 5.8.1-31: Plasma concentrations of Reg.No. 5916421 twenty-four hours after administration of a dose of 2000 mg/kg bw by gavage

Animal No	Sample Name	Concentration [ng/ml]	Sample Name	Concentration [ng/ml]
1 (♂)	Sample 1L	n.d.	Sample 1	257.3
2 (♂)	Sample 2L	n.d.	Sample 2	156.2
3 (♀)	Sample 3L	n.d.	Sample 3	137.6
4 (♀)	Sample 4L	n.d.	Sample 4	44.5*

n.d. = not detected
* < wLOQ (working limit of quantification)
Samples 1L, 2L, 3L and 4L: Untreated control samples
Samples 1, 2, 3 and 4: 24 hours after 2000 mg/kg bw dosage

The quality control samples (analysed three times during the measurement of the sample, i.e. at the beginning, mid and end of the sequence) revealed Reg.No. 5916421 concentrations between 94.2 and 106.6% of the nominal values [see Table 5.8.1-32].

Table 5.8.1-32: Quality control samples: Recovery of Reg.No. 5916421 from plasma samples spiked at 3 concentrations

Sample identifier	Area [Au]	Determined concentration [ng/mL]	Nominal concentration [ng/mL]	Nominal concentration [%]
QC 1 1	81910	14.12	14.58	96.8
QC 1 2	85658	14.76	14.58	101.2
QC 1 3	83049	14.31	14.58	98.1
QC 2 1	877531	154.4	145.8	105.9
QC 2 2	878475	154.5	145.8	106.0
QC 2 3	847990	149.2	145.8	102.3
QC 3 1	5329929	932.6	874.8	106.6
QC 3 2	4709741	824.2	874.8	94.2
QC 3 3	5105592	893.4	874.8	102.1

III. CONCLUSION

Reg.No. 5916421 (500M24; metabolite of pyraclostrobin) concentrations of 44.5 to 257.3 ng/mL were determined in plasma of mice 24 hours after administration of a dose of 2000 mg/kg bw. This demonstrates that the highly blood perfused bone marrow as the target organ in the in vivo mouse micronucleus assay was exposed to Reg.No. 5916421.

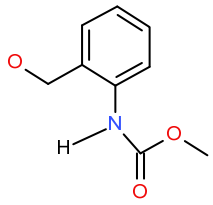
Overall toxicological evaluation of 500M24 (Reg.No. 5916421)

The QSAR evaluation of 500M24 is of low reliability and by weight of evidence there was no conclusive alert on genotoxicity.

500M24 is considered to be not genotoxic based on the in vitro and in vivo studies conducted. Therefore, 500M24 is considered to be **not toxicologically relevant**.

With regard to consumer exposure the TTC concept for a non-genotoxic compound was applied. Thus an ADI of 0.0015 mg/kg bw/day as well as an ARfD of 0.005 mg/kg bw/day was established. The estimated exposure to 500M24 is low (9% of TTC of 0.0015 mg/kg bw/day).

500M49 (other denominator: Reg.No. 5916420)



500M49 (Reg.No. 5916420) is a metabolite found in the hen metabolism study and in a hydrolysis study at exaggerated temperatures with olive oil (simulating oil deodorization).

A) QSAR Predications for 500M049 (Reg.No. 5916420)

OECD Toolbox (Version: 3.2) [see DocID 2014/1172955]

The OECD Toolbox revealed the alerts '*Radical|Radical >> Radical mechanism via ROS formation (indirect)|Radical >> Radical mechanism via ROS formation (indirect) >> Single-Ring Substituted Primary Aromatic Amines|SN1|SN1 >> Nucleophilic attack after metabolic nitrenium ion formation|SN1 >> Nucleophilic attack after metabolic nitrenium ion formation >> Single-Ring Substituted Primary Aromatic Amines*' and '*AN2|AN2 >> Carbamoylation after isocyanate formation|AN2 >> Carbamoylation after isocyanate formation >> N-Hydroxylamines|Radical |Radical >> Radical mechanism via ROS formation (indirect)|Radical >> Radical mechanism via ROS formation (indirect) >> N-Hydroxylamines|SN1|SN1 >> Nucleophilic attack after metabolic nitrenium ion formation|SN1 >> Nucleophilic attack after metabolic nitrenium ion formation >> N-Hydroxylamines*' as DNA Alert for Ames, MN and CA and DNA binding. For protein binding 3 alerts were provided: '*Acylation|Acylation >> Direct acylation involving a leaving group|Acylation >> Direct acylation involving a leaving group >> Carbamates*' and '*Schiff base formation|Schiff base formation >> Schiff base formation with carbonyl compounds|Schiff base formation >> Schiff base formation with carbonyl compounds >> Aldehydes*'. The third alert was a combination of the two above.

Discussion: At least the second identified alert for DNA binding and DNA Alert for Ames, MN and CA is present in a number of metabolites which - like 500M49 (Reg.No. 5916420) - were tested negative in the Ames test (500M02 (Reg No 3693159) and 500M62 (Reg No 412785)). Additionally, in view of the negative in mammalian gene mutation test with 500M49 (Reg.No. 5916420), the prediction does not adequately reflect the experimental database and therefore the prediction is rejected.

The situation for protein binding, which is also considered to be indicative for in vitro chromosome aberration, is similar. At least the first alert was also found for the metabolite 500M51 (Reg.No. 78810), which like 500M49 (Reg.No. 5916420) was negative in the in vivo micronucleus assay. Therefore, the prediction does not adequately reflect the experimental database and the prediction is rejected.

OASIS TIMES (MIX V.2.27.13 TB; Mutagenicity S-9 activated v08.08) [see molecule 5 of report DocID 2014/1172952 and 2014/1172953]

The Ames mutagenicity alert for 500M49 (Reg.No. 5916420) was negative (out of domain), however 3/13 in-silico generated metabolites had a positive alert (N-Hydroxylamines or Single-ring Substituted PrimaryAromatic Amines; in domoain).

The prediction of in vitro CA for 500M49 (Reg.No. 5916420) and 5/13 in-silico generated metabolites were positive. The identified alerts were carbamates, N-hydroxalamines and single-ring substituted primary aromatic anilines). Except for 500M49 (Reg.No. 5916420) all positive alerts were in domain.

Discussion: The alerts identified for the Ames test are also present in 500M62 (Reg.No. 412785) and/or 500M02 (Reg.No. 369315), which like 500M49 (Reg.No. 5916420) tested negative in the Ames test.

Single of the alerts identified for the in vitro chromosome aberration were also present in metabolites 500M51 (Reg.No. 78810) and 500M24 (Reg.No. 5916421). The in vitro CA for 500M51 (Reg.No. 78810) was - like that for 500M49 (Reg.No. 5916420) - negative. In the cases 500M24 (Reg.No.5916421) the positive in vitro CA was not confirmed in the negative higher tier in vivo mouse micronucleus test. Therefore, the prediction does not adequately reflect the experimental database and the prediction is rejected.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 5 of report BASF DocID 2014/1172954; for both VEGA models]

The prediction for 500M49 (Reg.No. 5916420) is non-mutagen (out of model applicability domain). This is in agreement with the experimental data (see below).

VEGA: Mutagenicity model (SarPy; version 1.0.4-BETA)

500M49 (Reg.No. 5916420) is out of model applicability domain. The prediction is ‘mutagen’ with the structural alert SA 98. As discussed above, this alert was also obtained for pyraclostrobin and a number of pyraclostrobin metabolites, which like 500M49 (Reg.No. 5916420) were actually tested negative. The predicition is therefore rejected.

DEREK (Version 2.0.0.201011301322; Knowledge base version: 11_20_05_2010)

The prediction for genotoxicity and neurotoxicity is negative.

Genotoxicity studies on 500M49 (Reg.No. 5916420)

Report:	CA 5.8.1/28 Woitkowiak C., 2013b Reg.No. 5916420 (metabolite of BAS 500 F, Pyraclostrobin) - Salmonella Typhimurium / Escherichia Coli reverse mutation assay 2013/1281928
Guidelines:	OECD 471, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.13/B.14 No. L 142, EPA 870.5100
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

S. typhimurium strains TA98, TA100, TA 1535 and TA 1537 and E. coli strain WP2 uvrA were exposed to Reg.No. 5916420 (Metabolite of BAS 500 F, pyraclostrobin); batch: L82-115, purity: 100.0%) using dimethylsulfoxide (DMSO) as a solvent in the presence and absence of metabolic activation in two independent experiments. Triplicate plates were used per dose and per test condition. Vehicle and positive controls were included in each experiment.

In both assays, the plate incorporation assay and the preincubation assay, the test substance was tested in concentrations of 33, 100, 333, 1000, 2500 and 5000 µg/plate.

No biologically relevant increase in the number of revertant colonies was noted in any of the strains tested in presence or absence of metabolic activation in both experiments. The positive controls induced the appropriate response in the corresponding strains, thus demonstrating the sensitivity of the test system.

Except for a slight decrease in the number of his^+ revertants in the plate incorporation assay with TA 1535 in presence of S9 mix and in the preincubation assay with TA 98 without S9 mix, both at 5000 µg/plate, no indication of bacteriotoxicity was observed. Precipitation of the test substance did not occur up to the highest concentration tested.

The test substance Reg.No. 5916420 (Metabolite of BAS 500 F, pyraclostrobin) is not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions of the study.

(BASF DocID 2013/1281928)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Reg.No. 5916420 (metabolite of BAS 500 F, pyraclostrobin)

Description: Solid, white
Lot/Batch #: L82-115
Purity: 100.0% (tolerance +/- 1.0%)
Stability of test compound: The test substance was stable over the study period under the storage conditions and guaranteed until 01 Apr 2015. The homogeneity of the test substance was ensured by mixing prior to preparation of test substance solutions and on account of the high purity. The stability of the test substance in the vehicle DMSO over a period of 4 h was verified analytically.
Solvent used: Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control: In parallel to each experiment, negative control experiments were carried out in order to check for possible contaminants (sterility control) and to determine the spontaneous mutation rate (vehicle control).
Vehicle control: The vehicle control with and without S-9 mix only contained the vehicle used for the test substance at the same concentration and volume for all tester strains.
Solvent/final concentration: 100 µL/plate
Positive control compounds tested without addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1535	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1537	9-Aminoacridine (AAC)	DMSO	100 µg/plate
TA 98	4-nitro-o-phenylendiamine (NOPD)	DMSO	10 µg/plate
WP2 uvrA	4-nitroquinoline-N-oxide (4-NQO)	DMSO	5 µg/plate

Positive control compounds tested with addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1535	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1537	2-aminoanthracene	DMSO	2.5 µg/plate
TA 98	2-aminoanthracene	DMSO	2.5 µg/plate
WP2 uvrA	2-aminoanthracene	DMSO	60 µg/plate

3. Activation:

S9 was produced from the livers of induced male Sprague-Dawley rats. The rats received on three consecutive days intraperitoneal injections of 80 mg phenobarbital and 80 mg β-naphthoflavone orally per kg body weight. 24 hours after the last administration the animals were sacrificed. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction is thawed at room temperature and 1 volume of S9-fraction is mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9 mix, was kept on ice until used.

The S9 mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

To demonstrate the efficacy of the S9 mix in this assay, the S9 batch was further characterized with benoz(a)pyrene in the strains TA 100 and TA 98 as required in OECD 471.

4. Test organisms:

S. typhimurium strains: TA98, TA100, TA1535, TA1537
E. coli: WP2 uvrA

Salmonella typhimurium:

The Salmonella strains are checked for the following characteristics at regular intervals: deep rough character (rfa); UV sensitivity (uvrB); ampicillin resistance (R factor plasmid). E. coli WP2 uvrA is checked for UV sensitivity.

Histidine and tryptophan auxotrophy is automatically proven in each experiment via the spontaneous rate.

5. Test concentrations:

Plate incorporation assay: In the first experiment triplicate plates were prepared for each concentration (neg. control; 33, 100, 333, 1000, 2500 and 5000 µg/plate and positive controls at the concentrations indicated above) and conditions (i.e. with and without S9) for all tester strains indicated above.

Pre-incubation assay: In the second experiment the test article / vehicle / positive control substance, bacterial and S-9 mix or phosphate buffer were incubated at 37°C for the duration of about 20 minutes. Triplicate plates were prepared for each concentration (neg. control; 33, 100, 333, 1000, 2500 and 5000 µg/plate and positive controls at the concentrations indicated above) and condition (i.e. with and without S9) for all tester strains.

B. TEST PERFORMANCE:

1. Dates of experimental work: 25-Jun-2013 to 04-Jul-2013

2. Plate incorporation assay:

To test tubes containing 2-mL portions of warm soft agar (containing 0.5 mM histidine + 0.5 mM biotin), 0.1 mL test solution or vehicle, 0.1 mL fresh bacterial culture, 0.5 mL S9-mix (in tests with metabolic activation) or 0.5 mL phosphate buffer (in tests without metabolic activation) were added in the given order. After mixing, the samples are poured onto Merckoplate® plates (minimal glucose agar plates). In the experiments with E. coli the warm soft agar contains 0.5 mM tryptophan instead of histidine + biotin.

3. Pre-incubation assay:

100 µL of test solution or vehicle, 0.1 mL bacterial suspension and 0.5 mL S9 mix or phosphate buffer were incubated at 37°C for about 20 minutes. Subsequently, 2 mL of soft agar was added and, after mixing, the samples are poured onto the agar plates.

After incubation in the dark for 48 to 72 hours at 37°C each plate was checked for precipitates and status of the background lawn. Revertant colonies were counted. Means and standard deviations were calculated.

4. Titer determination:

In order to assess bacteriotoxic effects, the titer was additionally determined in experimental parts with S9 mix using the vehicle control and the two highest doses. The procedure followed in both experiments (plate incorporation and pre-incubation) was the same as described above for the individual experiments with the exception that the soft agar used contained maximal amino acid solution (5 mM tryptophan or 5 mM histidine + 0.5 mM biotin). After the incubation in the dark for 48 to 72 hours at 37°C the number of bacterial colonies was determined.

5. Statistics:

No special statistical tests were performed.

6. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A dose-related and reproducible increase in the number of revertant colonies, i.e. about doubling of the spontaneous mutation rate in at least one tester strain either without S9 mix or after adding a metabolizing system.

A test substance is generally considered non-mutagenic in this test if:

- The number of revertants for all tester strains was within the historical negative control range under all experimental conditions in two experiments carried out independently of each other.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The test substance was stable over the study period under the storage conditions.

The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically.

B. TOXICITY

A preliminary cytotoxicity assay was not performed in this laboratory. Cytotoxicity was determined in the course of the mutation assay.

A weak bacteriotoxic effect (slight decrease in the number of his^+ revertants) was observed in the standard plate test in tester strain TA1535 in the presence of S9 mix at 5000 µg/plate only. In the preincubation assay slight bacteriotoxicity (slight decrease in the number of his^+ revertants) was observed only in tester strain TA98 without S9 mix at 5000 µg/plate.

C. MUTATION ASSAYS

Neither in the plate incorporation nor in the preincubation experiment with and without metabolic activation was a biologically relevant increase in number of revertants observed in any strain tested [see Table 5.8.1-33]. The positive controls yielded revertant numbers in a range expected for the respective strains and thus demonstrated the sensitivity of the test system.

Precipitation was not observed up to the maximum concentration.

III. CONCLUSION

According to the results of the present study, the test substance 500M49 (Reg.No. 5916420, metabolite of pyraclostrobin) is not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions chosen here.

Report:	CA 5.8.1/29 Schulz M., Landsiedel R., 2014d Reg.No. 5916420 (metabolite of BAS 500 F, Pyraclostrobin) - In vitro gene mutation test in L5178Y mouse lymphoma cells (TK+/- locus assay, microwell version) 2013/1298447
Guidelines:	OECD 476, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.17, EPA 870.5300
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Reg.No. 5916420 (metabolite of 500 F; pyraclostrobin; batch: L82-115, purity: 100.0%) was tested in vitro for its ability to induce forward mutations in L5178Y cells by assessing the mutation of the $TK^{+/-}$ locus. Two independent experiments were conducted in the presence and absence of metabolic activation with treatment intervals of 4 or 24 hours and concentrations from 62.5 to 2000 µg/mL. Methyl methanesulfonate (MMS) and cyclophosphamide (CPP) served as positive controls in the experiments without and with metabolic activation, respectively.

The test substance did not cause any biologically relevant increase in the mutant frequencies neither without S9 mix nor after adding a metabolizing system in two experiments performed independently of each other. The positive control substances, however, induced a marked increase in mutant frequency and the negative controls gave mutant frequencies within the range expected for the L5178Y TK+/- mouse lymphoma cell line.

Cytotoxicity indicated by clearly reduced relative total growth (RTG) of below 20% of control was observed after 24 hours exposure in the 2nd experiment in the absence of metabolic activation only.

Based on the results of the study it is concluded that under the conditions of the test Reg.No. 5916420 (Metabolite of 500 F; pyraclostrobin) does not induce forward mutations in mammalian cells in vitro.

(BASF DocID 2013/1298447)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

	Reg.No. 5916420 (metabolite of 500 F; pyraclostrobin)
Description:	Solid, white
Lot/Batch #:	L82-115
Purity:	100.0% (tolerance ± 1.0%)
Stability of test compound:	Stable - expiry date: 01-Apr-2015. The homogeneity of the test substance was guaranteed on account of the high purity and ensured by mixing prior to preparation of test substance solutions. The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically.
Solvent used:	Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control:	A negative control was not employed in this study
Solvent control:	The vehicle controls with and without S9 mix contained the vehicle selected for the test substance at the same volume and concentration as used in the test cultures.
Positive control -S9:	Methyl methanesulfonate (MMS) 15 µg/mL (4-hour exposure period) and 5 µg/mL (24-hour exposure period)
Positive control +S9:	Cyclophosphamide (CPP) 2.5 µg/mL

3. Activation:

S9 was produced from the livers of at least 5 induced male Wistar [Crl:WI(Han)] rats. The rats were administered injections of phenobarbital (80 mg/kg; i.p.) and ß-napthtoflavone (80 mg/kg; per gavage) on three consecutive days. 24 h after the last administration the animals were sacrificed.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4. Test organism: Mouse lymphoma L5178Y $TK^{+/-}$ cell line. This is a cell line with a high proliferation rate (doubling time of about 9 - 10 hours), a high plating efficiency (about 90%) and a stable karyotype with a near diploid number of 40 ± 1 chromosomes. Each batch used for mutagenicity testing was checked for mycoplasma contamination.

5. Culture media:

Culture medium:	RPMI 1640 medium including stable glutamine supplemented with: 1% (v/v) penicillin/streptomycin (10000 IU / 10000 µg/mL) and 1% (v/v) sodium pyruvate (10 mM) = RPMI-0 For treatment medium (with S9 mix): RPMI-0 supplemented with 5% (v/v) fetal calf serum (FCS) = RPMI-5 For treatment medium (without S9 mix) and subculturing cells: RPMI-0 is supplemented with 10% (v/v) FCS = RPMI-10 For cloning efficiency and selection medium: RPMI-0 supplemented with 20% (v/v) FCS = RPMI-20
Pretreatment medium:	A ("THMG" medium): RPMI-10 supplemented with thymidine (3.0 µg/mL), hypoxanthine (5.0 µg/mL), methotrexate (0.1 µg/mL) and glycine (7.5 µg/mL) B ("THG" medium): RPMI-10 supplemented with thymidine (3.0 µg/mL), hypoxanthine (5.0 µg/mL), and glycine (7.5 µg/mL)
Selection medium:	("TFT" medium): RPMI-20 supplemented with trifluorthymidine (TFT, 4.0 µg/mL)

6. Locus examined: thymidine kinase (TK)

7. Test concentrations:

a) Preliminary toxicity assay:	Nine concentrations ranging from 7.8 to 2000 µg/mL
b) Mutation assay:	
1st experiment:	125.0, 250.0, 500.0, 1000.0 and 2000 µg/mL with and without metabolic activation (4-hour exposure)
2nd experiment:	62.5, 125.0, 250.0, 500.0, 1000 and 2000 µg/mL without (24-hour exposure) and 375.0, 750.0, 1500 and 2000 µg/mL with metabolic activation (4-hour exposure)

B. TEST PERFORMANCE:

1. Dates of experimental work: 17-Jun-2013 to 14-Jan-2014

2. Preliminary cytotoxicity assay:

In the pretest for toxicity based on the molecular weight of the test substance 2000 µg/mL (approx. 10 mM) Reg.No. 5916420 was used as top concentration both with and without S9 mix at 4 hour exposure time and without S9 mix at 24 hour exposure time.

The pretest was performed at 9 concentrations spaced by a factor of two following the method described for the main experiment. The relative suspension growth (RSG) was determined as toxicity indicator for dose selection and various parameters were checked for all or at least for some selected doses. Additionally, pH and solubility were determined.

3. Mutation Assay:

Pretreatment of Cells: During the week prior to treatment, spontaneous TK deficient mutants ($TK^{-/-}$) were eliminated from the stock cultures by incubating 3 x 10^5 cells per 75 cm² flask in a total volume of 30 mL for 1 day in “THMG" medium (pretreatment medium A), and for the following 3 days in “THG" medium (pretreatment medium B).

Cell treatment: For each test group, about 1.5 x 10^7 cells per flask were seeded into 75 cm^2 flasks containing RPMI-10 for exposures without S9 mix and RPMI-5 medium for exposures with S9 mix and incubated for the respective exposure period (1st experiment: 4-hour exposure with and without S9 mix and 2nd experiment 24 hours without S9 mix and 4 hours with S9 mix) with 5% CO_2 at 37°C and ≥90% humidity for cell attachment. 2 cultures were treated in parallel for each test group.

Expression:	At the end of the exposure period, the cells were transferred in tubes, centrifuged for 5 minutes at and were resuspended in RPMI-5 medium. The washing of the cells was repeated at least once. Then the cells were centrifuged and were resuspended in RPMI-10 medium. From each culture a sample of treated cells (2 x 10^5 cells/mL or 6 x 10^6 cells/flask) were pipetted in 75 cm² flasks and were incubated for a 2-day expression period. To maintain exponential growth during this phase, each culture was counted daily and the cell numbers were adjusted at each day to 2 x 10^5 cells/mL in 30 mL RPMI-10 medium.
Selection:	For the mutant selection, the cells were resuspended in selection medium ("TFT" medium) and two 96-well plates per cultures were seeded with 2000 cells/well. After incubation of at least 9 days, both the number of negative wells and the number of wells containing small or large colonies were scored for calculation of the mutant frequency (MF).
Size distribution of the colonies:	The colonies are classified into large colonies (indication of gene mutation) and small colonies (indication of chromosome breakage). Small colonies are defined as less than 1/4 of the diameter of the well. Size is the key factor and morphology (the optical density of the small colonies is considerably higher) should be secondary.
Determination of Cytotoxicity:	Cloning efficiency 1 (survival): The survival (cloning efficiency 1; CE_1) was determined in parallel to the mutagenicity test. At the end of the exposure period, the cells were centrifuged and 400 cells from each culture were resuspended in 50 mL RPMI-20 medium (8 cells/mL). Per culture 200 µL were dispensed in each well of two 96-well plates (1.6 cells/well). After incubation for 9 to 11 days the plates were scored for empty wells.
Cloning efficiency 2 (viability):	The viability (cloning efficiency 2; CE_2) was determined after the expression period. 2 days after end of exposure, the cells were centrifuged and 400 cells from each culture were resuspended in 50 mL RPMI-20 medium (8 cells/mL). Per culture 200 µL were dispensed in each well of two 96-well plates (1.6 cells/well). After incubation for at least 9 days the plates were scored for empty wells.

Suspension growth (RSG) and relative total growth (RTG):

For calculation of the suspension growth (SG) and the relative total growth (RTG) the cell counts determined within the expression period at 2nd and 3rd passage after exposure in the case of 4-hour exposure and 1st, 2nd and 3rd passage after exposure in the case of 24-hour exposure were used.

This measure includes the relative growth in suspension during the expression period (RSG) and the relative cloning efficiency (RCE_2; viability) at the time the mutants are selected.

For taking into account any loss of cells during the 4-hour treatment period a relative growth during treatment factor (RGDT, %) was calculated by comparing the growth of each treated culture relative control.

Calculations:

Mutant frequency:

Uncorrected mutant frequency:

$$MF_{uncorr} = \frac{-\ln(\text{total number of empty well s} \div \text{total number of seeded wells (96)})}{\text{number of seeded cells per well (2000)}} \times 10^6$$

Corrected mutant frequency:

$$MF_{corr} = \frac{MF_{uncorr}}{CE_2} \times 100$$

Cloning efficiency (CE, %) absolute:

$$CE_x = \frac{-\ln(\text{total number of empty well s} \div \text{total number of seeded wells (96)})}{\text{number of seeded cells per well (1.6)}} \times 100$$

Cloning efficiency relative, in comparison to control:

$$RCE_x = \frac{CE_x \text{ of the test group}}{CE_x \text{ of the negative / vehicle control}} \times 100$$

Relative total growth:

Relative growth during treatment (RGDT, %)

$$\text{RGDT} = \frac{\text{Cell count after 4 h of the test group}}{\text{Cell count after 4 h of the negative/v ehicle control}} \times 100$$

Total suspension growth (SG) after 4 hour-exposure:

$$SG = \frac{\text{Cell count after 24 h}}{2 \text{ x } 10^5 \text{ cells per mL}^{1,2}} \times \frac{\text{Cell count after 48 h}}{2 \text{ x } 10^5 \text{ cells per mL}^2} \times \frac{\text{RGDT}}{100}$$

Total suspension growth (SG) after 24 hour-exposure:

$$SG = \frac{\text{Cell count after 24 h}}{2 \text{ x } 10^5 \text{ cells per mL}} \times \frac{\text{Cell count after 48 h}}{2 \text{ x } 10^5 \text{ cells per mL}^2} \times \frac{\text{Cell count after 72 h}}{2 \text{ x } 10^5 \text{ cells per mL}^2}$$

$$\text{RSG} = \frac{\text{SG of the test group}}{\text{SG of the negative/v ehicle control}} \times 100$$

$$RTG = \frac{RSG \times RCE_2}{100}$$

[1] Cell number seeded following 4-hour treatment
[2] If cell number was lower than 2 x 10^5 cells per mL all remaining cells were seeded

4. Statistics:

An appropriate statistical trend test (MS EXCEL function RGP; 9) was performed to assess a dose-related increase of mutant frequencies. The number of mutant colonies obtained for the test substance treated groups was compared with that of the respective vehicle control groups. A trend is judged as statistically significant whenever the one-sided p-value (probability value) is below 0.05 and the slope was greater than 0. Both, biological and statistical significance will be considered together. However, both, biological and statistical significance has been considered together.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- The mutation frequency exceeds a threshold of 126 mutant colonies per 10^6 cells (GEF: Global Evaluation Factor) above the concurrent negative/vehicle control value.

and

- Evidence of reproducibility of any increase in mutant frequencies, means the mutagenic response occurs at least in both parallel cultures of one experiment.

and

- A statistically significant dose-related increase in mutant frequencies using an appropriate statistical trend test.

A test substance is generally considered negative in this test system if:

- The mutation frequency is below a threshold of 126 mutant colonies per 10^6 cells (GEF) above the concurrent negative/vehicle control value.

or

- No evidence of reproducibility of an increase in mutant frequencies is obtained.

or

- No statistically significant dose-related increase in mutant frequencies using an appropriate statistical trend test is observed.

However, in the evaluation of the test results the historical variability of the mutation rates in negative and vehicle controls and the mutation rates of all negative and vehicle controls of this study were also taken into consideration. Results of test groups have been rejected if the relative total growth (RTG) and/or the cloning efficiency 1 (CE_1) were less than 10% of the respective vehicle controls. Whenever a test substance is considered mutagenic according to the above mentioned criteria, the ratio of small versus large colonies is used to differentiate point mutations from clastogenic effects. If the increase of the mutation frequency is accompanied by a reproducible and dose-related shift in the ratio of small versus large colonies clastogenic effects are indicated.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically (see BASF study code 01Y0174/13Y004).

B. PRELIMINARY CYTOTOXICITY ASSAY

Cytotoxicity - as determined by reduced relative suspension growth of about or below 20% - was only observed without metabolic activation. This was observed at 2000 µg/mL in the experiment with 4 treatment and at ≥ 1000 µg/ml after 24 hour treatment.

The pH value was not influenced by the addition of the test substance preparation to the culture medium at all concentrations. In addition, no test substance precipitation was observed in the vehicle DMSO or in culture medium up to the highest required test substance concentration.

Based on these data the highest concentration tested in the mutagenicity experiments was 2000 µg/mL without and with metabolic activation.

C. MUTAGENICITY ASSAYS

No relevant increase in the number of mutant colonies was observed without or with metabolic activation. The corrected mutant frequencies obtained for both experiments were always below the calculated threshold taking into consideration the Global Evaluation Factor (GEF) [see Table 5.8.1-36].

The statistical analyses by testing for linear trend led to a negative finding for the 1st experiment in the absence of S9 mix. In contrast, in the 2nd experiment in the absence of S9 mix and both experiments in the presence of S9 mix the mutant frequencies were statistically significant dose-related increased. However, all values were below the respective mutant frequency threshold and, therefore, the statistical significance was considered as biologically irrelevant.

Treatment with the positive controls MMS and CCP resulted in increased mutant frequencies as expected.

In both experiments after 4 hours exposure, no cytotoxic effects were observed neither in the presence nor in the absence of S9 mix. However, in the 2nd experiment after 24 hours exposure in the absence of metabolic activation the relative total growth (RTG) was reduced at 2000 µg/mL [see Table 5.8.1-36].

Osmolarity and pH values were not influenced by test substance treatment. Likewise, no precipitation of the test-item was observed in the vehicle DMSO or in culture medium at any concentration.

III. CONCLUSION

Based on the results of the study it is concluded that 500M49 (Reg.No. 5916420, metabolite of pyraclostrobin) does not induce forward mutations in vitro in the mouse lymphoma assay with L5178Y $TK^{+/-}$ cells in the absence and the presence of metabolic activation.

Report:	CA 5.8.1/30 Schulz M., Landsiedel R., 2014c Reg.No. 5916420 (Metabolite of BAS 500 F, Pyraclostrobin) - In vitro micronucleus assay in V79 cells (cytokinesis block method) 2013/1361921
Guidelines:	OECD 487 (2010), Commission Regulation EU No. 640/2012 of 06 July 2012 - B.49: In vitro Mammalian Cell Micronucleus Test
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Reg.No. 5916420 (Metabolite of BAS 500 F, pyraclostrobin) (batch L82-115; purity 100.0%) was tested in vitro for its potential to induce micronuclei in V79 cells of the Chinese hamster in the absence and presence of metabolic activation in two independent experiments. In the 1st experiment (62.5-2000 µg/mL), the exposure period was 4 hours with and without S9 mix. In 2nd experiment, the exposure periods were 4 hours with S9 mix (62.5-2000 µg/mL) and 24 hours without S9 mix (62.5-2000 µg/mL). The cells were prepared 24 hours after start of treatment with the test item, except for the 4 hour treatment interval in the presence of metabolic activation in the 2nd experiment. In this experimental part cells were harvested after 44 hours to consider possibly occurring mitotic delay.

No statistically significant or biologically relevant increase in the number of micronucleated cells was observed either without S9 mix or after the addition of a metabolizing system.

Cytotoxicity was only observed in the 2nd experiment after 24 hours continuous treatment in the absence of S9 mix. In both experiments no test substance precipitation in culture medium was noted.

Vehicle and positive controls revealed the expected results of micronucleated cells thereby ensuring the validity of the test.

Based on the results of this study, Reg.No. 5916420 is not considered to have neither chromosome-damaging (clastogenic) nor aneugenic activity under in vitro conditions in V79 cells in the absence and the presence of metabolic activation.

(BASF DocID 2013/1361921)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg.No. 5916420 (metabolite of pyraclostrobin)

Description:	Solid, white
Lot/Batch #:	L82-115
Purity:	100.0% (tolerance ± 1.0%)
Stability of test compound:	Stable - expiry date: 01 Apr 2015. The homogeneity of the test substance was ensured by mixing prior to preparation of test substance preparations. The stability of the test substance dissolved in the vehicle DMSO over a period of 4 hours was verified analytically.
Solvent used:	Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control:	A negative control was not employed in this study.
Solvent control:	DMSO
Positive control, -S9:	Ethylmethanesulfonate (EMS, 300, 400 and 500 µg/mL, dissolved in MEM without FCS)
Positive control, +S9:	Cyclophosphamide (CPA, 1.0 and 2.5 µg/mL, dissolved in MEM without FCS)

3. Activation: S9 was prepared from the liver of male Wistar rats. The rats were induced by intraperitoneal applications of 80 mg/kg bw phenobarbital and by oral administrations of 80 mg/kg bw β-naphthoflavone each, on three consecutive days. The livers were prepared 24 hours after the last treatment. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction was thawed at room temperature and 1 volume of S9-fraction was mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9 mix, was kept on ice until used.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4. Test organisms:

Chinese hamster V79 cells
This is a continuous cell line with a high proliferation doubling time of 12-14 hours, a high plating efficiency (≥ 90%) and a stable karyotype (modal number of 22 chromosomes).

5. Culture medium/conditions:

Culture media:

Minimal essential medium with Earle's salts (MEM) containing a L-glutamine source supplemented with 10% (v/v) fetal calf serum (FCS), 1% (v/v) penicillin/streptomycin (10 000 IU / 10000 µg/mL) and 1% (v/v) amphotericine B (250 µg/mL). During exposure to the test substance in the presence of S9 mix MEM medium was used without FCS supplementation.

Cell culture:

Deep-frozen cell stocks were thawed at 37°C in a water bath, and volumes of 0.5 mL were transferred into 25 cm^2 plastic flasks containing about 5 mL MEM supplemented with 10% (v/v) fetal calf serum (FCS). Cells were grown with 5% (v/v) CO2 at 37°C and ≥ 90% humidity and subcultured twice weekly. Cell monolayers were suspended in culture medium after detachment with 0.25% (w/v) trypsin solution.

Cell cycle and harvest time:	The cell cycle of the untreated V79 cells lasts for about 12 to 14 hours under the selected culture conditions. Thus, a harvest time of 24 hours is about 2 times the normal cell cycle length. V79 cells are an asynchronous cell population, i.e. at the time of test substance treatment there are different cell stages. Since the effect on these cell stages may vary for different test substances, more than one harvest time after treatment may be appropriate. Furthermore, substance-induced mitotic delay may considerably delay the first post-treatment mitosis. Therefore, delayed harvest times (e.g. 44 hours) and prolonged exposure periods (e.g. 24 hours treatment) were considered.

6. Test concentrations:

a) Preliminary toxicity assay:	15.6 to 2000.0 µg/mL with and without metabolic activation Exposure period: 4 hours with and without metabolic activation; 24 hours without metabolic activation Harvest time: 24 hours
b) Cytogenicity assay:	
1st experiment:	62.5, 125, 250, 500, 1000 and 2000 µg/mL with and without S9 mix (4 hours exposure, 24 hour preparation interval)
2nd experiment:	125, 250, 500, 1000 and 2000 µg/mL with and without metabolic activation (24 hour exposure, 24- and 44-hour preparation interval)

B. TEST PERFORMANCE:

1. Dates of experimental work: 10-Jun-2013 to 20-Nov-2013

2. Preliminary cytotoxicity assay:

In the pretest for toxicity based on the purity and the molecular weight of the test substance 2000 µg/mL (approx. 10 mM) Reg.No. 5916420 (Metabolite of BAS 500 F, pyraclostrobin) was used as top concentration. The pretest was performed following the method described for the main experiment. As indication of test substance toxicity relative increase in cell count (RICC) and cell attachment (morphology) were determined for dose selection. pH and solubility were additionally determined.

3. Cytogenicity Assay:

Two independent experiments were performed. In experiment I, the exposure period was 4 hours with and without S9 mix. In experiment II, the exposure periods were 4 hours with S9 mix and 24 hours without S9 mix. The cells were prepared 24 hours after start of treatment with the test item, except for the 4 hour treatment interval in the presence of metabolic activation (experiment II). In this experimental part cells were harvested after 44 hours to consider possibly occurring mitotic delay.

Cell seeding / treatment:	Routinely grown cells that did not exceed a max. of 15 passages and reached a confluency of at least 50%, were detached by trypsination and used to prepare a single cell suspension with the required cell count (3-5x10^5 cells per culture, depending on the schedule) in MEM incl. 10% (v/v) FCS. 5 mL cell suspension was transferred into 25 cm² cell culture flasks using a dispenser. Subsequently, the test cultures were incubated. After an attachment period of about 20 - 24 hours, the medium was removed from the flasks and the treatment medium was added. In case of experiments without metabolic activation the treatment medium consisted of 5 or 4 mL MEM medium with FCS plus 1 mL positive control or 0.05 mL test substance preparation/ vehicle, respectively. In case of metabolic activation, the treatment medium consisted of 4 or 3 mL MEM medium without FCS, 1 mL positive control or 0.05 mL test substance preparation/ vehicle and 1 mL S9-mix, respectively. The cultures were incubated for the respective exposure period at 37°C, 5% (v/v) CO_2 and ≥ 90% humidity. At the end of the exposure period, the medium was removed and the cultures were rinsed twice with 5 mL HBSS (Hanks Balanced Salt Solution). Subsequently, 5 mL MEM incl. 10% FCS supplemented with Cytochalasin B (CytB, final concentration: 3 µg/mL; stock: 0.6 mg/mL in DMSO) was added and incubated for the respective recovery time. In the case of 24-hour continuous exposure, CytB was added to the treatment medium at start of treatment, and cell preparation was started directly at the end of exposure. At 44 hours preparation interval in the presence of S9 mix the supplementation of CytB was 24 hours before preparation of the cultures.

Cell harvest, preparation of slides and staining:	Just before preparation the culture medium was completely removed. Single cell suspensions were prepared from each test group by trypsination. Then, the cell numbers per flask of each single cell suspension were determined using a cell counter. Subsequently, $5x10^4$ cells per slide were centrifuged at 1400 rpm for 7 minutes onto labelled slides using a Cytospin centrifuge. After drying, the slides were fixed in 90% (v/v) methanol for 10 minutes. Before scoring, the slides were stained with a mixture of 4',6-diamidino-2-phenylindole dihydrochloride (DAPI) and propidium iodide (PI) in Fluoroshield™ at a concentration of 0.25 µg/mL each. By the use of the combination of both fluorescence dyes it can be differentiated between DNA (DAPI; excitation: 350 nm, emission: 460 nm) and cytoplasm (PI; excitation: 488 nm, emission: 590 nm).
Analysis of micronuclei and cytotoxicity:	Cytospin slides were scored by fluorescence microscopy. At least 1000 cells per culture, means at least 2000 cells per test group, were evaluated and the number of micronuclei-containing binucleated cells was recorded. Analysis of micronuclei was carried out following the criteria: The diameter of the micronucleus is less than 1/3 of the main nucleus; the micronucleus and main nucleus retain the same color; the micronucleus is not linked to the main nucleus and is located within the cytoplasm of the cell; only cells clearly surrounded by a nuclear membrane were scored. Cultures with few isolated cells were not analyzed for micronuclei.

Relative increase in cell count (RICC):

$$RICC = \frac{\text{(Increase in number of cells in treated cultures (final} - \text{starting))}}{\text{(Increase in number of cells in control cultures (final} - \text{starting))}} \text{x } 100$$

Thus, a RICC of 53% indicates 47% cytotoxicity/cytostasis.

Proliferation Index (CBPI):

$$CBPI = \frac{\big(\text{(No. mononucleated cells)} + \text{(2 x No. binucleated cells}\big) + \text{(3 x No. mulitnucleated cells))}}{\text{(Total number of cells)}}$$

The CBPI was used to calculate the % cytostasis (relative inhibition of cell growth compared to the respective vehicle control group) - a CBPI of 1 (all cells are mononucleate) is equivalent to 100% cytostasis.

% Cytostasis = 100 - 100 $\{(CBPI_T - 1) / (CBPI_C - 1)\}$

(T- test substance treated culture; C = vehicle control)

Replicative Index (RI):

$$RI = \frac{\text{(((No. binucleate cells)} + \text{(2xmultinucleate cells)} \div \text{(Total number of cells))}_T}{\text{(((No. binucleate cells)} + \text{(2xmultinucleate cells)} \div \text{(Total number of cells))}_C} x100$$

(T = test substance treated culture; C = vehicle control culture)

Thus, an RI of 53% means that in comparison to the respective control cultures only 53% of the cells divided in the treated test group (= 47% cytotoxicity/cytostasis).

4. Statistics:

The statistical evaluation of the data was carried out using the MUVIKE program system (BASF SE). The proportion of cells containing micronuclei was calculated for each group. A comparison of each dose group with the concurrent vehicle control group was carried out using Fisher's exact test for the hypothesis of equal proportions. This test is Bonferroni-Holm corrected versus the dose groups separately for each time and was performed one-sided. If the results of this test were statistically significant compared with the respective vehicle control, labels (* $p \leq 0.05$, ** $p \leq 0.01$) have been be printed in the tables.

5. Evaluation criteria:

A test item is considered "positive" in this assay if the following criteria are met:

- A significant, dose-related and reproducible increase in the number of cells containing micronuclei was observed.
- The number of micronucleated cells exceeded both the value of the concurrent vehicle control and the range of our laboratory's recent negative control data.

A test substance is generally considered "negative" in this test system if:

- The number of micronucleated cells in the test groups is not distinctly inceased above the concurrent vehicle control and is within our laboratory's recent negative control data range.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS:

The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically (see BASF study code 01Y0174/13Y004).

B. PRELIMINARY CYTOTOXICITY ASSAY:

A preliminary cytotoxicity assay was performed to determine appropriate test substance concentrations for the main test. After 4 hours treatment in the absence and presence of S9 mix no cytotoxicity was observed. In the pretest with 24 hours continuous treatment in the absence of S9 mix, the relative increase in cell count was clearly reduced at 2 000 µg/mL.

C. CYTOGENICITY ASSAYS:

In this study, no statistically significant or biologically relevant increase in the number of micronucleated cells was observed either without S9 mix or after the addition of a metabolizing system [see Table 5.8.1-34 and Table 5.8.1-35]. In both experiments the incidences of micronucleated cells (0.2 - 1.3%) were close to the concurrent vehicle control values (0.4 - 1.2%) and clearly within historical negative control data range (0.1 - 1.8%).

The positive control substances EMS (without S9 mix; 300 µg/mL) and CPP (with S9 mix; 1.0 µg/mL) induced statistically significant increased micronucleus frequencies in both independently performed experiments.

Growth inhibition as indicated by reduced cell numbers or RICC was observed in the 1st experiment in the absence of S9 mix at ≥ 1000 µg/mL and likewise in the 2nd experiment in the absence of S9 mix after 24 hours continuous treatment at ≥ 1000 µg/mL. In the latter case a reduced proliferative activity (CBPI) and reduced replicative index (RI) was also observed. Likewise, cell morphology/attachment was adversely influenced (grade > 2).

In both experiments with and without metabolic activation neither test substance precipitation nor changes of osmolarity and pH values were observed.

Table 5.8.1-34: Summary of results of micronucleus test with Reg.No. 5916420 (Metabolite of BAS 500 F, pyraclostrobin) - without metabolic activation

III. CONCLUSION

Based on the results of the study it is concluded that 500M49 (Reg.No. 5916420, metabolite of pyraclostrobin) has not the potential to induce micronuclei (clastogenic and/or aneugenic activity) under the in vitro conditions of this study.

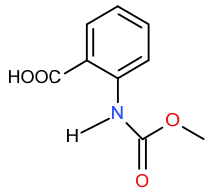
Overall toxicological evaluation of 500M49 (Reg.No. 5916420)

The QSAR evaluation of 500M49 is of low reliability and by weight of evidence there was no conclusive alert for genotoxicity.

500M49 is considered to be not genotoxic based on the in vitro studies conducted. Therefore, 500M49 is considered to be **not toxicologically relevant**.

With regard to consumer exposure the TTC concept for a non-genotoxic compound was applied. Thus an ADI of 0.0015 mg/kg bw/day as well as an ARfD of 0.005 mg/kg bw/day was established. The estimated exposure (0.2% of TTC of 0.005 mg/kg bw/day for acute and 0.1% of TTC 0.0015 mg/kg bw/day for chronic exposure) is low.

500M51 (other denominator: Reg.No. 78810)



500M51 (Reg.No. 78810) is a metabolite of pyraclostrobin found in rat and goat metabolism studies.

A) QSAR Predicitions for 500M51 (Reg.No. 78810)

OECD Toolbox (Version: 3.2) [see DocID 2014/1172955]

In the OECD toolbox no DNA alerts for genotoxicity (Ames, MN, CA) or alerts for DNA binding were observed. For protein binding, which is also taken as supportive evidence for a positive in vitro CA, the alert was '*Acylation|Acylation >> Direct acylation involving a leaving group|Acylation >> Direct acylation involving a leaving group >> Carbamates*'. It is unclear how to interpret the positive protein binding alert in absence of a DNA alert for Ames, MN and CA.

Discussion: The same alert was also found for 500M49 (Reg.No. 5916420), which like 500M51 (Reg.No. 78810) was tested negative for in vitro chromosome aberration. The positive prediction is there rejected.

OASIS TIMES (MIX V.2.27.13 TB; Mutagenicity S-9 activated v08.08) [see molecule 6 of report DocID 2014/1172952 and 2014/1172953]

There were no Ames mutagenicity alerts for 500M51 (Reg.No. 78810) or in-silico generated metabolites. In all cases the structures were out of domain. For in vitro chromosome aberration the prediction for 500M51 (Reg.No. 78810) was positive with the alert info 'carbamates' (out of domain). In contrast all 8 in-silico metabolites were predicted negative (out of domain).

Discussion: The result of the in vitro micronucleus assay (see CA 5.8.1/2 below) revealed no chromosome damaging potential of 500M51 (Reg.No. 78810). Therefore, the positive prediction for CA is not reflecting the toxicological database and is therefore rejected.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 6 of report DocID 2014/1172954 for both VEGA models]

500M51 (Reg.No. 78810) is out of model applicability domain. The prediction is 'non mutagen' with no specific structural alerts.

VEGA: Mutagenicity model (SarPy; version 1.0.4-BETA)

500M51 (Reg.No. 78810) is out of model applicability domain. The prediction is 'mutagen' with the structural alert SA 98. As discussed above, this alert was also obtained for pyraclostrobin and a number of pyraclostrobin metabolites, which like 500M51 (Reg.No. 78810) were actually tested negative. The predicition is therefore rejected.

DEREK (Version 2.0.0.201011301322; Knowledge base version: 11_20_05_2010)

The prediction for genotoxicity and neurotoxicity is negative.

Genotoxicity studies on 500M51 (Reg.No. 78810)

Report:	CA 5.8.1/31 Woitkowiak C., 2013a Reg.No. 78810 (metabolite of BAS 500 F, Pyraclostrobin) - Salmonella typhimurium / Escherichia coli reverse mutation assay 2013/1255749
Guidelines:	OECD 471, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.13/B.14 No. L 142, EPA 870.5100
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

S. typhimurium (strains TA98, TA 100, TA 1535 and TA 1537) and E. coli strain WP2 uvrA were exposed to Reg.No. 78810 (Metabolite of BAS 500 F, pyraclostrobin); batch: L82-117, purity: 97.9%) using dimethylsulfoxide (DMSO) as a solvent in the presence and absence of metabolic activation in two independent experiments. Triplicate plates were used per dose and per test condition. Vehicle and positive controls were included in each experiment. In the plate incorporation assay Reg.No. 78810 was tested in concentrations of 33, 100, 333, 1000, 2600 and 5200 µg/plate. In the preincubation test Reg.No. 78810 were tested in concentrations of 10, 33, 100, 333, 1000 and 2600 µg/plate. In both, the plate incorporation assay and the preincubation assay occasionally a weak bacteriotoxic effect was observed depending on the strain and test conditions at concentrations from about 1000 µg/plate onwards. Precipitation of the test substance did not occur up to the highest tested concentration.

A biologically relevant increase in the number of revertant colonies was not noticed in any of the strains tested in presence or absence of metabolic activation in any of the experiments. The positive controls induced the appropriate response in the corresponding strains, thus demonstrating the sensitivity of the test system.

According to the results of the study the test substance Reg.No. 78810 was not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions of the study.

(BASF DocID 2013/1255749)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

	Reg.No. 78810 (Metabolite of BAS 500 F, pyraclostrobin)
Description:	Solid, white
Lot/Batch #:	L82-117
Purity:	97.9% (tolerance +/- 1.0%)
Stability of test compound:	The test substance was stable over the study period under the storage conditions and guaranteed until 01 May 2015. The homogeneity of the test substance was ensured by mixing prior to preparation of test substance solutions. The stability of the test substance in the vehicle DMSO over a period of 4 h was verified in the analytical study project 01Y0175/13Y005.
Solvent used:	Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control:	In parallel to each experiment, negative control experiments were carried out in order to check for possible contaminants (sterility control) and to determine the spontaneous mutation rate (vehicle control).
Vehicle control:	The vehicle control with and without S-9 mix only contained the vehicle used for the test substance at the same concentration and volume for all tester strains.
Solvent/final concentration:	100 µL/plate

Positive control compounds tested without addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1535	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1537	9-Aminoacridine (AAC)	DMSO	100 µg/plate
TA 98	4-nitro-o-phenylendiamine (NOPD)	DMSO	10 µg/plate
WP2 uvrA	4-nitroquinoline-N-oxide (4-NQO)	DMSO	5 µg/plate

Positive control compounds tested with addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1535	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1537	2-aminoanthracene	DMSO	2.5 µg/plate
TA 98	2-aminoanthracene	DMSO	2.5 µg/plate
WP2 uvrA	2-aminoanthracene	DMSO	60.0 µg/plate

To demonstrate the efficacy of the S9 mix in this assay, the S9 batch was further characterized with benoz(a)pyrene in the strains TA 100 and TA 98 as required in OECD 471.

3. Activation:

S9 was produced from the livers of induced male Sprague-Dawley rats. The rats received on three consecutive days intraperitoneal injections of 80 mg phenobarbital and 80 mg β-naphthoflavone orally per kg body weight. 24 hours after the last administration the animals were sacrificed. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction is thawed at room temperature and 1 volume of S9-fraction is mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9-mix, was kept on ice until used.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4. Test organisms:

S. typhimurium strains: TA98, TA100, TA1535, TA1537
E. coli: WP2 uvrA

Salmonella typhimurium: The Salmonella strains are checked for the following characteristics at regular intervals: deep rough character (rfa); UV sensitivity (uvrB); ampicillin resistance (R factor plasmid). E. coli WP2 uvrA is checked for UV sensitivity.

Histidine and tryptophan auxotrophy is automatically proven in each experiment via the spontaneous rate.

5. Test concentrations:

Plate incorporation assay: In the first experiment triplicate plates were prepared for each concentration (neg. control; 33, 100, 333, 1000, 2600 and 5200 µg/plate and positive controls at the concentrations indicated above) and conditions (i.e. with and without S9) for all tester strains indicated above.

Pre-incubation assay: In the second experiment the test article / vehicle / positive control substance, bacterial and S-9 mix or phosphate buffer were incubated at 37°C for the duration of about 20 minutes. Triplicate plates were prepared for each concentration (neg. control; 10, 33, 100, 333, 1000 and 2600 µg/plate and positive controls at the concentrations indicated above) and condition (i.e. with and without S9) for all tester strains.

B. TEST PERFORMANCE:

1. Dates of experimental work: 25-Jun-2013 to 04-Jul-2013

2. Plate incorporation assay:

To test tubes containing 2-mL portions of warm soft agar (containing 0.5 mM histidine + 0.5 mM biotin), 0.1 mL test solution or vehicle, 0.1 mL fresh bacterial culture, 0.5 mL S9-mix (in tests with metabolic activation) or 0.5 mL phosphate buffer (in tests without metabolic activation) were added in the given order. After mixing, the samples are poured onto Merckoplate® plates (minimal glucose agar plates). In the experiments with E. coli the warm soft agar contained 0.5 mM tryptophan instead of histidine + biotin.

3. Pre-incubation assay:

100 µL of test solution or vehicle, 0.1 mL bacterial suspension and 0.5 mL S9 mix or phosphate buffer were incubated at 37°C for about 20 minutes. Subsequently, 2 mL of soft agar was added and, after mixing, the samples are poured onto the agar plates.

After incubation in the dark for 48 to 72 hours at 37°C each plate was checked for precipitates and status of the background lawn. Revertant colonies were counted. Means and standard deviations were calculated.

4. Titer determination:

In order to assess bacteriotoxic effects, the titer was additionally determined in experimental parts with S9 mix using the vehicle control and the two highest doses. The procedure followed in both experiments (plate incorporation and pre-incubation) was the same as described above for the individual experiments with the exception that the soft agar used contained maximal amino acid solution (5 mM tryptophan or 5 mM histidine + 0.5 mM biotin). After the incubation in the dark for 48 to 72 hours at 37°C the number of bacterial colonies was determined.

5. Statistics:

No special statistical tests were performed.

6. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A dose-related and reproducible increase in the number of revertant colonies, i.e. about doubling of the spontaneous mutation rate in at least one tester strain either without S9 mix or after adding a metabolizing system.

A test substance is generally considered non-mutagenic in this test if:

- The number of revertants for all tester strains was within the historical negative control range under all experimental conditions in two experiments carried out independently of each other.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The test substance was stable over the study period under the storage conditions.

The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically (see above).

B. TOXICITY

A preliminary cytotoxicity assay was not performed in this laboratory. Cytotoxicity was determined in the course of the mutation assay.

A bacteriotoxic effect (reduced his^- or trp^- background growth, decrease in the number of his^+ or trp^+ revertants, reduction in the titer) was observed in the standard plate test and in the preincubation test depending on the strain and test conditions from about 1 000 µg/plate onwards.

C. MUTATION ASSAYS

Neither in the plate incorporation nor in the preincubation experiment with and without metabolic activation was a biologically relevant increase in number of revertants observed in any strain tested [see Table 5.8.1-37]. The positive controls yielded revertant numbers in a range expected for the respective strains and thus demonstrated the sensitivity of the test system.

Precipitation was not observed up to the maximum concentration.

III. CONCLUSION

According to the results of the present study, the test substance Reg.No. 78810 is not mutagenic in the Ames standard plate test and in the preincubation test under the experimental conditions chosen here.

Report:	CA 5.8.1/32 Schulz M., Landsiedel R., 2014b Reg.No. 78810 (metabolite of BAS 500 F, Pyraclostrobin) - In vitro gene mutation test in L5178Y mouse lymphoma cells (TK+ locus assay, microwell version) 2013/1298448
Guidelines:	OECD 476, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.17, EPA 870.5300
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Reg.No. 78810 (Metabolite of 500 F; pyraclostrobin; batch: L82-117, purity: 97.9%) was tested in vitro for its ability to induce forward mutations in L5178Y cells by assessing the mutation of the $TK^{+/-}$ locus. Two independent experiments were conducted in the presence and absence of metabolic activation with concentrations of 7.8 to 2000 µg/mL. The treatment intervals in the absence of metabolic activation were 4 and 24 h in the first and second experiment, respectively. The treatment interval for cultures treated with the test substance in the presence of metabolic activation was 4 h for both experiments. Methyl methanesulfonate (MMS) and cyclophosphamide (CPP) served as positive controls in the experiments without and with metabolic activation, respectively.

Cytotoxicity indicated by clearly reduced relative total growth (RTG) of below 20% of control was observed after 24 hours exposure in the 2nd experiment in the absence of metabolic activation only.

The test substance did not cause any biologically relevant increase in the mutant frequencies neither without S9 mix nor after adding a metabolizing system in two experiments performed independently of each other. The positive control substances, however, induced a marked increase in mutant frequency and the negative controls gave mutant frequencies within the range expected for the L5178Y $TK^{+/-}$ mouse lymphoma cell line.

Based on the results of the study it is concluded that under the conditions of the test Reg.No. 78810 (metabolite of 500 F; pyraclostrobin) does not induce forward mutations in mammalian cells in vitro.

(BASF DocID 2013/1298448)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Description:	Reg.No. 78810 (metabolite of pyraclostrobin) Solid, white
Lot/Batch #:	L82-117
Purity:	97.9% (tolerance ± 1.0%)
Stability of test compound:	The test substance was stable over the study period under the storage conditions and guaranteed until 01 May 2015. The homogeneity of the test substance was ensured by mixing prior to preparation of test substance solutions. The stability of the test substance in the vehicle DMSO over a period of 4 h was verified analytically.
Solvent used:	Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control:	A negative control was not employed in this study
Solvent control:	The vehicle controls with and without S9 mix contained the vehicle selected for the test substance at the same volume and concentration as used in the test cultures.
Positive control -S9:	Methyl methanesulfonate (MMS) 15 µg/mL (4-hour exposure period) and 5 µg/mL (24-hour exposure period)
Positive control +S9:	Cyclophosphamide (CPP) 2.5 µg/mL

3. Activation:

S9 was produced from the livers of at least 5 induced male Wistar [Crl:WI(Han)] rats. The rats were administered injections of phenobarbital (80 mg/kg; i.p.) and ß-napthtoflavone (80 mg/kg; per gavage) on three consecutive days. 24 h after the last administration the animals were sacrificed.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4.	**Test organism:**	Mouse lymphoma L5178Y $TK^{+/-}$ cell line: This is a cell line with a high proliferation rate (doubling time of about 9 - 10 hours), a high plating efficiency (about 90%) and a stable karyotype with a near diploid number of 40 ± 1 chromosome. Each batch used for mutagenicity testing was checked for mycoplasma contamination.
5.	**Culture media:**	
	Culture medium:	RPMI 1640 medium including stable glutamine supplemented with: 1% (v/v) penicillin/streptomycin (10 000 IU / 10 000 µg/mL) and 1% (v/v) sodium pyruvate (10 mM) = RPMI-0 For treatment medium (with S9 mix): RPMI-0 supplemented with 5% (v/v) fetal calf serum (FCS) = RPMI-5 For treatment medium (without S9 mix) and subculturing cells: RPMI-0 is supplemented with 10% (v/v) FCS = RPMI-10 For cloning efficiency and selection medium: RPMI-0 supplemented with 20% (v/v) FCS = RPMI-20
	Pretreatment medium:	A ("THMG" medium): RPMI-10 supplemented with thymidine (3.0 µg/mL), hypoxanthine (5.0 µg/mL), methotrexate (0.1 µg/mL) and glycine (7.5 µg/mL) B ("THG" medium): RPMI-10 supplemented with thymidine (3.0 µg/mL), hypoxanthine (5.0 µg/mL), and glycine (7.5 µg/mL)
	Selection medium:	("TFT" medium): RPMI-20 supplemented with trifluorthymidine (TFT, 4.0 µg/mL)
6.	**Locus examined:**	thymidine kinase (TK)

7. Test concentrations:

a) Preliminary toxicity assay: Nine concentrations ranging from 7.8 to 2000 µg/mL

b) Mutation assay:
1st experiment: 250.0, 500.0, 1000.0 and 2000 µg/mL with and without metabolic activation

2nd experiment: 7.8, 15.6, 31.3, 62.5, 125.0, 250.0, 500.0, 1000 and 2000 µg/mL without metabolic activation and 375.0, 750.0, 1500 and 2000 µg/mL with metabolic activation

B. TEST PERFORMANCE:

1. Dates of experimental work: 10-Jun-2013 to 14-Jan-2014

2. Preliminary cytotoxicity assay:

In the pretest for toxicity based on the molecular weight of the test substance 2 000 µg/mL (approx. 10 mM) Reg.No. 78810 (Metabolite of BAS 500 F, pyraclostrobin) was used as top concentration both with and without S9 mix at 4 hour exposure time and without S9 mix at 24 hour exposure time.
The pretest was performed following the method described for the main experiment. The relative suspension growth (RSG) was determined as toxicity indicator for dose selection and various parameters were checked for all or at least for some selected doses. Additionally, pH and solubility were determined.

3. Mutation Assay:

Pretreatment of Cells: During the week prior to treatment, spontaneous TK deficient mutants ($TK^{-/-}$) were eliminated from the stock cultures by incubating 3 x 10^5 cells per 75 cm² flask in a total volume of 30 mL for 1 day in “THMG" medium (pretreatment medium A), and for the following 3 days in “THG" medium (pretreatment medium B).

Cell treatment:	For each test group, about 1.5 x 10^7 cells per flask were seeded into 75 cm^2 flasks containing RPMI-10 for exposures without S9 mix and RPMI-5 medium for exposures with S9 mix and incubated for the respective exposure period (1st experiment: 4-hour exposure with and without S9 mix and 2nd experiment 24 hours without S9 mix and 4 hours with S9 mix) with 5% CO_2 at 37°C and ≥90% humidity for cell attachment. 2 cultures were treated in parallel for each test group.
Expression:	At the end of the exposure period, the cells were transferred in tubes, centrifuged for 5 minutes at 1000 rpm and were resuspended in RPMI-5 medium. The washing of the cells was repeated at least once. Then the cells were centrifuged and were resuspended in RPMI-10 medium. From each culture a sample of treated cells (2 x 10^5 cells/mL or 6 x 10^6 cells/flask) were pipetted in 75 m^2 flasks and were incubated for a 2-day expression period. To maintain exponential growth during this phase, each culture was counted daily and the cell numbers were adjusted at each day to 2 x 10^5 cells/mL in 30 mL RPMI-10 medium.
Selection:	For the mutant selection, the cells were resuspended in selection medium ("TFT" medium) and two 96-well plates per cultures were seeded with 2000 cells/well. After incubation of at least 9 days, both the number of negative wells and the number of wells containing small or large colonies were scored for calculation of the mutant frequency (MF).
Size distribution of the colonies:	The colonies are classified into large colonies (indication of gene mutation) and small colonies (indication of chromosome breakage). Small colonies are defined as less than 1/4 of the diameter of the well. Size is the key factor and morphology (the optical density of the small colonies is considerably higher) should be secondary.
Determination of Cytotoxicity:	Cloning efficiency 1 (survival): The survival (cloning efficiency 1; CE_1) was determined in parallel to the mutagenicity test. At the end of the exposure period, the cells were centrifuged and 400 cells from each culture were resuspended in 50 mL RPMI-20 medium (8 cells/mL). Per culture 200 µL were dispensed in each well of two 96-well plates (1.6 cells/well). After incubation for 9 - 11 days the plates were scored for empty wells.

Cloning efficiency 2 (viability):

The viability (cloning efficiency 2; CE_2) was determined after the expression period. 2 days after end of exposure, the cells were centrifuged and 400 cells from each culture were resuspended in 50 mL RPMI-20 medium (8 cells/mL). Per culture 200 µL were dispensed in each well of two 96-well plates (1.6 cells/well). After incubation for at least 9 days the plates were scored for empty wells.

Suspension growth (RSG) and relative total growth (RTG):
For calculation of the suspension growth (SG) and the relative total growth (RTG) the cell counts determined within the expression period at 2nd and 3rd passage after exposure in the case of 4-hour exposure and 1st, 2nd and 3rd passage after exposure in the case of 24-hour exposure were used.

This measure includes the relative growth in suspension during the expression period (RSG) and the relative cloning efficiency (RCE_2; viability) at the time the mutants are selected.

For taking into account any loss of cells during the 4-hour treatment period a relative growth during treatment factor (RGDT, %) was calculated by comparing the growth of each treated culture relative control.

Calculations:

Mutant frequency:
Uncorrected mutant frequency:

$$MF_{uncorr} = \frac{-\ln(\text{total number of empty well s} \div \text{total number of seeded wells (96)})}{\text{number of seeded cells per well (2000)}} \times 10^6$$

Corrected mutant frequency:

$$MF_{corr} = \frac{MF_{uncorr}}{CE_2} \times 100$$

Cloning efficiency (CE, %) absolute:

$$CE_x = \frac{-\ln(\text{total number of empty wells} \div \text{total number of seeded wells (96)})}{\text{number of seeded cells per well (1.6)}} \times 100$$

Cloning efficiency relative, in comparison to control:

$$RCE_x = \frac{CE_x \ of \ the \ test \ group}{CE_x \ of \ the \ negative \ / \ vehicle \ control} \times 100$$

Relative total growth:

Relative growth during treatment (RGDT, %)

$$\text{RGDT} = \frac{\text{Cell count after 4 h of the test group}}{\text{Cell count after 4 h of the negative/v ehicle control}} \times 100$$

Total suspension growth (SG) after 4 hour-exposure:

$$SG = \frac{\text{Cell count after 24 h}}{2 \text{ x } 10^5 \text{ cells per mL}^{1,2}} \times \frac{\text{Cell count after 48 h}}{2 \text{ x } 10^5 \text{ cells per mL}^2} \times \frac{\text{RGDT}}{100}$$

Total suspension growth (SG) after 24 hour-exposure:

$$SG = \frac{\text{Cell count after 24 h}}{2 \text{ x } 10^5 \text{ cells per mL}} \times \frac{\text{Cell count after 48 h}}{2 \text{ x } 10^5 \text{ cells per mL}^2} \times \frac{\text{Cell count after 72 h}}{2 \text{ x } 10^5 \text{ cells per mL}^2}$$

$$\text{RSG} = \frac{\text{SG of the test group}}{\text{SG of the negative/v ehicle control}} \times 100$$

$$RTG = \frac{RSG \times RCE_2}{100}$$

[1] Cell number seeded following 4-hour treatment
[2] If cell number was lower than 2 x 10^5 cells per mL all remaining cells were seeded

4. Statistics:

An appropriate statistical trend test (MS EXCEL function RGP; 9) was performed to assess a dose-related increase of mutant frequencies. The number of mutant colonies obtained for the test substance treated groups was compared with that of the respective vehicle control groups. A trend is judged as statistically significant whenever the one-sided p-value (probability value) is below 0.05 and the slope was greater than 0. Both, biological and statistical significance will be considered together. However, both, biological and statistical significance has been considered together.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- The mutation frequency exceeds a threshold of 126 mutant colonies per 10^6 cells (GEF: Global Evaluation Factor) above the concurrent negative/vehicle control value.

and

- Evidence of reproducibility of any increase in mutant frequencies, means the mutagenic response occurs at least in both parallel cultures of one experiment.

and

- A statistically significant dose-related increase in mutant frequencies using an appropriate statistical trend test.

A test substance is generally considered negative in this test system if:

- The mutation frequency is below a threshold of 126 mutant colonies per 10^6 cells (GEF) above the concurrent negative/vehicle control value.

or

- No evidence of reproducibility of an increase in mutant frequencies is obtained.

or

- No statistically significant dose-related increase in mutant frequencies using an appropriate statistical trend test is observed.

However, in the evaluation of the test results the historical variability of the mutation rates in negative and vehicle controls and the mutation rates of all negative and vehicle controls of this study were taken into consideration. Results of test groups have been rejected if the relative total growth (RTG) and/or the cloning efficiency 1 (CE_1) were less than 10% of the respective vehicle controls. Whenever a test substance is considered mutagenic according to the above mentioned criteria, the ratio of small versus large colonies is used to differentiate point mutations from clastogenic effects. If the increase of the mutation frequency is accompanied by a reproducible and dose-related shift in the ratio of small versus large colonies clastogenic effects are indicated.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically (see BASF study code 01Y0175/13Y005).

B. PRELIMINARY CYTOTOXICITY ASSAY

After 4 hours treatment in the absence and presence of S9 mix no cytotoxicity indicated by reduced relative suspension growth of about or below 20% was observed. After 24 hours treatment in the absence of S9 mix reduced relative suspension growth of about or below 20% was observed after treatment with 125 µg/mL and above.

With exception of the highest concentration (2000 µg/ml) the pH value was not influenced by the addition of the test substance preparation to the culture medium at all concentrations. At the highest concentrationthe pH was adjusted to a physiological value by addition of small amounts of 2N NaOH. In this study, in the absence and the presence of S9 mix neither in the vehicle DMSO nor in culture medium test substance precipitation was observed up to the highest required test substance concentration.

Based on these data the highest concentration tested in the mutagenicity experiments was 2000 µg/mL without and with metabolic activation.

C. MUTAGENICITY ASSAYS

In this study, no relevant increase in the number of mutant colonies was observed either without S9 mix or after the addition of a metabolizing system. The corrected mutant frequencies obtained for both experiments were always below the calculated threshold taking in consideration the Global Evaluation Factor (GEF).

In both experiments after 4 hours treatment in the absence and presence of metabolic activation the values for the corrected mutation frequencies (MFcorr.: 32.6 - 62.0 per 10^6 cells) were close to the respective vehicle control values (MFcorr.: 49.8 - 58.1 per 10^6 cells, see Table 5.8.1-38) and clearly within the range of historical negative control data (without S9 mix: MFcorr.: 23.7 - 92.4 per 10^6 cells; with S9 mix: MFcorr.: 21.4 - 103.0 per 10^6 cells). In addition, in the 2nd experiment after 24 hours treatment in the absence of metabolic activation the values for the corrected mutation frequencies (MFcorr.: 55.8 - 109.8 per 10^6 cells) were close to the respective vehicle control value (MFcorr.: 52.6 per 10^6 cells, see Table 5.8.1-38) and nearby the range of historical negative control data range (without S9 mix: MFcorr.: 12.2 - 80.6 per 10^6 cells). There was no statistically significant dose-related increase in both experiments with and without S9 mix.

Treatment with the positive controls MMS and CCP resulted in clearly increased mutant frequencies as expected. The values of the corrected mutant frequencies (MFcorr.: 465.0 - 674.5 per 10^6 cells) clearly exceeded the respective calculated thresholds for a mutagenic effect based on the GEF (126 plus the mutant frequency of the respective negative control).

In both experiments after 4 hours exposure, no cytotoxic effects indicated by reduced cloning efficiencies or reduced relative total growth of below 20% of control were observed neither in the presence nor in the absence of S9 mix. In contrast, in the 2nd experiment after 24 hours exposure in the absence of metabolic activation the RTG was clearly reduced from 250 µg/mL (RTG: 20.8%) onwards.

The pH value of the test substance preparation was adjusted by adding small amounts of NaOH. In this study, in the absence and the presence of S9 mix neither in the vehicle DMSO nor in culture medium test substance precipitation was observed up to the highest required test substance concentration.

III. CONCLUSION

Based on the results of the study it is concluded that 500M51 (Reg.No. 78810, metabolite of pyraclostrobin) does not induce forward mutations in vitro in the mouse lymphoma assay with L5178Y $TK^{+/-}$ cells in the absence and the presence of metabolic activation.

Report: CA 5.8.1/33
Schulz M., Landsiedel R., 2014a
Reg.No. 78810 (metabolite of BAS 500 F, Pyraclostrobin) - In vitro micronucleus assay in V79 cells (cytokinesis block method)
2013/1361922

Guidelines: OECD 487 (2010), Commission Regulation EU No. 640/2012 of 06 July 2012 - B.49: In vitro Mammalian Cell Micronucleus Test

GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Reg.No. 78810 (Metabolite of BAS 500 F, pyraclostrobin) (batch L82-117; purity 97.9%) was tested in vitro for its potential to induce micronuclei in V79 cells of the Chinese hamster in the absence and presence of metabolic activation by S9 mix in two independent experiments with different exposure periods (4 and 24 hours).

Cytotoxicity as indicated by clearly reduced relative increase in cell count (RICC), proliferation index (CBPI) or replicative index (RI) was only observed at 2000 µg/mL in the 2nd experiment after 24 hours continuous treatment in the absence of S9 mix. In both experiments with and without metabolic activation, no test substance precipitation in culture medium at the end of exposure period was macroscopically observed. No statistically significant or biologically relevant increase in the number of micronucleated cells was observed either without S9 mix or after the addition of a metabolizing system.

Vehicle and positive controls revealed the expected results of micronucleated cells thereby ensuring the validity of the test.

Based on the results of this study, Reg.No. 78810, metabolite of pyraclostrobin, is considered not to have a chromosome-damaging (clastogenic) effect nor to induce numerical chromosomal aberrations (aneugenic activity) under in vitro conditions in V79 cells in the absence and the presence of metabolic activation.

(BASF DocID 2013/1361922)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg.No. 78810 (Metabolite of BAS 500 F, pyraclostrobin)

Description:	Solid, white
Lot/Batch #:	L82-117
Purity:	97.9% (tolerance ± 1.0%)
Stability of test compound:	The test substance was stable over the study period under the storage conditions and guaranteed until 01 May 2015. The homogeneity of the test substance was ensured by mixing prior to preparation of test substance solutions. The stability of the test substance in the vehicle DMSO over a period of 4 h was verified in the analytical study project 01Y0175/13Y005.
Solvent used:	Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control:	A negative control was not employed in this study.
Solvent control:	DMSO
Positive control, -S9:	Ethylmethanesulfonate (EMS, 300, 400 and 500 µg/mL, dissolved in MEM without FCS)
Positive control, +S9:	Cyclophosphamide (CPA, 1.0 and 2.5 µg/mL, dissolved in MEM without FCS)

3. Activation: S9 was produced from male Wistar rats. The rats were induced by intraperitoneal applications of 80 mg/kg bw phenobarbital and by oral administrations of 80 mg/kg bw β-naphthoflavone each, on three consecutive days. The livers were prepared 24 hours after the last treatment. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction was thawed at room temperature and 1 volume of S9-fraction was mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9 mix, was kept on ice until used.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4. Test organisms:

Chinese hamster V79 cells
This is a continuous cell line with a high proliferation doubling time of 12-14 hours, a high plating efficiency (≥ 90%) and a stable karyotype (modal number of 22 chromosomes).

5. Culture medium/conditions:

Culture media:

Minimal essential medium with Earle's salts (MEM) containing a L-glutamine source supplemented with 10% (v/v) fetal calf serum (FCS), 1% (v/v) penicillin/streptomycin (10000 IU / 10000 µg/mL) and 1% (v/v) amphotericine B (250 µg/mL). During exposure to the test substance in the presence of S9 mix MEM medium was used without FCS supplementation.

Cell culture:

Deep-frozen cell stocks were thawed at 37°C in a water bath, and volumes of 0.5 mL were transferred into 25 cm^2 plastic flasks containing about 5 mL MEM supplemented with 10% (v/v) fetal calf serum (FCS). Cells were grown with 5% (v/v) CO2 at 37°C and ≥ 90% humidity and subcultured twice weekly. Cell monolayers were suspended in culture medium after detachment with 0.25% (w/v) trypsin solution.

Cell cycle and harvest time: The cell cycle of the untreated V79 cells lasts for about 12 - 14 hours under the selected culture conditions. Thus, a harvest time of 24 hours is about 2 times the normal cell cycle length. V79 cells are an asynchronous cell population, i.e. at the time of test substance treatment there are different cell stages. Since the effect on these cell stages may vary for different test substances, more than one harvest time after treatment may be appropriate. Furthermore, substance-induced mitotic delay may considerably delay the first post-treatment mitosis. Therefore, delayed harvest times (e.g. 44 hours) and prolonged exposure periods (e.g. 24 hours treatment) were considered.

6. Test concentrations:

a) Preliminary toxicity assay: Eight concentrations spaced by a factor of 2 ranging von 15.6 to 2000 µg/ml were used with and without metabolic activation
Exposure period: 4 hours with and without metabolic activation; 24 hours without metabolic activation
Harvest time: 24 hours

b) Cytogenicity assay:
1st experiment: 62.5, 125, 250, 500, 1000 and 2000 µg/mL with and without S9 mix (4 hours exposure, 24 hour preparation interval)
2nd experiment: 62.5, 125, 250, 500, 1000 and 2000 µg/mL without metabolic activation (24 hour exposure, 24 hour preparation interval)
125, 250, 500, 1000 and 2000 µg/mL with metabolic activation (4 hour exposure, 44 hour preparation interval)

B. TEST PERFORMANCE:

1. Dates of experimental work: 17-Jun-2013 to 21-Nov-2013

2. Preliminary cytotoxicity assay:

In the pretest for toxicity based on the purity and the molecular weight of the test substance 2000 µg/mL (approx. 10 mM) Reg.No. 78110 (Metabolite of BAS 500 F, pyraclostrobin) was used as top concentration. The pretest was performed following the method described for the main experiment. As indication of test substance toxicity relative increase in cell count (RICC) and cell attachment (morphology) were determined for dose selection. pH and solubility were additionally determined.

3. Cytogenicity Assay:

Two independent experiments were performed. In experiment I, the exposure period was 4 hours with and without S9 mix. In experiment II, the exposure periods were 4 hours with S9 mix and 24 hours without S9 mix. The cells were prepared 24 hours after start of treatment with the test item, except for the 4 hour treatment interval in the presence of metabolic activation (experiment II). In this experimental part cells were harvested after 44 hours to consider possibly occurring mitotic delay.

Cell seeding / treatment:	Routinely grown cells that did not exceed a max. of 15 passages and reached a confluency of at least 50%, were detached by trypsination and used to prepare a single cell suspension with the required cell count (3-5x10^5 cells per culture, depending on the schedule) in MEM incl. 10% (v/v) FCS. 5 mL cell suspension were transferred into 25 cm² cell culture flasks using a dispenser. Subsequently, the test cultures were incubated. After an attachment period of about 20 - 24 hours, the medium was removed from the flasks and the treatment medium was added. In case of experiments without metabolic activation the treatment medium consisted of 5 or 4 mL MEM medium with FCS plus 1 mL positive control or 0.05 mL test substance preparation/vehicle, respectively. In case of metabolic activation, the treatment medium consisted of 4 or 3 mL MEM medium without FCS, 1 mL positive control or 0.05 mL test substance preparation/vehicle and 1 mL S9-mix, respectively. The cultures were incubated for the respective exposure period at 37°C, 5% (v/v) CO_2 and ≥ 90% humidity. At the end of the exposure period, the medium was removed and the cultures were rinsed twice with 5 mL HBSS (Hanks Balanced Salt Solution). Subsequently, 5 mL MEM incl. 10% FCS supplemented with Cytochalasin B (CytB, final concentration: 3 µg/mL; stock: 0.6 mg/mL in DMSO) was added and incubated for the respective recovery time. In the case of 24-hour continuous exposure, CytB was added to the treatment medium at start of treatment, and cell preparation was started directly at the end of exposure. At 44 hours preparation interval in the presence of S9 mix the supplementation of CytB was 24 hours before preparation of the cultures.

Cell harvest, preparation of slides and staining:	Just before preparation the culture medium was completely removed. Single cell suspensions were prepared from each test group by trypsination. Then, the cell numbers per flask of each single cell suspension were determined using a cell counter. Subsequently, $5x10^4$ cells per slide were centrifuged at 1400 rpm for 7 minutes onto labelled slides using a Cytospin centrifuge. After drying, the slides were fixed in 90% (v/v) methanol for 10 minutes. Before scoring, the slides were stained with a mixture of 4',6-diamidino-2-phenylindole dihydrochloride (DAPI) and propidium iodide (PI) in Fluoroshield™ at a concentration of 0.25 µg/mL each. By the use of the combination of both fluorescence dyes it can be differentiated between DNA (DAPI; excitation: 350 nm, emission: 460 nm) and cytoplasm (PI; excitation: 488 nm, emission: 590 nm).
Analysis of micronuclei and cytotoxicity:	Cytospin slides were scored by fluorescence microscopy. At least 1000 cells per culture, means at least 2000 cells per test group, were evaluated and the number of micronuclei-containing binucleated cells was recorded. Analysis of micronuclei was carried out following the criteria: The diameter of the micronucleus is less than 1/3 of the main nucleus; the micronucleus and main nucleus retain the same color; the micronucleus is not linked to the main nucleus and is located within the cytoplasm of the cell; only cells clearly surrounded by a nuclear membrane were scored. Cultures with few isolated cells were not analyzed for micronuclei.

Relative increase in cell count (RICC):

$$RICC = \frac{(\text{Increase in number of cells in treated cultures (final} - \text{starting}))}{(\text{Increase in number of cells in control cultures (final} - \text{starting}))} \text{x } 100$$

Thus, a RICC of 53% indicates 47% cytotoxicity/cytostasis.

Proliferation Index (CBPI):

$$CBPI = \frac{\big((\text{No. mononucleated cells}) + (2 \text{ x No. binucleated cells}\big) + (3 \text{ x No. mulitnucleated cells}))}{(\text{Total number of cells})}$$

The CBPI was used to calculate the % cytostasis (relative inhibition of cell growth compared to the respective vehicle control group) - a CBPI of 1 (all cells are mononucleate) is equivalent to 100% cytostasis.

% Cytostasis = 100 - 100 $\{(CBPI_T - 1) / (CBPI_C - 1)\}$

(T- test substance treated culture; C = vehicle control)

Replicative Index (RI):

$$RI = \frac{(((\text{No. binucleate cells}) + (2\text{xmultinucleate cells}) \div (\text{Total number of cells}))_T}{(((\text{No. binucleate cells}) + (2\text{xmultinucleate cells}) \div (\text{Total number of cells}))_C} x100$$

(T = test substance treated culture; C = vehicle control culture)

Thus, an RI of 53% means that in comparison to the respective control cultures only 53% of the cells divided in the treated test group (= 47% cytotoxicity/cytostasis).

4. Statistics:

The statistical evaluation of the data was carried out using the MUVIKE program system (BASF SE). The proportion of cells containing micronuclei was calculated for each group. A comparison of each dose group with the concurrent vehicle control group was carried out using Fisher's exact test for the hypothesis of equal proportions. This test is Bonferroni-Holm corrected versus the dose groups separately for each time and was performed one-sided. If the results of this test were statistically significant compared with the respective vehicle control, labels (* $p \leq 0.05$, ** $p \leq 0.01$) have been be printed in the tables.

5. Evaluation criteria:

A test item is considered "positive" in this assay if the following criteria are met:

- A significant, dose-related and reproducible increase in the number of cells containing micronuclei was observed.
- The number of micronucleated cells exceeded both the value of the concurrent vehicle control and the range of our laboratory's recent negative control data.

A test substance is generally considered "negative" in this test system if:

- The number of micronucleated cells in the test groups is not distinctly increased above the concurrent vehicle control and is within our laboratory's recent negative control data range.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS:

The stability of the test substance at room temperature in the vehicle DMSO over a period of 4 hours was verified analytically (see BASF study code 01Y0175/13Y005).

B. PRELIMINARY CYTOTOXICITY ASSAY:

A preliminary cytotoxicity assay was performed to determine appropriate test substance concentrations for the main test. After 4 hours treatment in the absence and presence of S9 mix no cytotoxicity was observed as indicated by a reduced RICC of about or below 40 - 50%. In contrast, in the pretest with 24 hours continuous treatment in the absence of S9 mix, the relative increase in cell count was clearly reduced after treatment with ≥ 1000 µg/mL (RICC 32.9 and 27.2% at 1000 and 2000 µg/mL).

C. CYTOGENICITY ASSAYS:

In this study, no statistically significant or biologically relevant increase in the number of micronucleated cells was observed either without S9 mix or after the addition of a metabolizing system. In both experiments in the absence and presence of metabolic activation after 4 and 24 hours treatment with the test substance the values (0.2 - 1.5% micronucleated cells) were close to the concurrent vehicle control values (0.5 - 1.5% micronucleated cells) and clearly within our historical negative control data range (0.1 - 1.8% micronucleated cells) [see Table 5.8.1-39 and Table 5.8.1-40].

In the 1st experiment with S9 mix a statistically significant percentage of micronucleated cells was obtained when compared to the respective vehicle control value at an intermediate concentration of 1000 µg/mL (1.5% micronucleated cells). This significant difference was due to the low rate of micronucleated cells in the concurrent vehicle control group (0.5%). The value at 1000 µg/ml was clearly within the historical negative control data range and the increase was not dose-dependent, therefore, this finding was regarded as biologically irrelevant.

The positive control substances EMS (without S9 mix; 300 and 400 µg/mL) and CPP (with S9 mix; 1.0 µg/mL) induced statistically significant increased micronucleus frequencies in both independently performed experiments.

Growth inhibition indicated by reduced cell counts (RICC: -30.7%) was only observed in the 2nd experiment in the absence of S9 mix after 24 hours continuous treatment at the highest applied test substance concentration [see Table 5.8.1-39].

After 4 hours treatment in absence or presence of S9 mix, no reduced proliferative activity was observed at the test groups scored for cytogenetic damage. Contrary, in the 2nd experiment after 24 hours treatment in the absence of metabolic activation the proliferation index (CBPI) was decreased at 250 µg/mL and above.

In addition, in the 2nd experiment in the absence of S9 mix growth inhibition indicated by strongly reduced replicative index (RI) was observed at 500 µg/mL (32.2%). Cell morphology /attachment was only adversely influenced (grade > 2) in the 2nd experiment in the absence of S9 mix after 24 hours continuous treatment at the highest applied concentration of 2000 µg/mL.

In both experiments with and without metabolic activation, test substance precipitation was observed neither in the vehicle DMSO nor in culture medium. Osmolarity and pH values were not influenced by test substance treatment. The pH of the stock solutions was adjusted to a physiological value using small amounts of NaOH.

Table 5.8.1-39: Summary of results of micronucleus test with Reg.No. 78810 (Metabolite of BAS 500 F, pyraclostrobin)

					Genotoxicity	Cytotoxicity

III. CONCLUSION

Based on the results of the study it is concluded that 500M51 (Reg.No. 78810, metabolite of pyraclostrobin) does not induce micronuclei (clastogenic and/or aneugenic activity) under the in vitro conditions of this study.

Toxicological evaluation of 500M51 (Reg.No. 78810)

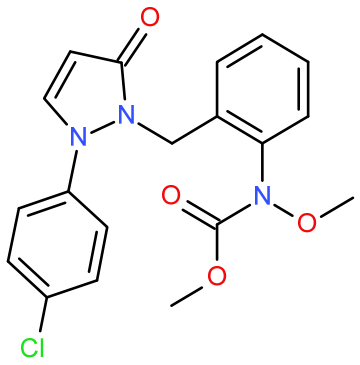
The QSAR evaluation of 500M51 is of low reliability and by weight of evidence there was no conclusive alert for genotoxity.

500M51 is considered to be not genotoxic based on the in vitro studies conducted. Therefore, 500M51 is considered to be **not toxicologically relevant**.

With regard to consumer exposure the TTC concept for a non-genotoxic compound was applied. Thus an ADI of 0.0015 mg/kg bw/day as well as an ARfD of 0.005 mg/kg bw/day was established. 500M51 which was identified in livestock metabolism only, accounts for 0.2% of the ARfD and has a negligible chronic exposure.

Group 6: Photometabolite 500M76

500M76 (other denominators: Reg.No. 413038, BF 500-14)



500M76 (Reg.No. 413038) is a photolysis metabolite found in surface water. The highest calculated concentration (PEC_{sw}) is 0.352 µg/L. In contrast to the other two surface water photolysis metabolites, 500M76 (Reg.No. 413038) is also found as a plant metabolite in wheat forage.

A) QSAR Predicitions for 500M76 (Reg.No. 413038)

OECD Toolbox (Version: 3.2) [see DocID 2014/1172955]
For 500M76 (Reg.No. 413038) the OECD toolbox does not indicate any alerts.

OASIS TIMES (MIX V.2.27.13 TB; Mutagenicity S-9 activated v08.08) [see molecule 4 of report DocID 2014/1172952 and 2014/1172953]

There were no Ames mutagenicity alerts for 500M76 (Reg.No. 413038) or in-silico generated metabolites. In all cases the structures were out of domain. The prediction in vitro chromosome aberration for 500M76 (Reg.No. 413038) was negative (out of domain). However, the CA prediction was positive for 1 out of 14 in-silico generated metabolites. The respective alert was ‘phenols’ (in domain).

Discussion: The alert ‘phenols’ identified for the in vitro chromosome aberration was also present for pyraclostrobin and metabolite 500M60 (Reg.No. 411847). Whereas the in vitro study with pyraclostrobin was negative, the in vitro study with 500M60 (Reg.No. 411847) - like that with 500M76 (Reg.No. 413038) - was positive. However, the in vitro results were not confirmed in the higher tier in vivo mouse micronucleus studies. Therefore, the weight of evidence indicates that 500M76 (Reg.No. 413038) is not genotoxic.

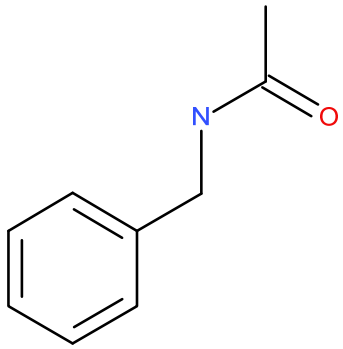
VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 4 of report DocID 2014/1172954 for both VEGA models]

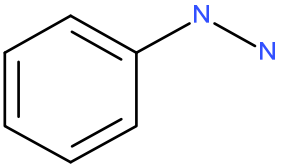
500M76 (Reg.No. 413038) is out of model applicability domain. The prediction is 'non mutagen'.

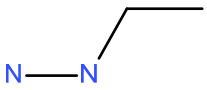
VEGA: Mutagenicity model (SarPy; version 1.0.4-BETA)

500M76 (Reg.No. 413038) is out of model applicability domain. The prediction is 'mutagen' with the structural alerts SA 47, SA 87, SA98 and SA 103. As discussed above, the alert SA 98 was also obtained for pyraclostrobin and a number of pyraclostrobin metabolites, which like 500M76 (Reg.No. 413038) were actually tested negative.

The substructures for the other alerts are depicted below. The predictions of the structural alerts SA 47, SA 87 and SA 103 are each based on 3 molecules of the training set which structurally were not very similar to 500M76 (Reg.No. 413038) as the similarity ranged from 0.515 to 0.637). For the alert SA 47 2 of the 3 predicted molecules were actually tested positive. This ratio was 1 of 3 for the alerts SA 87 and SA 103.

SA 47	SA 87	SA 103
		






Discussion: In view of the negative Ames test (see below) the prediction of gene mutation in bacteria is rejected.

DEREK (Version 2.0.0.201011301322; Knowledge base version: 11_20_05_2010)

The prediction for genotoxicity and neurotoxicity is negative.

Genotoxicity studies on 500M76 (Reg.No. 413038)

Study already submitted:

In the original submission an Ames test on Reg.No. 413038 was submitted and assessed (BASF DocID 2000/1000005). A standard plate test and a pre-incubation test with and without metabolic activation was performed at concentrations of 22 - 5500 µg/plate in S. typhimurium strains TA 98, TA 100, TA 1535 and TA 1537 as well as in E. coli WP2 uvrA. A slight bacteriotoxicity was noted at 5500 µg/plate in the standard plate test and at concentrations ≥ 2750 µg/plate in the pre-incubation assay, while no precipitations were noted at any concentration. No increase of revertant colonies was observed in any of the tests performed.

New studies submitted in this dossier:

Report:	CA 5.8.1/34 Engelhardt G., Leibold E., 2003b In vitro gene mutation test with Reg.No. 413038 in CHO cells (HPRT locus assay) 2003/1004384
Guidelines:	OECD 476, EEC 2000/32 B.17
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

Reg. No. 413038 (Metabolite of BAS 500F; batch: 01586-236, purity: 94.5%) was tested in vitro for its ability to induce forward mutations in mammalian cells by assessing the mutation of the HPRT locus in Chinese Hamster CHO cells. Two independent experiments were conducted in the presence and absence of metabolic activation at concentrations of up to 1000 µg/mL. The treatment interval in the absence and presence of metabolic activation was 4 h in both experiments. Ethylmethanesulfonate (EMS) and 3-methylcholanthrene (MCA) served as positive controls in the experiments without and with metabolic activation, respectively.

Cytotoxic effects indicated by reduced cloning efficiencies below 20% of the respective vehicle control were observed in the experiments without metabolic activation at concentrations ≥ 300 µg/mL and in the experiments with metabolic activation at 1000 µg/mL.

Neither in the original nor in the confirmatory experiments a relevant increase in the mutant frequency was observed. The positive control substances, however, induced a marked increase in mutant frequency.

Based on the results of the study, it is concluded that under the conditions of the test Reg. No. 413038 does not induce forward mutations in mammalian cells in vitro.

(BASF DocID 2003/1004384)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

	Reg. No. 413038 (Metabolite of BAS 500F)
Description:	Solid, lightbrown
Lot/Batch #:	01586-236
Purity:	94.5%
Stability of test compound:	Expiry date: November 2003. The homogeneity of the test substance was guaranteed by grinding before preparation of the test substance formulations. The stability of a comparable batch (01586-90) at room temperature in the vehicle DMSO over a period of 4 hours and in water over a period of 96 hours was verified analytically.
Solvent used:	Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control:	A negative control was not employed in this study
Solvent control:	1% (v/v) DMSO in culture medium
Positive control -S9:	Ethyl methanesulfonate (EMS) 300 µg/mL
Positive control +S9:	3-Methylcholantrene (MCA) 10 µg/mL

3. Activation:

S9 was produced from the livers of 5 induced male Wistar Sprague-Dawley rats. The rats received a single intraperitoneal injection of 500 mg Aroclor 1254 (as solution in corn oil with a concentration of 20 g/100 mL) per kg body weight. 5 days after administration the animals were sacrificed. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction was thawed at room temperature and 1 volume of S9-fraction was mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9-mix, was kept on ice until used.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	50 µM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	30 mM
$MgCl_2$	10 mM
$CaCl_2$	10 mM
S9	10%

4. Test organism:

Chinese hamster CHO cells (sub-strain K1). Stocks of the CHO cell line were maintained at -196°C in liquid nitrogen. Each batch used for mutagenicity testing was checked for mycoplasma contamination. The week prior to treatment, spontaneous HPRT-deficient mutants were eliminated from the stock cultures by growing the cells for 3 to 4 days in pretreatment medium (see below).

5. Culture media:

Culture medium: Ham's F12 medium with L-glutamine and hypoxanthine supplemented with 10% (v/v) fetal calf serum (FCS).

Pretreatment medium: ("HAT" medium): FCS-supplemented Ham's F12 medium with L-glutamine containing per mL 13.6 µg hypoxanthine, 0.18 µg aminopterin and 3.88 µg thymidine.

Selection medium: ("TG" medium): L-Glutamine- and FCS-supplemented, hypoxanthine-free Ham's F12 medium with 6-thioguanine at a final concentration of 10 µg/mL

All media were supplemented with
- 1% (v/v) penicillin/streptomycin (10000 IU / 10000 µg/mL)
- 1% (v/v) amphotericine B (250 µg/mL)

During pulse exposure (4 hours) to the test substance, Ham‘s F12 medium was used without FCS supplementation. In the case of continuous treatment (24 hours) Ham‘s F12 medium with FCS supplementation was used.

6. Locus examined:

hypoxanthine-guanine-phosphoribosyl transferase (H(G)PRT)

7. Test concentrations:

a) Preliminary toxicity assay:	Nine concentrations ranging from 5 to 2000 µg/mL
b) Mutation assay:	
1st experiment:	12.5, 25.0, 50.0, 100.0, 200.0 and 400.0 µg/mL without and 62.5, 125.0, 250.0, 500.0, 750.0 and 1000.0 µg/mL with metabolic activation
2nd experiment	9.38, 18.75, 37.5, 75.0, 150.0 and 300.0 µg/mL without and 62.5, 125.0, 250.0, 500.0, 750.0 and 1000.0 µg/mL with metabolic activation

B. TEST PERFORMANCE:

1. Dates of experimental work: 04-Nov-2002 to 20-Jan-2003

2. Preliminary cytotoxicity assay:

Cytotoxicity was assessed by determination of the cloning efficiency. About 200 cells were incubated in 25-cm² flasks with 9 test substance concentrations (5 - 2000 µg/mL) in serum-free Ham's F12 medium for about 4 hours (with and without metabolic activation) after an attachment period of 24 hours. At the end of the exposure period, the cells were washed with Hanks' balanced salt solution (HBSS), covered with Ham's F12 and incubated for a further 5 - 7 days. After this incubation period, colonies were fixed, stained and counted. In addition to the cloning efficiency the following parameters were measured: pH, osmolality and the determination of precipitates (solubility).

3. Mutation Assay:

Pretreatment of Cells:	After thawing from the frozen stock, cells were seeded into flasks and incubated with "HAT" medium during the week prior to treatment to eliminate spontaneous HPRT-deficient mutants.
Cell treatment:	For each test group, about $5x10^5$ cells per flask were seeded into 75 cm^2 flasks containing about 10 mL Ham's F12 medium supplemented with 10% FCS and incubated for about 24 hours with 5% CO_2 at 37°C and ≥ 90% humidity for cell attachment. 2 x 2 flasks were used for each test group.

After the cell attachment period, the medium was replaced by the fresh (treatment) medium. In case of experiments without metabolic activation the treatment medium consisted of 9.9 mL Ham's F12 medium without FCS plus 100 µL positive control or test substance. In case of metabolic activation the treatment medium consisted of 7.9 mL Ham's F12 medium without FCS, 100 µL positive control or test substance preparation and 2 mL S9-mix.

The vehicle controls with and without S-9 mix only contained the vehicle DMSO at the same concentration and volume used in the cultures treated with either test substance or positive control (1%).

Concurrent negative and positive controls were tested in parallel. The cells were exposed for 4 hours both with and without S9-mix at 5% CO_2, 37°C and ≥ 90% humidity.

Expression:

After incubation for 4 hours, the treatment medium was replaced by 10 mL Ham's F12 medium with 10% FCS after having been rinsed twice with Hanks' balanced salt solution (HBSS). Subsequently, the flasks were incubated for another 17 - 24 hours; two flasks were pooled in each case and then subcultured (1^{st} passage). After two further passages (duration of the expression period is about 7-9 days), cells were transferred into selection medium (TG medium) at the 4^{th} passage.

Selection:

For the mutant selection, six 75-cm^2 flasks each were seeded with $3x10^5$ cells from each treatment group in selection medium (TG medium) and incubated for about 1 week. At the end of the selection period, colonies were fixed with methanol, stained with Giemsa and counted.

Determination of Cytotoxicity:

Cloning efficiency 1 (survival):

The survival (cloning efficiency 1; CE_1) was determined in parallel to the mutagenicity test. Approximately 200 cells per dose group were seeded into duplicate 25 cm^2 flasks using 5 mL Ham`s F12 medium with 10% FCS. After an approximately 24-hour attachment period, the cells were incubated with vehicle, test substance or the positive control for 4 hours. At the end of the treatment period the cells were washed twice with HBSS and the treatment medium was replaced by 5 mL Ham's F12 medium with 10% FCS. After a further incubation for 1 week the colonies were fixed, stained and counted.

Cloning efficiency 2 (viability):

The viability (cloning efficiency 2; CE_2) was determined in parallel to the selection of mutants. For each treatment group approx. 200 cells of each dose (cells pooled from 2 flasks) were taken in duplicate, seeded into Ham's F12 medium with 10% FCS (25-cm² flasks) and allowed to form colonies (incubator; 1 week). Afterwards, the colonies were fixed, stained and counted.

Calculations:

Mutant frequency:

Uncorrected mutant frequency:

$$MF_{uncorr} = \frac{total\,number\,of\ mutant\ colonies}{number\,of\ seeded\,cells} x\,10^6$$

Corrected mutant frequency:

$$MF_{corr} = \frac{MF_{uncorr}}{CE_{2\,absolute}} x\,100$$

Cloning efficiency (CE, %)

absolute:

$$CE_{absolute} = \frac{total\,number\,of\,colonies\,in\,the\,test\,group}{total\,number\,of\,seeded\,cells\,in\,the\,test\,group} x100$$

relative, in comparison to control:

$$CE_{relative} = \frac{CE\,of\,the\,dose\,group}{CE\,of\,the\,vehicle\,control} x100$$

4. Statistics:

Due to the negative findings, a statistical evaluation was not carried out.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- Increases of the corrected mutation frequencies ($MF_{corr.}$) both above the concurrent vehicle control values and the historical negative control range.
- Evidence of reproducibility of any increase in mutant frequencies.
- A statistically significant increase in mutant frequencies and the evidence of a dose-response relationship. Isolated increases of mutant frequencies above the historical negative control range (i.e. 15 mutants per 10^6 clonable cells) or isolated statistically significant increases without a dose-response relationship may indicate a biological effect but are not regarded as sufficient evidence of mutagenicity.

A test substance is generally considered negative in this test system if:

- The corrected mutation frequency ($MF_{corr.}$) in all dose groups is within the historical control range and is not significantly above the concurrent negative control.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance under storage conditions throughout the study period was guaranteed (Expiry date of the test item: November 2003). The stability of a comparable batch (01586-90) at room temperature in the vehicle DMSO over a period of 4 hours and in water over a period of 96 hours was verified analytically.

B. PRELIMINARY CYTOTOXICITY ASSAY

In the preliminary experiment, a test substance induced cytotoxicity leading to a reduction of relative cloning efficiency below 20% was observed at ≥ 500 µg/mL in the absence of metabolic activation. With metabolic activation the relative cloning efficiency was markedly reduced at ≥ 1000 µg/ml.

Precipitation of the test substance was only observed in the experiment without metabolic activation at concentrations ≥ 1000 µg/mL. No marked effect on osmolality and pH were observed.
Based on these data the highest concentration tested in the mutagenicity experiments without and with metabolic activation was 400 and 1000 µg/mL, respectively.

C. MUTAGENICITY ASSAYS

No relevant increase in the number of mutant colonies was observed in the original and confirmatory experiments with and without metabolic activation [see Table 5.8.1-41 and Table 5.8.1-42]. The mutant frequencies obtained at any tested concentration with or without metabolic activation were within the range of the historical negative control data.

Cytotoxicity as determined by the relative cloning efficiency was decreased at concentrations > 200 µg/mL in the first and second experiment without metabolic activation. With metabolic activation cytotoxicity was observed at 1000 µg/mL in both experiments.

Treatment with the positive controls EMS and MCA resulted in a marked increase in the number of mutant colonies as well as of mutant frequencies in all experiments, thus demonstrating the sensitivity of the test.

The pH and osmolality of the tested concentrations were not altered at the concentrations tested. Test substance precipitation did not occur up the highest tested concentration of 1000 µg/mL.

III. CONCLUSION

Based on the results of the study it is concluded that under the conditions of the test 500M76 (Reg. No. 413038, metabolite of pyraclostrobin) does not induce forward mutations in the HPRT locus in CHO cells in vitro.

Executive Summary

Reg.No. 413038 (metabolite of pyraclostrobin; batch: 01586-236, purity: 94.5%) was tested in vitro for the ability to induce chromosome and numerical aberrations in Chinese Hamster V79 cells in two independent experiments in the presence and absence of metabolic activation at concentrations of 62.5 µg/mL to 850 µg/mL with a pulse treatment of 4 hours. The cells were prepared 18 h post treatment-begin. Vehicle (DMSO) and positive controls (cyclophosphamide (CPP) and ethylmethanesulfonate (EMS) for the experiment with and without metabolic activation, respectively) were included to demonstrate the sensitivity of the test system.

Strong cytotoxicity was found from concentrations of ≥ 600 µg/mL in experiments without metabolic activation and ≥ 800 µg/mL in the experiments with metabolic activation.

The test substance caused a statistically significant increase in the number of structurally aberrant metaphases incl. and excl. gaps after 4 hours treatment at 18-hour sampling time in the absence and presence of a metabolizing system. In the presence of metabolic activation, the increase was confirmed in an independently performed repeat experiment. No biologically relevant increase in the frequency of cells containing numerical chromosome aberrations was observed.
Based on the results of this study, Reg.No. 413038 is considered to have a clastogenic potential in vitro in Chinese hamster V79 cells in the presence or absence of metabolic activation.

(BASF DocID 2012/1044766)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg.No. 413038 (Metabolite of BAS 500 F, pyraclostrobin)

Description:	Solid, lightbrown
Lot/Batch #:	01586-236
Purity:	94.5%
Stability of test compound:	The test substance was stable over the study period under the storage conditions (Expiry date: 01-Nov-2003). The homogeneity of the test substance was guaranteed, by grinding before preparation of the test substance preparations. The stability of a comparable batch (01586-90) at room temperature in the vehicle DMSO over a period of 4 hours and in water over a period of 96 hours was verified analytically (BASF study code 40M0249/994128).
Solvent used:	Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control:	A negative control was not employed in this study
Solvent control:	DMSO
Positive control, -S9:	Ethylmethanesulfonate 350 µg/mL
Positive control, +S9:	Cyclophosphamide 0.5 µg/mL

3. Activation: S9 was produced from the livers of 5 induced male Wistar Sprague-Dawley rats. The rats received a single intraperitoneal injection of 500 mg Aroclor 1254 (as solution in corn oil with a concentration of 20 g/100 mL) per kg body weight. 5 days after administration the animals were sacrificed. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction was thawed at room temperature and 1 volume of S9-fraction was mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9-mix, was kept on ice until used.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4. Test organisms: Chinese hamster V79 cells

5. Culture medium: MEM medium containing a L-glutamine source supplemented with
- 10% (v/v) fetal calf serum (FCS)
- 1% (v/v) penicillin/streptomycin (10000 IU/10000 µg/mL)
- 1% (v/v) amphotericine B (250 µg/mL)

During exposure to the test substance (only 4-hour treatment), MEM medium was used without FCS supplementation.

6. Test concentrations:

a) Preliminary toxicity assay: Eight to nine concentrations ranging from 5 to 4000 µg/mL were used in pretests for dose selection for the main experiments. V79 cells were prepared at a sampling time of 18 hours after 4 and 18 hours exposure time without metabolic activation and after 4 hours exposure time with metabolic activation.

b) Mutation assay:

1st experiment: 62.5, 125, 250, 500 and 750 µg/mL with and without metabolic activation (18 h preparation interval)

2nd experiment: 400, 450, 500, 550, 600 and 650 µg/mL without metabolic activation (18 h preparation interval)
600, 650, 700, 750, 800 and 850 µg/mL with metabolic activation (18 h preparation interval)

B. TEST PERFORMANCE:

1. Dates of experimental work: 25-Sep-2002 to 17-Jan-2003

2. Preliminary cytotoxicity assay:

A range-finding cytotoxicity test was conducted with V79 cultures exposed to test substance concentrations of 5 - 4000 µg/mL for 4 and 18 hours without metabolic activation and for 4 hours with metabolic activation, respectively. At the end of the exposure period, cell count, cell attachment, mitotic index and the quality of slides were determined in order to derive appropriate test substance concentrations for the main test.

3. Cytogenicity Assay:

Cell treatment:	Cells were exposed to the test substance, solvent or positive control in pulse treatment experiments for 4 hours with or without metabolic activation. The cells were incubated in Quadriperm® dishes at 37°C, 5% CO_2 and ≥ 90% humidity. Two chambers of a Quadriperm dish were used for each concentration (=duplicate cultures). The preparation interval was 18 h post treatment-begin. For determination of cytotoxicity, additional cell cultures (using 25 cm² plastic flasks) were treated in the same way as in the main experiment. Growth inhibition was estimated by comparing the cell number in the treated groups with the concurrent control.
Spindle inhibition:	100 µL colcemide (stock: 10 µg/mL phosphate buffered saline) was added to the cultures 2 - 3 hours prior to harvesting.
Cell harvest:	At the end of the incubation time the culture medium was completely removed. For hypotonic treatment, 5 mL of a 0.4% KCl solution (37°C) was added for about 20 minutes. The cells were fixed by addition of 5 mL methanol/glacial acetic acid (3:1 v/v). The fixative was changed twice.
Slide preparation:	The slides were removed from the Quadriperm chambers, briefly allowed to drip off and passed through a Bunsen burner flame. After drying, the cells were stained with Giemsa and Titrisol. After rinsing and clarifying in Xylene the cover slips were mounted in Corbit-Balsam.

Metaphase analysis:	Slides were coded prior to analysis. As a rule, the first 100 consecutive well spread metaphases of each culture were counted for all test groups, and if cells had 20 - 22 chromosomes, they were analyzed for structural chromosome aberrations. Numerical chromosome aberrations were also recorded. If there is a clear increase in chromosomally damaged cells, the number of metaphases to be analyzed can be reduced to at least 50 mitoses/test group. A mitotic index based on 1000 cells per culture was determined for all evaluated test groups in both experiments.

4. Statistics:

The proportion of metaphases with aberrations was calculated for each group.

A comparison of each dose group with the vehicle control group was carried out using Fisher's exact test for the hypothesis of equal proportions. This test was Bonferroni-Holm corrected versus the dose groups separately for each time and was performed one-sided.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A statistically significant, dose-related, and reproducible increase in the number of structural chromosomal aberrations (excl. gaps).
- The proportion of aberrations (excl. gaps) exceeded both the concurrent negative control range and the historical negative control range.

A test substance is generally considered negative in this test system if:

- The number of cells with structural aberrations (excl. gaps) in the dose groups is not statistically significant increased above the concurrent vehicle control value and is within the historical negative control data range.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS:

The stability of the test substance under storage conditions throughout the study period was proven. The stability of a comparable batch (01586-90) at room temperature in the vehicle DMSO over a period of 4 hours and in water over a period of 96 hours was verified analytically (BASF study code 40M0249/994128).

B. PRELIMINARY CYTOTOXICITY ASSAY:

A preliminary cytotoxicity assay was performed to determine appropriate test substance concentrations for the main test. A recduction of cell counts or mitotic indices below 50% of the control value were observed at concentrations ≥ 500 µg/mL in the absence and at condentrations ≥ 750 µg/mL in the presence of metabolic activation. Accordingly, 750 µg/mL with and without metabolic activation was selected as the top dose for the 1st experiment of the main test. 850 µg/mL with metabolic activation and 650 µg/mL without metabolic activation were selected as the top doses for the 2nd experiment of the main test.

C. CYTOGENICITY ASSAYS:

In this study, cells could be evaluated up to 600 µg/mL in the experiments without metabolic activation and up to 800 µg/mL in the experiments with metabolic activation. Higher concentrations were not scorable due to strong cytotoxicity and/or poor metaphase quality.

In the first experiment, a staticitcally significant increase in structural aberrant metaphase cells was observed after 4 hours of exposure in the absence of metabolic activation at a concentration of 500 µg/mL. This increase was not confirmed under the same conditions in the 2nd experiment. In the 1st experiment with metabolic activation a statistically significant increase of structural chromosome aberrations was noted at 750 µg/mL. In the 2nd experiment performed with metabolic activation, the aberration rates at 700 and 750 µg/mL were below the concurrent vehicle control, but at 800 µg/mL an increased aberration rate was observed, exceeding the vehicle control and the historical vehicle control data [see Table 5.8.1-43 to Table 5.8.1-46].

With regard to numerical chromosome abberations, an increase in endopolyploid cells of about 6.1% was observed in the 1st experiment after 4 hours of exposure without metabolic activation at 500 µg/mL and an increase of 2.4% at 750 µg/mL with metabolic activation. Whereas the former exceeded the negative historical control range the latter was well within the historical control. As these increases were not reproducible in the second experiment they were regarded as incidental and not biologically relevant.

The osmolarity and pH values were not relevantly influenced by the test substance treatment. Precipitation of the test substance did not occur up to the highest tested concentration. Vehicle and positive controls were all in a range to ensure the validity of the test.

III. CONCLUSION

500M76 (Reg.No. 413038, a metabolite of pyraclostrobin) is considered to have a clastogenic potential under in vitro conditions in V79 cells at least in the presence of metabolic activation. The situation without metabolic activation is unclear as the clastogenic activity observed after 4 hours could not be confirmed in the second experiment under the same conditions. In absence of an experiment with 18 hour exposure without metabolic activation a final assessment can not be conducted. Nonetheless, this does not affect the principal fact that Reg.No. 413038 has clastogenic activity in vitro.

The relevance of this in vitro result was evaluated in a higher tier in vivo study (see below) according to Commission Regulation (EU) No 283/2013, Section 5.4.2.

Table 5.8.1-43: Chromosome aberration test with Reg.No. 413038 without metabolic activation (4 hours treatment, harvest after 18 hours) - Experiment 1

#. Evaluation of a sample of 400 metaphases due to inhomogeneous data, when scoring a reduced sample

Report:	CA 5.8.1/37 [redacted] 2012e Reg.No. 413038 (Metabolite of BAS 500 F, Pyraclostrobin) - Micronucleus test in bone marrow cells of the mouse 2012/1220183
Guidelines:	OECD 474 (1997), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.12, EPA 870.5395
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Reg.No. 413038 (metabolite of BAS 500 F; batch: L83-122, purity: 99.0%) was tested for chromosomal damage (clastogenicity) and for the ability to induce spindle poison effects (aneugenic activity) in NMRI mice using the micronucleus test method. For this purpose, the test substance was administered once orally to groups of 5 male mice at dose levels of 125, 250 and 500 mg/kg body weight. The vehicle served as negative and cyclophosphamide and vincristine sulfate as positive controls. The animals were sacrificed 24 or 48 (additional high dose and vehicle group) hours after the administration and the bone marrow of the two femora was prepared and investigated for micronuclei.

The oral administration of Reg.No. 413038 did not lead to any biologically relevant increase in the number of polychromatic erythrocytes containing either small or large micronuclei. The rate of micronuclei was mostly close to the concurrent negative control and was within the range of the historical control data. Inhibition of erythropoiesis, determined from the ratio of polychromatic to normochromatic erythrocytes, did not occur. At the MTD (500 mg/kg body weight) lethality was observed in several animals. Due to a missing indication for a genotoxic effect induced by the test substance in any dose group this deviation from the guidelines is considered to have no detrimental impact on the validity of the study. It has to be assumed that the unexpected strong systemic toxicity in deviation to the pretest is due to the use of a highly purified batch of the test substance in the main experiment.

Both of the positive control chemicals, i.e. cyclophosphamide for clastogenic effects and vincristine for induction of spindle poison effects, led to the expected increase in the rate of polychromatic erythrocytes containing small (cyclophosphamide) or small and large (vincristine sulphate) micronuclei, thus demonstrating the sensitivity of the test system.

Reg.No. 413038 does not induce the formation of micronuclei in mouse polychromatic erythrocytes under the conditions of the study, i.e. is devoid of clastogenic or aneugenic activity in vivo.

(BASF DocID 2012/1220183)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description:	Reg.No. 413038 (Metabolite of pyraclostrobin)
Lot/Batch #:	Solid, yellowish
Purity:	L83-122
Stability of test compound:	99.0% (tolerance ± 1.0%)
	The stability of the test substance under storage conditions throughout the study period was guaranteed until 01 Apr 2014 as indicated by the sponsor. Homogeneity of the test substance was guaranteed on account of the high purity and was ensured by mixing before test substance preparation.
Vehicle used:	DMSO and subsequent emulsion in corn oil

2. Control Materials:

Negative:	No negative control was employed in this study.
Vehicle control:	DMSO and subsequent emulsion in corn oil
Positive control:	Cyclophosphamide (CCP) 20 mg/kg for the determination of clastogenic effects Vincristine sulphate (VCR) 0.15 mg/kg for the determination aneugenic effects

3. Test animals:

Species:	Albino mice
Strain:	Crl:NMRI
Sex:	Male for the main study; male and female for the range finding study
Age:	5 - 8 weeks
Mean body weight at dosing:	30.0 g
Source:	Charles River Laboratories Germany GmbH
Number of animals per dose:	
Range finding study:	Not indicated in the report
Micronucleus assay:	5 males/dose; due to the unexpected mortality at 500 mg/kg bw, each two additional animals were dosed for the 24 and 48 hour sacrifice, respectively.
Acclimation period:	At least 5 days
Diet:	Standardized pelleted feed (Maus/Ratte Haltung "GLP", Provimi Kliba SA, Kaiseraugst, Switzerland)
Water:	Drinking water in bottles, ad libitum
Housing:	During the study the mice were housed individually in Makrolon cages, type MII

4. Environmental conditions:

Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	frequency not indicated (fully air-conditioned rooms)
Photo period:	12-hour light-dark cycle (06:00 - 18:00, 18:00 - 06:00)

5. Test compound doses:

Range finding test:	500, 750 and 1000 mg/kg (The pretests with 500 and 1000 mg/kg body weight were performed with a different batch (No. L83-78) with a reduced purity of only 92.1%.)
Micronucleus assay:	125, 250 and 500 mg/kg The test substance was administered once by oral gavage using an application volume of 10 mL/kg.

B. TEST PERFORMANCE

1. Dates of experimental work: 30-Apr-2012 to 29-Aug-2012

2. Preliminary range finding test:

Male and female NMRI mice were treated once by oral gavage with a test substance dose of 500, 750 or 1000 mg/kg bw.

3. Micronucleus test:

Treatment and sampling:	Groups of 5 male mice were treated once with either the vehicle or 125, 250 or 500 mg test substance/kg bw by oral gavage. Additional test groups treated with the vehicle control and the high dose were used for the second sampling period. The application volume was 10 mL/kg bw and the volume to be applied was calculated based on actual weight on the day of administration. The positive control substances CCP and VCR were administered once by oral gavage (CCP) or i.p. injection (VCR). The animals were observed for evident clinical signs of toxicity throughout the study.

Twenty-four hours after the administration the mice were sacrificed and the two femora were prepared free of all soft tissue. After cutting the epiphyses the bone marrow was flushed out in a centrifugation tube with fetal calf serum and subsequently centrifuged at 300xg for 5 minutes. The supernatant was discharged and the pellet resuspended in about 50 µl fresh FCS. The sampling of the femora from the additional high dose and vehicle control group was performed as described above 48 h after the treatment.

Slide preparation: One drop of the suspension was applied on a clean microscopic slide and smears were prepared. After air drying the smears were stained with May Grünwald solution, rinsed, and finally stained with Giemsa solution (7.5%). After rinsing and clarifying in xylene, the preparations were mounted. The slides were coded prior to microscopic evaluation.

Slide evaluation: In general, 2000 polychromatic erythrocytes (PCEs) from each male animal of every test group were evaluated and investigated for micronuclei (MN). The normochromatic erythrocytes (NCEs) that occurred were also scored.
The increase in the number of micronuclei in polychromatic erythrocytes of treated animals as compared to the vehicle control group provides an index of a chromosome-breaking (clastogenic) effect or of a spindle activity (aneugenic) of the substance tested.

In addition, the number of small micronuclei ($d < D/4$) and of large micronuclei ($d \geq D/4$) (d = diameter of micronucleus, D = cell diameter) was determined: The size of micronuclei may indicate the possible mode of action of the test substance, i.e. a clastogenic or a spindle poison effect.

The ratio of polychromatic to normochromatic erythrocytes was calculated. An alteration of this ratio indicates a toxic effect on erythropoieses and thus, that the test substance actually reached the target organ.

4. Statistics:

The number of polychromatic erythrocytes with micronuclei was analyzed by comparing the dose groups with the vehicle control using the Mann-Whitney U-test (modified rank test according to Wilcoxon). Here, the relative frequencies of cells with micronuclei of each animal were used.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A dose-related and significant increase in the number of micronucleated polychromatic erythrocytes was observed.
- The proportion of cells containing micronuclei exceeded both the values of the concurrent vehicle control range and the vehicle historical control range.

A test substance is generally considered negative in this test system if:

- There was no significant increase in the number of micronucleated polychromatic erythrocytes at any dose above concurrent control frequencies.
- The frequencies of cells containing micronuclei were within the historical control range.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance in the vehicle was verified analytically. The homogeneity of the test substance in the vehicle was guaranteed by constant stirring during the removal and administration of the test substance formulation and by analytical determination of 3 individual samples of each concentration. Due to a technical error in storage of the original samples, the retained samples were measured and reported. The mean test substance concentrations were determined as 13.7, 24.0, 50.2 and 51.7 mg/mL at nominal concentrations of 12.5, 25, 50 and 50 mg/mL, respectively (the latter 50 mg/mL value is for the dosing preparation used for the additional animals). These values correspond to 96% to 110% of the nominal cioncentration, which is within the expected range (90-110%). The preparations were homogenous as the relative standard deviations of the three individual samples were in the range of 1.0 to 0 6.2%. Only for the low concentration preparation the RDS was 15.1% indicating a lower homogeneity. However, as this was the low dose and no increase of micronucleated polychromatic erythrocytes was observed, this does not affect the validity of the study.

B. PRELIMINARY RANGE FINDING TEST

In the pretest in males and females, deaths were observed down to 750 mg/kg. At 500 mg/kg, all animals survived without signs of toxicity. There were no distinct differences between male and female animals. Thus, only male animals were used for the main experiment.

In contrast to the main study, the preliminary toxicity test was performed with batch L83-78 with a lower purity of 92.1%. The difference in toxicity observed at 500 mg/kg bw between the batches used for the pre-test and the main study may have been due to the higher purity of main study batch L83-122 (99.0% versus 92.1%).

C. MICRONUCLEUS ASSAY

Treatment of mice with Reg.No. 413038 did not lead to a biologically relevant increase in the rate of micronuclei (see Table 5.8.1-47). Micronucleus frequencies of treated animals were near to the concurrent vehicle control values and within the historical control range (0.3 to 3.0% for the vehicle olive/corn oil and 0.4 to 2.4% for the vehicle DMSO). The number of normochromatic or polychromatic erythrocytes containing small or large micronuclei did not deviate from the vehicle control value and was within the historical control range.

The PCE/NCE ratio was not affected by treatment with the test substance. Thus, there was no indication that erythropoiesis was inhibited.
The clastogenic activity of the positive control substance cyclophosphamide was evident by the increase in the number of PCE containing exclusively small micronuclei (16.0‰). The administration of the spindle poison vincristine resulted in an incidence of micronuclei in polychromatic erythrocytes of 30.7‰. This included 9.8‰ of PCE with large micronuclei. The positive controls thus demonstrated the sensitivity of the test system.

The administration of the test substance led to distinct clinical signs of toxicity. At 500 mg/kg body weight, three out of the ten animals died within 4 hours after test substance administration (2 animals of the 24 hour and 1 animal of the 48 hour sacrifice group). Therefore, additional four animals were treated with the top dose. However, further two animals died before reaching the respective sacrifice interval. As a consequence, there were only 4 instead of 5 animals for the determination of micronuclei for the 48 hour sacrifice group. In absence of an indication for a genotoxic effect in any dose group this deviation from the guideline is not considered to affect the validity of the study.

No signs of systemic toxicity were observed in any of the animals treated with the positive control substances or the vehicle.

The bioavailability of the test-item was determined by the analysis of blood samples withdrawn at sacrifice. In the 24 hours plasma samples the test item was quantifiable in 1/5 samples of the 250 mg/kg bw dose and in 5/5 samples of the 500 mg/kg bw dose group. In 4/5 samples of the 250 mg/kg bw group the test-item was detected, but the quantity was below the limit of quantification. Reg.No. 413038 was not detectable in samples from control animals, from the 125 mg/kg bw group and the 500 mg/kg bw 48 hour sacrifice group. The aforementioned analysis of the Reg.No. 413038 plasma concentration was performed with a method which was retrospectively validated. The validation report can be found in M-CA 4 (see BASF DocID 2016/1311551). As the bone marrow is highly perfused by blood, the plasma analysis revealed proof that Reg.No. 413038 reached its target tissue.

Table 5.8.1-47: Micronucleus test in mice administered Reg.No. 413038 by oral gavage

Treatment	PCE				NCE		PCE/NCE ratio

III. CONCLUSION

Based on the result of this study 500M76 (Reg.No. 413038, metabolite of pyraclostrobin) does not induce the formation of micronuclei in mouse polychromatic erythrocytes under the conditions of the study, i.e. is devoid of clastogenic or aneugenic activity in vivo. The analysis of Reg.No. 413038 in rat plasma demonstrated that the test item reached the target organ (bone marrow). Thus, the clastogenicity observed in vitro is not relevant under in vivo conditions.

Overall toxicological evaluation of 500M76 (Reg.No. 413038)

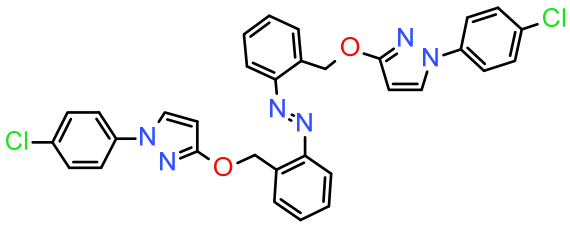
The QSAR evaluation of 500M76 is of low reliability and by weight of evidence there is no conclusive alert for genotoxicity.

By weight of evidence 500M76 is not genotoxic based on the in vitro and in vivo studies conducted. Therefore, 500M76 is considered to be **not toxicologically relevant**.

With regard to consumer exposure the TTC concept for non-genotoxic compounds was applied. Thus an ADI of 0.0015 mg/kg bw/day as well as an ARfD of 0.005 mg/kg bw/day was established. The estimated exposure (up to 15% of TTC of 0.005 mg/kg bw/day for acute and 0.2% of TTC 0.0015 mg/kg bw/day for chronic exposure) is low.

Metabolites identified in new metabolism studies

500M02 (other denominators: Reg.No. 369315, BF 500-7)



500M02 (Reg.No. 369315), a metabolite found in soil and sediment, was already evaluated during the previous Annex I listing process. It has been newly found in the comparative in vitro metabolism study (see M-CA 5.1).

A) QSAR Predicitions for 500M02 (Reg.No. 369315, BF 500-7)

OECD Toolbox (Version: 3.2) [see DocID 2014/1172955]

The OECD Toolbox revealed the alert '*AN2|AN2 >> Carbamoylation after isocyanate formation|AN2 >> Carbamoylation after isocyanate formation >> N-Hydroxylamines|Radical |Radical >> Radical mechanism via ROS formation (indirect)|Radical >> Radical mechanism via ROS formation (indirect) >> N-Hydroxylamines|SN1|SN1 >> Nucleophilic attack after metabolic nitrenium ion formation|SN1 >> Nucleophilic attack after metabolic nitrenium ion formation >> N-Hydroxylamines*' as DNA Alert for Ames, MN and CA. No protein binding alert was found.

Discussion: The identified alert is present in a number of metabolites which - like 500M02 (Reg.No. 369315) - were tested negative in Ames (Reg No 412785 - 500M62, 500M49 (Reg.No. 5916420)). In addition, 500M49 (Reg.No. 5916420) was in the mammalian gene mutation test. Therefore, the prediction does not adequately reflect the experimental database and the prediction is rejected.

OASIS TIMES (MIX V.2.27.13 TB; Mutagenicity S-9 activated v08.08) [see molecule 10 of report DocID 2014/1172952 and 2014/1172953]

The Ames mutagenicity alert for 500M02 (Reg.No. 369315) was negative (out of domain), however 1/5 in-silico generated metabolites had a positive alert (N-Hydroxylamines; in domoain). The in vitro CA alert for 500M02 (Reg.No. 369315) was negative (out of domain), however 5/6 in-silico generated metabolites had a positive alert with three different alerts (Phenols, Substituted Anilines, N-Hydroxylamines). All positive alerts were in domain.

Discussion: The alert identified for the Ames test is also present in 500M62 (Reg.No. 412785) and 500M49 (Reg.No. 5916420) which like 500M02 (Reg.No. 369315) tested negative in the Ames test. The alerts identified for the in vitro chromosome aberration were also present in pyraclostrobin (phenols) and metabolites 500M49 (Reg.No. 5916420; Substituted Anilines and N-Hydroxylamines), 500M60 (Reg.No. 411847) and 500M76 (Reg.No. 413038). The in vitro CA for pyraclostrobin and 500M49 (Reg.No.5916420) were negative. In the cases of 500M60 (Reg.No. 411847) and 500M76 (Reg.No. 413038) the positive in vitro CA was not confirmed in the negative higher tier in vivo mouse micronucleus test. Therefore, the weight of evidence indicates that 500M02 (Reg.No. 369315) does not cause chromosome aberrations. The positive alerts are therefore rejected.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 10 of report BASF DocID 2014/1172954 for bothVEGA models]

500M02 (Reg.No. 369315) is out of model applicability domain. The prediction is ‘mutagen’ with the alert ‘Aromatic diazo’. The prediction is based on 6 molecules, of which only one was a predicted, but not an actual mutagen. All other five molecules were predicted non-mutagens, which was experimentally confirmed. The similarity of the molecules in the data set to 500M02 (Reg.No. 369315) is low as indicated by similarity factors of 0.536 to 0.593. Based on the negative Ames test (see CA 5.8.1/9) the positive prediction for genotoxicity does not reflect the experimental evidence. Therefore, the positive prediction is rejected.

VEGA: Mutagenicity model (SarPy; version 1.0.4-BETA)

500M02 (Reg.No. 369315) is out of model applicability domain. The prediction is ‘mutagen’ with the structural alert SA 96. As discussed above, this alert was also obtained for pyraclostrobin and a number of pyraclostrobin metabolites, which like 500M02 (Reg.No. 369315) were actually tested negative. The predicition is therefore rejected.

DEREK (Version 2.0.0.201011301322; Knowledge base version: 11_20_05_2010)

This metabolite was not assessed.

Genotoxicity studies on 500M02 (Reg.No. 369315, BF 500-7)

Report: CA 5.8.1/38
Engelhardt G., Hoffmann H.D., 1999a
Salmonella typhimurium/Escherichia coli reverse mutation assay (AMES standard plate test and prival preincubation test) with Reg.No. 369 315
1999/10736
Guidelines: OECD 471, EEC 92/69 B 13, EEC 92/69 B 14
GLP: no

Executive Summary

S. typhimurium and E. coli were exposed to Reg.No. 369315 (batch: 01185-022, purity: 99.9%) using dimethylsulfoxide (DMSO) as a solvent in the presence and absence of metabolic activation in two independent experiments. Triplicate plates were used per dose and per test condition. Vehicle and positive controls were included in each experiment.

In the Ames standard plate test (SPT) Reg.No. 369315 was tested in concentrations of 20 to 5000 µg/plate with and without S9 mix (Aroclor-induced rat liver S9 mix). In the prival preincubation assay the test item was tested in concentrations of 4 to 2500 µg/plate only with metabolic activation (uninduced hamster liver S9 mix). As a deviation from the guidelines the pre-incubation test (PIT) was only performed with metabolic activation and the PIT lacked the use of E.coli WP2 uvrA.

Precipitation of the test substance was found from about 100 µg/plate onwards with and without S9 mix. A slight decrease in the number of revertants was occasionally observed in the preincubation assay depending on the strain from about 500 µg/plate onwards.

A biologically relevant increase in the number of revertant colonies was not noticed in any of the strains tested in presence or absence of metabolic activation in any of the experiments. The positive controls induced the appropriate response in the corresponding strains, thus demonstrating the sensitivity of the test system.

According to the results of the study, the test substance Reg.No. 369315 is not mutagenic in the Ames standard plate test and Prival preincubation test under the experimental conditions of the study.

(BASF DocID 1999/10736)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Reg.No. 369315

Description: Powder, orange

Lot/Batch #: 01185-022

Purity: 99.9%

Stability of test compound: The stability of the test substance throughout the study period has not been verified by reanalysis. The homogeneity of the test substance was guaranteed by mixing before preparation of the test substance formulations and on account of the high purity. The stability of the test substance in the vehicle DMSO has not been determined analytically.

Solvent used: Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control: In parallel to each experiment, negative control experiments were carried out in order to check for possible contaminants (sterility control) and to determine the spontaneous mutation rate (vehicle control).

Vehicle control: The vehicle control with and without S-9 mix only contained the vehicle used for the test substance at the same concentration and volume for all tester strains.

Solvent/final concentration: 100 µL/plate

Positive control compounds tested without addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1535	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1537	9-Aminoacridine (AAC)	DMSO	100 µg/plate
TA 98	4-nitro-o-phenylendiamine (NOPD)	DMSO	10 µg/plate
WP2 uvrA	4-nitroquinoline-N-oxide (4-NQO)	DMSO	5 µg/plate

Positive control compounds tested with addition of rat metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1535	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1537	2-aminoanthracene	DMSO	2.5 µg/plate
TA 98	2-aminoanthracene	DMSO	2.5 µg/plate
WP2 uvrA	2-aminoanthracene	DMSO	60.0 µg/plate

Positive control compounds tested with addition of hamster metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	2-aminoanthracene	DMSO	10 µg/plate
TA 1535	2-aminoanthracene	DMSO	10 µg/plate
TA 1537	2-aminoanthracene	DMSO	10 µg/plate
TA 98	2-aminoanthracene	DMSO	10 µg/plate
	Congo red	DMSO	0.3µmol/plate
	Benzidine	DMSO	0.3µmol/plate

3. Activation:

S9 was produced from the livers of induced male Sprague-Dawley rats and from male Syrian hamsters. The rats received a single intraperitoneal injection of 500 mg/kg bw Aroclor 1254, while the hamsters remained untreated. Five days after administration the animals were sacrificed. The hamsters were not subjected to any inducing agent. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction is thawed at room temperature and 1 volume of S9-fraction is mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9-mix, was kept on ice until used.

The rat liver S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

To demonstrate the efficacy of the rat liver S9 mix in this assay, the S9 batch was characterized with benzo(a)pyrene.

The hamster liver S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	20 mM
Glucose 6-phosphate dehydrogenase	2.8 units/mL
NADP	4 mM
NADH	2 mM
KCl	33 mM
$MgCl_2$	8 mM
FMN	2 mM
S9	10%

The efficacy of the hamster liver S9 mix was demonstrated by testing the two positive control articles Congo red and benzidine.

4. Test organisms:

S. typhimurium strains: TA98, TA100, TA1535, TA1537
E. coli: WP2 uvrA

Salmonella typhimurium:

The Salmonella strains are checked for the following characteristics at regular intervals: deep rough character (rfa); UV sensitivity (uvrB); ampicillin resistance (R factor plasmid).
E. coli: E. coli WP2 uvrA is checked for UV sensitivity.

Histidine and tryptophan auxotrophy is automatically proven in each experiment via the spontaneous rate.

5. Test concentrations:

Plate incorporation assay:

In the first experiment triplicate plates were prepared for each concentration (neg. control; 20, 100, 500, 2500 and 5000 µg/plate and positive controls at the concentrations indicated above) and conditions (i.e. with and without rat liver S9 mix) for all tester strains indicated above.

Prival preincubation assay:

In the second experiment the test article / vehicle / positive control substance, bacterial and hamster liver S9 mix were incubated at 30°C for the duration of about 30 minutes. Triplicate plates were prepared for each concentration (neg. control; 4, 20, 100, 500 and 2500 µg/plate and positive controls at the concentrations indicated above) for TA98, TA100, TA1535 and TA1537.

B. TEST PERFORMANCE:

1. Dates of experimental work: not given, finalization date: 09-June-1999

2. Plate incorporation assay:

To test tubes containing 2-mL portions of warm soft agar (containing 0.5 mM histidine + 0.5 mM biotin), 0.1 mL test solution or vehicle, 0.1 mL fresh bacterial culture, 0.5 mL S9-mix (in tests with metabolic activation) or 0.5 mL phosphate buffer (in tests without metabolic activation) were added in the given order. After mixing, the samples are poured onto Vogel-Bonner agar plates (minimal glucose agar plates). In the experiments with E. coli the warm soft agar contains 0.5 mM tryptophan instead of histidine + biotin and the samples were poured onto minimal agar plates. After incubation at 37°C for 48 - 72 hours in the dark, the bacterial conolonies (his^+ revertants) are counted.

3. Prival preincubation assay:

100 µL of test solution or vehicle, 0.1 mL bacterial suspension and 0.5 mL S9 mix were incubated at 30°C for about 30 minutes. Subsequently, 2 mL of soft agar was added and, after mixing, the samples are poured onto the agar plates.

After incubation in the dark for 48 to 72 hours at 37°C revertant colonies were counted. Means and standard deviations were calculated.

4. Titer determination:

In order to assess bacteriotoxic effects, the titer was additionally determined in experimental parts with S9 mix using the vehicle control and the two highest doses. The procedure followed in both experiments (plate incorporation and pre-incubation) was the same as described above for the individual experiments with the exception that the soft agar used contained maximal amino acid solution (5 mM tryptophan or 5 mM histidine + 0.5 mM biotin). After the incubation in the dark for 48 hours at 37°C the number of bacterial colonies was determined.

5. Statistics:

No special statistical tests were performed.

6. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A dose-related and reproducible increase in the number of revertant colonies, i.e. about doubling of the spontaneous mutation rate in at least one tester strain either without S9 mix or after adding a metabolizing system.

A test substance is generally considered non-mutagenic in this test if:

- The number of revertants for all tester strains was within the historical negative control range under all experimental conditions in two experiments carried out independently of each other.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance at room temperature in the vehicle DMSO and water was not verified analytically.

B. TOXICITY

A preliminary cytotoxicity assay was not performed in this laboratory. Cytotoxicity was determined in the course of the mutation assay.

No bacteriotoxic effect was observed in the Ames standard plate test. In the Prival preincubtion assay a slight decrease in the number of revertants was occasionally observed depending on the strain from about 500 µg/plate onwards.

C. MUTATION ASSAYS

Neither in the plate incorporation nor in the Prival preincubation experiment with and without metabolic activation was a biologically relevant increase in number of revertants observed in any strain tested [see Table 5.8.1-48]. The positive controls yielded revertant numbers in a range expected for the respective strains and thus demonstrated the sensitivity of the test system.

Test item precipitation was observed from 100 µg/plate onwards with and without S9 mix.

III. CONCLUSION

According to the results of the present study, the test substance 500M02 (Reg.No. 369315, BF 500-7) is not mutagenic in the Ames standard plate test and in the Prival preincubation test under the experimental conditions chosen here.

Based on some experimental deficits of the above study (no GLP status, no testing without metabolic activation in S. typhimurium and no testing of E.coli in the in the Prival preincubation assay), a second, fully guideline conform study was conducted.

Report:	CA 5.8.1/39 Woitkowiak C., 2016 a Reg.No. 369315 (metabolite of BAS 500 F, Pyraclostrobin) - Salmonella typhimurium/Escherichia coli - Reverse mutation assay (prival modification) 2016/1200488
Guidelines:	OECD 471, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.13/B.14 No. L 142, EPA 870.5100
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

S. typhimurium strains TA 98, TA 100, TA 1535 and TA 1537, and a strain of *E. coli* WP2 uvrA were exposed with Reg.No. 369315 (metabolite of pyraclostrobin, batch: L85-192, purity: 98.3%) in the presence and absence of metabolic activation for 48 - 72 hours. Vehicle (DMSO) and positive controls were included in each experiment. In the Ames standard plate test (SPT) and the Prival pre-incubation test (pPIT), the test item was tested in triplicates of six concentrations in a range of 33 to 5000 µg/plate with and without S9 mix (phenobarbital/ß-naphthoflavone-induced rat liver S9 fraction (SPT) or uninduced hamster liver S9 fraction (pPIT)). The modified Bacterial Reverse Mutation Test according to Prival, in which flavin mononucleotide (FMN), liver S9 mix from uninduced hamsters and a pre-incubation step are used facilitates azo reduction and is therefore the most appropriate method for the investigation of azo-dyes and diazo compounds.

Test substance precipitation was found from about 333 µg/plate onward in SPT and from about 1000 µg/plate onward in pPIT with and without S9 mix.
No bacteriotoxic effect was observed up to the highest concentration tested with and without metabolic activation.
A relevant increase in the number of his^+ and trp^+ revertants was not observed in SPT and pPIT either without S9 mix or after the addition of a metabolising system. The positive controls induced the appropriate response in the corresponding strains, thus demonstrating the sensitivity of the test system. The vehicle control induced number of revertants was within the range of the historical control data for each strain.

Based on the results of the present study, Reg.No. 369315 (Metabolite of pyraclostrobin) is not mutagenic in the Ames standard plate test and Prival pre-incubation test with and without metabolic activation under the experimental conditions chosen.

(BASF DocID 2016/1200488)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg.No. 369315 (metabolite of pyraclostrobin)

Description:	Solid, orange
Lot/Batch #:	L85-192
Purity:	98.3%
Stability of test compound:	The stability of the test substance is guaranteed until 01-May-2018 as indicated by the sponsor
Solvent used:	Dimethyl sulfoxide (DMSO) was used to suspend the test item. Homogeneity was ensured by shaking the preparation.

2. Control Materials:

Negative control:	In parallel to each experiment, negative control experiments were carried out in order to check for possible contaminants (sterility control) and to determine the spontaneous mutation rate (vehicle control).
Vehicle control:	The vehicle control with and without S9 mix only contained the solvent used for the test substance at the same concentration and volume for all tester strains.
Solvent/final concentration:	100 µL/plate

Positive control compounds tested without addition of metabolic activation system:

Strain	Mutagen	Solvent	Conc. [µg/plate]
TA 100	N-methyl-N'-nitroso-guanidine (MNNG)	DMSO	5
TA 1535	N-methyl-N'-nitroso-guanidine (MNNG)	DMSO	5
TA 1537	9-Aminoacridine (AAC)	DMSO	100
TA 98	4-nitro-o-phenylenediamine (NOPD)	DMSO	10
WP2 uvrA	4-Nitroguinoline-N-oxide (4-NQO)	DMSO	5

Positive control compounds tested with addition of rat metabolic activation system:

Strain	Mutagen	Solvent	Conc. [µg/plate]
TA 100	2-Aminoanthracene	DMSO	2.5
TA 1535	2-Aminoanthracene	DMSO	2.5
TA 1537	2-Aminoanthracene	DMSO	2.5
TA 98	2-Aminoanthracene	DMSO	2.5
WP2 uvrA	2-Aminoanthracene	DMSO	60

Positive control compounds tested with addition of hamster metabolic activation system:

Strain	Mutagen	Solvent	Conc. [µg/plate]
TA 100	2-Aminoanthracene	DMSO	10
TA 1535	2-Aminoanthracene	DMSO	10
TA 1537	2-Aminoanthracene	DMSO	10
TA 98	2-Aminoanthracene	DMSO	10
TA 98	Congo red	DMSO	210
WP2 uvrA	2-Aminoanthracene	DMSO	10

3. Activation:

Induced rat liver S9 fraction

S9 was produced from the livers of approximately 5 male Wistar rats (Crl:WI(Han); source: Charles River Laboratories Germany GmbH, Germany), weighting 200 – 300 g, that received 80 mg/kg bw phenobarbital i. p. and 80 mg/kg bw ß-naphthoflavone orally on 3 consecutive days.

The rat liver S9-mix was prepared freshly prior each experiment and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

Uninduced hamster liver S9 fraction

S9 was produced from the livers of approximately 10 male Syrian golden hamster (source: Charles River Laboratories Germany GmbH), 7 - 8 weeks old

The hamster liver S9-mix was prepared freshly prior each experiment and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	20 mM
Glucose 6-phosphate dehydrogenase	2.8 unit/mL
NADP	4 mM
NADH	2 mM
FMN (flavine mononucleotide)	2 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	30%

4. Test organisms: S. typhimurium strains: TA 98, TA 100, TA 1535, TA 1537
E. coli strains: WP2 uvrA
The bacterial strains are checked for the following characteristics at regular intervals: deep rough character (rfa), ampicillin resistance (R factor plasmid), and UV-light sensitivity (absence of uvrB and uvrA genes in Salmonella and E. coli strains, respectively).

Histidine and tryptophan auxotrophy was automatically proven in each experiment via the spontaneous rate.

5. Test concentrations:
SPT/pPIT (± S9): 0, 33, 100, 333, 1000, 2500, 5000 µg/plate

B. TEST PERFORMANCE:

1. Dates of work: experimental dates: 01-Jun to 17-Jun-2016,
finalisation date: 13-Sep-2016

2. Standard Plate Test (SPT):
A mixture of 2 mL portions of warm soft agar (containing 0.5 mM L-histidine + 0.5 mM (+)-biotin (S. typhimurium) or 0.5 mM L-tryptophan (E. coli)), 0.1 mL test solution or vehicle, 0.1 mL fresh bacterial culture, 0.5 mL S9 mix (in tests with metabolic activation) or 0.5 mL of phosphate buffer (in tests without metabolic activation) was poured onto minimal glucose agar plates. Each concentration and the controls were tested in triplicates. After incubation at 37°C for 48 - 72 hours in the dark, the bacterial colonies (his^+ or trp^+ revertants) were counted using an Image Analysis System. Colonies were counted manually, if precipitation of the test substance hindered the counting using the Image Analysis System.

3. Prival Pre-Incubation Test (pPIT):
The modified Bacterial Reverse Mutation Test according to Prival, in which flavin mononucleotide (FMN), liver S9 mix from uninduced hamsters and a pre-incubation step are used facilitates azo reduction and is therefore the most appropriate method for the investigation of azo-dyes and diazo compounds.
0.1 mL test solution or vehicle, 0.1 mL bacterial suspension and 0.5 mL S9 mix (in tests with metabolic activation) or 0.5 mL phosphate buffer (in tests without metabolic activation) were incubated at 30°C for 30 minutes using a shaker. Subsequently, 2 mL soft agar (containing 0.5 mM L-histidine + 0.5 mM (+)-biotin (S. typhimurium) or 0.5 mM L-tryptophan (E. coli)) was added. After mixing, the samples were poured onto the Vogel-Bonner agar plates. Each concentration and the controls were tested in triplicates. After incubation at 37°C for 48 - 72 hours in the dark, the bacterial colonies (his^+ or trp^+ revertants) were counted as described above.

4. Statistics:
No special statistical tests were performed.

5. Acceptance and assessment criteria:

Generally, the experiment was considered valid if the following criteria were met:

- The number of revertant colonies in the negative controls was within the range of the historical negative control data for each tester strain.
- The sterility controls revealed no indication of bacterial contamination.
- The positive control substances both with and without S9 mix induced a distinct increase in the number of revertant colonies within the range of the historical positive control data or above.
- Fresh bacterial culture containing approximately 10^9 cells per mL were used.

The test substance was considered positive in this assay if the following criteria were met:

- A dose-related and reproducible increase in the number of revertant colonies, i.e. at least doubling (bacteria strains with high spontaneous mutation rate, like TA 98, TA 100 and E. coli WP2 uvrA) or tripling (bacteria strains with low spontaneous mutation rate, like TA 1535 and TA 1537) of the spontaneous mutation rate in at least one tester strain either without S9 mix or after adding a metabolizing system.

A test substance was generally considered non-mutagenic in this test if:

- The number of revertants for all tester strains were within the historical negative control data range under all experimental conditions in at least two experiments carried out independently of each other.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

Stability of the test item in DMSO for a period of 4 hours at room temperature was verified analytically [BASF Study 01Y0277/15Y065].

B. TOXICITY

No bacteriotoxic effect (reduced his^- or trp^- background growth, decrease in the number of his^+ or trp^+ revertants) was observed in the SPT and in the pPIT up to the highest concentration tested.

C. SOLUBILITY

Test substance precipitation was found from about 333 µg/plate onward in SPT and from about 1000 µg/plate onward in pPIT with and without S9 mix.

D. MUTATION ASSAYS

In the SPT and pPIT [see Table 5.8.1-49] experiments with and without metabolic activation no biologically relevant increase in number of his^+ or trp^+ revertants was observed in any strain tested.

III. CONCLUSION

Based on the results of the present study, Reg.No. 369315 (metabolite of pyraclostrobin) is not mutagenic in the Ames standard plate test and Prival pre-incubation test with and without metabolic activation under the experimental conditions chosen.

Report:	CA 5.8.1/40 Schulz M., Landsiedel R., 2016 a Reg.No. 369315 (metabolite of BAS 500 F, Pyraclostrobin) - In vitro gene mutation test in L5178Y mouse lymphoma cells (TK Locus assay, microwell version) 2016/1225056
Guidelines:	OECD 490 (2015), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.17 No. L 142, EPA 870.5300
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany

Executive Summary

Reg.No. 369315 (Batch: L85-192, purity: 98.3%) was tested in vitro for its ability to induce forward mutations in mammalian cells by assessing the mutation of the TK locus in Mouse Lymphoma L5178Y cells. Two independent experiments were conducted in the presence 4-h incubation) or absence (4-h and 24-h incubation) of metabolic activation. In all cases two cultures were evaluated in parallel. Based on the results of a preliminary cytotoxicity assay concentrations of up to 150 µg/mL were used in the main experiment. Methylmethanesulfonate (MMS), 7,12-dimethylbenz[a]anthracene (DMBA) and Cyclophosphamide (CPA) served as positive controls in the experiments without and with metabolic activation, respectively.

No biologically relevant increase in the number of mutant colonies was observed in both experiments with and without metabolic activation. No relevant cytotoxicity as indicated by reduced relative total growth (RTG) of below 20% of control was observed in both experiments up to the highest concentration tested, which showed clear test substance precipitates in culture medium. The positive control mutagens (MMS, DMBA, and CPA) induced a distinct increase in mutant frequency, indicating that the tests were sensitive and valid.

Based on the results of the study it is concluded that under the conditions of this test Reg.No. 369315 (500M02; metabolite of pyraclostrobin) did not induce forward mutations and/or chromosomal aberrations in vitro in the mouse lymphoma assay with L5178Y $TK^{+/-}$ cells in the absence and presence of metabolic activation.

(BASF DocID 2016/1225056)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg. No. 369315 (Metabolite of BAS 500 F, Pyraclostrobin)

Description:	solid / orange
Lot/Batch #:	L85-192
Purity/content:	98.3% (tolerance ± 1.0%)
Stability of test compound:	The stability of the test item under storage conditions over the study period was guaranteed by the sponsor (expiry date May 01, 2018).
Vehicle:	DMSO (1% final concentration)

2. Control Materials:

Negative control:	A negative control was not employed in this study
Solvent control:	1% (v/v) DMSO in culture medium
Positive control -S9:	Methyl methanesulfonate (MMS) 15 and 5 µg/mL during the 4-h and 24-h exposure (dissolved in medium), respectively.
Positive control +S9:	Cyclophosphamide (CPP) 2.5 µg/mL (dissolved in medium); 7,12-dimethylbenz[a]anthracene (DMBA) 1 µg/mL (dissolved in DMSO)

3. Activation: S9 was produced from the livers of phenobarbital/β-naphthoflavone induced rats. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction is thawed at room temperature and an appropriate amount of S9-fraction is mixed with an equal volume of S9-cofactor solution. The co-factors in the S9-mix had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM

4. Test organism:	L5178Y mouse lymphoma cells were used. They have a high proliferation rate (doubling time about 9-10 h), a high plating efficiency (~90%) and a stable karyotype with a near diploid (40 ± 1) chromosome number. Stocks of the L5178Y cell line were maintained at -196°C in liquid nitrogen. Each batch used for mutagenicity testing was checked for mycoplasma contamination, karyotype stability, and spontaneous mutant frequency. Prior to treatment, spontaneous TK-deficient mutants were eliminated from the stock cultures by growing the cells for 1 day in pre-treatment medium A and 3 days in pre-treatment medium B (see below).
5. Culture media:	
Culture medium (basis):	RPMI-0 (RPMI 1640 medium with 1% of 10000 IU/10000 µg/mL Penicillin/Streptomycin, 1% Sodium Pyruvate (10 mM))
Medium (treatment +S9):	RPMI-0 + 5% FCS (RPMI-5)
Medium (treatment -S9):	RPMI-0 + 10% FCS (RPMI-10)
Medium (CE/selection):	RPMI-0 + 20% FCS (RPMI-20)
Pre-treatment medium A:	("THMG" medium): RPMI-10 medium containing hypoxanthine (5 µg/mL), thymidine (3 µg/mL), methotrexate (0.1 µg/mL), and glycine (7.5 µg/mL).
Pre-treatment medium B:	("THG" medium): RPMI-10 medium containing hypoxanthine (5 µg/mL), thymidine (3 µg/mL), and glycine (7.5 µg/mL).
Selection medium:	RPMI-20 supplemented with 4 µg/mL trifluorothymidine (TFT).
6. Locus examined:	thymidine kinase (TK)
7. Test concentrations:	
a) Preliminary toxicity assay:	Nine concentrations ranging from 7.81 to 2000 µg/mL (±S9)
b) Mutation assay:	
1st experiment:	4.69, 9.38, 18.75, 37.5, 75, 150 µg/mL with and without metabolic activation (4-h exposure)
2nd experiment:	1.56, 3.13, 6.25, 12.5, 25, 50, 100 µg/mL without metabolic activation (24-h exposure)
2nd experiment:	3.13, 6.25, 12.5, 25, 50, 100 µg/mL with metabolic activation (4-h exposure)

B. TEST PERFORMANCE:

1. Dates of experimental work: 06-June-2016 to 16-Sep-2016

2. Preliminary cytotoxicity assay:

A pre-test was performed in order to determine the concentration range of the mutagenicity experiments. Both, pH value and osmolarity were determined at the maximal concentration of the test item and in the solvent control without metabolic activation. Cells were treated for 4 h in the presence and absence of S9 mix with the test substance at concentrations from 7.81 to 2000 µg/mL. The relative suspension growth was determined.

3. Mutation Assay:

Pre-treatment of cells:
During the week prior to treatment $3x10^5$ cells were seeded into 75 cm^2-flasks and incubated for 1 day with "THMG" medium and for the following 3 days in "THG" medium to eliminate spontaneous TK-deficient mutants.

Cell treatment and expression period:
The assay was performed in two independent experiments, using two parallel cultures each. The first main experiment was performed with and without liver microsomal activation and a treatment period of 4 hours. The second experiment was performed with a treatment period of 24 hours in the absence of metabolic activation and a treatment period of 4 hours in the presence of metabolic activation.
For each test group, $1.5x10^7$ ($1x10^7$ during 24 h exposure) cells per flask (75 cm^2 flasks) suspended in 20 mL RPMI medium were exposed to various concentrations of the test item either in the presence or absence of metabolic activation. Positive and solvent controls were performed in parallel. After 4 h (24 h in the second experiment), the test item was removed by centrifugation (173 x g, 5 min) and the cells were washed twice in RPMI-5 medium. From each culture a sample of treated cells (2 x 10^5 cells/mL or 6 x 10^6 cells/flask) was pipetted in 75 cm^2 flasks and was incubated for a 2-day expression period. To maintain exponential growth during this phase, each culture was counted daily and the cell numbers were adjusted at each day to 2 x 10^5 cells/mL in 30 mL RPMI-10 medium. The cell numbers were determined using a cell counter.

Seeding for selection
For the selection of the mutants, the cells were centrifuged and resuspended in 50 mL selection medium. Per culture 200 µL were dispensed in each well of two 96-well plates (2000 cells/well). After incubation for at least 9 days, both the number of negative wells and the number of wells containing small or large colonies were scored for calculation of the mutant frequency (MF).

Cloning efficiency

For determination of cytotoxicity, at the end of the treatment (Cloning efficiency 1 (survival)) and expression period (Cloning efficiency 2 (viability)) the cells were centrifuged resuspended. Per culture 200 µL were dispensed in each well of two 96-well plates (1.6 cells/well). After incubation for 9 - 11 days the plates were scored for empty wells.

For calculation of the relative suspension growth (RSG) and the relative total growth (RTG) the cell counts determined within the expression period at 2nd and 3rd passage after exposure in the case of 4-hour exposure and 1st, 2nd and 3rd passage after exposure in the case of 24-hour exposure were used.

Colony counting

The number of empty wells and the number of wells containing colonies were scored and reported. The colonies are classified into large colonies (indication of gene mutation) and small colonies (indication of chromosome breakage). Small colonies are defined as less than 1/4 of the diameter of the well. Size is the key factor and morphology (the optical density of the small colonies is considerably higher) should be secondary.

Calculations and processing of the data:

Cloning efficiency 1 (survival) and 2 (viability) was determined for each test group and given as absolute and relative cloning efficiency (CE_x and RCE_x, respectively).

$$CE_x = \frac{-\ln(\text{total number of empty wells} \div \text{total number of seeded wells (96)})}{\text{number of seeded cells per well (1.6)}} \times 100$$

$$RCE_x = \frac{CE_x \text{ of the test group}}{CE_x \text{ of the negative / vehicle control}} \times 100$$

The RTG is the standard measure of cytotoxicity. This measure includes the relative growth in suspension (RSG) during the expression period and the relative cloning efficiency (RCE_2; viability) at the time the mutants are selected.

For taking into account any loss of cells during the 4-hour treatment period a relative growth during treatment factor (RGDT, %) was calculated by comparing the growth of each treated culture relative to the control:

$$\text{RGDT} = \frac{\text{Cell count after 4 h of the test group}}{\text{Cell count after 4 h of the negative/v ehicle control}} \times 100$$

The total suspension growth (SG) and the RSG (in %) were calculated for each test group as follows:

Total suspension growth after 4 hour-exposure

$$SG = \frac{\text{Cell count after 24 h}}{2 \text{ x } 10^5 \text{ cells per mL}^{1,2}} \times \frac{\text{Cell count after 48 h}}{2 \text{ x } 10^5 \text{ cells per mL}^2} \times \frac{\text{RGDT}}{100}$$

Total suspension growth (SG) after 24 hour-exposure:

$$SG = \frac{\text{Cell count after 24 h}}{2 \times 10^5 \text{ cells per mL}} \times \frac{\text{Cell count after 48 h}}{2 \times 10^5 \text{ cells per mL}^2} \times \frac{\text{Cell count after 72 h}}{2 \times 10^5 \text{ cells per mL}^2}$$

$$\text{RSG} = \frac{\text{SG of the test group}}{\text{SG of the negative/vehicle control}} \times 100$$

$$RTG = \frac{RSG \times RCE_2}{100}$$

[1] Cell number seeded following 4-hour treatment
[2] If cell number was lower than 2 x 10^5 cells per mL all remaining cells were seeded
The uncorrected mutant frequency per 10^6 cells ($MF_{uncorr.}$) was calculated for each test group as follows:

$$MF_{uncorr} = \frac{-\ln(\text{total number of empty well s} \div \text{total number of seeded wells (96)})}{\text{number of seeded cells per well (2000)}} \times 10^6$$

The corrected mutant frequency (MF_{corr}) was calculated regarding the values of CE_2:

$$MF_{corr} = \frac{MF_{uncorr}}{CE_2} \times 100$$

Determination of borderline mutant frequency based on GEF

The GEF (global evaluation factor) evaluation method requires that the MF exceeds a value based on the global distribution of the background MF of the test method. This value is defined as the mean of the negative/vehicle MF distribution plus one standard deviation. Based on a large data base (n = 493 experiments) from six laboratories a GEF of 126 mutant colonies per 10^6 cells (mean MF_{corr} = 99 x10^{-6} colonies; standard deviation = 27 x10^{-6} colonies) was calculated for the microwell method. To be judged positive the mutation frequency has to exceed a threshold of 126 colonies per 10^6 cells (GEF) above the concurrent negative/vehicle control value.

4. Statistics

An appropriate statistical method to test for linear trend (MS EXCEL function RGP; 10) was performed to assess a possible linear dose-relation in mutant frequencies. The dependent variable was the corrected mutant frequency and the independent variable was the concentration. A trend was judged as statistically significant whenever the one-sided p-value (probability value) was below 0.05 and the slope was greater than 0. However, both, biological and statistical significance has been considered together.

5. Acceptability criteria:

A mutation assay is considered acceptable if it meets the following criteria (the current recommendations of the IWGT are considered):

- The absolute cloning efficiency at the time of mutant selection (CE_2) of the solvent controls is 65 – 120%.
- The suspension growth (SG) of the negative/vehicle controls referring to the expression period following treatment should fall in the range of 8 - 32 for 4-hour exposure and 32 - 180 for 24-hour exposure.
- The range of the solvent control mutant frequency is in the range of 50 – 170 x 10^{-6} cells.
- The positive controls should yield an absolute increase in total mutant frequency (MF) that is an increase above the spontaneous background MF (an induced MF [IMF]) of at least 300 x 10^{-6} colonies. The small colony MF should account for at least 40% of that IMF, means a small colony IMF of at least 120 x 10^{-6} colonies. Alternatively, the positive controls should induce at least 150 x 10^{-6} small colonies above the spontaneous background MF. The upper limit of cytotoxicity observed in the positive controls should have a RTG that is greater than 10%.
- The highest applied concentration of the test substance should be 2 mg/mL, 2 µL/mL or 10 mM, unless limited by cytotoxicity or solubility of the test substance. If toxicity occurs, the highest concentration should lower the RTG to 10 to 20% of survival. If precipitation occurs, the highest evaluated concentration should be the lowest concentration where precipitation is observed by the unaided eye.

6. Evaluation criteria:

A test item is classified as mutagenic **if all** of the following criteria are met:

- The induced mutation frequency reproducibly exceeds a threshold of 126 colonies per 10^6 cells above the corresponding solvent control.
- Evidence of reproducibility of any increase in mutant frequencies, means the mutagenic response occurs at least in both parallel cultures of one experiment.
- A statistically significant dose-related increase in mutant frequencies using an appropriate tatistical trend test.

The test substance is considered non-mutagenic **if at least one** of the following criteria are met:

- The mutation frequency is below a threshold of 126 colonies per 10^6 cells above the concurrent solvent control value.
- No evidence of reproducibility of an increase in mutant frequencies is obtained.
- No statistically significant dose-related increase in mutant frequencies using an appropriate statistical trend test.

However, in the evaluation of the test results the historical variability of the mutation rates in negative and vehicle controls (95% control limit) and the mutation rates of all negative and vehicle controls of this study were taken into consideration.
Results of test groups are generally rejected if the relative total growth is less than 10% of the vehicle control.
Whenever a test item is considered mutagenic according to the above mentioned criteria, the ratio of small versus large colonies is used to differentiate point mutations from clastogenic effects. If the increase of the mutation frequency is accompanied by a reproducible and dose dependent shift in the ratio of small versus large colonies clastogenic effects are indicated.

II. RESULTS AND DISCUSSION

A. PRELIMINARY CYTOTOXICITY ASSAY

In the pretest the pH value was not influenced by the addition of the test substance preparation to the culture medium at the concentrations tested. Precipitation occurred at ≥ 62.5 µg/mL with and without metabolic activation. Neither with or without S9 a reduction of the relative suspension growth (RSG) below 20% was noted.

B. TREATMENT CONDITIONS

Osmolarity and pH values were not influenced by test substance treatment. The test substance was poorly soluble in the commonly used vehicles. DMSO was the most suitable one. Homogeneous suspensions were obtained at concentrations ≥ 37.5 µg/ml, while the test item was soluble in DMSA at ≤ 25 µg/ml. In the 1st Experiment, test substance precipitation in culture medium at the end of treatment was observed at 18.75 µg/mL and above with and without S9 mix. In the 2nd Experiment, test substance precipitation occurred at ≥ 25.0 µg/mL at all experimental conditions at the end of treatment.

C. CYTOTOXICITY

In both experiments the relative total growth (RTG) was above 20% and thus no considerable toxicity was noted. This is in agreement with the data of the preliminary toxicity test.

D. MUTAGENICITY ASSAYS

In this study, no relevant increase in the number of mutant colonies was observed either without S9 mix or after the addition of a metabolizing system [see Table 5.8.1-50 and Table 5.8.1-51]. The corrected mutant frequencies obtained for both experiments were always close to the respective vehicle control values and below the calculated threshold taking in consideration the Global Evaluation Factor (GEF).

The statistical analyses by testing for linear trend led to clearly negative findings for both experiments with and without S9 mix.

As expected, both positive control substances known to induce gene mutations, MMS (without S9 mix) and DMBA (with S9 mix), and the well-known clastogen CPP (with S9 mix) led to clearly increased mutant frequencies. The values of the corrected mutant frequencies exceeded the respective calculated thresholds for a mutagenic effect based on the GEF (126 plus the mutant frequency of the respective negative control). In addition, the corrected mutant frequencies were within the historical positive control data range (222.2 – 1490.7 per 10^6 cells; see Appendix 7 of the report).

III. CONCLUSION

Under the experimental conditions chosen here, Reg.No. 369315 (500M02; metabolite of pyraclostrobin) did not induce forward mutations and/or chromosomal aberrations in vitro in the mouse lymphoma assay with L5178Y $TK^{+/-}$ cells in the absence and presence of metabolic activation.

Report:	CA 5.8.1/41 Chang S., 2016 a Reg.No. 369315 (Metabolite of BAS 500 F, Pyraclostrobin) - Micronucleus test in human lymphocytes in vitro 2016/1135652
Guidelines:	OECD 487 (2014), Commission Regulation (EU) No 640/2012
GLP:	yes (Laboratory certified by Hess. Ministerium für Umwelt, Klimaschutz, Landwirtschaft und Verbraucherschutz, Wiesbaden, Germany)

Executive Summary

Reg.No. 369315 (metabolite of pyraclostrobin; batch: L85-192; purity: 98.3%) was tested for its potential to induce micronuclei in human lymphocytes *in vitro* in the absence and presence of metabolic activation by S9 mix. Two independent experiments were performed. In duplicate cultures the cells were incubated for 4 (±S9 mix) or 20 hours (-S9 mix) with the test substance at concentrations in the range of 2.9 to 2035 µg/mL. Three concentrations were evaluated, which were limited by the precipitation of the test item in the media. The vehicle DMSO (1.0% in culture medium) served as negative control, Mitomycin C (4 h) and Demecolcin (20 h) as positive controls in the absence of metabolic activation and Cyclophosphamide as positive control in the presence of metabolic activation. Treatments started after a 48-hour stimulation period with phytohemeagglutinine. Thereafter Cytochalasin B was added and the cultures were fixed and stained finally after another 20 hours. Cytokinesis-block proliferation index (CBPI) and cytostasis were determined in 1000 binucleated cells as cytotoxicity parameters. The number of micronucleated cells were determined in 2000 binucleated cells for evaluation of mutagenicity.

No cytotoxicity was observed up to the highest evaluated concentration, which showed precipitation in Experiment I at 13.2 µg/mL in the presence and absence of S9 mix and in Experiment II at 100 µg/mL in the absence of S9 mix and at 14.8 µg/mL and above in the presence of the S9 mix.
Independent of metabolic activation, no increase in the number of cells carrying micronuclei was observed in both experiments. The solvent control revealed values that were within the range of the laboratory historical negative control data. The positive control chemicals led to the expected increase in cells containing micronuclei that was within the range of the historical positive control data, thus demonstrating the sensitivity of the test system and the validity of the study.

In conclusion, under the experimental conditions Reg.No. 369315 (M50002; Metabolite of BAS 500 F (Pyraclostrobin)) did not induce the formation of micronuclei in human lymphocytes under in vitro conditions in presence and absence of metabolic activation.
(BASF DocID 2016/1135652)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg.No. 369315 (metabolite of pyraclostrobin)

Description:	Solid, orange
Lot/Batch #:	L85-192
Purity:	98.3%
Stability of test compound:	The stability of the test substance is guaranteed (expiry date 01-May-2018)
Solvent used:	DMSO

2. Control Materials:

Negative control:	A negative control was not employed in this study
Solvent control:	DMSO (1.0% final concentration in culture medium)
Positive control:	Without metabolic activation: Mitomycin C (MMC, 1.5 µg/mL; pulse treatment) dissolved in deionized water; Demecolcin (150 ng/mL; continuous treatment) dissolved in deionized water With metabolic activation: Cyclophosphamide (CPA, 17.5 µg/mL (Exp. I) or 15.0 µg/mL (Exp. II) dissolved in saline (0.9% NaCl))

3. Activation: S9 was produced from the livers of rats pretreated with β-naphthoflavone/phenobarbital. For testing, a sufficient amount of S9-fraction (protein content: 29.8 mg/mL) was thawed at room temperature and mixed with an appropriate volume of S9-supplement (cofactors). This preparation, the so-called S9-mix, was kept on ice until used.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	100 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM

50 µL S9 mix per mL culture medium were used, yielding a 2.5% S9 fraction or final protein concentration of 0.75 mg/mL in each culture.

4. Test organism: Human peripheral blood lymphocytes

Donor(s):	Experiment I: 22 years old male, non-smoking, not medicated Experiment II: 26 years old male, non-smoking, not medicated

5. Culture media:

Culture medium:	Dulbecco´s Modified Eagles medium/Ham´s F12 (1:1) with GlutaMAX™ (200 mM) supplemented with 10% (v/v) fetal bovine serum (FBS), Pen/Strep (100 U/mL / 100 µg/mL), HEPES (10 mM), heparin (125 U.S.P.-U/mL), and phytohemeagglutinine (PHA, 3 µg/mL).

6. Test concentrations:

Micronucleus assay

Experiment I	
(4-h exposure, ±S9):	**4.3, 7.6, 13.2**, 23.1, 40.5, 70.8, 124, 217, 379.7, 664.5, 1163 and 2035 µg/mL; precipitation at ≥ 13.2 µg/ml (evaluated concentrations are indicated in bold)
Experiment II	
(4-h exposure, +S9):	2.9, 4.4, **6.6, 9.9, 14.8**, 22.2, 33.3, 100 µg/mL; precipitation at ≥ 14.8 µg/ml (evaluated concentrations are indicated in bold)
(20-h exposure, -S9):	2.9, 4.4, 6.6, 9.9, 14.8, **22.2, 33.3, 100** µg/mL; precipitation at 100 µg/ml (evaluated concentrations are indicated in bold)

B. TEST PERFORMANCE

1. Dates of experimental work: 08-Jun-2016 to 27-Jul-2016

2. Dose selection:

Dose selection was performed according to the current OECD Guideline for the in vitro micronucleus test. The highest test item concentration should be 2000 µg/mL, 2 µL/mL or 10 mM, whichever is the lowest. At least three test item concentrations should be evaluated for cytogenetic damage.

A preliminary cytotoxicity test was performed to determine the concentrations to be used in the main experiment. Cytotoxicity is characterized by the percentages of reduction in the CBPI in comparison with the controls (% cytostasis) by counting 500 cells per culture in duplicate. The experimental conditions in this pre-experimental phase were identical to those required and described below for the mutagenicity assay. The pre-test was performed with 12 concentrations of the test item separated by no more than a factor of √10 and a solvent and positive control. All cell cultures were set up in duplicate. Exposure time was 4 hours (± S9 mix). The preparation interval was 40 hours after start of the exposure.

With regard to the purity (98.3%) of the test item, 2035 µg/mL were applied as top concentration for treatment of the cultures in the pre-test. Test item concentrations ranging from 4.3 to 2035 µg/mL (± S9 mix) were chosen for the evaluation of cytotoxicity. In the pre-test for toxicity, precipitation of the test item was observed at the end of treatment at 13.2 µg/mL and above in the absence and presence of S9 mix. Since the cultures fulfilled the requirements for cytogenetic evaluation, this preliminary test was designated Experiment I.

No cytotoxicity was observed in Experiment I after 4 hours treatment in the absence and presence of S9 mix. 100 µg/mL was chosen as top treatment concentration for Experiment II.

3. Micronucleus test:

Pulse exposure (±S9)

About 48 h after seeding, 2 blood cultures (10 mL each) were set up in parallel in 25 cm² cell culture flasks for each test item concentration. The culture medium was replaced with serum-free medium containing the test item. For the treatment with metabolic activation 50 µL S9 mix per mL culture medium was added. After 4 h the cells were spun down by gentle centrifugation for 5 minutes. The supernatant was discarded and the cells were resuspended in and washed with saline. The washing procedure was repeated once as described. The cells were resuspended in complete culture medium with 10 % FBS (v/v) and cultured for a 16-hour recovery period. After this period Cytochalasin B (4 µg/mL) was added and the cells were cultured another approximately 20 hours until preparation.

Continuous exposure (-S9)

About 48 h after seeding 2 blood cultures (10 mL each) were set up in parallel in 25 cm² cell culture flasks for each test item concentration. The culture medium was replaced with complete medium (with 10 % FBS) containing the test item. After 20 hours the cells were spun down by gentle centrifugation for 5 minutes. The supernatant was discarded and the cells were re-suspended in and washed with saline. The washing procedure was repeated once as described. After washing the cells were re-suspended in complete culture medium containing 10 % FBS (v/v). Cytochalasin B (4 µg/mL) was added and the cells were cultured another approximately 20 hours until preparation.

Preparation of cells

The cultures were harvested by centrifugation 40 h after beginning of treatment. The cells were spun down by gentle centrifugation for 5 minutes. The supernatant was discarded and the cells were re-suspended in approximately 5 mL saline and spun down once again by centrifugation for 5 minutes. Then the cells were resuspended in 5 mL KCl solution (0.0375 M) and incubated at 37°C for 20 minutes. 1 mL of ice-cold fixative mixture of methanol and glacial acetic acid (19 parts plus 1 part, respectively) was added to the hypotonic solution and the cells were resuspended carefully. After removal of the solution by centrifugation the cells were resuspended for 2 x 20 minutes in fixative and kept cold. The slides were prepared by dropping the cell suspension in fresh fixative onto a clean microscope slide. The cells were stained with Giemsa.

4. Statistics:

Statistical significance was confirmed by using the Chi-squared test ($\alpha < 0.05$) using the validated R Script CHI2.Rnw for those values that indicated an increase in the number of cells with micronuclei compared to the concurrent solvent control.

5. Cytotoxicity evaluation:

Evaluation of cytotoxicity and cytogenetic damage

Evaluation of the slides was performed using microscopes with 40 x objectives. The micronuclei were counted in cells showing a clearly visible cytoplasm area. The micronuclei had to be stained in the same way as the main nucleus. The area of the micronucleus should not extend the third part of the area of the main nucleus. At least 1000 binucleated cells per culture were evaluated for cytogenetic damage on coded slides. The frequency of micronucleated cells was reported as % micronucleated cells. To describe a cytotoxic effect, the CBPI (Cytokinesis-block proliferation index) was determined in 500 cells per culture and cytotoxicity is expressed as % cytostasis. A CBPI of 1 (all cells are mononucleate) is equivalent to 100 % cytostasis.

The CBPI was calculated as follows:

$$CBPI = \frac{(MONC \times 1) + (BINC \times 2) + (MUNC \times 3)}{n}$$

CBPI	Cytokinesis-block proliferation index
n	Total number of cells
MONC	Mononucleate cells
BINC	Binucleate cells
MUNC	Multinucleate cells

$$\text{Cytostasis \%} = 100 - 100\,[(CBPI_T - 1) / (CBPI_C - 1)]$$

T	Test item
C	Solvent control

6. Evaluation criteria:

Acceptability criteria:

- The rate of micronuclei in the solvent controls falls within the historical laboratory control data range.
- The rate of micronuclei in the positive controls is statistically significant increased.
- The quality of the slides must allow the evaluation of a sufficient number of analysable cells.

Evaluation criteria:

A test item can be classified as non-clastogenic and non-aneugenic if:

- the number of micronucleated cells in all evaluated dose groups is in the range of the historical laboratory control data and
- no statistically significant or concentration-related increase of the number of micronucleated cells is observed in comparison to the respective solvent control.

A test item can be classified as clastogenic and aneugenic if:

- the number of micronucleated cells is not in the range of the historical laboratory control data and
- either a concentration-related increase in three test groups or a statistically significant increase in the number of micronucleated cells is observed.

If the above mentioned criteria for the test item are not clearly met, the test item will be classified as equivocal or a confirmatory experiment may be performed. However, results may remain questionable regardless of the number of times the experiment is repeated.

An increase in the number of micronucleated mononucleate cells may indicate that the test item has aneugenic potential.

II. RESULTS AND DISCUSSION

A. ANALYTICS

Stability of the test item in DMSO for a period of 4 hours at room temperature was verified analytically [see separate report 01Y0701/14Y117].

B. CYTOTOXICITY, PRECIPITATION AND OSMOLARITY

Precipitation of the test item in the culture medium was observed in Experiment I at 13.2 µg/mL and above in the absence and presence of S9 mix and in Experiment II at 100 µg/mL in the absence of S9 mix and at 14.8 µg/mL and above in the presence of S9 mix at the end of treatment.
No relevant influence on osmolarity or pH was observed. When using 1% DMSO as solvent the osmolarity is generally high, if compared to the physiological level of approximately 300 mOsm. This effect, however, is based on a final concentration of 1% DMSO in medium. As the osmolarity is measured by freezing point reduction, 1% of DMSO has a substantial impact on the determination of osmolarity. The outcome of the study is not affected by this impact.
In the absence and presence of S9 mix, no cytotoxicity was observed up to the highest evaluated concentration, which showed precipitation.

C. MICRONUCLEUS ASSAY

In this study, neither a statistically significant nor a biologically relevant increase in the number of micronucleated cells was observed after treatment with the test item [see Table 5.8.1-52].
The micronucleus rates of the cells after treatment with the test item were close to the range of the respective solvent control values and within the range of the laboratory historical control data (HCD). The HCD in the absence of S9 mix were 0.15-1.25% (95% control limits 0.02 to 1.15%) for (4h) pulse treatment and 0.05-1.43% (95% limits: 0.05 – 1.05%) for continuous (20h) treatment. The HCD in the presence of S9 mix were 0.15-1.35% (95% limits: 0.08 – 1.20%) for pulse treatment.

All positive controls used, i.e. Demecolcin (150 ng/mL), MMC (1.5 µg/mL) or CPA (17.5 or 15.0 µg/mL), resulted in distinct increases in cells with micronuclei (3.3 to 9.25%). These responses were within the range of the laboratory historical positive control data thus demonstrating the sensitivity and validity of the test system.

Table 5.8.1-52 Summary of results of the in vitro micronucleus test in human lymphocytes with Reg.No. 369315

[5] CPA 15.0 µg/mL

III. CONCLUSION

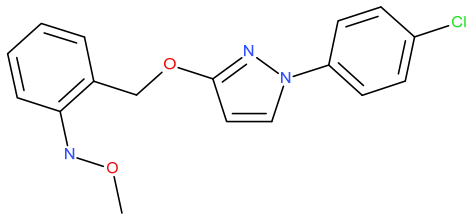
Under the experimental conditions of this study Reg.No. 369315 (500M02; metabolite of pyraclostrobin) did not induce micronuclei as determined by the in vitro micronucleus test in human lymphocytes when tested up to precipitating concentrations with and without metabolic activation.

Toxicological evaluation of 500M02 (Reg.No. 369315, BF 500-7)

By weight of evidence 500M02 is considered to be not genotoxic based on a set of three negative in vitro assays assessing the gene mutation in bacterial and mammalian cells as well as the effects on chromosomes. In conclusion 500M02 is considered to be **not toxicologically relevant**.

Based on the results of the in vitro comparison study, it cannot be excluded that metabolite 500M02 might be also formed in humans under in vivo conditions. Therefore, dietary exposure assessments have been performed (see M-CA 6.9).

500M106 (other denominator: Reg.No. 399379)



500M106 (Reg.No. 399379) is a metabolite newly found in the comparative in vitro metabolism study as well as in a new rat plasma study.

A) QSAR prediction for 500M106 (Reg.No. 399379)

OECD Toolbox (Version: 3.2) [see BASF DocID 2014/1172955]

In the OECD toolbox no DNA alerts for genotoxicity (Ames, MN, CA) or alerts for DNA or protein binding were observed for 500M106 (Reg.No. 399379). However, one of 3 in-silico generated metabolites generated two alerts: '*AN2|AN2 >> Michael-type addition, quinoid structures|AN2 >> Michael-type addition, quinoid structures >> Quinoneimines|Non-specific|Non-specific >> Incorporation into DNA/RNA, due to structural analogy with nucleoside bases |Non-specific >> Incorporation into DNA/RNA, due to structural analogy with nucleoside bases >> Specific Imine and Thione Derivatives|Radical|Radical >> Radical mechanism via ROS formation (indirect)|Radical >> Radical mechanism via ROS formation (indirect) >> Specific Imine and Thione Derivatives|Radical >> ROS formation after GSH depletion (indirect)|Radical >> ROS formation after GSH depletion (indirect) >> Quinoneimines|SN2|SN2 >> Nucleophilic substitution on diazonium ion|SN2 >> Nucleophilic substitution on diazonium ion >> Specific Imine and Thione Derivatives*' for genotoxicity (Ames, MN, CA) and DNA binding. For protein binding the alert was '*Michael Addition|Michael Addition >> Quinoide type compounds|Michael Addition >> Quinoide type compounds >> Quinone methide(s)/imines; Quinoide oxime structure; Nitroquinones, Naphthoquinone(s)/imines |Nucleophilic addition|Nucleophilic addition >> Addition to carbon-hetero double bonds|Nucleophilic addition >> Addition to carbon-hetero double bonds >> Ketones'*

OASIS TIMES (MIX V.2.27.13 TB; Mutagenicity S-9 activated v08.08) [see molecule 9 of report BASF DocID 2014/1172952 and 2014/1172953]

The alert for Ames mutagenicity of 500M106 (Reg.No. 399379) was negative (out of domain). However, one out of 7 in-silico generated metabolites displayed a positive alert (Quinoneimines, specific imine and thione derivatives). It is interesting to note that in contrast to the vast majority of positive alerts observed in the course of the QSAR evaluation of pyraclostrobin and its metabolites, the positive metabolite was out of domain!

For in vitro chromosome aberration the situation was similar. The prediction for 500M106 (Reg.No. 399379) was negative (out of domain). This time 3 out of 7 in-silico metabolites were predicted positive - 2 metabolites with the alert 'phenols' (in domain!) and one metabolite (the same as above for the Ames prediction) with the alert 'Quinoneimines, specific imine and thione derivatives, alpha, beta-unsaturated' (Out of domain!). Whereas the latter alert was unique in the set of molecules evaluated here, the alert 'phenols' was also present for pyraclostrobin and metabolites 500M76 (Reg.No. 413038) and 500M60 (Reg.No. 411847). Whereas the in vitro study with pyraclostrobin was negative, the in vitro study with 500M76 (Reg.No. 413038) and 500M60 (Reg.No. 411847) was positive. However, the in vitro results were not confirmed in the negative higher tier in vivo mouse micronucleus studies. Therefore, the weight of evidence at least for this alert indicates that 500M106 (Reg.No. 399379) is not genotoxic.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 9 of report BASF DocID 2014/1172954 for both VEGA models]

The prediction for 500M106 (Reg.No. 399379) is mutagen (out of domain) with no specific alert information. Of the 6 molecules with the highest structural similarity (0.561 to 0.657) the predicted mutagenicity was only confirmed for the two least similar molecules. As visible from the structures depicted below, the similarity to 500M106 (Reg.No. 399379) is low.

Predicted value: Mutagen

VEGA: Mutagenicity model (SarPy; version 1.0.4-BETA)

The prediction for 500M106 (Reg.No. 399379) is 'mutagen' with the structural alert SA 96. The prediction is based on the same molecules as described above for the CAESAR prediction model.
As discussed above, this alert was also obtained for pyraclostrobin and a number of pyraclostrobin metabolites, which were actually tested negative.

DEREK (Version 2.0.0.201011301322; Knowledge base version: 11_20_05_2010)

The molecule was not evaluated in this model.

Discussion: The prediction of genotoxicity in the OECD Toolbox and in OASIS Times is solely based on the same in-silico predicted metabolite (see 9.3 below) with well comparable alerts in both QSAR models. This is not surprising as the underlying algorithms were developed by the same scientists. The additional 4 metabolites in OASIS Times are simply glucuronic and gluthatione conjugates of metabolites 9.1 and 9.2. Obviously, the Phase II metabolite reactions are not implemented in the OECD Toolbox.

9.0 Parent 	9.1 Metabolite Predicted Ames Mutagenicity in vitro Ames negative **Alert info** **ModelReliability** **Total Domain** Out of Domain	**Predicted Ames Mutagenicity** in vitro Ames negative **Alert info** **ModelReliability** **Total Domain** N/A
9.2 Metabolite 	9.3 Metabolite Predicted Ames Mutagenicity in vitro Ames negative **Alert info** **ModelReliability** **Total Domain** N/A	**Predicted Ames Mutagenicity** in vitro Ames positive **Alert info** Quinoneimines,Specific Imine and Thione Derivatives **ModelReliability** High, >= 60% (n>=10) **Total Domain** Out of Domain

It is worth to note that it was impossible to actually find any half way similar reference compound with the respective structure in the OECD Toolbox, which has experimental data underpinning the alert. The only reference compound with experimental data was pyraclostrobin itself. The value of this alert is therefore highly questionable.

B) Subchronic toxicity of 500M106 (Reg.No. 399379)

Report:	CA 5.8.1/42 [redacted] 2017 a Reg.No. 399379 (metabolite of BAS 500 F, Pyraclostrobin) - Repeated-dose 28-day oral toxicity study in Wistar rats - Administration by gavage 2016/1288407
Guidelines:	OECD 407, OECD 408, EPA 870.3100, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.26
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Please note: This study was essentially conducted according to OECD 408, but the treatment period was only 28-days. Thus, it is an OECD 407 study with 10 animals/sex/dose enhanced by the additional parameters investigated in OECD 408.

Executive Summary

Administration of Reg.No. 399379 (metabolite of pyraclostrobin; batch L87-218; purity: 97.7%) to Wistar rats at dose levels of 0, 100, 300 and 1000 mg/kg bw/day for 28-days resulted in adverse signs of systemic toxicity at 1000 mg/kg bw/day in both sexes.

Treatment with Reg.No. 399379 did not affect the survival, body weight development or food consumption, FOB, clinical chemistry or urinalysis parameters. Treatment related effects at the high dose (1000 mg/kg) consisted of a regenerative normochromic-normocytic anemia characterized by decreased erythrocyte counts (RBC), hemoglobin (HGB) and hematocrit (HCT) in males and increased absolute reticulocyte counts in both sexes, increased duodenum weights in males without a histopathological correlate, increased absolute and relative liver weights in males accompanied by a minimal centrilobular hypertrophy of hepatocytes and extramedullary hematopoiesis in the spleen of both sexes. Only the anemia and the accompanying extramedullary hematopoiesis were considered to represent adverse findings.

In high dose males a slight regenerative normochromic-macrocytic anemia was noted. This was accompanied by an adaptive increase of extramedullary hematopoiesis in the spleen of high dose males. Finally, high dose males displayed some changes of clinical chemistry parameters, i.e. decreased total protein and globulin as well as increased triglyceride levels.

Under the conditions of the present study the no observed adverse effect level (NOAEL) in both sexes was 300 mg/kg bw/day.

(BASF DocID 2016/1288407)

I. MATERIAL AND METHODS

A. MATERIALS

1.	**Test Material:**	Reg.No. 399379 (metabolite of pyraclostrobin)
	Description:	Solid, orange
	Lot/Batch #:	L85-218
	Purity:	97.7% (tolerance ± 1.0%)
	Stability of test compound:	The test substance was stable over the study period until 01 Aug 2018
2.	**Vehicle and/or positive control:**	0.5% aqueous carboxymethylcellulose
3.	**Test animals:**	
	Species:	Rat
	Strain:	Crl:WI (Han)
	Sex:	Male and female
	Age:	35 ± 1 day at delivery
	Weight at dosing:	means: males: 159.6 ± 7.1 g, females: 127.7 ± 6.4 g
	Source:	Charles River Laboratories, Sulzfeld, Germany
	Acclimation period:	7 days
	Diet:	Kliba maintenance diet mouse/rats "GLP", Provimi Kliba SA, Kaiseraugst, Switzerland, ad libitum
	Water:	Drinking water from water bottles, ad libitum
	Housing:	Group housing (5 animals/cage) in type 2000P poly-sulfonate cages (TECNIPLAST, Hohenpeißenberg, Germany)
		floor area about 2065°cm²; bedding: wooden dust free bedding; enrichment: wooden gnawing blocks type NGM E-022 (Abedd® Lab. and Vet. Service GmbH, Austria)
	Environmental conditions:	
	Temperature:	20 - 24°C (central air-conditioning)
	Humidity:	30 - 70% (central air-conditioning)
	Air changes:	15 per hour
	Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN

7. Dates of experimental work: 16-Aug-2016 to 21-Dec-2016
Inlife dates:
23-Aug-2016 (start of administration) to
22-Sep-2016 (necropsy of last female animals)

8. Animal assignment and treatment:

Reg.No. 399379 was administered to groups of 10 male and 10 female Wistar rats by gavage at target concentrations of 0, 100, 300 and 1000 mg/kg bw/day for 28 days.

The animals were assigned to the treatment groups by means of a computer generated randomization list based on body weights. At the end of the administration period the animals were sacrificed after a fasting period of at least 16 hours.

9. Test item preparation and analysis:

The test item was administered as suspension in 0.5% aqueous CMC. Appropriate amounts of the test item were weighed and subsequently filled up with the vehicle. The suspension was prepared by mixing with an Ultraturrax and was kept homogenous by stirring with a magnetic stirrer. Suspensions were prepared weekly.

The stability of Reg.No. 399379 in suspension at room temperature for a period of 7 days was demonstrated before the start of the study (BASF project No. 01Y0701/14Y119; copy of the report included in Volume III of the report).

The homogenous distribution of Reg.No. 399379 in the diet was verified for the highest and lowest concentration (see below) using the first suspension preparation. Additionally, the test-item concentration was determined at the mid dose. These analyses were performed with a validated method (see M-CA 4; BASF DocID 2016/1230128).

Analysis of diet preparations for homogeneity and test-item content

Nominal concentration [g/100 ml]	Sampling	Concentration measured [g/100 ml] Mean ± SD#	Relative standard deviation [%]	% of nominal concentration
1.0	23.08.2016	0.895 ±0.031	3.4	89.5
3.0	23.08.2016	2.516		83.9
		2.583 (R)		86.1
10.0	23.08.2016	9.293 ±0.135	1.4	92.9

(R) Reserve sample
Values may not calculate exactly due to rounding of values

As indicated by relative standard deviations of 1.4 to 3.4%, the prepared dosing suspensions were homogenous. The test-item content at the low and high concentration was within the acceptable range of 90 to 110%. The concentration at the mid dose was slightly below this range.

4. Statistics:

Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to following tables:

Statistics of clinical examinations

Parameter	Statistical test
Body weight, body weight change	A comparison of each group with the control group was performed using DUNNETT's test (two-sided) for the hypothesis of equal means
Rearing, grip strength forelimbs, grip strength hind limbs, foots play test, motor activity	Non-parametric one-way analysis using KRUSKALWALLIS test (two-sided). If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using WILCOXON test (two-sided) for the equal medians

Statistics of clinical pathology

Parameter	Statistical test
Blood parameters	For parameters with bidirectional changes: Non-parametric one-way analysis using KRUSKAL-WALLIS test. If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using WILCOXON-test (two-sided) for the hypothesis of equal medians
Urinalysis parameters (apart from pH, volume, specific gravity, color and turbidity)	Pairwise comparison of each dose group with the control group using the WILCOXON-test (one-sided) for the hypothesis of equal medians. In case of exactly the same numbers of the dose group and the control, no statistical test is performed.
Urine pH, volume, specific gravity	Non-parametric one-way analysis using KRUSKAL-WALLIS test. If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using WILCOXON-test (two-sided) for the hypothesis of equal medians.
Urine color and turbidity	Urine color and turbidity are not evaluated statistically.

Statistics of pathology

Parameter	Statistical test
Weight parameters	Non-parametric one-way analysis using KRUSKAL-WALLIS test (two-sided). If the resulting p-value was equal or less than 0.05, a pair wise comparison of each dose group with the control group was performed using the WILCOXON test (two-sided) for the equal medians

C. METHODS

1. Observations:

The animals were examined for morbidity or mortality twice daily on working days and once daily on weekends and public holidays. If animals were in a moribund state, they were sacrificed and necropsied.
All animals were checked daily for any abnormal clinically signs before the administration as well as within 2 hours and within 5 hours after the administration.
Detailed clinical observations were performed in all animals prior to the start of the administration period and weekly thereafter. For this, the animals were transferred to a standard arena (50 x 37.5 cm; sides 25 cm high). The findings were ranked according to the degree of severity, if applicable. The following parameters were examined:

1. abnormal behavior during handling	10. abnormal movements
2. fur	11. impairment of gait
3. skin	12. lacrimation
4. body posture	13. palpebral closure
5. salivation	14. exophthalmus
6. respiration	15. feces (appearance/consistency)
7. activity/arousal level	16. urine
8. tremors	17. pupil size
9. convulsions	

2. Body weight:

The body weight of the animals was determined before the start of the administration period (in order to randomize the animals), at the start of the treatment (day 0) and at weekly intervals thereafter. The difference between the body weight on the respective day of weighing and the body weight on day 0 was calculated as body weight change.

3. Food consumption

Food consumption was determined weekly and calculated as mean food consumption in grams per animal and day.

4. Water consumption:

Drinking water consumption was monitored by daily visual inspection of the water bottles for any changes in volume.

5. Ophthalmoscopy:

The eyes of all animals were examined prior to the start of the administration period. At the end of the administration period, i.e. study day 27, the eyes of animals in test groups 0 (control) and 3 (1000 mg/kg bw/d) were examined for any changes using an ophthalmoscope (HEINE OPTOTECHNIK, Herrsching, Germany) after application of a mydriatic (Mydrum, Chauvin ankerpharm GmbH, Rudolstadt, Germany).

6. Functional observation battery (FOB):

A functional observational battery was performed in all animals at the end of the administration period starting at about 10:00 a.m. At least one hour before the start of the FOX the animals were transferred into single-animal polycarbonate cages. The FOB started with passive observations without disturbing the animals (home cage observations), followed by removal from the home cage and open field observations in a standard arena. Thereafter, sensorimotor tests and reflex tests were conducted. The examinations were carried out by trained technicians not being aware of the group allocation of the animals. The findings were ranked according to the degree of severity, if applicable.

During the home cage observation special attention was paid to posture, tremors and convulsions, abnormal movements and gait abnormalities.

For open field observation the animals were transferred to a standard arena (50 x 50 cm with sides of 25 cm high) and observed for at least 2 minutes. The following parameters were assessed:

1. behavior when removed from cage	10. respiration
2. fur	11. tremors
3. skin	12. convulsions
4. salivation	13. abnormal movements/stereotypes
5. nose discharge	14. impairment of gait
6. lacrimation	15. activity/arousal level
7. eyes/pupil size	16. feces (number of fecal pellets/appearance/ consistency) within two minutes
8. posture	17. urine (appearance/quantity) within two minutes
9. palpebral closure	18. number of rearings within two minutes
	19. other findings

For sensorimotor tests and reflexes the animals were removed from the open field. The following tests were performed:

1. approach response	8. behavior during "handling"
2. touch response	9. vocalization
3. vision ("visual placing response")	10. pain perception ("tail pinch")
4. pupillary reflex	11. grip strength of forelimbs
5. pinna reflex	12. grip strength of hind limbs
6. audition ("startle response")	13. landing foot-splay test
7. coordination of movements ("righting response")	14. other findings

7. Motor activity measurement:

Motor activity was measured at the same day when the FOB was performed in a randomized order. The measurement was performed in the dark using the TSE Labmaster System (TSE Systems GmbH, Bad Homburg, Germany) with 18 beams per cage. During the measurement the animals were kept in clean polycarbonate cages with absorbent material. Motor activity measurements were conducted from 2:00 p.m. onwards. The number of beam interrupts was counted over twelve 5 minute intervals. Measurement started when the first beam was interrupted by pushing the cage into the rack (staggered start). Measurements ended exactly 60 minutes thereafter. During the measurements the animals received no food and no water.

8. Hematology and clinical chemistry:

Blood was taken in the morning from fasted, isoflurane anesthetized animals from the retro-orbital venous plexus. The blood sampling procedure and the subsequent analysis of the blood and serum samples were carried out in a randomized sequence.

The following hematological and clinical chemistry parameters were determined for 10 animals per test group and sex:

Hematology:					
	Red blood cells		*White blood cells*		*Clotting Potential*
✓	Erythrocyte count (RBC)	✓	Total leukocyte count (WBC)	✓	Platelet count
✓	Hemoglobin (Hb)	✓	Differential blood count	✓	Prothrombin time
✓	Hematocrit (Hct)				
✓	Mean corp. volume (MCV)				
✓	Mean corp. hemoglobin (MCH)				
✓	Mean corp. Hb. conc. (MCHC)				
✓	Reticulocytes				
Clinical chemistry:					
	Electrolytes		*Metabolites and Proteins*		*Enzymes:*
✓	Calcium	✓	Albumin	✓	Alanine aminotransferase (ALT)
✓	Chloride	✓	Bile acids	✓	Aspartate aminotransferase (AST)
✓	Phosphorus (inorganic)	✓	Bilirubin (total)	✓	Alkaline phosphatase (ALP)
✓	Potassium	✓	Cholesterol	✓	γ-glutamyl transpeptidase (γ-GT)
✓	Sodium	✓	Creatinine		
		✓	Globulin (by calculation)		
		✓	Glucose		
		✓	Protein (total)		
		✓	Triglycerides		
		✓	Urea		

9. Urinalysis:

The dry chemical reactions on test strips (Combur-10-test M, Roche, Mannheim, Germany) used to determine urine constituents semiquantitatively were evaluated with a reflection photometer (Miditron M; Roche, Mannheim, Germany). The following parameters were determined in all animals:

Urinalysis					
	Quantitative parameters:		*Semiquantitative parameters*		
✓	Urine volume	✓	Bilirubin	✓	Protein
✓	Specific gravity	✓	Blood	✓	pH-value
		✓	Color and turbidity	✓	Urobilinogen
		✓	Glucose	✓	Sediment (microscopical exam.)
		✓	Ketones		

10. Sacrifice and pathology:

All animals were sacrificed by decapitation under isoflurane anesthesia. The exsanguinated animals were necropsied and assessed by gross pathology. Special attention was given to the gastrointestinal tract (duodenum). The organs were sampled, weighed, and examined histopathologically as indicated in the table below.

Pathology:

The following organs were collected (column C), weighed (W) and examined histopathologically (H, ✓: all groups, #: control and top dose).

C	W	H		C	W	H		C	W	H	
✓	✓	#	adrenals	✓		#	larynx	✓		#	skin

11. Plasma kinetics

On study day 15, EDTA blood samples (~ 200µL) were obtained from non-fasted animals by puncturing the retro-orbital plexus under isoflurane anesthesia. The first 5 animals of each group were bled 2 hours after the administration of the test substance while the last 5 animals of each group were bled 4 hours after administration. The plasma was analyzed for the test item concentration, i.e. Reg. No 399379 (500M106) and for its presumed metabolite Reg. No 298327 (500M04) as this metabolite was identified in urine of the ^{14}C-Reg.No. 339379 rat ADME study (see M-CA 5.1).

II. RESULTS AND DISCUSSION

A. Observations

1. Clinical signs of toxicity

No test substance-related effects were observed.

2. Mortality

No animal died prematurely in this study.

3. Ophthalmoscopy

No test substance-related effects were observed. The incidence and distribution of findings was comparable between control and high dose (1000 mg/kg bw/day) animals and typical for the strain and age of animals used.

B. Body weight and body weight gain

No test substance-related changes in body weight parameters of both sexes were observed in treated animals when compared to controls. All values represent the normal biological variability typical for animals of this strain and age [see Figure 5.8.1-4 and Table 5.8.1-53].

Figure 5.8.1-4: Body weight development of male and female rats administered Reg.No. 399379 for 28 days

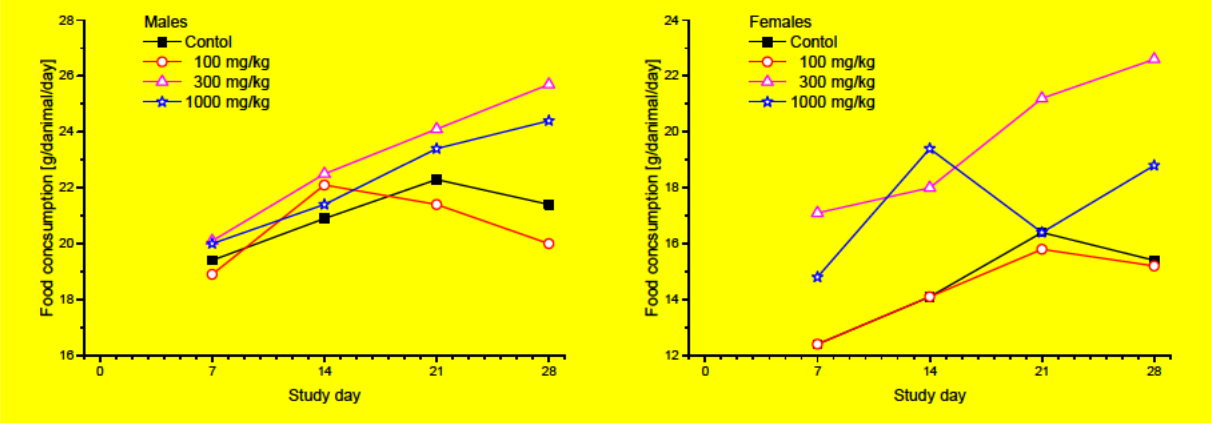
D. Food and water consumption

Food spillage was observed in all treated groups which led to the exclusion of some values in low (100 mg/kg bw/day) and mid dose (300 mg/kg bw/day) males. Even though there was a trend towards higher food consumption at dose levels ≥ 300 mg/kg bw/day, this increase was not strictly dose dependent and considered to be affected by the observed food spillage [see Figure 5.8.1-5].

Figure 5.8.1-5: Mean daily food consumption in rats administered Reg.No 399379 for 28 days



No treatment-related effects on food consumption were noted.

E. Functional observation battery and motor activity

1. Functional observational battery

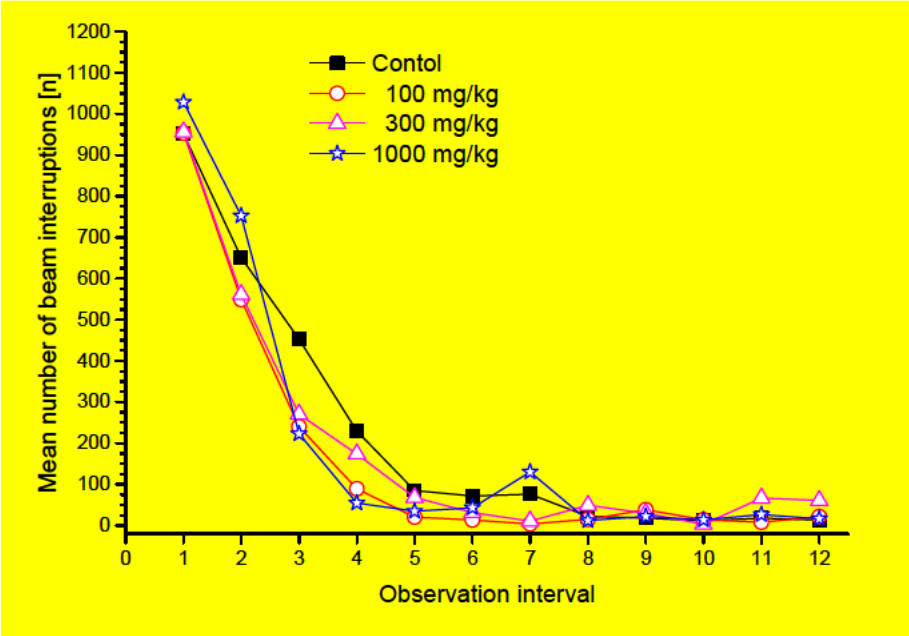
No treatment-related effects were observed during the FOB examinations. There were a few findings, which however were either equally distributed between treated groups and controls, were without a dose response relationship or occurred in single rats only. These observations were considered to be of incidental nature rather than related to treatment.

At the home cage observations and sensorimotor tests/reflexes the animals showed no test substance-related effects. Hind limb grip strength was significantly lower in low dose females. In absence of a dose-response relationship this was considered to be of incidental nature.

2. Motor activity measurement

No test substance-related effects were observed. In low dose males in the 7th observation interval the number of beam interruptions was statistically lower when compared to the control [see Figure 5.8.1-6]. In absence of a dose-response relationship this was considered to be unrelated to treatment. Furthermore, the total number of beam interruptions was comparable between all groups.

Figure 5.8.1-6: Motor activity of male rats administered Reg.No. 399379 for 28 days



F. Clinical biochemistry

1. Hematological findings

Treatment-related and adverse hematology changes were restricted to high dose males and females and consisted of a slight regenerative normochromic-normocytic anemia indicated by decreased erythrocyte counts (RBC), hemoglobin (HGB) and hematocrit (HCT) in males and increased absolute reticulocyte counts in both sexes [see Table 5.8.1-54].

Platelet counts were significantly higher in all treated male groups. However, the values were within the range observed in control animals of this strain and age (683-973 $x10^9$/L).
A statistically significant increase of the number of reticulocytes was noted in both sexes at the low dose level. Again, the numbers were within the historical control range (males: 102.1-184.6 $x10^9$/L; females: 102.2-189.8 $x10^9$/L) and not dose-related. The apparently dose related increase of reticulocytes in mid dose females appeared due to animal #64, which displayed a spontaneous malignant lymphoma resulting in a marked increase of reticulocyte counts (405.7 $x10^9$/L]. In addition, red blood cell counts (5.88 $x10^{12}$/L), hemoglobin (7.2 mmol/L) and hematocrit (0.332 L/L) indicated an anemic condition of this animal. If this animal is for good reasons excluded from calculation, the mean reticulocyte counts are well within the historical control range (see separate row at the end of Table 5.8.1-54).

A non-parametic trend test according to Jonkheere-Terpstra (Jonckheere A. R. (1954): A distribution-free k-sample test again ordered alternatives. Biometrika 41, 133–145; Terpstra T. J. (1952): The asymptotic normality and consistency of Kendall's test against trend, when ties are present in one ranking. Indagationes Mathematicae 14, 327–333) was performed using SAS as a step-down test to identify the minimum effective dose for effecs on reticulocyte counts. Statistical significance was only observed for the high dose of 1000 mg/kg (see BASF DocID 2017/1025730, available on request), confirming the view that values at the mid and low dose are not indicative for an effect of treatment.
A significantly prolonged prothrombin time (HepatoQuick) was noted in mid dose males, which was not dose-dependent and thus - like the other findings above – considered incidental and not related to treatment.

Table 5.8.1-54: Selected hematological parameters of rats administered Reg.No. 399379 for 28 days (Group means ± SD)

Parameter/Dose level [mg/kg]	0	100	300	1000

* $p \leq 0.05$, ** $p \leq 0.01$ (Kruskal-Wallis + Wilcoxon test (two-sided))
HCD Reticulocytes: males: 102.1-184.6 x10^9/L; females: 102.2-189.8 x10^9/L
HCD Platelets: males: 683-973 x10^9/L

2. Clinical chemistry findings

There were no treatment-related changes of clinical chemistry parameters. The only statistically significant difference consisted of a lower alanine amino transferase (ALT) activity in mid dose females (0.54 ± 0.11, 0.55 ± 0.08, 0.42* ± 0.08 and 0.51 ± 011 µkat/L at 0, 100, 300, 1000 mg/kg bw/day, respectively).

3. Urinalysis

No treatment-related changes of urinalysis parameters were noted.

4. Plasma kinetics

The concentrations of Reg.No. 399379 and its metabolite Reg.No. 298327 in plasma were determined using a validated analytical method (see M-CA 4, BASF DocID 2016/1333356). No detectable concentrations of Reg.No. 298327 were noted at any sampling time or administered dose. A number of Reg.No. 399379 concentrations were below the working Limit of Quantification (wLOQ) of 50 ng/ml plasma. This was especially the case at the low dose (all sampling times) and the mid and high dose in samples of the 4 hour sampling time. Thus, these values are of limited precision [see Table 5.8.1-55].

Table 5.8.1-55: Reg.No 399379 plasma levels 2 and 4 hours after administration [ng/ml]

Sex	Males		Females	
Sampling time [h]	2	4	2	4
0 mg/kg	n.d.	n.d.	n.d.	n.d
100 mg/kg	40.3 ±14.6	16.7 ± 5.7	15.8 ± 4.9	11.3 ± 7.9
300 mg/kg	70.4 ±28.9	48.1 ±34.1	64.1 ±31.8	15.9 ± 4.8
1000 mg/kg	143.3 ±39.7	118.5 ±37.4	132.0 ±18.4	47.6 ±15.7

Figures calculated based on unrounded values

The measurements were additionally affected by the low recovery observed in the stability samples. An initial investigation of Reg. No. 399379 stability samples (950 ng/mL) in plasma revealed a recovery of about 65% of the spiked concentration. These samples were generated at the day the plasma samples were obtained from the treated animals (07 September 2016) and stored frozen with the study plasma samples until analysis beginning of January 2017.
As the highest measured plasma concentrations at maximum reached about a fifth of the stability sample concentration, the recovery analysis of Reg. No. 399379 from spiked plasma samples was repeated at 5 concentrations ranging from about 50 (LOQ) to 250 ng/mL. The spiked plasma samples were frozen for about 48 hours prior to extraction and analysis. In order to investigate the influence of the extraction media on recovery, the plasma samples were either extracted with acetonitrile, which was used in the previous analyses, acetonitrile + acetone (4 + 1) or acetone. The samples were extracted and analyzed after stored frozen for about 48 hours. The analyses revealed a concentration dependent decrease of the recovery ranging from about 30% at 50 mg/mL to about 60% at 250 ng/ml [see Table 5.8.1-56]. The different extraction media did not have a substantial effect on the recovery.

Table 5.8.1-56: Recovery of spiked Reg.No 399379 from rat plasma

Samples	Determined concentration [ng/ml]	Nominal concentration [ng/ml]	Nominal concentration [% of nominal]
LS 1A	15.4	50.9	30.2
LS 2A	38.3	101.8	37.6
LS 3A	70.3	152.7	46.1
LS 4A	103.8	203.6	51.0
LS 5A	154.5	254.5	60.7
LS 5A Mix	161.9	254.5	63.6
LS 5A Acetone	144.5	254.5	56.8

Samples LS 1A – LS 5A: Standard extraction (100 % acetonitrile)
Sample LS 5A Mix: Extracted with acetonitrile + acetone (4 + 1)
Sample LS 5A Acetone: Extracted with 100 % acetone

The above investigation was likewise performed for Reg.No. 298327, as no 4-month stability samples were prepared for this metabolite. This was due to the fact that the decision to determine the plasma concentrations of Reg.No. 298327 was taken only in November 2016, i.e. about two months after blood sampling for plasma analysis (Amendment No. 6 to the study plan dated November 15, 2016). In contrast to Reg. No. 399379, recovery of Reg. No. 298327 was about 100% independent on the spiked concentration and the extraction media used [see Table 5.8.1-57.]

Table 5.8.1-57: Recovery of spiked Reg.No 298327 from rat plasma

Samples	Determined concentration [ng/ml]	Nominal concentration [ng/ml]	Nominal concentration [% of nominal]
LS 1B	56.4	55.4	101.8
LS 2B	107.9	110.8	97.4
LS 3B	166.9	166.2	100.4
LS 4B	218.0	221.6	98.4
LS 5B	275.3	277.0	99.4
LS 5B Mix	275.7	277.0	99.5
LS 5B Acetone	277.5	277.0	100.2

Samples LS 1B – LS 5B: Standard extraction (100 % acetonitrile)
Sample LS 5B Mix: Extracted with acetonitrile + acetone (4 + 1)
Sample LS 5B Acetone: Extracted with 100 % acetone

The Quality Control samples used in the initial plasma analysis for Reg.No. 399379 consistently revealed values within ± 10% of the nominal concentrations. As these samples were immediately extracted after addition of Reg. No. 399379, it was speculated that the decreased recovery is due to the increased storage time and/or freezing procedure. In order to test this hypothesis, 5 replicate spiked plasma samples were extracted and analyzed immediately after preparation and after freezing for 2, 5 and 12 days.

Table 5.8.1-58: Time dependence of the recovery of spiked Reg.No 298327 from rat plasma

LS 3d	14.0	52.5	26.6
LS 4d	14.2	52.5	27.1
LS 5d	13.0	52.5	24.7
Mean ± SD			**26.0 ± 1.1**

Samples LS 1x – LS 5x: 5 Replicates spiked with about 50 ng/mL
a to d indicated the storage duration (a = no storage at -80°C, b, c, d = frozen storage for 2, 5, and 12 days, respectively)

The results this analysis confirmed the hypothesis as the recovery of spiked Reg.No. 399379 was 100% when the plasma was extracted at the day of preparation without freezing. In contrast, a time dependent decrease of the recovery of spiked Reg.No. 399379 was noted, decreasing from about 52% after 2 days freezing to about 26% after 12 days freezing [see Table 5.8.1-58]. Due to time constraints no further time points could be evaluated. But as the decline of recovery diminished with time, it is to assumed that at a certain storage time the maximum decrease of the recovery is reached. This time is probably dependent of the amount of spiked Reg.No. 299378.

However, irrespective of the analytical difficulties to correctly determine the Reg. No. 399379 plasma concentrations, the concentrations are relatively low. The decrease of plasma concentrations in samples taken 2 and 4 hours after gavage application indicate that the peak plasma concentrations were probably reached prior to the 2 hour sampling time.

The low Reg.No. 399379 concentrations in plasma are not necessarily indicating a low systemic bioavailability of the test item and its metabolites. This is indicated by the fact that in the absorption and distribution study with Reg.No. 399379 in mice (see BASF DocID 2016/1225930), total radioactivity levels in plasma equivalent to about 110 µg/mL were determined 4 hours after single gavage administration of 500 mg/kg bw. It is important to note that the vehicle and the route of application in both studies, i.e. the 28-day rat and the mouse study were identical. This plasma concentration of Reg.No. 399379 and its metabolites in mice is 3 orders of magnitude higher than the concentration of Reg.No. 399379 in rats.

Furthermore, the ^{14}C-Reg.No. 399379 metabolism study in rats revealed a systemic bioavailability of at least 17% as shown by the amount of radioactivity excreted in the urine after administration of a single dose of 10 mg/kg bw by gavage as suspension in 0.5% aqueous CMC (see BASF DocID 2015/1198482).

G. Necropsy

1. Organ weight

Changes of absolute and or relative organ weights were noted in high dose males and consisted of increased liver and duodenum weights. In addition, relative liver weights significantly increased in high dose females [see Table 5.8.1-59].
While the increased liver weights in males were accompanied by histopathological changes, no corroborative changes were noted in the duodenum in males. Despite the lack of a histopathological correlate, the weight changes in the duodenum were – like those in the liver of males – considered to be related to treatment.
In contrast, the marginal, but statistically significant increase of relative liver weights in high dose females was within the historical control range (2.525 - 2.918%) and not corroborated by histopathological changes. Thus, this change was considered to be of incidental nature.

The liver (8.15 g) and especially spleen weights (3.31 g) of mid dose female #64, which displayed a spontaneous malignant lymphoma, increased because of infiltrations with this tumor. This considerably affected the mean weights for these organs. Therefore, these organs were excluded from the calculation of means.

Table 5.8.1-59: Selected absolute and relative weights of rats administered Reg. No. 399379 for 28 days§

Sex		Males				Females			
Organ weight	Dose [mg/kg]	Absolute weight	Δ%	Relative weight [% of b.w.]	Δ% #	Absolute weight	Δ%	Relative weight [% of b.w.]	Δ% #

* $p \leq 0.05$; ** $p \leq 0.01$ (Kruskal-Wallis and Wilcoxon-test. two sided)
# Values may not calculate exactly due to rounding of figures
§ Female animal #64 excluded from calculation of liver and spleen group means

2. Gross and histopathology

There were no treatment-related gross necropsy findings. All findings were either observed in single incidences only and/or without a dose response.

Treatment-related histopathological findings were restricted to the high dose level and noted in the liver of high dose males and the spleen of high dose males and females [see Table 5.8.1-60]. In the liver of high dose males a minimal centrilobular hepatocellular hypertrophy was noted, which correlated to the increased liver weights. In the spleen an increased incidence and severity of extramedullary hematopoiesis was noted, which correlated to the slight anemia observed at this dose level. There was no histopathological correlate to the slightly increased absolute and relative duodenum weights.
The extramedullary hematopoiesis observed in low and mid dose animals was minimal only. Minimal extramedullary hematopoiesis is occasionally observed in control animals at incidences up to 100% (HCD: >47 studies conducted between 2011 and 2015). Thus the slightly increased incidence of this finding in mid dose females is considered incidental and unrelated to treatment.

Table 5.8.1-60: Selected histopathological findings in rats administered Reg.No 399379 for 28 days

Sex	Males				Females			
Dose [mg/kg]	0	100	300	1000	0	100	300	1000
Animals in group	10	10	10	10	10	10	10	10
Liver # examined	10	10	10	10	10	10	10	10
- hypertrophy, centrilob. (Zone 3)	0 -	0 -	0 -	4 *[1.0]*	0 -	0 -	0 -	0 -
Spleen # examined	10	10	10	10	10	10	10	10
- Extramedullary hematopoiesis	2	2	3	8	1	0	3	6
	[1.0]	*[1.0]*	*[1.0]*	*[1.9]*	*[1.0]*	-	*[1.0]*	*[1.5]*

[ ] mean severity grading; histopathological findings were graded minimal (Grade 1), slight (Grade 2), moderate (Grade 3), marked (Grade 4) and massive/severe (Grade 5). The mean severity is the sum of the gradings divided by the incidence

Overall, only the increased extramedullary hematopoiesis in the spleen was considered to represent an adverse treatment-related pathology finding. The minimal hepatocellular hypertrophy and slightly increased liver weights in high dose males as well as the slightly increased duodenum weights without histopathological correlate were considered treatment-related, but not adverse.

III. CONCLUSIONS

The administration of Reg.No. 399379 (500M106, metabolite of pyraclostrobin) as suspension in 0.5% aqueous CMC to male and female Wistar rats for 28-days caused treatment-related effects on red blood cell parameters (regenerative anemia in both sexes), the duodenum (increased weight in males), the liver (increased weight and hepatocellular hypertrophy in males) and the spleen (extramedullary hematopoiesis).

Therefore, under the conditions of the present study the no observed adverse effect level (NOAEL) was 300 mg/kg bw/d in male and female Wistar rats, respectively.

Genotoxicity studies of 500M106 (Reg.No. 399379)

Report:	CA 5.8.1/43 Woitkowiak C., Landsiedel R., 2016 a Reg.No. 399379 (Metabolite of BAS 500 F, Pyraclostrobin) - Salmonella Typhimurium / Escherichia Coli reverse mutation assay 2016/1119837
Guidelines:	OECD 471 (1997), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.13/B.14 No. L 142, EPA 870.5100
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

S. typhimurium and E. coli were exposed to Reg.No. 399379 (metabolite of pyraclostrobin; batch: L87-58, purity: 97.6%) using dimethylsulfoxide (DMSO) as a solvent in the presence and absence of metabolic activation in a standard plate and preincubation test. Triplicate plates were used per dose and per test condition. Vehicle and positive controls were included in each experiment. In the standard plate and preincubation test Reg.No. 399379 was tested at concentrations of 3.3 to 5200 µg/plate. In the plate incorporation assay a weak bacteriotoxic effect was observed in the tester strain TA 98 in the presence of S9 mix at 5200 µg/plate. In the preincubation assay a weak bacteriotoxic effect was observed in TA 1537 with S9 mix at a concentration of 1000 µg/plate. Precipitation of the test substance was found from 1000 µg/mL onward in the presence or absence of S9 mix.

A biologically relevant increase in the number of revertant colonies was not noticed in any of the strains tested in the presence or absence of metabolic activation in any of the experiments. The slight increase in the number of his^+ revertants observed in tester strain TA 100 with S9 mix was under the threshold of factor 2.0 and only at doses where evident test substance precipitations were found. The number of revertant colonies in the negative controls was within the range of the historical negative control data for each tester strain in the presence or absence of S9 mix. The positive controls induced the appropriate response in the corresponding strains, thus demonstrating the sensitivity of the test system.

According to the results of the study, test substance Reg.No. 399379 was not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions of the study.

(BASF DocID 2016/1119837)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg. No. 399379 (metabolite of pyraclostrobin)

Description: Solid, orange

Lot/Batch #: L87-58

Purity: 97.6% (tolerance ± 1.0%)
Impurities: 1.6% Reg.No. 369315 (azo), 0.2% Reg.No. 364380 (azoxy)

Stability of test compound: The stability of the test item under storage conditions over the study period was guaranteed by the sponsor (expiry date June 01, 2017). The stability in DMSO over 4 h was verified analytically.

Solvent used: Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control: In parallel to each experiment, negative control experiments were carried out in order to check for possible contaminants (sterility control) and to determine the spontaneous mutation rate (vehicle control).

Vehicle control: The vehicle control with and without S-9 mix only contained the vehicle used for the test substance at the same concentration and volume for all tester strains.

Solvent/final concentration: 100 µL/plate

Positive control compounds tested without addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1535	N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	5 µg/plate
TA 1537	9-Aminoacridine (AAC)	DMSO	100 µg/plate
TA 98	4-nitro-o-phenylendiamine (NOPD)	DMSO	10 µg/plate
WP2 uvrA	4-nitroquinoline-N-oxide (4-NQO)	DMSO	5 µg/plate

Positive control compounds tested with addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1535	2-aminoanthracene	DMSO	2.5 µg/plate
TA 1537	2-aminoanthracene	DMSO	2.5 µg/plate
TA 98	2-aminoanthracene	DMSO	2.5 µg/plate
WP2 uvrA	2-aminoanthracene	DMSO	60.0 µg/plate

To demonstrate the efficacy of the S9 mix in this assay, the S9 batch was further characterized with benoz(a)pyrene in the strains TA 100 and TA 98 as required in OECD 471.

3. Activation:

S9 was produced from the livers of induced male Wistar rats. The rats received phenobarbital (80 mg/kg bw; i.p.) and β-naphthoflavone (80 mg/kg bw; orally) each on three consecutive days. 24 h after the last administration the animals were sacrificed and the livers were prepared. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction is thawed at room temperature and 1 volume of S9-fraction is mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9-mix, was kept on ice until used.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10 %

4. Test organisms:

S. typhimurium strains: TA98, TA100, TA1535, TA1537
E. coli: WP2 uvrA
Salmonella typhimurium:
The Salmonella strains are checked for the following characteristics at regular intervals: deep rough character (rfa); UV sensitivity (uvrB); ampicillin resistance (R factor plasmid). E. coli WP2 uvrA is checked for UV sensitivity.
Histidine and tryptophan auxotrophy is automatically proven in each experiment via the spontaneous rate.

5. Test concentrations:

Plate incorporation assay:	In the first experiment triplicate plates were prepared for each concentration (neg. control; 33, 100, 333, 1000, 2600, 5200 µg/plate and positive controls at the concentrations indicated above) and conditions (i.e. with and without S9) for all tester strains indicated above.
Pre-incubation assay:	In the second experiment triplicate plates were prepared for each concentration (neg. control; 3.3, 10, 33, 100, 333, and 1000 µg/plate and positive controls at the concentrations indicated above) and condition (i.e. with and without S9) for all tester strains. Due to high precipitation in the first assay the doses were adjusted.

B. TEST PERFORMANCE:

1. Dates of experimental work: 22-Mar-2016 to 01-Apr-2016

2. Plate incorporation assay:

To test tubes containing 2 mL portions of warm soft agar (containing 0.5 mM histidine + 0.5 mM biotin), 0.1 mL test solution or vehicle, 0.1 mL fresh bacterial culture, 0.5 mL S9-mix (in tests with metabolic activation) or 0.5 mL phosphate buffer (in tests without metabolic activation) were added in the given order. After mixing, the samples are poured onto Minimal glucose agar plates. In the experiments with E. coli the warm soft agar contains 0.5 mM tryptophan instead of histidine + biotin. After incubation for 48-72 h at 37°C, his^+ or trp^+ revertants were counted.

3. Pre-incubation assay:

100 µL of test solution or vehicle, 0.1 mL bacterial suspension and 0.5 mL S9 mix or phosphate buffer were incubated at 37°C for about 20 minutes. Subsequently, 2 mL of soft agar was added and, after mixing, the samples are poured onto the agar plates.
After incubation in the dark for 48 to 72 hours at 37°C the bacterial colonies were counted.

4. Statistics:

No special statistical tests were performed.

5. Acceptance and assessment criteria:

Generally, the experiment was considered valid if the following criteria were met:

- The number of revertant colonies in the negative controls was within the range of the historical negative control data for each tester strain.
- The sterility controls revealed no indication of bacterial contamination.
- The positive control substances both with and without S9 mix induced a distinct increase in the number of revertant colonies within the range of the historical positive control data or above.
- Fresh bacterial culture containing approximately 10^9 cells per mL were used.

The test substance was considered positive in this assay if the following criteria were met:

- A dose-related and reproducible increase in the number of revertant colonies, i.e. at least doubling (bacteria strains with high spontaneous mutation rate, like TA 98, TA 100 and E. coli WP2 uvrA) or tripling (bacteria strains with low spontaneous mutation rate, like TA 1535 and TA 1537) of the spontaneous mutation rate in at least one tester strain either without S9 mix or after adding a metabolizing system.

A test substance was generally considered non-mutagenic in this test if:

- The number of revertants for all tester strains were within the historical negative control data range under all experimental conditions in at least two experiments carried out independently of each other.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The test substance was stable over the study period under the storage conditions. The stability of the test substance at room temperature in the vehicle DMSO was verified analytically.

B. TOXICITY AND SOLUBILITY

A weak bacteriotoxic effect (slight decrease in the number of his+ revertants) was observed in the standard plate test and only in the tester strain TA 98 with S9 mix at 5200 µg/plate.
In the preincubation assay, bacteriotoxicity (slight decrease in the number of his+ revertants) was observed in tester strains TA 1537 with S9 mix at a concentration of 1000 µg/plate only.
Strong test substance precipitation was found from about 1000 µg/plate onward with and without S9 mix. Furthermore, it was very difficult to distinguish between revertant colonies and precipitation at concentrations of 2600 and 5200 µg/plate in the 1st Experiment.

C. MUTATION ASSAYS

Neither in the plate incorporation nor in the preincubation experiment with and without metabolic activation was a biologically relevant increase in number of revertants observed in any strain tested [see Table 5.8.1-61]. The slight increase in the number of his+ revertants observed in tester strain TA 100 with S9 mix was under the threshold of factor 2.0 and only at doses where evident test substance precipitations were found.
In the 1st Experiment the counting of the revertant colonies of the two highest dose groups was extremely difficult and finally done manually. It cannot be excluded that the precipitates interfered with scoring. So, according to the OECD Guideline the test substance was tested up to one concentration that was insoluble in the final treatment mixture in the 2nd Experiment.
In this study with and without S9 mix, the number of revertant colonies in the negative controls was within the range of the historical negative control data for each tester strain. The positive controls yielded revertant numbers in a range expected for the respective strains and thus demonstrated the sensitivity of the test system.

III. CONCLUSION

According to the results of the present study, the test substance Reg.No. 399379 (metabolite of pyraclostrobin) is not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions chosen here.

Report:	CA 5.8.1/44 Schulz M., Landsiedel, R., 2016 b Reg.No. 399379 (metabolite of BAS 500 F, Pyraclostrobin) - In vitro gene mutation test in L5178Y mouse lymphoma cells ($TK^{+/-}$ locus assay, microwell version) 2016/1171390
Guidelines:	OECD 490 (2015), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.17 No. L 142, EPA 870.5300
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Reg.No. 399379 (metabolite of pyraclostrobin, batch: L87-58, purity: 97.6%) was tested in vitro for its ability to induce forward mutations in mammalian cells by assessing the mutation of the TK locus in Mouse Lymphoma L5178Y cells. Two independent experiments were conducted in the presence (4-h incubation) or absence (4-h and 24-h incubation) of metabolic activation with two parallel cultures each. Based on the results of a preliminary cytotoxicity assay, concentrations of up to 100 µg/mL were used in the main experiment. Methylmethanesulfonate (MMS), 7,12-dimethylbenz[a]anthracene (DMBA) and Cyclophosphamide (CPA) served as positive controls in the experiments without and with metabolic activation, respectively. After the incubation period treatment media were replaced by culture medium in both experiments and the cells were incubated for 48 h for expression of mutant cells. This was followed by incubation of cells in selection medium containing TFT for about 9 - 11 days.

In both experiments without S9 mix, no biologically relevant increase in the number of mutant colonies was observed independent of the treatment duration. However, in the presence of S9 mix, Reg.No. 399379 led to a concentration-dependent statistically significant increase in the number of mutant colonies in both experiments. From 50 µg/mL (Exp. 1) and from 18.75 µg/mL (Exp. 2) onward, the MF was clearly above the vehicle control and historical control data and was also exceeding the calculated borderline MF using the GEF of 126. In both experimental parts in the presence of S9 mix, markedly increased mutation rates were obtained, when RTG was reduced to values below 50%. Therefore, it cannot be ruled out that cytotoxicity contributed to the observed genotoxicity. In these experimental parts the ratio of small to large colonies was close to the observation after treatment with the positive control CPP. Thus, it has to be considered that the test substance may have induced clastogenic effects. The positive controls showed a distinct increase in induced mutant colonies, indicating that the tests were sensitive and valid.

Based on the results of the study it is concluded that under the conditions of this test Reg.No. 399379 (metabolite of pyraclostrobin) and/or its metabolites induced forward mutations and/or chromosomal aberrations in vitro in the mouse lymphoma assay with L5178Y TK+/- cells in the presence of metabolic activation.

(BASF DocID 2016/1171390)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg. No. 399379 (metabolite of pyraclostrobin)

Description:	Solid, orange
Lot/Batch #:	L87-58
Purity/content:	97.6% (tolerance ± 1.0%) Impurities: 1.6% Reg.No. 369315 (azo), 0.2% Reg.No. 364380 (azoxy)
Stability of test compound:	The stability of the test item under storage conditions over the study period was guaranteed by the sponsor (expiry date June 01, 2017).
Vehicle:	DMSO (1% final concentration)

2. Control Materials:

Negative control:	A negative control was not employed in this study
Solvent control:	1% (v/v) DMSO in culture medium
Positive control -S9:	Methyl methanesulfonate (MMS) 15 and 5 µg/mL during the 4-h and 24-h exposure (dissolved in medium)
Positive control +S9:	Cyclophosphamide (CPP) 2.5 µg/mL (dissolved in medium); 7,12-dimethylbenz[a]anthracene (DMBA) 1 µg/mL (dissolved in DMSO)

3. Activation: S9 was produced from the livers of phenobarbital/β-naphthoflavone induced rats. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction is thawed at room temperature and an appropriate amount of S9-fraction is mixed with an equal volume of S9-cofactor solution. The co-factors in the S9-mix had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2 \times 6H_2O$	8 mM

4. Test organism:	L5178Y mouse lymphoma cells were used. They have a high proliferation rate (doubling time about 9-10 h), a high plating efficiency (~90%) and a stable karyotype with a near diploid (40 ± 1) chromosome number. Stocks of the L5178Y cell line were maintained at -196°C in liquid nitrogen. Each batch used for mutagenicity testing was checked for mycoplasma contamination, karyotype stability, and spontaneous mutant frequency. Prior to treatment, spontaneous TK-deficient mutants were eliminated from the stock cultures by growing the cells for 1 day in pretreatment medium A and 3 days in pretreatment medium B (see below).
5. Culture media:	
Culture medium (basis):	RPMI-0 (RPMI 1640 medium with 1% of 10000 IU/10000 µg/mL Penicillin/Streptomycin, 1% Sodium Pyruvate (10 mM))
Medium (treatment +S9):	RPMI-0 + 5% FCS (RPMI-5)
Medium (treatment -S9):	RPMI-0 + 10% FCS (RPMI-10)
Medium (CE/selection):	RPMI-0 + 20% FCS (RPMI-20)
Pretreatment medium A:	("THMG" medium): RPMI-10 medium containing hypoxanthine (5 µg/mL), thymidine (3 µg/mL), methotrexate (0.1 µg/mL), and glycine (7.5 µg/mL).
Pretreatment medium B:	("THG" medium): RPMI-10 medium containing hypoxanthine (5 µg/mL), thymidine (3 µg/mL), and glycine (7.5 µg/mL).
Selection medium:	Complete culture medium supplemented with 4 µg/mL trifluorothymidine (TFT).
6. Locus examined:	thymidine kinase (TK)
7. Test concentrations:	
a) Preliminary toxicity assay:	Nine concentrations ranging from 8.2 to 2100 µg/mL (±S9)
b) Mutation assay:	
1st experiment:	1.56, 3.13, 6.25, 12.5, 25, 50, 100 µg/mL with and without metabolic activation (4-h exposure)
2nd experiment:	1.56, 3.13, 6.25, 12.5, 25, 50, 100 µg/mL without metabolic activation (24-h exposure)
2nd experiment:	4.69, 9.38, 18.75, 37.5, 50, 75, 100 µg/mL with metabolic activation (4-h exposure)

B. TEST PERFORMANCE:

1. Dates of experimental work: 18-Apr-2016 to 16-June-2016

2. Preliminary cytotoxicity assay:

A pre-test was performed in order to determine the concentration range of the mutagenicity experiments. Both, pH value and osmolarity were determined at the maximal concentration of the test item and in the solvent control without metabolic activation. Cells were treated for 4 h in the presence and absence of S9 mix with the test substance at concentrations from 8.2 to 2100 µg/mL. The relative suspension growth was determined.

3. Mutation Assay:

Pretreatment of cells:

During the week prior to treatment $3x10^5$ cells were seeded into 75 cm^2-flasks and incubated for 1 day with "THMG" medium and for the following 3 days in “THG” medium to eliminate spontaneous TK-deficient mutants.

Cell treatment and expression period:

The assay was performed in two independent experiments, using two parallel cultures each. The first main experiment was performed with and without liver microsomal activation and a treatment period of 4 hours. The second experiment was performed with a treatment period of 24 hours in the absence of metabolic activation and a treatment period of 4 hours in the presence of metabolic activation.

For each test group, $1.5x10^7$ ($1x10^7$ during 24 h exposure) cells per flask (75 cm^2 flasks) suspended in 20 mL RPMI medium were exposed to various concentrations of the test item either in the presence or absence of metabolic activation. Positive and solvent controls were performed in parallel. After 4 h (24 h in the second experiment), the test item was removed by centrifugation (173 x g, 5 min) and the cells were washed at least once in RPMI-5 medium. From each culture a sample of treated cells (2 x 10^5 cells/mL or 6 x 10^6 cells/flask) was pipetted in 75 cm² flasks and was incubated for a 2-day expression period. To maintain exponential growth during this phase, each culture was counted daily and the cell numbers were adjusted at each day to 2 x 10^5 cells/mL in 30 mL RPMI-10 medium. The cell numbers were determined using a cell counter.

Seeding for selection

For the selection of the mutants, the cells were centrifuged and resuspended in 50 mL selection medium. Per culture 200 µL were dispensed in each well of two 96-well plates (2000 cells/well). After incubation for at least 9 days, both the number of negative wells and the number of wells containing small or large colonies were scored for calculation of the mutant frequency (MF).

Cloning efficiency

For determination of cytotoxicity, at the end of the treatment (Cloning efficiency 1 (survival)) and expression period (Cloning efficiency 2 (viability)) the cells were centrifuged resuspended. Per culture 200 µL were dispensed in each well of two 96-well plates (1.6 cells/well). After incubation for 9 - 11 days the plates were scored for empty wells.
For calculation of the relative suspension growth (RSG) and the relative total growth (RTG) the cell counts determined within the expression period at 2nd and 3rd passage after exposure in the case of 4-hour exposure and 1st, 2nd and 3rd passage after exposure in the case of 24-hour exposure were used.

Colony counting

The number of empty wells and the number of wells containing colonies were scored and reported. The colonies are classified into large colonies (indication of gene mutation) and small colonies (indication of chromosome breakage). Small colonies are defined as less than 1/4 of the diameter of the well. Size is the key factor and morphology (the optical density of the small colonies is considerably higher) should be secondary.

Calculations and processing of the data:

Cloning efficiency 1 (survival) and 2 (viability) was determined for each test group and given as absolute and relative cloning efficiency (CE_x and RCE_x, respectively).

$$CE_x = \frac{-\ln(\text{total number of empty wells} \div \text{total number of seeded wells (96)})}{\text{number of seeded cells per well (1.6)}} \times 100$$

$$RCE_x = \frac{CE_x \text{ of the test group}}{CE_x \text{ of the negative / vehicle control}} \times 100$$

The RTG is the standard measure of cytotoxicity. This measure includes the relative growth in suspension (RSG) during the expression period and the relative cloning efficiency (RCE_2; viability) at the time the mutants are selected.
For taking into account any loss of cells during the 4-hour treatment period a relative growth during treatment factor (RGDT, %) was calculated by comparing the growth of each treated culture relative to the control:

$$\text{RGDT} = \frac{\text{Cell count after 4 h of the test group}}{\text{Cell count after 4 h of the negative/v ehicle control}} \times 100$$

The total suspension growth (SG) and the RSG (in %) were calculated for each test group as follows:

Total suspension growth after 4 hour-exposure

$$SG = \frac{\text{Cell count after 24 h}}{2 \times 10^5 \text{ cells per mL}^{1,2}} \times \frac{\text{Cell count after 48 h}}{2 \times 10^5 \text{ cells per mL}^2} \times \frac{\text{RGDT}}{100}$$

Total suspension growth (SG) after 24 hour-exposure:

$$SG = \frac{\text{Cell count after 24 h}}{2 \times 10^5 \text{ cells per mL}} \times \frac{\text{Cell count after 48 h}}{2 \times 10^5 \text{ cells per mL}^2} \times \frac{\text{Cell count after 72 h}}{2 \times 10^5 \text{ cells per mL}^2}$$

$$\text{RSG} = \frac{\text{SG of the test group}}{\text{SG of the negative/vehicle control}} \times 100$$

$$RTG = \frac{RSG \times RCE_2}{100}$$

[1] Cell number seeded following 4-hour treatment
[2] If cell number was lower than 2 x 10^5 cells per mL all remaining cells were seeded
The uncorrected mutant frequency per 10^6 cells ($MF_{uncorr.}$) was calculated for each test group as follows:

$$MF_{uncorr} = \frac{-\ln(\text{total number of empty well s} \div \text{total number of seeded wells (96)})}{\text{number of seeded cells per well (2000)}} \times 10^6$$

The corrected mutant frequency (MF_{corr}) was calculated regarding the values of CE_2:

$$MF_{corr} = \frac{MF_{uncorr}}{CE_2} \times 100$$

Determination of borderline mutant frequency based on GEF

The GEF (global evaluation factor) evaluation method requires that the MF exceeds a value based on the global distribution of the background MF of the test method. This value is defined as the mean of the negative/vehicle MF distribution plus one standard deviation. Based on a large data base (n = 493 experiments) from six laboratories a GEF of 126 mutant colonies per 10^6 cells (mean MF_{corr} = 99 x10^{-6} colonies; standard deviation = 27 x10^{-6} colonies) was calculated for the microwell method. To be judged positive the mutation frequency has to exceed a threshold of 126 colonies per 10^6 cells (GEF) above the concurrent negative/vehicle control value.

4. Statistics:

An appropriate statistical method to test for linear trend (MS EXCEL function RGP; 10) was performed to assess a possible linear dose-relation in mutant frequencies. The dependent variable was the corrected mutant frequency and the independent variable was the concentration. A trend was judged as statistically significant whenever the one-sided p-value (probability value) was below 0.05 and the slope was greater than 0. However, both, biological and statistical significance have been considered together.

5. Acceptability criteria:

A mutation assay is considered acceptable if it meets the following criteria (the current recommendations of the IWGT are considered):

- The absolute cloning efficiency obtained at the time of mutant selection (CE_2) of the negative/vehicle controls should fall in the range of 65 - 120%.
- The suspension growth (SG) of the negative/vehicle controls referring to the expression period following treatment should fall in the range of 8 - 32 for 4-hour exposure and 32 - 180 for 24-hour exposure.
- The mutant frequency of the negative/vehicle controls should fall within the range of 50 - 170 $x10^{-6}$ colonies.
- The positive controls should yield an absolute increase in total MF that is an increase above the spontaneous background MF (an induced MF [IMF]) of at least 300 $x10^{-6}$ colonies. The small colony MF should account for at least 40% of that IMF, means a small colony IMF of at least 120 x 10^{-6} colonies. Alternatively, the positive controls should induce at least 150 x 10^{-6} small colonies above the spontaneous background MF. The upper limit of cytotoxicity observed in the positive controls should have a RTG that is greater than 10%.
- The highest applied concentration of the test substance should be 2 mg/mL, 2 µL/mL or 10 mM, unless limited by cytotoxicity or solubility of the test substance. If toxicity occurs, the highest concentration should lower the RTG to 10 to 20% of survival. If precipitation occurs, the highest evaluated concentration should be the lowest concentration, where precipitation is observed by the unaided eye.

6. Evaluation criteria:

A test item is classified as mutagenic **if all** of the following criteria are met:

- The induced mutation frequency reproducibly exceeds a threshold of 126 colonies per 10^6 cells (GEF: Global Evaluation Factor) above the corresponding solvent control.
- Evidence of reproducibility of any increase in mutant frequencies, means the mutagenic response occurs at least in both parallel cultures of one experiment.
- A statistically significant dose-related increase in mutant frequencies using an appropriate statistical trend test.

The test substance is considered non-mutagenic **if at least one** of the following criteria are met:

- The mutation frequency is below a threshold of 126 colonies per 10^6 cells (GEF: Global Evaluation Factor) above the concurrent solvent control value.
- No evidence of reproducibility of an increase in mutant frequencies is obtained.
- No statistical significant dose-related increase in mutant frequencies using an appropriate statistical trend test.

However, in the evaluation of the test results the historical variability of the mutation rates in the solvent controls of this study were taken into consideration.
Results of test groups are generally rejected if the relative total growth is less than 10% of the vehicle control.
Whenever a test item is considered mutagenic according to the above mentioned criteria, the ratio of small versus large colonies is used to differentiate point mutations from clastogenic effects. If the increase of the mutation frequency is accompanied by a reproducible and dose dependent shift in the ratio of small versus large colonies clastogenic effects are indicated.

II. RESULTS AND DISCUSSION

A. PRELIMINARY CYTOTOXICITY ASSAY

In culture medium test substance precipitation occurred at 65.6 µg/mL and above at the end of treatment in the absence and the presence of S9 mix. After 4 hours treatment in the absence of S9 mix cytotoxicity indicated by reduced relative suspension growth of about or below 20% was observed at 131.3 µg/mL and above, while in the presence of S9 mix the cultures were not continued due to strong cytotoxicity at concentrations ≥ 65.6 µg/mL.

B. TREATMENT CONDITIONS

Osmolarity and pH values were not influenced by test substance treatment. In the 1st experiment, test substance precipitation in the culture medium was noted at the end of treatment at the highest concentration (100 µg/mL) in absence and presence of metabolic activation. In the 2nd experiment no precipitation was noted at the end of treatment.

C. CYTOTOXICITY

In the 1st experiment, no clear cytotoxic effects (indicated by reduced cloning efficiencies or reduced relative total growth (RTG) of below 20% of control) were observed irrespective of the presence of S9 mix. However, in both experimental parts at the highest applied concentrations, the RTG was reduced [see Table 5.8.1-62].
In contrary, in the 2nd experiment a decreased relative total growth was observed in the absence of S9 mix at 25 µg/mL (RTG: 17.7%) and above. In the presence of S9 mix a RTG of 14.0% was noted at 100 µg/mL [see Table 5.8.1-63].

D. MUTAGENICITY ASSAYS

No biologically relevant increase in the number of mutant colonies was observed in the 1st and 2nd experiment without metabolic activation after 4 and 24 hour exposure. In line with the recommendations of the current OECD Guideline No. 490, the mutation rate obtained in the 2nd experiment without S9 (24 hour exposure) at 50 µg/mL ($MF_{corr.}$: 166.0 per 10^6 cells) was excluded from assessment due to extremely strong cytotoxicity (RTG: 4.4%).

In contrast, a statistically significant and concentration related increase in the number of mutant colonies was observed after the addition of a metabolizing system in both experiments [see Table 5.8.1-62 and Table 5.8.1-63]. The corrected mutant frequencies were above the calculated threshold for a biologically relevant increase taking the Global Evaluation Factor (GEF) into consideration. The increase in mutation rates in the experiments in the presence of S9 mix displayed a statistically significant concentration dependent trend.

In both experiments at higher concentrations, the ratio of small to large colonies was close to the observation of effects after treatment with the positive control CPP. Thus, it has to be considered that the test substance may have induced clastogenic effects.

Both positive control substances known to induce gene mutations, MMS and DMBA, and the well-known clastogen CPP led to clearly increased mutant frequencies as expected. Currently only a small data set for the positive control substance DMBA is available for comparison. The mutant frequencies of the positive control clearly exceeded the respective calculated thresholds for a mutagenic effect based on the GEF. In addition, the corrected mutant frequencies were within or above our historical positive control data range (222.2 – 1496.6 per 10^6 cells; see report Appendix 7).

III. CONCLUSION

Under the experimental conditions chosen in this test, it is concluded that Reg.No. 399379 (metabolite of pyraclostrobin) and/or its metabolites induced forward mutations and/or chromosomal aberrations in vitro in the mouse lymphoma assay with L5178Y $TK^{+/-}$ cells in the presence of metabolic activation.

Report:	CA 5.8.1/45 Chang S., 2016 b Reg.No. 399379 (metabolite of BAS 500 F, Pyraclostrobin) - Micronucleus test in human lymphocytes in vitro 2016/1109533
Guidelines:	OECD 487 (2014), Commission Regulation (EU) No 640/2012, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.49
GLP:	yes (certified by Hessisches Ministerium für Umwelt, Klimaschutz, Landwirtschaft und Verbraucherschutz, Wiesbaden, Germany)

Executive Summary

Reg.No. 399379 (metabolite of pyraclostrobin; batch: L87-58; purity: 97.6%) was tested for its potential to induce micronuclei in human lymphocytes in vitro in the absence and presence of metabolic activation by S9 mix. At least two independent experiments were performed where the cells were incubated for 4 (±S9 mix) or 20 hours (-S9 mix) with the test substance at concentrations in the range of 1.1 up to 2049 µg/mL. The vehicle DMSO served as negative control, mitomycin C (4 h) and demecolcin (20 h) as positive controls in the absence of metabolic activation and cyclophosphamide as positive control in the presence of metabolic activation. Treatments started after a 48 hour stimulation period with phytohemeagglutinine. Twenty hours after commencement of treatment, cytochalasin B was added and the cultures were fixed and stained finally after another 20 hours. Cytokinesis-block proliferation index and cytostasis were determined in 500 binucleated cells/culture as cytotoxicity parameters and number of micronucleated cells were determined in 1000 binucleated cells/culture for evaluation of cytogenetic damage.

In the pulse (4h) experiments IA, IB and II in presence and absence of S9 mix, no cytotoxicity was observed up to the highest evaluated concentration, which is limited by precipitation. However, the continuous exposure experiment (20h) without metabolic activation (experiment II), the lowest precipitating concentration could not be evaluated due to strong cytotoxic effects. No relevant influence on osmolarity or pH value was observed.

In this study, neither a statistically significant nor a biologically relevant increase in the number of micronucleated cells was observed after treatment with the test item. The micronucleus rates of the cells after treatment with the test item were close to the range of the respective solvent controls and within the range of the laboratory historical control data (HCD). The positive control chemicals led to the expected increase in cells containing micronuclei, thus demonstrating the sensitivity of the test system.

In conclusion, Reg.No. 399379 (metabolite of pyraclostrobin) is considered to be non-mutagenic in this in vitro micronucleus test when tested up to precipitating or the highest evaluable concentration.

(BASF DocID 2016/1109533)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg. No. 399379 (metabolite of pyraclostrobin)

Description:	Solid, orange
Density:	NA
Lot/Batch #:	L87-58
Purity/content:	97.6% (tolerance ± 1.0%) Impurities: 1.6% Reg.No. 369315 (azo), 0.2% Reg.No. 364380 (azoxy)
Stability of test compound:	The stability of the test item under storage conditions over the study period was guaranteed by the sponsor (expiry date June 01, 2017).
Vehicle used:	DMSO (0.5% or 1% final concentration)

2. Control Materials:

Negative:	No negative control was employed in this study.
Vehicle control:	Culture medium with 0.5% (Exp. 1) and 1% (Exp. 2) DMSO
Positive control:	Without metabolic activation: Mitomycin C (MMC, 1 µg/mL; pulse treatment) dissolved in deionized water; Demecolcin (150 ng/mL; continuous treatment) dissolved in deionized water With metabolic activation: Cyclophosphamide (CPA, 12.5-17.5 µg/mL) dissolved in saline (0.9% NaCl)

3. Activation: S9 was produced from the livers of rats pretreated with β-naphthoflavone/phenobarbital. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction was thawed at room temperature and mixed with an appropriate volume of S9-supplement (cofactors). This preparation, the so-called S9-mix, was kept on ice until used.
The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	100 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM

A final protein concentration of 0.75 mg/mL was used. The S9 preparation had a protein concentration of 27.2 mg/mL.

4. Test organism: Human peripheral blood lymphocytes (drawn from healthy non-smoking donors not receiving medication)

5. Culture media:

Culture medium: Dulbecco´s Modified Eagles medium/Ham´s F12 (1:1) with GlutaMAX™ (200 mM) supplemented with 10% (v/v) fetal bovine serum (FBS), Pen/Strep (100 U/mL/100 µg/mL), HEPES (10 mM), heparin (125 U.S.P.-U/mL), phytohemeagglutinine (PHA, 3 µg/mL)

6. Test concentrations: (**bold**: groups evaluated for cytogenicity)

Experiment IA
(4-h exposure, ±S9): **2.6, 4.6, 8.0, 14**, 24.5, 42.8, 74.9, 131, 328, 820, 2049 µg/mL

Experiment IB
(4-h exposure, ±S9): **1.9, 3.3, 5.8**, 10.2, 17.8, 31.2, 54.6, 95.6, 167, 585, 2049 µg/mL

Experiment II
(4-h exposure, +S9): 1.1, 2.0, **3.5, 6.1, 10.7**, 18.7, 32.7, 57.1, 100, 175 µg/mL
(20-h exposure, -S9): 1.1, 2.0, 3.5, 6.1, **10.7, 18.7, 32.7**, 57.1, 100, 175 µg/mL

B. TEST PERFORMANCE

1. Dates of experimental work: 06-Apr-2016 to 24-May-2016

2. Dose selection:

Dose selection was performed according to the current OECD Guideline for the in vitro micronucleus test. The highest test item concentration should be 2000 µg/mL, 2 µL/mL or 10 mM, whichever is the lowest. At least three test item concentrations should be evaluated for cytogenetic damage.

A preliminary cytotoxicity test was performed to determine the concentrations to be used in the main experiment. Cytotoxicity is characterized by the percentages of reduction in the CBPI (Cytokinesis-block proliferation index) in comparison with the controls (% cytostasis) by counting 500 cells per culture in duplicate. The experimental conditions in this pre-experimental phase were identical to those required and described below for the mutagenicity assay. The pre-test was performed with 11 concentrations of the test item separated by no more than a factor of √10 and a solvent and positive control. All cell cultures were set up in duplicate. Exposure time was 4 hours (with and without S9 mix). The preparation interval was 40 hours after start of the exposure.

With regard to the purity (97.6 %) of the test item, 2049.0 µg/mL of Reg.No. 399379 (metabolite of pyraclostrobin) were applied as top concentration for treatment of the cultures in the pre-test. Test item concentrations ranging from 1.1 to 2049 µg/mL (with and without S9 mix) were chosen for the evaluation of cytotoxicity.

Precipitation of the test item was observed at the end of treatment at 8.0 µg/mL and above in the absence of S9 mix and at 14.0 µg/mL and above in the presence of S9 mix. Since the cultures fulfilled the requirements for cytogenetic evaluation, this preliminary test was designated Experiment IA.
On request of the sponsor, Experiment IA was repeated with 1% DMSO as solvent to achieve a solution and to analyze the precipitation limit in more detail by using the same top concentration (Exp. IB). In this experiment, precipitation of the test item was observed at the end of treatment at 5.8 µg/mL and above in the absence and presence of S9 mix.
Considering the precipitation in the experiments IA and IB, 175 µg/mL (with and without S9 mix) were chosen as top concentration in Experiment II.

3. Micronucleus test:

Pulse exposure:
About 48 h after seeding two blood cultures (10 mL each) were set up in parallel in 25 cm² cell culture flasks for each test item concentration. The culture medium was replaced with complete medium (with 10 % FBS) containing the test item. After 20 hours the cells were spun down by gentle centrifugation for 5 minutes. The supernatant was discarded and the cells were re-suspended in and washed with saline. The washing procedure was repeated once as described. After washing the cells were re-suspended in complete culture medium containing 10 % FBS (v/v). Cytochalasin B (4 µg/mL) was added and the cells were cultured another approximately 20 hours until preparation.

Continuous exposure:
About 48 h after seeding two blood cultures (10 mL each) were set up in parallel in 25 cm² cell culture flasks for each test item concentration. The culture medium was replaced with complete medium (with 10 % FBS) containing the test item. After 20 hours the cells were spun down by gentle centrifugation for 5 minutes. The supernatant was discarded and the cells were re-suspended in and washed with saline. The washing procedure was repeated once as described. After washing the cells were re-suspended in complete culture medium containing 10 % FBS (v/v). Cytochalasin B (4 µg/mL) was added and the cells were cultured another approximately 20 hours until preparation.

Preparation of cells:
The cultures were harvested by centrifugation 40 h after beginning of treatment. The cells were spun down by gentle centrifugation for 5 minutes. The supernatant was discarded and the cells were re-suspended in approximately 5 mL saline G and spun down once again by centrifugation for 5 minutes. Then the cells were re-suspended in 5 mL KCl solution (0.0375 M) and incubated at 37°C for 20 minutes. 1 mL of ice-cold fixative mixture of methanol and glacial acetic acid (19 parts plus 1 part, respectively) was added to the hypotonic solution and the cells were re-suspended carefully. After removal of the solution by centrifugation the cells were re-suspended for 2 x 20 minutes in fixative and kept cold. The slides were prepared by dropping the cell suspension in fresh fixative onto a clean microscope slide. The cells were stained with Giemsa.

4. Statistics:

The number of polychromatic erythrocytes with micronuclei was analyzed by comparing the dose groups with the vehicle control using the Chi square test.

5. Cytotoxicity evaluation:

Evaluation of cytotoxicity and cytogenetic damage:

Evaluation of the slides was performed using NIKON microscopes with 40 x objectives. The micronuclei were counted in cells showing a clearly visible cytoplasm area. The micronuclei have to be stained in the same way as the main nucleus. The area of the micronucleus should not extend the third part of the area of the main nucleus. 1000 binucleate cells per culture were evaluated for cytogenetic damage on coded slides. The frequency of micronucleated cells was reported as % micronucleated cells. To describe a cytotoxic effect, the CBPI (Cytokinesis-block proliferation index) was determined in 500 cells per culture and cytotoxicity is expressed as % cytostasis. A CBPI of 1 (all cells are mononucleate) is equivalent to 100 % cytostasis.

$$CBPI = \frac{(MONC \times 1) + (BINC \times 2) + (MUNC \times 3)}{n}$$

CBPI	Cytokinesis-block proliferation index
n	Total number of cells
MONC	Mononucleate cells
BINC	Binucleate cells
MUNC	Multinucleate cells

$$\text{Cytostasis \%} = 100 - 100\,[(CBPI_T - 1) / (CBPI_C - 1)]$$

T	Test item
C	Solvent control

6. Evaluation criteria:

Acceptability criteria:

- The rate of micronuclei in the solvent controls falls within the historical laboratory control data range.
- The rate of micronuclei in the positive controls is statistically significant increased.
- The quality of the slides must allow the evaluation of a sufficient number of analyzable cells.

Evaluation criteria:

A test item can be classified as non-clastogenic and non-aneugenic if:

- the number of micronucleated cells in all evaluated dose groups is in the range of the historical laboratory control data and
- no statistically significant or concentration-related increase of the number of micronucleated cells is observed in comparison to the respective solvent control.

A test item can be classified as clastogenic and aneugenic if:

- the number of micronucleated cells is not in the range of the historical laboratory control data and
- either a concentration-related increase in three test groups or a statistically significant increase in the number of micronucleated cells is observed.

If the above-mentioned criteria for the test item are not clearly met, the test item will be classified as equivocal or a confirmatory experiment may be performed. However, results may remain questionable regardless of the number of times the experiment is repeated.

An increase in the number of micronucleated mononucleate cells may indicate that the test item has aneugenic potential.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance in DMSO over 4 h was verified analytically (see separate report 01Y0701/14Y117).

B. CYTOTOXICITY

The highest treatment concentration in this study, 2049 µg/mL was chosen with regard to the purity (97.6 %) of the test item and with respect to the OECD Guideline 487 for the in vitro mammalian cell micronucleus test.
In Experiment IA, precipitation of the test item was observed at the end of treatment at 8.0 µg/mL and above in the absence of S9 mix and at 14.0 µg/mL and above in the presence of S9 mix. In Experiment IB, precipitation of the test item was observed at the end of treatment at 5.8 µg/mL and above irrespective of the presence of S9 mix. In addition, precipitation occurred in Experiment II in the absence of S9 mix at 57.1 µg/mL and above and in the presence of S9 mix at 10.7 µg/mL and above at the end of treatment.
No relevant influence on osmolarity or pH was observed.
When using 1% DMSO as solvent, the osmolarity is generally high compared to the physiological level of approximately 300 mOsm. This effect however, is based on a final concentration of 1% DMSO in medium. As the osmolarity is measured by freezing point reduction, 1% of DMSO has a substantial impact on the determination of osmolarity. The outcome of the study is not affected by this impact.
In Experiment IA and IB and in Experiment II in the presence of S9 mix, no cytotoxicity was observed up to the highest evaluated concentration, which is limited by precipitation. However, in Experiment II in the absence of S9 mix (20 hour treatment) strong cytotoxicity was observed at the first precipitating concentration (57.1 µg/mL), preventing the evaluation of the cultures.

B. MICRONUCLEUS ASSAY

In this study, neither a statistically significant nor a biologically relevant increase in the number of micronucleated cells was observed after treatment with the test item [see Table 5.8.1-64 and Table 5.8.1-65].

Table 5.8.1-64: Summary of results of the in vitro micronucleus test in human lymphocytes with Reg.No. 399379 (metabolite of pyraclostrobin) without S9 mix

Exp.	Preparation interval	Test item concentration in µg/mL	Proliferation index CBPI	Cytostasis in %[a]	Micronucleated cells in %[b]

		10.7[P]	2.03	16.1	0.35

a: For the positive control groups and the test item treatment groups the values are related to the solvent controls

b: The number of micronucleated cells was determined in a sample of 2000 binucleated cells

*: The number of micronucleated cells is statistically significantly higher than corresponding control values

P: Precipitation occurred at the end of treatment

n.c.: Not calculated as the CBPI is equal or higher than the solvent control value

1 DMSO 0.5 % (v/v)

2 DMSO 1.0 % (v/v)

3 CPA 15 µg/mL

4 CPA 12.5 µg/mL

5 CPA 17.5 µg/mL

The micronucleus rates of the cells after treatment with the test item were close to the range of the respective solvent control values and within the range of the laboratory historical control data (HCD). The HCD in the absence of S9 mix were 0.15-1.25% (95% control limits: 0.02 to 1.15%) for (4h) pulse treatment and 0.05-1.43% (95% limits: 0.05 – 1.05%) for continuous (20h) treatment. The HCD in the presence of S9 mix were 0.15-1.35% (95% limits: 0.08 – 1.20%) for pulse treatment.
All positive controls used, i.e. Demecolcin (150.0 ng/mL), MMC (1.0 µg/mL) or CPA (15.0, 12.5 or 17.5 µg/mL), caused distinct increases in the number of cells with micronuclei (4.0 – 10.05%), indicating the sensitivity of the test system.

III. CONCLUSION

In conclusion, it can be stated that under the experimental conditions reported, Reg.No. 399379 (500M106) did not induce micronuclei as determined by the in vitro micronucleus test in human lymphocytes. Therefore, the test item is considered to be non-mutagenic in this in vitro micronucleus test when tested up to precipitating or the highest evaluable concentrations.

Based on the positive invitro gene mutation assay in mammalian cells (mouse lymphoma $TK^{+/-}$ assay (MLA), higher tier in vivo mutagenicity assays were conducted. As the high number of small mutant colonies in the MLA indicated the possible induction of clastogenic effects, an in vivo micronucleus assay in mice was performed. The possible induction of gene mutations in vivo was investigated in a transgenic rodent assay using the Muta™Mouse model. The exposure of the target organs in these two assays was confirmed in a study investigating the absorption and distribution of ^{14}C-Reg.No. 399379 in mice using the same vehicle as in the in vivo mutagenicity assays.

Executive Summary

Reg.No. 399379 (500M106; metabolite of pyraclostrobin; batch: L87-58; purity: 97.6%) was tested for chromosomal damage (clastogenicity) and for the ability to induce spindle poison effects (aneugenic activity) in NMRI mice using the micronucleus test method. For this purpose, the test substance was administered once orally to groups of 7 male mice at dose levels of 500, 1000 and 2000 mg/kg bw. The vehicle served as negative and cyclophosphamide as positive control. The animals were sacrificed 24 or 48 (additional high dose and vehicle group) hours after the administration and the bone marrow was prepared and 4000 polychromatic erythrocytes per animal were scored for micronuclei.

The oral administration of Reg.No. 399379 did not lead to any biologically relevant increase in the number of polychromatic erythrocytes containing micronuclei. The rate of micronuclei was close to the concurrent negative control and was within the range of the historical control data. Inhibition of erythropoiesis, determined from the ratio of polychromatic to normochromatic erythrocytes, did not occur. A separate study demonstrated that Reg.No. 379379 and its metabolites reached the bone marrow. Weak signs of systemic toxicity were observed in all dose groups consisting of ruffled fur.

The positive control cyclophosphamide led to the expected increase in the rate of polychromatic erythrocytes containing micronuclei, thus demonstrating the sensitivity of the test system.

In conclusion, under the experimental conditions of this study, the test substance Reg. No. 399379 (500M106) does not induce cytogenetic damage in bone marrow cells of NMRI mice in vivo.

(BASF DocID 2016/1295116)

I. MATERIAL AND METHODS

A. MATERIALS

1.	**Test Material:**	Reg.No. 399379 (metabolite of pyraclostrobin)
	Description:	Solid, orange
	Lot/Batch #:	L87-58
	Purity:	97.6% (tolerance ± 1.0%) Impurities: 1.6% Reg.No. 369315 (azo), 0.2% Reg.No. 364380 (azoxy)
	Stability of test compound:	The stability of the test substance under storage conditions throughout the study period was guaranteed until 01 June 2018 as indicated by the sponsor. Homogeneity of the test substance was guaranteed on account of the high purity and was ensured by mixing before test substance preparation.
	Vehicle used:	0.5% aqueous Carboxy Methyl Cellulose (CMC)

2.	**Control Materials:**	
	Negative:	No negative control was employed in this study.
	Vehicle control:	0.5% aqueous CMC
	Positive control:	Cyclophosphamide (CPA) 40 mg/kg, dissolved in water

3. Test animals:

Species:	Albino mice
Strain:	Crl:NMRI
Sex:	Males
Age:	6 - 7 weeks at commencement of treatment
Mean body weight at dosing:	36.3 ± 1.3 g
Source:	Charles River Laboratories Germany GmbH
Number of animals per dose:	7
Acclimation period:	At least 5 days
Diet:	Standardized pelleted feed (Maus/Ratte Haltung "GLP", Provimi Kliba SA, Kaiseraugst, Switzerland)
Water:	Drinking water in bottles, ad libitum
Housing:	During the study the mice were housed individually in Makrolon cages, type MII

4. Environmental conditions:

Temperature:	22 ± 2°C
Humidity:	45 - 65%
Air changes:	frequency not indicated (fully air-conditioned rooms)
Photo period:	12-hour light-dark cycle (06:00 - 18:00, 18:00 - 06:00)
Husbandry:	Single housing in Makrolon Type II cages with wire mesh top and granulated soft wood bedding
Diet:	Standard pelleted diet (Teklad Certified Global 18% Protein Rodent diet)

5. Test compound doses:

Micronucleus assay:	500, 1000 and 2000 mg/kg The test substance was administered once by oral gavage using an application volume of 10 mL/kg.

B. TEST PERFORMANCE

1. Dates of experimental work: 15-Sep-2016 to 04-Oct-2016

2. Preliminary range finding test:

No preliminary range finding test was performed based on existing data showing that the compound is virtually non-toxic to mice.

3. Micronucleus test:

Treatment and sampling:	For the 24-hour sacrifice interval, groups of 7 male mice were treated once with either vehicle or 500, 1000 or 2000 mg test item/kg bw or the positive control Cyclophosphamide at 40 mg/kg bw by oral gavage. For the 48-hour sacrifice interval, additional groups of 7 male mice were treated with either the vehicle control or the high dose 2000 mg/kg bw. The application volume was 10 mL/kg bw and the volume to be applied was calculated based on actual weight on the day of administration. The animals were observed for evident clinical signs of toxicity at intervals of around 0-1 h, 2-4 h, 5-6 h, 24 h and/or 48 h. Twenty-four or 48 hours after administration, mice were sacrificed and the two femora were prepared. The epiphyses were cut off and the marrow was flushed out with foetal calf serum. The cell suspension was centrifuged at 1500 rpm (390 x g) for 10 minutes and the supernatant was discarded. A small drop of the re-suspended cell pellet was spread on a slide. The smear was air-dried and then stained with May-Grünwald/Giemsa. At least one slide was made from each bone marrow sample. Additional bone marrow smears (3 additional slides per animal) were made and were air-dried and fixed with ice-cold absolute methanol (fixation time: 10 minutes). These slides were stored frozen at ≤ -18°C until possible further use.
Slide evaluation:	Microscopic evaluation of the slides was at 100x magnification. Per animal 4000 polychromatic erythrocytes (PCE) were analyzed for micronuclei. To describe a cytotoxic effect, the ratio between polychromatic and normochromatic erythrocytes was determined in the same sample and expressed in polychromatic erythrocytes per 500 erythrocytes. The analysis was performed with coded slides. All animals per group were evaluated.

4. Statistics:

The study results were tested for statistical significance using the non-parametric Mann-Whitney test.

5. Acceptance criteria:

The study is considered acceptable if the following criteria are met:

- The concurrent negative control is considered acceptable for addition to the laboratory historical control database (should ideally be within the 95% control limits of the distribution of the historical negative control database).
- At least 5 animals per group can be evaluated.
- The appropriate number of doses and cells have been analyzed.
- PCE to total erythrocyte ratio should not be less than 20% of the negative control.
- The positive control shows a statistically significant increase of micronucleated PCEs compared to the negative control and is comparable to those in the historical positive control database.

6. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- At least one of the treatment groups exhibits a statistically significant increase in the frequency of micronucleated immature erythrocytes compared with the concurrent negative control,
- This increase is dose-related at least at one sampling time when evaluated with an appropriate trend test, and
- Any of these results are outside the distribution of the historical negative control data (e.g. Poisson-based 95% control limits).

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance in the vehicle was verified analytically (see Study 01Y0701/14Y119 included in Volume III of the Reg.No. 399379 28-day study (BASF DocID 2016/1288407)). The homogeneity of the test substance in the vehicle was guaranteed by constant stirring. As indicated by relative standard deviations in the range of 1.8 to 2.5% the dosing suspensions were homogenous and within the expected range (90-110%) [see Table 5.8.1-66].

Table 5.8.1-66: Analysis of Reg.No. 399379 dosing suspension for homogeneity and test-item content

Nominal concentration [mg/mL]	Sampling	Concentration measured [g/100 ml] Mean ± SD[#]	Relative standard deviation [%]	% of nominal concentration
50	20.09.2016	44.7 ± 1.0	2.3	89.5
100	20.09.2016	100.6 ± 1.8	1.8	100.6
200	20.09.2016	189.0 ± 4.7	2.5	94.5

[#] Values may not calculate exactly due to rounding of values

B. PRELIMINARY RANGE FINDING TEST

Existing information indicated that Reg.No. 399379 is of low toxicity to mice. Thus, no range finding study was conducted in the context of this micronucleus study in mice.

C. MICRONUCLEUS ASSAY

1. Clinical signs of toxicity

No mortality was observed up to the highest dose tested (2000 mg/kg bw). A dose dependent increase of the incidence of ruffled fur was noted, which (with the exception of one mid dose mouse) was reversible within 24 hours.

2. Evaluation for micronuclei

Micronucleus frequencies of Reg.No. 399379 treated animals were near to the concurrent vehicle control values irrespective of the applied dose or the sampling time [see Table 5.8.1-67] as well as within the historical control range [see Table 5.8.1-68].
The positive control cyclophosphamide resulted in a statistically significant increase of the number of micronuclei in polychromatic erythrocytes, thus demonstrating the sensitivity of the test system.

3. Proof of bone marrow exposure

The PCE/NCE ratio was not affected by treatment with the test substance [see Table 5.8.1-67], i.e. no adverse effect on the bone marrow was noted. However, administration of ^{14}C-Reg.No. 399379 to male mice at a dose of 500 mg/kg by oral gavage revealed radioactivity equivalent to 109.4 µg Eq/g plasma and 46.1 µg Eq/g bone marrow 4 hours after administration [see below BASF DocID 2016/1225930]. These data clearly demonstrate that the bone marrow as highly blood perfused organ is exposed to Reg.No. 399379 and its metabolites.

Table 5.8.1-67: Micronucleus test in mice administered Reg.No. 399379 by oral gavage

Test Group	Dose [mg/kg bw]	Sampling time	MN/4000 PCE [Mean ± SD]	% MN [Mean ± SD]	Range		Ratio PCE /total Ery	% ratio Vehicle
					min	max		
Vehicle (0.5% CMC)	0	24	4.6 ± 1.9	0.12 ± 0.05	2	7	0.648	100.00
Dose 1	500	24	6.7 ± 3.2	0.17 ± 0.08	2	11	0.625	96.45
Dose 2	1000	24	6.9 ± 2.4	0.17 ± 0.06	4	9	0.655	101.08
Dose 3	2000	24	6.9 ± 2.0	0.17 ± 0.05	4	10	0.636	98.15

Range (individual animal data)	0 – 17	37 – 217
No. of Experiments	37	37

III. CONCLUSION

Based on the result of this study Reg.No. 399379 (500M106) does not induce the formation of micronuclei in mouse polychromatic erythrocytes under the conditions of the study, i.e. is devoid of clastogenic or aneugenic activity in vivo. A kinetic study demonstrated that Reg.No. 399379 reached the target organ (bone marrow) via the blood.

Report:	CA 5.8.1/48 [redacted], 2016 b 14C-Reg.No. 399379 (metabolite of BAS 500 F, Pyraclostrobin) - Study on the kinetics on mice 2016/1225930
Guidelines:	OECD 417, EPA 870.7485, JMAFF, (EC) No 440/2008 of 30 May 2008 - Part B No. L 142
GLP:	yes (certified by Landesanstalt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Rheinland-Pfalz, Mainz)

Executive Summary

A single target dose of 500 mg/kg bw of ^{14}C-Reg.No. 399379 (500M106) was administered to four male mice. Four hours after dosing, mice were sacrificed under isoflurane anesthesia and blood cells, plasma, bone marrow, liver, glandular und vestibule stomach were sampled and worked up for the detection of the radioactive residues in order to demonstrate that the test item and/or its metabolites reached the systemic circulation including organs/tissues. Corresponding samples of untreated mice served as controls.
The mean total radioactive residues (TRR) 4 h post dosing were 109.4 µg Eq/g in plasma and 46.1 µg Eq/g in bone marrow. In liver, blood cells, vestibule stomach and glandular stomach, mean total radioactive residues of 267.0, 33.8, 7798.5 and 397.2 µg Eq/g were found, respectively. Taken together, the data demonstrate that ^{14}C-Reg.No. 399379 and/or its metabolites reach the systemic circulation including bone marrow, vestibule and glandular stomach as well as liver after single oral administration of the test substance at a target dose of 500 mg/kg bw.

(BASF DocID 2016/1225930)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material (labelled):	^{14}C-Reg.No. 399379 (metabolite of pyraclostrobin)
Description:	Solid, orange
Lot/Batch #:	1166-1102
Purity (radiochemical):	>95% (96.8% according to the CoA)
Purity (chemical):	87.7%
Specific activity of AI:	6.44 MBq/mg
Specific activity:	29.6 MBq/g in acetonitrile
Stability of test compound:	The stability was verified within the current study.

2. Test Material (non-labelled):	Reg.No. 399379 (metabolite of pyraclostrobin)
Description:	Solid, orange
Lot/Batch #:	L87-58
Purity:	97.6%
Stability of test compound:	The stability was guaranteed by the sponsor (expiry date: 01 June 2017).
3. Vehicle:	0.5% CMC-solution (sodium carboxymethylcellulose) in tap water
4. Test animals:	
Species:	Mouse
Strain:	Crl:NMRI
Sex:	Male
Age:	4 weeks
Weight at dosing:	31.8 – 37.7 g
Source:	Charles River Laboratories, Research Models and Services, Germany GmbH, Sulzfeld, Germany
Acclimation period:	At least 5 days
Diet:	Kliba lab diet (mouse / rat "GLP") pellets, Provimi Kliba SA, Kaiseraugst, Basel, Switzerland, ad libitum
Water:	Tap water, ad libitum
Housing:	During acclimatization: Polycarbonate Cages (Type III)
	During the experiment: individual housing in Polycarbonate Cages (1291H; PC, 820 cm^2, Techniplast) with steel wire mesh ground (7 x 7 mm mesh wire).
Environmental conditions:	
Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	15 per h
Photo period:	Alternating 12-hour light and dark cycles, artificial light from 6 am to 6 pm

B. STUDY DESIGN AND METHODS

1. Dates of work: 19-July-2016 to 22-Aug-2016

2. Test substance preparation:

^{14}C-Reg.No. 399379 in acetonitrile (51.51 MBq) was taken to dryness under a stream of nitrogen and resuspended with an appropriate volume of a 0.5% aqueous CMC containing 47.49 mg/g of the non-radioactive test item by stirring with a magnetic stirrer and additional ultrasonication.

Before start and at the end of the administration, samples were taken to determine the specific activity of the test substance in the preparation and to demonstrate the correct concentration of the test substance, its homogeneity, stability as well as its radiochemical purity.
Based on the current data, the nominal concentration of the test substance preparation was 50.2 mg/mL and the nominal specific activity was 21.5 MBq/mL. The dosed amount of radioactivity per animal was between 5.2 and 6.5 MBq.

2. Homogeneity/Concentration and stability control:

The amount of radioactivity of ^{14}C-Reg.No. 399379 and the total amount of Reg.No. 399379 (sum of ^{14}C and non-radioactive) in the test substance preparation was determined by LSC, Radio-HPLC as well as HPLC-UV in samples that were taken before and after administration of the test substance preparation to the animals. The samples were prepared for analysis using conventional methods described in standard operating procedures. The analyses of these samples allow to demonstrate the homogeneity, correctness of the concentration and the stability of the test substance in the test substance preparation.

3. Study design and test groups:

The study was designed to obtain data to demonstrate that the test substance reaches the systemic circulation and defined organs / tissues. For this purpose, blood cells, plasma, bone marrow from the two femora, liver, glandular und vestibule stomach were prepared.
Additionally, a number of other organs were collected and stored frozen for potential future investigations (lung, heart, kidney, testes, epididymis and gut).
Treated animals were sacrificed 4 hours after administration, control animals were not treated and were sacrificed independently of any administration.

Two experiments were performed according to the following scheme:

Experiment 0	
Animals:	4 males
Radioactivity per animal:	untreated control
Dosing:	Untreated
Analysis:	total radioactivity (for determination of the detection limit)
Experiment 1	
Animals:	4 males
Radioactivity per animal:	4 – 8 MBq
Dosing:	1 oral dose, 500 mg/kg bw
Analysis:	total radioactivity

4. Experimental procedure and observations:

The animals were dosed at a volume of 10 mL/kg bw by oral gavage.

A check for moribund and dead animals was conducted at least once daily. A cage side examination was conducted at least once daily for any signs of morbidity, pertinent behavioral changes and signs of overt toxicity.

The body weight was determined on the day of administration prior to dosing for the animals of experiment 1; the animals of experiment 0 were weighed subsequently.

5. Sample work up and measurement:

Whole blood samples were inverted several times to ensure homogeneity and then separated into plasma and blood cells by centrifugation.

After weighing, aliquots of plasma were mixed with scintillation cocktail (Hionic Fluor, Perkin Elmer) and analyzed for radioactivity without any additional treatment.

The liver was homogenized. Subsequently 1 mL Soluene®-350 was added to aliquots of the suspensions and incubated over night at about 37°C and isopropanol was added afterwards. Bleaching was performed with 1 mL 30% H_2O_2 followed by incubation at room temperature at least over night. Hionic Fluor was added before measurement of radioactivity by LSC.

Blood cells, vestibule and glandular stomach were dissolved in Soluene®-350 and processed as described above. Bone marrow from the two femora was removed with a cotton ball, which transferred into a scintillation vial. After addition of Soluene the samples were processed as described for the liver.

All values given in the project and in the report are background corrected. The background values of LSC analyses were 10 to 170 cpm. The quantification limit (LOQ) for LSC measurement was set twice the background. For further calculations (e.g. mean values and standard deviations) samples < LOQ were set to 0.

II. RESULTS AND DISCUSSION

A. ANALYTICS

Concentration control analysis revealed that the dosing suspension had a concentration of 96.9% ± 4.9 (Mean ± RSD) of the nominal content (50.2 mg/mL).
The measured specific activity of the test-substance preparation (16.8 MBq/ml) compared to its target value (20 MBq/mL) was assessed to be acceptable within the precision of the method. Radio-HPLC analyses confirmed the stability of the radiolabelled test substance over the administration period by radiochemical purities of ^{14}C-Reg.No. 399379 (metabolite of pyraclostrobin) > 95%.

B. CLINICAL OBSERVATIONS AND MORTALITY

No mortality occurred during the study period. No clinical signs and findings were observed.

C. BODY WEIGHT

As to be expected for a short-term experiment (4 h), no effects on body weight were noted.

D. BIOKINETICS

After a single administration of ^{14}C-Reg.No. 399379 (Metabolite of BAS 500 F, Pyraclostrobin) to male mice at a target dose level 500 mg/kg bw, the mean actual nominal dose level was 497.1 mg/kg bw [see Table 5.8.1-69].

Quantifiable radioactive residues were observed in all organs and tissues examined. As to be expected the highest residues were found in the vestibular stomach in the mg Eq/g range. Lower residues in the µg Eq/g range were determined in glandular stomach, liver, plasma, bone marrow and blood cells [see Table 5.8.1-69]. Variabilities of the single animal data are assessed to reflect inter-individual variability in a normal range for kinetic studies.

Blood cells, plasma, bone marrow, vestibule and glandular stomach as well as liver from four untreated mice were collected and measured for total radioactivity (background levels). Taking the specific activity of administered ^{14}C-Reg.No. 399379 and the measured sample weights into account, double background levels corresponded to < 0.2 µg Eq/g for plasma, < 0.7 and 0.6 µg Eq/g for blood cells and liver, < 10 µg Eq/g for vestibule and glandular stomach and < 15 µg Eq/g for bone marrow, respectively.
These data demonstrate that the detected residue levels in blood cells, plasma, bone marrow, vestibule and glandular stomach as well as liver in mice dosed with ^{14}C-Reg.No. 399379 (metabolite of pyraclostrobin) at a dose level of 500 mg/kg bw were significantly above background.

Table 5.8.1-69: Radioactive residues (µg Eq/g) in selected organs and tissues of male mice treated with ^{14}C-Reg.No. 399379 at a target dose level of 500 mg/kg bw 4 hours after dosing

Parameter	Animal No.	5	6	7	8	Mean	SD

Bone marrow	[µg Eq/g]	41.2	32.6	58.4	52.1	46.1	11.4
Liver	[µg Eq/g]	302.5	264.9	235.6	264.8	267.0	27.4
Vestibule stomach	[µg Eq/g]	15840.8	3675.0	9323.7	2354.3	7798.5	6154.9
Glandular stomach	[µg Eq/g]	943.7	297.9	182.6	164.6	397.2	369.1

III. CONCLUSION

The current study demonstrated that radioactive residues of ^{14}C-Reg.No. 399379 are present in the systemic circulation and in bone marrow, vestibule and glandular stomach as well as liver of mice, four hours after single oral administration of the test substance at a target dose level of 500 mg/kg bw.

Report:	CA 5.8.1/49 [redacted] 2017 a Reg.No. 399379 (metabolite of BAS 500 F, Pyraclostrobin): Transgenic mice (MUTA mouse) gene mutation assay 2017/1002442
Guidelines:	OECD 488
GLP:	yes (certified by Ministry of Health and Welfare, Tokyo, Japan)

Executive Summary

Administration of Reg.No. 399379 (metabolite of pyraclostrobin; batch L85-218; purity: 97.7%) to groups of 6 Wistar rats at dose levels of 0, 100, 300 and 1000 mg/kg bw/day for 28-days resulted in adverse signs of systemic toxicity at 1000 mg/kg bw/day in both sexes.

Treatment with Reg.No. 399379 did not affect the survival, body weight development or food consumption or organ weights. The only histopathological finding consisted of an infiltration of inflammatory cells in one control and two top dose males (1000 mg/kg), which was considered to represent an incidental finding.

The evaluation of the mutant frequency in the target gene (lacZ), which in the strain of mice used is incorporated in about 80 copies into the mouse genome in a λ phage vector on chromosome 3, did not indicate an increased mutation rate. In contrast, the positive control N-ethyl-N-nitrosourea resulted in a statistically significant increase in mutant frequency, indicating the sensitivity of the test system.

Under the conditions of the present study Reg.No. 399379 (500M106) is not.

(BASF DocID 2017/1002442)

I. MATERIAL AND METHODS

A. MATERIALS

1.	**Test Material:**	Reg.No. 399379 (Metabolite of pyraclostrobin)
	Description:	Solid, orange
	Lot/Batch #:	L85-218
	Purity:	97.7% (tolerance ± 1.0%) 1.4% Reg.No. 369315, 0.2% Reg.No. 364380, 0.1% Reg.No. 4108340
	Stability of test compound:	The test substance was stable over the study period until 01 Jun 2017.

2. Vehicle and/or positive control: 0.5% aqueous Carboxymethylcellulose (vehicle)
N-ethyl-*N*-nitrosourea (ENU; positive control)

3. Test animals:

Species:	Mouse
Strain:	CD_2-LacZ80/HazfBR (Muta™Mouse)
Sex:	Male
Age:	8 weeks
Weight at dosing:	24.2 to 28.2 g
Source:	Japan Laboratory Animals, Inc.
Acclimation period:	7 days
Diet:	CRF-1 (lot No. 160607, Oriental Yeast) ad libitum
Water:	Drinking water from water bottles, ad libitum
Housing:	Group housing (2 to 3 animals/cage) in plastic cages (18.2 x 26.0 x 12.8 cm (WxDxH)) with cellulose bedding (ALPHA-dri™, Shepherd Specialty Papers)
Environmental conditions:	
Temperature:	20 - 26°C (central air-conditioning) Actually measured 22.9 to 23.3°C
Humidity:	35 - 70% (central air-conditioning) Actually measured: 47 to 60%
Air changes:	≥ 12 per hour
Photo period:	12 h light / 12 h dark (07:00 - 19:00 / 19:00 - 07:00)

B. STUDY DESIGN

1. Dates of experimental work: 24-Oct-2016 to 28-Dec-2018
Inlife dates:
01-Nov-2016 (start of administration) -
01-Dec-2016 (necropsy for organ harvest)

The study was performed at Biosafety Research Center.

2. Animal assignment and treatment:

Reg.No. 399379 was administered to groups of 6 male mice by gavage at target concentrations of 0, 100, 300 and 1000 mg/kg bw/day for 28 days. Animals were assigned to groups based on their body weights on Day 1 using LATOX-F/V5 software. After finalisation of treatment period the animals were left untreated for another 3 days for manifestation of potential mutagenic effects.
Positive control animals were treated twice with ENU at a dose of 100 mg/kg bw on study days 7 and 8 and left untreated for another 10 days for manifestation of mutagenic effects.

3. Test item preparation and analysis:

The test item was administered as suspension in 0.5% aqueous CMC. Appropriate amounts of the test item were weighed and ground with mortar and pestle. Subsequently, small portions of vehicle (0.5% aqueous CMC) was added and the preparation transferred to a measuring cylinder. The mortar was flushed with vehicle and the cylinder filled up to volume. The suspensions were kept homogenous by stirring with a magnetic stirrer. Suspensions were divided into aliquots for daily use and stored at room temperature until use. Freshly prepared suspensions were used for up to 6 days.

The stability of Reg.No. 399379 in suspension at room temperature for a period of 7 days was demonstrated before the start of the study (BASF project No. 01Y0701/14Y119; copy of the report included in Volume III of the report).

The positive control administration solution was prepared by weighing 50 mg ENU into a graduated test tube, which was filled up to 5 ml with a sodium-phosphate buffer (pH 6.0) to make up a 10.0 mg/mL solution. The positive control formulation was prepared just before use.

The homogenous distribution of Reg.No. 399379 in the diet was verified for all concentrations (see below) using the first suspension preparation.

Analysis of diet preparations for homogeneity and test-item content

Nominal concentration [mg/ mL]	Concentration measured [g/100 ml] Mean ± SD[#]	Relative standard deviation [%]	% of nominal concentration
10.0	9.544 ±0.073	0.8	95.4
30.0	28.85 ± 0.26	0.9	96.2
100.0	102.9 ± 0.8	0.8	102.9

[#] Values may not calculate exactly due to rounding of values

As indicated by relative standard deviations below 1% the prepared dosing suspensions were homogenous.

4. Statistics on in-life parameters

The data of body weight, body weight gain, organ weight, absolute organ weight / body weight ratio and food consumption from the negative control group and each test substance-treated group were tested by Bartlett's test for homogeneity of variance (two-sided, significance level of 0.05) first. If homogeneity was determined (not significant on Bartlett's test), then Dunnett's multiple comparison test was performed to assess the statistical significance of differences between the negative control group and each test substance-treated group (two-sided, familywise significance level of 0.05). If there was no homogeneity (significant on Bartlett's test), Steel's test (two-sided, significance level of 0.05) was performed to analyze the differences.

C. METHODS

1. Observations:

Animals were observed for clinical signs once daily until organ removal. During the administration period they were observed twice daily.

2. Body weight:

The body weight of the animals was determined at Day 1 (day of assignment to groups) and days 8, 15, 22, 29 and 31 (just before sacrifice). The weights of positive control animals were determined on days 1, 7 (before first dosing), and 18 (day of sacrifice).

3. Food consumption

Food consumption was determined on days 3, 7, 14, 22, and 28.

4. Water consumption:

Monitoring of drinking water consumption was not indicated in the report.

5. Ophthalmoscopy:

Not performed.

6. Clinical biochemistry:

Not performed.

7. Sacrifice and pathology:

All animals were sacrificed by exsanguination under isoflurane anesthesia. The external surface and orifices were observed, followed by observation of the organs and tissues in the abdominal, thoracic, pelvic and cranial cavities. All macroscopic abnormalities were recorded as to the location, size, color tone, etc. The following organs were collected, weighed and histopathologically examined:

Pathology:

The following organs were collected (column C), weighed (W) and examined histopathologically (H, ✓: all groups, #: control and top dose).

C	W	H		C	W	H		C	W	H	
			adrenals				larynx				skin
			aorta	✓	✓	✓	liver				spinal cord (3 levels)

§ vas deferens/cauda epididymis; & The seminiferous tubules and vas deferens/cauda epididymis were cut a little and be placed in a Petri dish containing 1.5 mL of cold Dulbecco's phosphate-buffered saline (PBS). The germ cells suspended in this PBS were filtered using a cell strainer (pore size 40 µm, corning). About 1 mL of cell suspension was put into microtube and frozen in liquid nitrogen.

Organs or pieces of organs not fixed for histopathological evaluation were stored in liquid nitrogen. In this study glandular stomach (site of first contact) and liver (main organ of metabolization of xenobiotics) were examined for potential mutations.

8. Assessment of mutagenicity:

In the following the principle of the mutagenicity assay is described. A detailed, step-by-step description of the procedures performed in this experiment is given in the study report.

The Muta™Mouse contains about 80 copies of the complete bacterial lacZ gene integrated in a bacteriophage λ vector (λgt10) at chromosome 3. Administration of potential mutagens result – along to mutations at other genes – in mutations of the lacZ gene. Genomic DNA of the organs of interest is isolated according to standard procedures. The enzymes in commercial packaging kits excise the λ-vector including the lacZ gene (wild-type or mutated) from the genomic DNA and insert it together with the full-length λ DNA into λ phage heads to produce infectious phage particles. In this study the Agilent Technologies Transpack packaging extract was used to separately generate infective phages from every animal and organ of interest.

The generated λ pages were used to infect E. coli C (lacZ$^-$, galE$^-$). A small aliquot of the infected E. coli C broth is mixed with non-infected E. coli C and plated for tittering.
In this study 30µl of the infected E. coli C broth (total volume about 2700 µl) was diluted 1:10 and 30 µl of this dilution was added to 1 ml non infected E. coli C prior to plating. In infected E. coli C the λ phage multiplies and infects surrounding E. coli C after lysis of the infected bacterium. By this, every single λ phage generates a plaque in the lawn of uninfected E. coli. After incubation over night the number of plaques is counted and multiplied by 900 to determine the total number of assembled phages. Packaging of genomic DNA is repeated until at least 300,000 plaques per organ and animal were generated.

The major part of the infected E. coli C broth is plated on a medium for selection. This plate contains P-gal (phenyl-β-D-galactopyranoside). E. coli cells receiving the wild-type lacZ gene convert P-gal to galactose and are unable to grow and subsequently die, as they cannot convert the toxic UDP-galactose into the normal metabolite UDP-glucose because of the lack of UDP galactose epimerase (galE$^-$). In contrast, E. coli C receiving the mutated lacZ do not form galactose and are able replicate and to produce λ phages. These phages infect surrounding bacteria and thus form plaques in the lawn formed by non-infected E. coli C, which likewise grow on the selection media. The principle of the selection is depicted below.

(Scheme included in WHO Environmental Health Criteria 233 (2006); β-gal = β-galactosidase, galE = uridine diphosphate galactose-4-epimerase)

The mutant frequency is calculated as depicted below and expressed as mutants per 10^6 plaques.

$$Mutant\ frequency = \frac{Number\ of\ mutant\ plaques}{Total\ number\ of\ plaques}$$

9. Statistics on mutant frequencies

The data on the mutant frequency from the negative control group and each test substance-treated group were tested by Bartlett's test for homogeneity of variance (two-sided, significance level of 0.05) first. If homogeneity was determined (not significant on Bartlett's test), then Dunnett's multiple comparison test was performed to assess the statistical significance of differences between the negative control group and each test substance-treated group (two-sided, familywise significance level of 0.05). If there was no homogeneity (significant on Bartlett's test), Steel's test (two-sided, significance level of 0.05) was performed to analyze the differences.
The data on the mutant frequency from the negative control group and the positive control group were tested by F test for homogeneity of variance (two-sided, significance level of 0.05) first. If homogeneity of variance was determined (not significant on F test), Student's t test (two-sided, significance level of 0.05) was performed to assess the statistical significance of differences between the negative control group and the positive control group. If there was no homogeneity (significant on F test), Aspin-Welch's t test (two-sided, significance level of 0.05) was performed to analyze the differences.

10. Validity of the study

The study was considered valid as

- the mutant frequency of the positive control groups for liver and stomach markedly increased and were statistically different from the negative control group
- the mutant frequency in the negative control groups were within the acceptable range (mean ± 3SD) calculated from the historical data base of the laboratory

II. RESULTS AND DISCUSSION

A. Observations

1. Clinical signs of toxicity

No test substance-related effects were observed.

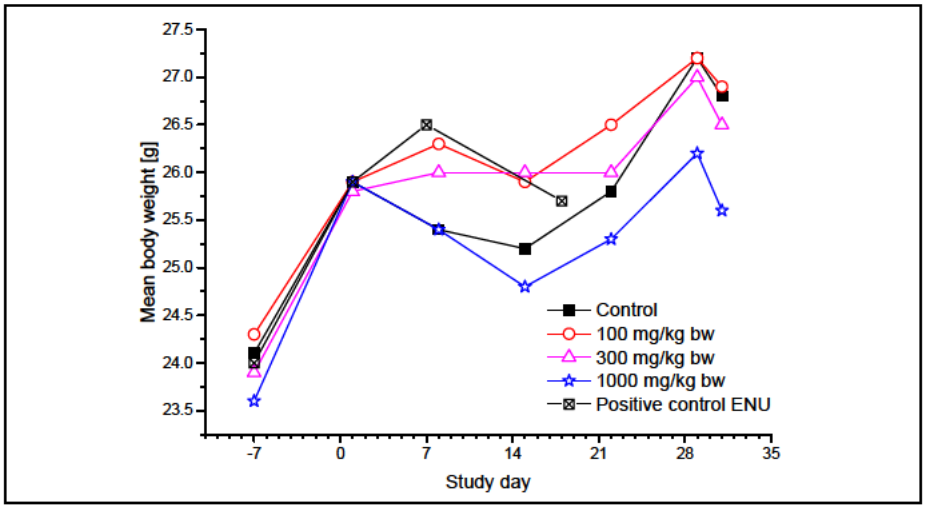
2. Mortality

No animal died prematurely in this study.

B. Body weight and body weight gain

No treatment-related effects on body weight development were noted between treated and control males [Figure 5.8.1-7]. The observed differences in mean body weights were small and due to biological variability.

Figure 5.8.1-7: Body weight development of Muta™Mice administered Reg.No. 399379 for 28 days



C. Food consumption

No substantial differences of food consumption were noted between the control and treated groups.

D. Necropsy

1. Organ weight

No effects on absolute or relative liver or stomach weights were observed [see Table 5.8.1-70].

Table 5.8.1-70: Absolute and relative weights of Muta™Mice administered Reg. No. 399379 for 28 days

Organ weight	Dose [mg/kg]	Absolute weight		Δ%	Relative weight [% of b.w.]		Δ% #
Terminal weight [g]	0	26.8	±1.8				
	100	26.9	±1.7	(0.4)			
	300	26.5	±0.9	(-1.1)			
	1000	25.6	±0.8	(-4.5)

	300	0.17	±0.02	(0.0)	0.64	±0.08	(-1.5)
	1000	0.16	±0.02	(-5.9)	0.64	±0.08	(-1.5)
ENU	100	0.18	±0.01	(5.9)	0.69	±0.08	(6.2)

Values may not calculate exactly due to rounding of figures

2. Gross and histopathology

There were no treatment-related gross necropsy findings. The only finding consisted of a single white nodule at the right epididymis of one high dose (1000 mg/kg bw) animal.
Histopathological examination revealed inflammatory infiltrations in the glandular stomach of one control and two high dose animals. This was considered to represent an incidental finding.

E. Assessment of mutagenicity

Up to 3 times packaging of genomic DNA from liver and stomach was performed to obtain the minimum required 300,000 plaque forming units (i.e. functionally reconstituted λ phages). Neither in liver [see Table 5.8.1-71] nor in the stomach [Table 5.8.1-72] of Reg.No. 399379 treated Muta™Mice a statistically significant increase of the mutant frequency was observed when compared with the vehicle.

Table 5.8.1-71: Mutant frequency in the liver of Muta™Mice administered Reg. No. 399379 for 28 days

Substance and dose	Animal ID	Number of plaque forming units	Number of packagings	Number of mutants	Mutant frequency [x10^6]	Group Mean ± SD

*: Significant difference from negative control ($p<0.05$), Aspin-Welch's t test

The results of this study do not meet the criteria for a positive response as lined out in paragraph 41 of the OECD Guideline 488 (2013): "There are several criteria for determining a positive result, such as a dose-related increase in the mutant frequency, or a clear increase in the mutant frequency in a single dose group compared to the solvent/vehicle control group. At least three treated dose groups should be analysed in order to provide sufficient data for dose-response analysis. While biological relevance of the results should be the primary consideration, appropriate statistical methods may be used as an aid in evaluating the test results. Statistical tests used should consider the animal as the experimental unit." The proof of exposure as required in paragraph 42 for a negative result was provided by the above discussed AD study in mice using radioactive Reg.No. 399379 (see BASF DocID 2016/1225930).

III. CONCLUSION

After treatment of Muta™Mice with Reg.No. 399379 for 28 days followed by a 3 days expression period no statistically or biologically significant increase of the mutant frequency was observed at dose levels up to the limit dose of 1000 mg/kg. Therefore, under the conditions of this test, Reg.No. 399379 (500M106, metabolite of pyraclostrobin) is not genotoxic in vivo.

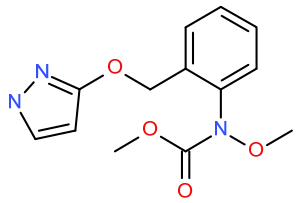
Overall toxicological evaluation of 500M106

As a conclusion based on the weight of evidence provided above, 500M106 (Reg.No. 399379) is not considered to be genotoxic in vivo and thus **not considered to be toxicologically relevant**. Reg.No. 399379 is of low toxicity when administered to rats for 28 days. Identified target organs were duodenum, liver, spleen and the hematological system. The NOAEL in the 28-day study was 300 mg/kg bw/day. Based on this NOAEL and a safety factor of 600 (extra SF of 3 for extrapolation of 28-day to 90-day and SF 2 for extrapolation of subchronic to chronic) an ADI of 0.5 mg/kg bw/day can be established.

Based on the results of the in vitro comparison study, it cannot be excluded that metabolite 500M106 might be also formed in humans under in vivo conditions. Therefore, dietary exposure assessments have been performed (see M-CA 6.9).

(Surface) Water metabolites

500M60 (other denominators: Reg.No. 411847, BF 500-11)



500M60 (Reg.No. 411847, BF 500-11) is a photolysis metabolite found in surface water.

A) QSAR Predicitions for 500M60 (Reg.No. 411847, BF 500-11)

OECD Toolbox (Version: 3.2) [see DocID 2014/1172955]

For 500M60 (Reg.No. 411847) the OECD toolbox does not indicate any alerts.

OASIS TIMES (MIX V.2.27.13 TB; Mutagenicity S-9 activated v08.08) [see molecule 2 of report BASF DocID 2014/1172952 and 2014/1172953]

There were no Ames mutagenicity alerts for 500M60 (Reg.No. 411847) or in-silico generated metabolites. In all cases the structures were out of domain. The prediction in vitro chromosome aberration for 500M60 (Reg.No. 411847) was negative (out of domain), whereas it was positive for 4 out of 11 in-silico generated metabolites. The respective alert was ‘phenols’ (in domain).

Discussion: The alert ‘phenols’ identified for the in vitro chromosome aberration was also present for pyraclostrobin (phenols) and metabolite 500M76 (Reg.No. 413038). Whereas the in vitro study with pyraclostrobin was negative, the in vitro study with 500M76 (Reg.No. 413038) - like that with 500M60 (Reg.No. 411847) - was positive. However, the in vitro results were not confirmed in the higher tier in vivo mouse micronucleus studies. Therefore, the weight of evidence indicates that 500M60 (Reg.No. 411847) is not genotoxic.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 2 of report DocID 2014/1172954 for both VEGA models]

500M60 (Reg.No. 411847) is out of model applicability domain. The prediction is ‘non mutagen’.

VEGA: Mutagenicity model (SarPy; version 1.0.4-BETA)

500M60 (Reg.No. 411847) is out of model applicability domain. The prediction is ‘mutagen’ with the structural alerts SA 96 and SA98. As discussed above, this alert was also obtained for pyraclostrobin and a number of pyraclostrobin metabolites, which like 500M60 (Reg.No. 411847) were actually tested negative. The predicition is therefore rejected.

DEREK (Version 2.0.0.201011301322; Knowledge base version: 11_20_05_2010)

The metabolite 500M60 (Reg.No. 411847) was not evaluated in this system.

Genotoxicity studies on 500M60 (Reg.No. 411847, BF 500-11)

Study already submitted:

In the original submission an Ames test on Reg.No. 411847 was submitted and assessed (BASF DocID 1999/12017). A standard plate test and a pre-incubation test with and without metabolic activation was performed at concentrations of 20 - 5000 µg/plate in S. typhimurium strains TA 98, TA 100, TA 1535 and TA 1537 as well as in E. coli WP2 uvrA. A slight bacteriotoxicity was occasionally noted at concentrations ≥ 2500 µg/plate while no precipitations were noted at any concentration. No increase of revertant colonies was observed in any of the tests performed.

New studies submitted in this dossier:

Report:	CA 5.8.1/50 Schulz M., Landsiedel R., 2012c Reg.No. 411847 (metabolite of BAS 500 F, Pyraclostrobin) - In vitro gene mutation test in CHO cells (HPRT locus assay) 2012/1148607
Guidelines:	OECD 476, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.17, EPA 870.5300
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Reg. No. 411847 (metabolite of pyraclostrobin; batch: L83-76; purity: 94.5%) was tested in vitro for its ability to induce forward mutations in mammalian cells by assessing the mutation of the HPRT locus in Chinese Hamster CHO cells. Two independent experiments were conducted in the presence and absence of metabolic activation at concentrations of up to 2000 µg/mL. The treatment intervals in the absence of metabolic activation were 4 and 24 h in the first and second experiment, respectively. With metabolic activation treatment was 4 h for the orginal and confirmatory experiment. Ethylmethanesulfonate (EMS) and methylcholanthrene (MCA) served as positive controls in the experiments without and with metabolic activation, respectively.

Cytotoxic effects indicated by reduced cloning efficiencies of below 20% of the respective vehicle control were observed at 1000 µg/mL in the experiments without metabolic activation and at ≥ 1500 µg/mL with metabolic activation.

Neither in the original nor in the confirmatory experiments a relevant increase in the mutant frequency was observed. The positive control substances, however, induced a marked increase in mutant frequency.

Based on the results of the study it is concluded that under the conditions of the test Reg. No. 411847 does not induce forward mutations in mammalian cells in vitro.

(BASF DocID 2012/1148607)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Description:	Reg. No. 411847 (metabolite of pyraclostrobin)
Lot/Batch #:	Solid, beige
Purity:	L83-76
Stability of test compound:	94.5% (tolerance ± 1.0%)
	The stability of the test substance under storage conditions was guaranteed until 01-Jan-2014. The homogeneity of the test substance was ensured by mixing prior to preparation of test substance solutions. The stability of a comparable batch (01183-172) at room temperature in the vehicle DMSO and in water over a period of 4 hours was verified analytically.
Solvent used:	Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control:	A negative control was not employed in this study
Solvent control:	1% (v/v) DMSO in culture medium
Positive control -S9:	Ethyl methanesulfonate (EMS) 300 µg/mL
Positive control +S9:	Methylcholantrene (MCA) 20 µg/mL

3. Activation:

S9 was produced from the livers of at least 5 induced male Wistar [Crl:WI(Han)] rats. The rats were administered injections of phenobarbital (80 mg/kg; i.p.) and ß-napthtoflavone (80 mg/kg; per gavage) on three consecutive days. 24 h after the last administration the animals were sacrificed.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4. Test organism: Chinese hamster CHO cells. Stocks of the CHO cell line were maintained at -196°C in liquid nitrogen. Each batch used for mutagenicity testing was checked for mycoplasma contamination. The week prior to treatment, spontaneous HPRT-deficient mutants were eliminated from the stock cultures by growing the cells for 3 to 4 days in pretreatment medium (see below).

5. Culture media:

Culture medium: Ham's F12 medium with L-glutamine and hypoxanthine supplemented with 10% (v/v) fetal calf serum (FCS).

Pretreatment medium: ("HAT" medium): FCS-supplemented Ham's F12 medium with L-glutamine containing per mL 13.6 µg hypoxanthine, 0.18 µg aminopterin and 3.88 µg thymidine.

Selection medium: ("TG" medium): L-Glutamine- and FCS-supplemented, hypoxanthine-free Ham's F12 medium with 6-thioguanine at a final concentration of 10 µg/mL
All media were supplemented with
- 1% (v/v) penicillin/streptomycin (10000 IU / 10000 µg/mL)
- 1% (v/v) amphotericine B (250 µg/mL)
During pulse exposure (4 hours) to the test substance, Ham‘s F12 medium was used without FCS supplementation. In the case of continuous treatment (24 hours) Ham‘s F12 medium with FCS supplementation was used.

6. Locus examined: hypoxanthine-guanine-phosphoribosyl transferase (H(G)PRT)

7. Test concentrations:

a) Preliminary toxicity assay: Nine concentrations ranging from 11.7 to 3000 µg/mL

b) Mutation assay:
1st experiment: 62.5, 125, 250, 500, 1000 and 2000 µg/mL with and without metabolic activation
2nd experiment: 93.8, 187.5, 375, 750, 1500 and 2000 µg/mL with and 31.3, 62.5, 125, 250, 500, 1000 µg/mL without metabolic activation

B. TEST PERFORMANCE:

1. Dates of experimental work: 05-Mar-2012 to 18-Jun-2012

2. Preliminary cytotoxicity assay:

Cytotoxicity was assessed by determination of the cloning efficiency. About 200 cells were incubated in 25 cm² flasks with 9 test substance concentrations in serum-free Ham's F12 medium for about 4 hours (with and without metabolic activation) or 24 hours (only without metabolic activation; serum-supplemented medium) after an attachment period of 20-24 hours. At the end of the exposure period, the cells were washed with Hanks' balanced salt solution (HBSS) or PBS, covered with Ham's F12 and incubated for a further 5 - 8 days. After this incubation period, colonies were fixed, stained and counted. In addition to the cloning efficiency the following parameters were measured: pH, osmolarity and the determination of precipitates (solubility).

3. Mutation Assay:

Pretreatment of Cells: Cells with a passage number ≥ 2 after thawing from the frozen cells stock were seeded into 75 cm^2-flasks and incubated for 3-4 days with "HAT" medium during the week prior to treatment to eliminate spontaneous HPRT-deficient mutants. Afterwards, a passage into culture medium followed and the cells were incubated for further 3-4 days.

Cell treatment: For each test group, about $1x10^6$ cells per flask were seeded into 175 cm^2 flasks containing about 20 mL Ham's F12 medium supplemented with 10% FCS and incubated for about 20 - 24 hours with 5% CO_2 at 37°C and ≥ 90% humidity for cell attachment. 2 flasks were used for each test group.

After the cell attachment period the medium was replaced by the treatment medium. In case of experiments without metabolic activation the treatment medium consisted of 18 mL Ham's F12 medium without FCS plus 2 mL positive control substance. For the vehicle control and the test groups, 20 mL of the treatment medium was supplemented with 0.2 mL of the vehicle or test substance preparation. In case of metabolic activation, the treatment medium consisted of 14 mL Ham's F12 medium without FCS, 2 mL positive control and 4 mL S9-mix.

Analogously, for the vehicle control and test groups, 16 mL of medium was supplemented with 0.2 mL vehicle or test substance preparation and 4 mL S9-mix.

Concurrent negative and positive controls were tested in parallel. The cells were exposed for 4 hours both with and without S9-mix (or for 24 hours without S9-mix in the second experiment) at 5% CO_2, 37°C and ≥ 90% humidity.

Expression:

After incubation for 4 or 24 hours, respectively, the treatment medium was replaced by at least 20 mL Ham's F12 medium with 10% FCS after having been rinsed several times with Hanks' balanced salt solution (HBSS). The following 1st passage was carried out after an incubation period of about 3 days following the 4 hour exposure or 2 days following the 24 hour exposure period. After an entire expression period of 7 - 9 days the cells were transferred into the selection medium (2nd passage).

Selection:

For the mutant selection, six 75-cm^2 flasks each were seeded with $3x10^5$ cells from each treatment group in selection medium (TG medium) and incubated for about 6 to 7 days. At the end of the selection period, colonies were fixed with methanol, stained with Giemsa and counted.

Determination of Cytotoxicity:

Cloning efficiency 1 (survival):

The survival (cloning efficiency 1; CE_1) was determined in parallel to the mutagenicity test. Approximately 200 cells per dose group were seeded into duplicate 25 cm^2 flasks using 5 mL Ham`s F12 medium with 10% FCS. After a 20-24 hour attachment period the cells were incubated with vehicle, test substance or the positive control for 4 or 24 hours as described above. At the end of the treatment period the cells were washed with HBSS and the treatment medium was replaced by Ham's F12 medium with 10% FCS. After a further incubation for about 5 to 8 days the colonies were fixed, stained and counted.

Cloning efficiency 2 (viability):

The viability (cloning efficiency 2; CE_2) was determined after the expression period. About 200 cells were separated during the transfer into selection medium and seeded in two flasks (25 cm^2) containing 5 mL Ham's F12 medium incl. 10% (v/v) FCS each.
After seeding of the cells, the flasks were incubated for 5 - 8 days to form colonies. These colonies were fixed, stained and counted.

Calculations:

Mutant frequency:

Uncorrected mutant frequency:

$$MF_{uncorr} = \frac{total\ number\ of\ mutant\ colonies}{number\ of\ seeded\ cells} x\,10^6$$

Corrected mutant frequency:

$$MF_{corr} = \frac{MF_{uncorr}}{CE_{2\ absolute}} x\,100$$

Cloning efficiency (CE, %)

absolute:

$$CE_{absolute} = \frac{total\ number\ of\ colonies\ in\ the\ test\ group}{total\ number\ of\ seeded\ cells\ in\ the\ test\ group} x100$$

relative, in comparison to control:

$$CE_{relative} = \frac{CE\ of\ the\ dose\ group}{CE\ of\ the\ vehicle\ control} x100$$

4. Statistics:

An appropriate statistical trend test was performed to assess a dose-related increase of mutant frequencies. The number of mutant colonies obtained for the test substance treated groups was compared with that of the respective vehicle control groups. A trend is judged as statistically significant whenever the p-value (probability value) is below 0.10 and the slope is greater than 0. Both, biological and statistical significance will be considered together. However, due to the negative findings, a statistical evaluation was not carried out.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- Increases of the corrected mutation frequencies ($MF_{corr.}$) both above the concurrent vehicle control values and the historical negative control range.
- Evidence of reproducibility of any increase in mutant frequencies.
- A statistically significant increase in mutant frequencies and the evidence of a dose-response relationship. Isolated increases of mutant frequencies above the historical negative control range (i.e. 15 mutants per 10^6 clonable cells) or isolated statistically significant increases without a dose-response relationship may indicate a biological effect but are not regarded as sufficient evidence of mutagenicity.

A test substance is generally considered negative in this test system if:

- The corrected mutation frequency ($MF_{corr.}$) in all dose groups is within the historical control range and is not significantly above the concurrent negative control.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance under storage conditions was guaranteed until 01 Jan 2014 as indicated by the Sponsor. The stability of a comparable batch (01183-172) at room temperature in the vehicle DMSO and in water over a period of 4 hours was verified analytically.

B. PRELIMINARY CYTOTOXICITY ASSAY

After 4 hours treatment in the absence and presence of S9 mix cytotoxicity indicated by reduced relative cloning efficiency of about or below 20% relative survival was observed at ≥ 1500 µg/mL. Treatment for 24 hours in the absence of S9 mix reduced relative cloning efficiency of below 20% relative survival at concentrations ≥ 750 µg/mL.

Precipitation of the test substance was observed at ≥ 1500 µg/mL at the end of treatment in the absence and presence of metabolic activation. No marked effect on osmolarity and pH value was observed.

Based on these data the highest concentration tested in the mutagenicity experiments was 2000 µg/mL without and with metabolic activation.

C. MUTAGENICITY ASSAYS

No relevant increase in the number of mutant colonies was observed in the original and confirmatory experiments with and without metabolic activation [see Table 5.8.1-73 and Table 5.8.1-74]. The mutant frequencies obtained displayed no dose-dependency and were within the range of the historical negative control data.

Treatment with the positive controls EMS and MCA resulted in a marked increase in the number of mutant colonies as well as of mutant frequencies in all experiments, thus demonstrating the sensitivity of the test.

Cytotoxic effects indicated by reduced cloning efficiencies of below 20% of control value were observed in both experiments in the absence and presence of S9 mix at concentrations ≥ 1000 µg/mL and > 1000/750 µg/mL, respectively [see Table 5.8.1-73 and Table 5.8.1-74].

The pH and osmolarity of the tested concentrations were not altered at the concentrations tested. Test substance precipitation was observed from 1000 µg/mL onwards in the presence and absence of metabolic activation.

III. CONCLUSION

Based on the results of the study it is concluded that under the conditions of the test Reg. No. 411847 does not induce forward mutations in the HPRT locus in CHO cells in vitro.

Report: CA 5.8.1/51
Engelhardt G., Leibold E., 2003a
In vitro chromosome aberration assay with Reg.No. 411847 in V79 cells
2003/1004383
Guidelines: OECD 473, EEC 2000/32 B.10, EPA 870.5375
GLP: yes
(certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

Reg.No. 411847 (metabolite of pyraclostrobin; batch: 01183-172; purity: 98.9%) was tested in vitro for the ability to induce chromosome and numerical aberrations in Chinese Hamster V79 cells in two independent experiments in the presence and absence of metabolic activation at concentrations of 62.5 µg/mL to 1000 µg/mL with a pulse treatment of 4 hours. The cells were prepared 18 hours after the start of treatment. Vehicle (DMSO) and positive controls (cyclophosphamide (CPP) and ethylmethanesulfonate (EMS) for the experiment with and without metabolic activation, respectively) were included to demonstrate the sensitivity of the test system.

In the test without metabolic activation Reg.No. 411847 induced a statistically significant and dose-dependent increase in the number of structurally aberrant metaphases including and excluding gaps in two experiments performed independently of each other. An increase in the number of polyploid/endopolyploid metaphases was observed in the experimental part without metabolic activation. In the experiment with metabolic activation, a dose-related increase in the number of structurally aberrant metaphases including and excluding gaps and an increase in the number of endopolyploid metaphases starting from the mid dose onwards was also observed.

Based on the results of this study, Reg.No. 411847 is considered to have both a clastogenic and aneugenic potential in vitro in Chinese hamster V79 cells.

(BASF DocID 2003/1004383)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg.No. 411847 (Metabolite of pyraclostrobin)

Description:	Crystalline, white
Lot/Batch #:	01183-172
Purity:	98.9%
Stability of test compound:	The stability of the test substance was guaranteed by the sponsor, and the sponsor holds this responsibility. The homogeneity of the test substance was ensured by mixing prior to preparation of test substance formulations and on account of the high purity. The stability of the test substance dissolved in the vehicle DMSO and in aqueous solution over a period of 4 hours was verified analytically.
Solvent used:	Dimethylsulfoxide (DMSO)

2. Control Materials:

Negative control:	A negative control was not employed in this study.
Solvent control:	DMSO
Positive control, -S9:	Ethylmethanesulfonate 350 µg/mL
Positive control, +S9:	Cyclophosphamide 0.5 µg/mL

3. Activation: S9 was produced from the livers of 5 induced male Wistar Sprague-Dawley rats. The rats received a single intraperitoneal injection of 500 mg Aroclor 1254 (as solution in corn oil with a concentration of 20 g/100 mL) per kg body weight. 5 days after administration the animals were sacrificed. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction was thawed at room temperature and 1 volume of S9-fraction was mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9-mix, was kept on ice until used.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	15 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10%

4. Test organisms: Chinese hamster V79 cells

5. Culture medium: MEM medium with glutamine supplemented with
- 10% (v/v) fetal calf serum (FCS)
- 1% (v/v) penicillin/streptomycin (10000 IU/10000 µg/mL)
- 1% (v/v) amphotericine B (250 µg/mL)

During exposure to the test substance (4-hour treatment), MEM medium was used without FCS supplementation.

6. Test concentrations:

a) Preliminary toxicity assay: Nine to ten concentrations ranging from 1 to 2800 µg/mL were used in experiments with or without metabolic activation for exposure duration of 4 and 18 hours.

b) Mutation assay:
1st experiment: 62.5, **125**, **250**, **500** and 750 µg/mL without metabolic activation; **125**, **250**, **500**, 750 and 1000 µg/mL with metabolic activation (18 h preparation interval)
[bold concentrations were evaluated]

2nd experiment: 100, 200, **300**, **400**, **500**, 600 and 700 µg/mL without metabolic activation (18 h preparation interval)

[bold concentrations were evaluated]

B. TEST PERFORMANCE:

1. Dates of experimental work: 30-Sep-2002 to 14-Jan-2003

2. Preliminary cytotoxicity assay:

A range-finding cytotoxicity test was conducted with V79 cultures exposed for 4 and 18 hours to test substance concentrations of 1 - 2800 µg/mL both with and without metabolic activation. At the end of the exposure period, cell count, cell attachment, mitotic index and the quality of metaphases were determined in order to derive appropriate test substance concentrations for the main test.

3. Cytogenicity Assay:

Two independent experiments were performed. In the first experiment cells were exposed for 4 hours with the test substance either without or with metabolic activation and harvested after 18 hours. For clarification/conformation of the results of the first experiment, the second experiment was done with the same exposure and harvest time but only treatment without metabolic activation. Duplicate curltures were used for all experimental groups.

Cell treatment:	Cells were exposed to the test substance, solvent or positive control in pulse treatment experiments for 4 hours with or without metabolic activation. The cells were incubated in Quadriperm® dishes at 37°C, 5% CO_2 and ≥ 90% humidity. Two chambers of a Quadriperm dish were used for each concentration (=duplicate cultures). The preparation interval was 18 h post treatment-begin. For determination of cytotoxicity, additional cell cultures (using 25 cm² plastic flasks) were treated in the same way as in the main experiment. Growth inhibition was estimated by comparing the cell number in the treated groups with the concurrent control.
Spindle inhibition:	0.2 µg/mL of Colcemid was added to the cultures 2 - 3 hours prior to harvesting.
Cell harvest:	At the end of the incubation time the culture medium was completely removed. For hypotonic treatment, 5 mL of a 0.4% KCl solution (37°C) was added for about 20 minutes. The cells were fixed by addition of 5 mL methanol/glacial acetic acid (3:1 v/v). The fixative was changed twice.

Slide preparation:	The slides were removed from the Quadriperm chambers, briefly allowed to drip off and passed through a Bunsen burner flame. After drying, the cells were stained with Giemsa and Titrisol. After rinsing and clarifying in Xylene the cover slips were mounted in Corbit-Balsam.
Metaphase analysis:	Slides were coded prior to analysis. As a rule, the first 100 consecutive well-spread metaphases of each culture were counted for all test groups, and if cells had 20 - 22 chromosomes, they were analyzed for structural chromosome aberrations. Numerical chromosome aberrations were also recorded. If there is a clear increase in chromosomally damaged cells, the number of metaphases to be analyzed is reduced from the planned 200 mitoses/test group. A mitotic index based on 1000 cells per culture was determined for all evaluated test groups in both experiments.

4. Statistics:

B)

The proportion of metaphases with aberrations was calculated for each group.

A comparison of each dose group with the vehicle control group was carried out using Fisher's exact test for the hypothesis of equal proportions. This test was Bonferroni-Holm corrected versus the dose groups separately for each time and was performed one-sided.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A dose-related and reproducible significant increase in the number of structural chromosomal aberrations.
- The proportion of aberrations exceeded both the concurrent negative control range and the historical negative control range.

A test substance is generally considered non-clastogenic in this test system if:

- There was no significant increase in the number of chromosomally damaged cells at any dose above concurrent control frequencies.
- The aberration frequencies were within the historical negative control range.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS:

The stability of the test substance at room temperature in the vehicle DMSO and in water over a period of 4 hours was verified analytically.

B. PRELIMINARY CYTOTOXICITY ASSAY:

A preliminary cytotoxicity assay was performed to determine appropriate test substance concentrations for the main test. Dose selection was based on the cell count, cell attachment, mitotic index and the quality of metaphases. Based on the preliminary cytotoxicity assay, 750 µg/mL without metabolic activation and 1000 µg/mL with metabolic activation were selected as the top doses for the main test.

C. CYTOGENICITY ASSAYS:

RegNo. 411847 led to a dose-dependent and statistically significant increase in the number of structural chromosomal aberrations, including and excluding gaps without metabolic activation in two independently experiments [see Table 5.8.1-75 to Table 5.8.1-77]. In the experiment with metabolic activation, a dose-related, not statistically significant increase in the number of structurally aberrant metaphases was observed [see Table 5.8.1-76]. However, the incidences were within the historical control range and thus not considered to be indicative of a clastogenic effect.

In addition to the clastogenic effects aneugenic effects were observed with and without metabolic activation [see Table 5.8.1-75 to Table 5.8.1-77]. Here the increase in the incidence of endopolyploid metaphases was higher than that of polyploid metaphases. The aneugenic effects were less pronounced with metabolic activation.

Vehicle and positive controls were all in the expected range demonstrating the validity of the test.

The osmolarity and pH values were not influenced by the test substance treatment. Precipitation of the test substance did not occur up to the highest tested concentration. No suppression of the mitotic activity was observed up tho the highest concentration tested. Regarding cell countst, a growth inhibition was observed from at concentration ≥ 500 - 600 µg/mL without metabolic activation and at ≥ 750 µg/mL with metabolic activation.

III. CONCLUSION

Based on the results of the study it is concluded that Reg.No. 411847 has both, a clastogenic and an aneugenic potential under the in vitro conditions of this study. The relevance of this in vitro result was evaluated in a higher tier in vivo study (see below) according to Commission Regulation (EU) No 283/2013, Section 5.4.2.

Report:	CA 5.8.1/52 [redacted] 2012d Reg.No. 411847 (metabolite of BAS 500 F, Pyraclostrobin) - Micronucleus test in bone marrow cells of the mouse 2012/1218557
Guidelines:	OECD 474 (1997), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.12, EPA 870.5395
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Reg.No. 411847 (metabolite of pyraclostrobin; batch: L83-76; purity: 94.5%) was tested for chromosomal damage (clastogenicity) and for the ability to induce spindle poison effects (aneugenic activity) in NMRI mice using the micronucleus test method. For this purpose, the test substance was administered once orally to groups of 5 male mice at dose levels of 125, 250 and 500 mg/kg body weight. The vehicle served as negative and cyclophosphamide and vincristine sulfate as positive controls. The animals were sacrificed 24 or 48 (additional high dose and vehicle group) hours after the administration and the bone marrow of the two femora was prepared and investigated for micronuclei. The results of plasma analysis demonstrated the bioavailability of the test item.

The oral administration of Reg.No. 411847 did not lead to any biologically relevant increase in the number of polychromatic erythrocytes containing either small or large micronuclei. The rate of micronuclei was below the concurrent negative control and was within the range of the historical control data. Inhibition of erythropoiesis, determined from the ratio of polychromatic to normochromatic erythrocytes, did not occur. Signs of systemic toxicity were not observed up to the highest dose of 500 mg/kg bw.

Both of the positive control chemicals, i.e. cyclophosphamide for clastogenic effects and vincristine for induction of spindle poison effects, led to the expected increase in the rate of polychromatic erythrocytes containing small (cyclophosphamide) or small and large (vincristine sulphate) micronuclei, thus demonstrating the sensitivity of the test system.

In conclusion, under the experimental conditions of this study, the test substance Reg.No. 411847 (metabolite of pyraclostrobin) does not induce cytogenetic damage in bone marrow cells of NMRI mice in vivo.

(BASF DocID 2012/1218557)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

	Reg.No. 411847 (metabolite of pyraclostrobin)
Description:	Solid, beige
Lot/Batch #:	L83-76
Purity:	94.5% (tolerance ± 1.0%)
Stability of test compound:	The stability of the test substance under storage conditions was guaranteed until 01 Jan 2014 as indicated by the sponsor. Homogeneity of the test substance was guaranteed by mixing before preparation of the test substance emulsions.
Vehicle used:	DMSO and subsequent emulsion in corn oil

2. Control Materials:

Negative:	No negative control was employed in this study.
Vehicle control:	DMSO and subsequent emulsion in corn oil
Positive control:	Cyclophosphamide (CCP) 20 mg/kg for the determination of clastogenic effects Vincristine sulphate (VCR) 0.15 mg/kg for the determination aneugenic effects

3. Test animals:

Species:	Albino mice
Strain:	Crl:NMRI
Sex:	Male for the main study; male and female for the range finding study
Age:	5 - 8 weeks
Mean weight at dosing:	31.3 g
Source:	Charles River Laboratories Germany GmbH
Number of animals per dose:	
Range finding study:	Not indicated in the report
Micronucleus assay:	5 males/dose (exception for the additional 1000 mg/kg bw dose group: 10 animals)
Acclimation period:	At least 5 days
Diet:	Standardized pelleted feed (Maus/Ratte Haltung "GLP", Provimi Kliba SA, Kaiseraugst, Switzerland)
Water:	Drinking water in bottles, ad libitum
Housing:	During the study the mice were housed individually in Makrolon cages, type MII

4. Environmental conditions:

Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	frequency not indicated (fully air-conditioned rooms)
Photo period:	12-hour light-dark cycle (06:00 - 18:00, 18:00 - 06:00)

5. Test compound doses:

Range finding test:	500 and 1000 mg/kg
Micronucleus assay:	125, 250 and 500 mg/kg (an additional test group treated with 1000 mg/kg was treated in parallel to verify the bioavailability of the test substance after oral administration) The test substance was administered once by oral gavage using an application volume of 10 mL/kg.

B. TEST PERFORMANCE

1. Dates of experimental work: 24-Apr-2012 to 28-Aug-2012

2. Preliminary range finding test:

Male and female mice were treated once by oral gavage of test item doses of 500 and 1000 mg/kg bw.

3. Micronucleus test:

Treatment and sampling:	Groups of 5 male mice were treated once by oral gavage with either vehicle, 125, 250, or 500 mg test substance/kg bw. Additional test groups treated with the vehicle control and the high dose were used for the second sampling period. A further test group of 10 animals was treated at 1000 mg/kg bw for determination of plasma levels of the test item. The application volume was 10 mL/kg bw and the volume to be applied was calculated based on actual weight on the day of administration. The positive control substances CCP and VCR were administered once by oral gavage (CCP) or i.p. injection (VCR). The animals were observed for evident clinical signs of toxicity throughout the study.

	Twenty-four hours after the administration the mice were sacrificed and the two femora were prepared free of all soft tissue. After cutting the epiphyses the bone marrow was flushed out in a centrifugation tube with fetal calf serum and subsequently centrifuged at 300xg for 5 minutes. The supernatant was removed and the pellet resuspended in about 50 µl fresh FCS. The sampling of the femora from the additional high dose and vehicle control group was performed as described above 48 h after the treatment.
Slide preparation:	One drop of the suspension was applied on a clean microscopic slide and smears were prepared. After air drying the smears were stained with May Gruenwald solution, rinsed, and finally stained with Giemsa solution (7.5%). After rinsing and clarifying in xylene, the preparations were mounted. The slides were coded prior to microscopic evaluation.
Slide evaluation:	In general, 2000 polychromatic erythrocytes (PCEs) from each male animal of every test group were evaluated and investigated for micronuclei (MN). The normochromatic erythrocytes (NCEs) that occurred were also scored. The increase in the number of micronuclei in polychromatic erythrocytes of treated animals as compared to the vehicle control group provides an index of a chromosome-breaking (clastogenic) effect or of a spindle activity (aneugenic) of the substance tested. In addition, the number of small micronuclei ($d < D/4$) and of large micronuclei ($d \geq D/4$) (d = diameter of micronucleus, D = cell diameter) was determined: The size of micronuclei may indicate the possible mode of action of the test substance, i.e. a clastogenic or a spindle poison effect. The ratio of polychromatic to normochromatic erythrocytes was calculated. An alteration of this ratio indicates a toxic effect on erythropoieses and thus, that the test substance actually reached the target organ.

4. Statistics:

The number of polychromatic erythrocytes with micronuclei was analyzed by comparing the dose groups with the vehicle control using the Mann-Whitney U-test (modified rank test according to Wilcoxon). Here, the relative frequencies of cells with micronuclei of each animal were used.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A dose-related and significant increase in the number of micronucleated polychromatic erythrocytes was observed.
- The proportion of cells containing micronuclei exceeded both the values of the concurrent vehicle control range and the vehicle historical control range.

A test substance is generally considered negative in this test system if:

- There was no significant increase in the number of micronucleated polychromatic erythrocytes at any dose above concurrent control frequencies.
- The frequencies of cells containing micronuclei were within the historical control range.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance in the vehicle DMSO/corn oil was verified analytically. The homogeneity of the test substance in the vehicle was guaranteed by constant stirring during the removal and administration of the test substance formulation and by analytical determination of 3 individual samples of each concentration. The mean test substance concentrations were determined as 12.193, 23.631, 50.447 and 99.792 mg/mL at nominal concentrations of 12.5, 25, 50 and 100 mg/mL, respectively. Thus, the actual concentrations were in the range of 98 to 101% of the nominal concentrations. The homogeneity of the preparations was indicated by relative standard deviations in the range of 4.3 to 5.4%.

In order to demonstrate the bioavailability of the test item blood plasma analyses from blood sampled at necropsy were performed. In blood plasma samples obtained in the preliminary range finding test, Reg.No. 411847 was detectable in the samples from the 1000 mg/kg bw treated animals, but not 500 mg/kg bw. A plausible explanation for this is the assumption that the severely intoxicated mice at 1000 mg/kg bw were not able to completely metabolize the test-item whereas this was the case at the lower dose of 500 mg/kg bw. The aforementioned analysis of the Reg.No. 411847 plasma concentration was performed with a method, which was retrospectively validated. The validation report can be found in M-CA 4 (see BASF DocID 2016/1321627).

In the main study blood was sampled for plasma analysis at necropsy from all animals including the additional 10 animals dosed at 1000 mg/kg bw, which were solely dosed for this purpose.

No test-item was detected in the plasma samples from mice at 125 mg/kg bw after 24 hours and at 500 mg/kg bw after 48 hours. However, in the plasma sampled after 24 hours of 1/5, 3/5 and 2/2 mice Reg.No. 411847 was quantifiable at 250, 500 and 1000 mg/kg bw, respectively. This demonstrates that the test-item is bioavailable and reaches the highly blood perfused bone marrow. This is also demonstrated by the signs of systemic toxicity observed in treated mice.

B. PRELIMINARY RANGE FINDING TEST

In a pretest, deaths were observed at 1000 mg/kg. At 500 mg/kg, all animals survived but distinct signs of toxicity were observed consisting of hunched posture, abdominal position, reduced general condition, irregular respiration and respiration shallow. However, there were no distinct differences in clinical observations between male and female animals. Thus, only male animals were used in the main experiment.

C. MICRONUCLEUS ASSAY

Treatment of mice with Reg.No. 411847 did not lead to a biologically relevant increase in the rate of micronuclei (see Table 5.8.1-78). Micronucleus frequencies in PCE of the animals treated with the indicated doses of the test substance were below the concurrent vehicle control values and within the historical control range.

The PCE/NCE ratio was not affected by treatment with the test substance which indicates that erythropoiesis was not inhibited.

The clastogenic activity of the positive control substance cyclophosphamide was evident by the increase in the number of PCE containing exclusively small micronuclei. The administration of the spindle poison vincristine resulted in an incidence of small and large micronuclei in polychromatic erythrocytes.

Dose dependent signs of systemic toxicity were observed in test substance treated mice at all dose levels. These consisted of piloerection, hunched posture (at ≥ 250 mg/kg bw), abdominal position, reduced general condition, and shallow respiration (at ≥ 500 mg/kg bw) and a narcotic like state (1000 mg/kg bw only). At 1000 mg/kg body weight eight out of ten animals died as early as 1 hour after administration. No signs of systemic toxicity were observed in any of the animals treated with the positive control substances or the vehicle.

Table 5.8.1-78: Micronucleus test in mice administered Reg.No. 411847 by oral gavage

Treatment	PCE				NCE		PCE/NCE ratio

III. CONCLUSION

Based on the result of this study 500M60 (Reg.No. 411847, BF 500-11) does not induce the formation of micronuclei in mouse polychromatic erythrocytes under the conditions of the study, i.e. is devoid of clastogenic or aneugenic activity in vivo. The analysis of Reg.No. 411847 in rat plasma demonstrated that the test item reached the target organ (bone marrow). Thus, the clastogenicity observed in vitro is not relevant under in vivo conditions.

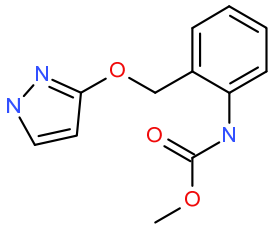
Overall toxicological evaluation of 500M60 (Reg.No. 411847, BF 500-11)

The QSAR evaluation of 500M60 is of low reliability and by weight of evidence there was no conclusive alert for genotoxity.

By weight of evidence 500M60 is considered to be not genotoxic based on the in vitro and in vivo studies conducted. Therfore, 500M60 is considered to be **not toxicologically relevant**.

The highest calculated concentration (PEC_{sw}) is 0.266 µg/L. No relevant human exposure is to be expected.

500M62 (other denominators: Reg.No. 412785, BF 500-13)



500M62 (Reg.No. 412785, BF 500-13) is a photolysis metabolite found in surface water.

A) QSAR Predicitions for 500M62 (Reg.No. 412785, BF 500-13)

OECD Toolbox (Version: 3.2) [see DocID 2014/1172955]

For 500M62 (Reg.No. 412785)the OECD toolbox reveald no alert for protein binding but two complex alerts for DNA binding and DNA alerts for Ames, MN and CA, i.e. '*Radical|Radical >> Radical mechanism via ROS formation (indirect)|Radical >> Radical mechanism via ROS formation (indirect) >> Single-Ring Substituted Primary Aromatic Amines|SN1|SN1 >> Nucleophilic attack after metabolic nitrenium ion formation|SN1 >> Nucleophilic attack after metabolic nitrenium ion formation >> Single-Ring Substituted Primary Aromatic Amines*' and '*AN2|AN2 >> Carbamoylation after isocyanate formation|AN2 >> Carbamoylation after isocyanate formation >> N-Hydroxylamines|Radical|Radical >> Radical mechanism via ROS formation (indirect)|Radical >> Radical mechanism via ROS formation (indirect) >> N-Hydroxylamines|SN1|SN1 >> Nucleophilic attack after metabolic nitrenium ion formation|SN1 >> Nucleophilic attack after metabolic nitrenium ion formation >> N-Hydroxylamines*'

Discussion: The above alerts were also identified for 500M49 (Reg.No. 5916420). This metabolite - like 500M62 (Reg.No. 412785) - was negative in the Ames test. Metabolite 500M49 (Reg.No. 5916420) was also negative for in vitro chromosome aberration in the in vitro micronucleus test and in the mouse lymphoma assay investigating mutagenicity in mammalian cells. Therefore, the predicted alerts do not reflect the experimental data and are thus rejected. Therefore, the weight of evidence indicates that 500M60 (Reg.No. 411847) is not genotoxic.

OASIS TIMES (MIX V.2.27.13 TB; Mutagenicity S-9 activated v08.08) [see molecule 3 of report DocID 2014/1172952 and 2014/1172953]

There was no Ames mutagenicity alert for 500M62 (Reg.No. 412785). However, 4 of 7 or in-silico generated metabolites were predicted positive (in domain) with the alerts 'Single-ring substituted primary aromatic amines' and 'N-Hydroxylamines'. The prediction in vitro chromosome aberration for 500M62 (Reg.No. 412785) was poitive (out of domain), as it was positive for 4 out of 7 in-silico generated metabolites. The respective alerts were 'Single-ring substituted primaryaromatic amines', 'substituted anilines' and 'N-Hydroxylamines'. All positive in vitro CA alerts were 'in domain'.

Discussion: As discussed above for the alerts found in the OECD Toolbox, the OASIS TIMES alerts were also identified for 500M49 (Reg.No. 5916420). This metabolite - like 500M62 (Reg.No. 412785) - was negative in the Ames test. Metabolite 500M49 (Reg.No. 5916420) was also negative for in vitro chromosome aberration in the in vitro micronucleus test and in the mouse lymphoma assay investigating mutagenicity in mammalian cells. Therefore, the predicted alerts do not reflect the experimental data and are thus rejected. Therefore, the weight of evidence indicates that 500M60 (Reg.No. 411847) is not genotoxic.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 3 of report BASF DocID 2014/1172954 for both VEGA models]

500M62 (Reg.No. 412785) is out of model applicability domain. The prediction is 'non mutagen'.

VEGA: Mutagenicity model (SarPy; version 1.0.4-BETA)

500M62 (Reg.No. 412785) is out of model applicability domain. The prediction is 'mutagen' with the structural alerts SA 96 and SA98. As discussed above, this alert was also obtained for pyraclostrobin and a number of pyraclostrobin metabolites, which like 500M62 (Reg.No. 412785) were actually tested negative. The predicition is therefore rejected.

DEREK (Version 2.0.0.201011301322; Knowledge base version: 11_20_05_2010)

Metabolite 500M62 (Reg.No. 412785) was not evaluated in this system.

Studies on 500M62 (Reg.No. 412785, BF 500-13)

Study already submitted:

In the original submission, an Ames test on 500M62 (Reg.No. 412785; BF 500-13) was submitted and assessed (BASF DocID 1999/12020). A standard plate test (SPT) and a pre-incubation test (PIT) with and without metabolic activation was performed at concentrations of 22 - 5000 µg/plate (SPT) and 4 - 2500 µg/plate (PIT) in S. typhimurium strains TA 98, TA 100, TA 1535 and TA 1537 as well as in E. coli WP2 uvrA. A slight bacteriotoxicity was noted at ≥ 2500 µg/plate in the SPT and (depending on the strain) at concentrations ≥ 500 µg/plate in the PIT while no precipitations were noted at any concentration. No increase of revertant colonies was observed in any of the tests performed.

New studies submitted in this dossier:

Report:	CA 5.8.1/53 Nauman S., 2017 Reg.No. 412785 (Metabolite of BAS 500 F, Pyraclostrobin) - Micronucleus test in human lymphocytes in vitro 2017/1024661
Guidelines:	OECD 487 (2016), Commission Regulation (EU) No 640/2012
GLP:	yes (Laboratory certified by Hess. Ministerium für Umwelt, Klimaschutz, Landwirtschaft und Verbraucherschutz, Wiesbaden, Germany)

Executive Summary

Reg.No. 412785 (metabolite of pyraclostrobin; batch: 01586-60; purity: 99.5%) was tested for its potential to induce micronuclei in human lymphocytes *in vitro* in the absence and presence of metabolic activation by S9 mix. Two independent experiments were performed. In duplicate cultures the cells were incubated for 4 (±S9 mix) or 20 hours (-S9 mix) with the test substance at concentrations in the range of 13.1 to 2010 µg/mL. At least three concentrations were evaluated, which were either limited by cytotoxicity or the precipitation of the test item in the media. The vehicle DMSO (0.5% in culture medium) served as negative control, Mitomycin C (4 h) and Demecolcin (20 h) as positive controls in the absence of metabolic activation and Cyclophosphamide as positive control in the presence of metabolic activation. Treatments started after a 48-hour stimulation period with phytohemeagglutinine. Thereafter, Cytochalasin B was added and the cultures were fixed and stained finally after another 20 hours. Cytokinesis-block proliferation index (CBPI) and cytostasis were determined in 1000 binucleated cells as cytotoxicity parameters. The number of micronucleated cells were determined in 2000 binucleated cells for evaluation of mutagenicity.

In both experiments without metabolic activation and in one experiment with metabolic activation, no cytotoxicity was observed up to the highest evaluated concentration, which showed precipitation without addition of S9 mix from 1149 µg/mL onwards and with addition of S9 mix at the top dose of 2010 µg/mL. In the other experiment with metabolic activation, precipitation at the top dose was accompanied by cytotoxicity.
Independent of metabolic activation, no increase in the number of cells carrying micronuclei was observed in both experiments. The solvent control revealed values that were within the range of the laboratory historical negative control data. The positive control chemicals led to the expected increase in cells containing micronuclei that was within the range of the historical positive control data, thus demonstrating the sensitivity of the test system and the validity of the study.

In conclusion, under the experimental conditions Reg.No. 412785 (= 500M62, metabolite of pyraclostrobin) did not induce the formation of micronuclei in human lymphocytes under in vitro conditions in presence and absence of metabolic activation.

(BASF DocID 2017/1024661)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Reg.No. 412785 (metabolite of pyraclostrobin)

Description:	Solid (crystals) / white
Lot/Batch #:	01586-60
Purity:	99.5%
Stability of test compound:	The stability of the test substance is guaranteed (expiry date 01-May-2020)
Solvent used:	DMSO

2. Control Materials:

Negative control:	A negative control was not employed in this study.
Solvent control:	DMSO (0.5% final concentration in culture medium)
Positive control:	Without metabolic activation: Mitomycin C (MMC, 1.5 µg/mL; pulse treatment) dissolved in deionized water; Demecolcin (125 ng/mL; continuous treatment) dissolved in deionized water With metabolic activation: Cyclophosphamide (CPA, 15 µg/mL (Exp. I) or 17.5 µg/mL (Exp. II) dissolved in saline (0.9% NaCl))

3. Activation: S9 was produced from the livers of rats pretreated with β-naphthoflavone/phenobarbital. For testing, S9-fraction (protein content: 30.1 mg/mL (Exp. I) and 34.9 mg/mL (Exp. II)) was thawed at room temperature and mixed with S9-supplement (cofactors). This preparation, the so-called S9-mix, was kept on ice until used.

The S9-mix was prepared immediately before use and had the following final composition:

Component	Concentration
Phosphate buffer (pH 7.4)	100 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM

50 µL S9 mix per mL culture medium were used, yielding a 2.5% S9 fraction or final protein concentration of 0.75 mg/mL in each culture.

4. Test organism: **Human** peripheral blood lymphocytes

Donor(s): Experiment I: 26 years old male
Experiment II: 23 years old male

5. Culture media:

Culture medium: Dulbecco´s Modified Eagles medium/Ham´s F12 (1:1) with GlutaMAX™ (200 mM) supplemented with 10% (v/v) fetal bovine serum (FBS), Pen/Strep (100 U/mL / 100 µg/mL), HEPES (10 mM), heparin (125 U.S.P.-U/mL), and phytohemeagglutinine (PHA, 3 µg/mL).

6. Test concentrations:

Micronucleus assay

Experiment I

(4-h exposure, -S9): 13.1, 22.9, 40.0, 70.0, 122, 214, **375, 656, 1149** and 2010 µg/mL; precipitation at ≥ 1149 µg/mL (evaluated concentrations are indicated in bold)

(4-h exposure, +S9): 13.1, 22.9, 40.0, 70.0, 122, 214, 375, **656, 1149** and **2010** µg/mL; precipitation at 2010 µg/mL (evaluated concentrations are indicated in bold)

Experiment II

(4-h exposure, +S9): 176, 265, 397, 596, **893, 1340** and **2010** µg/mL; precipitation at 2010 µg/mL (evaluated concentrations are indicated in bold)

(20-h exposure, -S9): 176, 265, **397, 596, 893,** 1340 and **2010** µg/mL; precipitation at ≥ 1340 µg/ml (evaluated concentrations are indicated in bold)

B. TEST PERFORMANCE

1. Dates of experimental work: 22-Feb-2017 to 28-Mar-2017

2. Dose selection:

Dose selection was performed according to the current OECD Guideline for the in vitro micronucleus test. The highest test item concentration should be 2000 µg/mL, 2 µL/mL or 10 mM, whichever is the lowest, or be limited by cytotoxicity (up to 55 ± 5% cytostasis) and/or limited solubility visible by test item precipitation. At least three test item concentrations should be evaluated for cytogenetic damage.

A preliminary cytotoxicity test was performed to determine the concentrations to be used in the main experiment. Cytotoxicity is characterized by the percentages of reduction in the Cytokinesis-block proliferation index (CBPI) in comparison with the controls (% cytostasis) by counting 500 cells per culture in duplicate. The experimental conditions in this pre-experimental phase were identical to those required and described below for the mutagenicity assay. The pre-test was performed with 10 concentrations of the test item separated by no more than a factor of √10 and a solvent and positive control. All cell cultures were set up in duplicate. Exposure time was 4 hours (± S9 mix). The preparation interval was 40 hours after start of the exposure.

With regard to the purity (99.5%) of the test item, 2010 µg/mL were applied as top concentration for treatment of the cultures in the pre-test. Test item concentrations ranging from 13.1 to 2010 µg/mL (with and without S9 mix) were chosen for the evaluation of cytotoxicity.
In the pre-test for toxicity, precipitation of the test item was observed at the end of treatment at 1149 µg/mL and above in the absence of S9 mix and at 2010 µg/mL in the presence of S9 mix. Since the cultures fulfilled the requirements for cytogenetic evaluation, this preliminary test was designated Experiment I.
Using a CBPI as an indicator for toxicity, no cytotoxic effects were observed in Experiment I after 4 hours treatment in the absence and presence of S9 mix. Therefore, 2010 µg/mL were chosen as top treatment concentration for Experiment II.

3. Micronucleus test:

Pulse exposure (±S9)

About 48 h after seeding two blood cultures (10 mL each) were set up in parallel in 25 cm² cell culture flasks for each test item concentration. The culture medium was replaced with complete medium (with 10 % FBS) containing the test item. After 20 hours, the cells were spun down by gentle centrifugation for 5 minutes. The supernatant was discarded and the cells were re-suspended in and washed with saline. The washing procedure was repeated once as described. After washing, the cells were re-suspended in complete culture medium containing 10 % FBS (v/v). Cytochalasin B (4 µg/mL) was added and the cells were cultured another approximately 20 hours until preparation.

Continuous exposure (-S9)

About 48 h after seeding 2 blood cultures (10 mL each) were set up in parallel in 25 cm² cell culture flasks for each test item concentration. The culture medium was replaced with complete medium (with 10 % FBS) containing the test item. After 20 hours, the cells were spun down by gentle centrifugation for 5 minutes. The supernatant was discarded and the cells were re-suspended in and washed with saline. The washing procedure was repeated once as described. After washing the cells were re-suspended in complete culture medium containing 10 % FBS (v/v). Cytochalasin B (4 µg/mL) was added and the cells were cultured another approximately 20 hours until preparation.

Preparation of cells

The cultures were harvested by centrifugation 40 h after beginning of treatment. The cells were spun down by gentle centrifugation for 5 minutes. The supernatant was discarded and the cells were re-suspended in approximately 5 mL saline and spun down once again by centrifugation for 5 minutes. Then the cells were resuspended in 5 mL KCl solution (0.0375 M) and incubated at 37°C for 20 minutes. 1 mL of ice-cold fixative mixture of methanol and glacial acetic acid (19 parts plus 1 part, respectively) was added to the hypotonic solution and the cells were resuspended carefully. After removal of the solution by centrifugation the cells were resuspended for 2 x 20 minutes in fixative and kept cold. The slides were prepared by dropping the cell suspension in fresh fixative onto a clean microscope slide. The cells were stained with Giemsa.

4. Statistics:

Statistical significance was confirmed by the Chi square test ($\alpha < 0.05$), using a validated test script of "R", a language and environment for statistical computing and graphics. Within this test script a statistical analysis was conducted for those values that indicated an increase in the number of cells with micronuclei compared to the concurrent solvent control.

5. Cytotoxicity evaluation:

Evaluation of cytotoxicity and cytogenetic damage

Evaluation of the slides was performed using microscopes with 40 x objectives. The micronuclei were counted in cells showing a clearly visible cytoplasm area. The micronuclei had to be stained in the same way as the main nucleus. The area of the micronucleus should not extend the third part of the area of the main nucleus. At least 1000 binucleated cells per culture were evaluated for cytogenetic damage on coded slides. The frequency of micronucleated cells was reported as % micronucleated cells. To describe a cytotoxic effect, the CBPI (Cytokinesis-block proliferation index) was determined in 500 cells per culture and cytotoxicity is expressed as % cytostasis. A CBPI of 1 (all cells are mononucleate) is equivalent to 100 % cytostasis.

The CBPI was calculated as follows:

$$CBPI = \frac{(MONC \times 1) + (BINC \times 2) + (MUNC \times 3)}{n}$$

CBPI	Cytokinesis-block proliferation index
n	Total number of cells
MONC	Mononucleate cells
BINC	Binucleate cells
MUNC	Multinucleate cells

$$\text{Cytostasis \%} = 100 - 100\,[(CBPI_T - 1) / (CBPI_C - 1)]$$

T	Test item
C	Solvent control

6. Evaluation criteria:

Acceptability criteria

- The rate of micronuclei in the solvent controls falls within the historical laboratory control data range.
- The rate of micronuclei in the positive controls is statistically significantly increased.
- The quality of the slides must allow the evaluation of a sufficient number of evaluable cells.

Evaluation criteria

A test item can be classified as non-clastogenic and non-aneugenic if:

- the number of micronucleated cells in all evaluated dose groups is in the range of the historical laboratory control data and
- no statistically significant or concentration-related increase of the number of micronucleated cells is observed in comparison to the respective solvent control.

If the above-mentioned criteria for the test item are not clearly met, the test item will be classified as equivocal or a confirmatory experiment may be performed. However, results may remain questionable regardless of the number of times the experiment is repeated.

An increase in the number of micronucleated mononucleate cells may indicate that the test item has aneugenic potential.

II. RESULTS AND DISCUSSION

A. ANALYTICS

Stability of the test item in DMSO for a period of 4 hours at room temperature was verified analytically (see separate report 01Y0253/12Y146; BASF DocID 2017/1078583 - available upon request).

B. CYTOTOXICITY, PRECIPITATION AND OSMOLARITY

In Experiment I, precipitation of the test item in the culture medium was observed at 1149 µg/mL and above in the absence of S9 mix and at 2010 µg/mL in the presence of S9 mix at the end of treatment. In addition, precipitation occurred in Experiment II in the absence of S9 mix at 1340 µg/mL and above and in the presence of S9 mix at 2010 µg/mL at the end of treatment [see Table 5.8.1-80].
No relevant influence on osmolarity or pH was observed.
In Experiment I in the absence of S9 mix and in Experiment II in the presence of S9 mix, no cytotoxicity was observed up to the highest evaluated concentration, which showed precipitation. In Experiment I in the presence of S9 mix, the highest applied and evaluated concentration showed cytotoxicity and precipitation. In Experiment II in the absence of S9 mix, no cytotoxicity was observed up to the highest applied concentration and precipitation occurred in the two highest applied concentrations (1340 and 2010 µg/mL). Since the cultures treated with 1340 µg/mL did not fulfill the criteria for genotoxic evaluation (at least 1000 evaluable cells per duplicate culture), the highest applied concentration was evaluated for genotoxicity.

C. MICRONUCLEUS ASSAY

In this study, neither a statistically significant nor a biologically relevant increase in the number of micronucleated cells was observed after treatment with the test item [see Table **5.8.1-52**5.8.1-80].
The micronucleus rates of the cells after treatment with the test item were close to the range of the respective solvent control values and within the range of the laboratory historical control data (HCD). The HCD in the absence of S9 mix were 0.15-1.65% (95% control limits 0.08-1.12%) for (4h) pulse treatment and 0.05-1.35% (95% limits: 0.12-1.03%) for continuous (20h) treatment. The HCD in the presence of S9 mix were 0.15-1.30% (95% limits: 0.16-1.08%) for pulse treatment.

All positive controls used, i.e. Demecolcin (150 ng/mL), MMC (1.5 µg/mL) or CPA (17.5 or 15.0 µg/mL), resulted in distinct increases in cells with micronuclei (3.15-14.85%). These responses were within the range of the laboratory historical positive control data thus demonstrating the sensitivity and validity of the test system.

Table 5.8.1-80: Summary of results of the in vitro micronucleus test in human lymphocytes with Reg.No. 412785

Exp.	Exposure period [h]	Test item concentration [µg/mL]	Proliferation index CBPI	Cytostasis [%[a]]	Micronucleated cells [%[b]]

		2010[P]	1.90	24.6	0.50

a: For the positive control groups and the test item treatment groups the values are related to the solvent controls.
b: The number of micronucleated cells was determined in a sample of 2000 binucleated cells.
P: Precipitation occurred at the end of treatment by the unaided eye.
CBPI: cytokinesis-block proliferation index
n. e. Not evaluable; the cultures did not fulfill the criteria for genotoxic evaluation (≤ 1000 appropriate binucleate cells per culture).
*: The number of micronucleated cells is statistically significantly higher than corresponding control values ($p \leq 0.05$, Chi-squared test).
[1] DMSO 0.5% (v/v)
[2] MMC 1.5 µg/mL
[3] Demecolcin 125 ng/mL
[4] CPA 15.0 µg/mL
[5] CPA 17.5 µg/mL

III. CONCLUSION

Under the experimental conditions of this study Reg.No. 412785 (metabolite of pyraclostrobin) did not induce micronuclei as determined by the in vitro micronucleus test in human lymphocytes when tested up to precipitating concentrations with and without metabolic activation.

Toxicological evaluation of 500M62 (Reg.No. 412785, BF 500-13)

The QSAR evaluation of 500M62 is of low reliability and by weight of evidence there was no conclusive alert for genotoxity. Metabolite 500M62 was neither genotoxic in the Ames test nor in an in-vitro micronucleus assay in human lymphocytes. In conclusion, 500M62 is considered to be **not toxicologically relevant**.

The highest calculated concentration in surface water (PEC_{sw}) is 0.413 µg/L. No relevant human exposure is to be expected as untreated surface water is not used as drinking water.

CA 5.8.2 Supplementary studies on the active substance

Studies evaluated in the draft monograph of Rapporteur Member State Germany of August 01, 2001:

No supplemental studies on the active substance were evaluated in the previous Annex I listing process besides those indicated in M-CA 5.8.1.

Submission of not yet per-reviewed studies in this dossier:

A study investigating the effects of pyraclostrobin administration on blood plasma and urine iron as well as plasma transferrin levels was performed. Lower serum iron levels were noted, which were however not accompanied by lower serum transferrin levels or higher urinary iron excretion.

Upon request of US EPA, studies were conducted investigating the T-cell dependent antigen response and the natural killer cell mediated immune response. The respective studies are listed in Table 5.8.2-1. The immunotoxicity studies did not reveal a specific effect on the T-cell dependent or NK-cell mediated immune response.

Additionally, a 28-day range finding study was performed to set the dose levels for the subsequent immunotoxicity studies. The T-cell dependent antigen response had to be repeated because of an abnormal, 2-fold higher humoral immune response in control animals when compared to the historical control. These two studies are not listed in Table 5.8.2-1 as the results are not end-point relevant.

In addition, literature data were taken into account (see CA 5.8.2/6 to CA 5.8.2/9). However, these data are judged to represent supplemental information only and do not provide relevant endpoints.

Table 5.8.2-1: Summary of not yet peer-reviewed supplemental studies with pyraclostrobin

Study	Dosages (mg/kg bw/day)	NOAEL (mg/kg bw/day)	Main adverse effect	Reference (BASF DocID)
Immunotoxicity, mouse, T-cell dependent immune response 0, 50, 200, 750 ppm	F: 14, 55, 191	55 (systemic) 55 (immunotox NOEL)	Body weight effects, lower thymus and spleen weights, lower number of spleen cells, but no adverse effect on functional T-cell dependent immune response	2012/1084176
Immunotoxicity, mouse, NK-cell mediated immune response 0, 50, 200, 750 ppm	F: 13, 50, 165	50 (systemic) 165 (immunotox)	Body weight effects, lower thymus and spleen weights, lower number of spleen cells, but no effect on NK cell activity	2011/1035857
Effects on iron blood serum and urine levels, 14-day study in rats 0, 50, 500, 1500 ppm	M: 3.8, 33.9, 73.9 F: 4.1, 37.4, 78.3	3.8	Lower serum iron level in blood serum	2003/1009534

Thus, the conclusion for relevant endpoints for the current renewal is as follows:

Other toxicological studies (SANCO/11802 data point 5.8)

Supplementary studies on the active substance	**Immunotoxicity of pyraclostrobin** No evidence for specific immunotoxicity No classification required
	Effect of pyraclostrobin on iron levels in rats Decreased blood plasma iron levels (NOAEL = 3.8 mg/kg bw/day)

Effect of pyraclostrobin on iron levels in rats (CA 5.8.2/1)

Report: CA 5.8.2/1
[redacted], 2003a
BAS 500 F - Determination of iron in urine and serum of Wistar rats - Administration in the diet over 14 days
2003/1009534
Guidelines: none
GLP: no

Executive Summary

The aim of this study was to determine the level of iron in serum and urin after oral administration of pyraclostrobin (BAS 500 F). Pyraclostrobin was administered to groups of 10 female Wistar rats at dietary concentrations of 0, 50, 500 and 1500 ppm over a period of 14 days.

Food consumption and body weight development was impaired in both sexes at ≥ 500 ppm. At the high dose level an overall body weight loss was observed.

Serum iron concentrations were dose- and time dependently decreased in mid and high dose animals up to 50% when compared to the control. Serum transferrin levels or urinary iron excretion were not affected by treatment. No treatment related effects were noted at 50 ppm. Thus, regarding the decrease of serum iron concentration, the no observed effect level was 50 ppm (3.8 mg/kg bw/day in males, 4.1 mg/kg bw/day in females).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Pyraclostrobin

Description:	solid / crystalline / yellowish
Lot/Batch #:	CP 029053
Purity:	99.0%
Stability of test compound:	Stable - Expiry date July 2005

2. Vehicle and/or positive control: None

3. Test animals:

Species:	Rat
Strain:	Wistar (CrlGlxBrlHan:WI)
Sex:	Male and female
Age:	about 8 weeks
Weight at dosing:	mean ♂: 237 g, ♀ 167 g
Source:	Charles River, Sulzfeld, Germany
Acclimation period:	6 days
Diet:	basic maintenance diet for rat/mouse/hamster, meal from Provimi KLIBA SA, Kaiseraugust, Switzerland, ad libitum
Water:	water, ad libitum
Housing:	type DK III stainless steel wire mesh cages, floor area about 800 cm²

Environmental conditions:

Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	not reported
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 18-Mar-2003 - 10-Apr-2003
(In life dates: 19-Mar-2003 (start of administration) to 03-Apr-2003 (necropsy)

2. Animal assignment and treatment:

Pyraclostrobin was administered to groups of 10 male and 10 female rats at dietary concentrations of 0, 50 (low dose), 500 (mid dose) and 1500 ppm (high dose) for up to 14 days. The animals were assigned to the treatment groups by means of a computer generated randomization list based on body weights.

3. Test substance preparation and analysis:

An acetonic solution of the test substance was prepared. This solution was sprayed on about three kilograms of food under partial vacuum in a laboratory evaporator. Subsequently, acetone was removed at 900 mbar at a temperature of about 40°C. This premix was then adjusted to the desired concentration with the addition afappropriate amounts of food and mixed in a laboratory mixer for about 10 minutes.

The stability of the test substance in the diet over a period of up to 43 days at room temperature was proven earlier. No further analyses of the test substance preparations were carried out for this study.

4. Statistics:

Means and standard deviations (S.D.) of each test group were calculated for several parameters. Further statistical analyses were performed according to following table:

Statistics of clinical examinations, clinical pathology and pathology

Parameter	Statistical test
food consumption, body weight	A comparison of the dose group with the control group was performed using Welch t-test (two-sided) for the hypothesis of equal means.
Clinical phathology	Non-parametric one-way analysis using KRUSKAL-WALLIS test (two-sided). If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using Wilcoxon-test (two-sided) for the equal medians.

C. METHODS

1. Observations:

The animals were examined for evident signs of toxicity or mortality twice daily on working days and once daily on weekends and public holidays. Observations for general clinical signs of toxicity were performed once daily.

2. Body weight:

The body weight of the animals was determined on the day of randomization, at the start of the treatment (day 0), and weekly thereafter.

3. Food consumption and compound intake:

Individual food consumption was determined weekly (according to body weight) and calculated as mean food consumption in grams per animal and day.

The mean daily intake of test substance (group means) was calculated based upon individual values for body weight and food consumption.

$$Substance\ intake\ for\ day\ x = \frac{FC_x \times C}{BW_x}$$

with FC_x as the mean daily food consumption (in g/day) on day x, C as the dose in ppm, and BW_x as body weight on day x of the study (in g).

4. Water consumption:

Not performed in this study.

5. Ophthalmoscopy:

Not performed in this study.

6. Hematology and clinical chemistry:

Blood samples were taken from the retroorbital venous plexus in the morning (day 14) from non-fasted animals. Iron and transferrin levels were determined for all animals.

7. Urinalysis:

For determination of iron in urine spechimens individual animals were transferred to metabolism cages (withdrawal of food and water) and urine was collected overnight.

8. Sacrifice and pathology:

The animals were sacrificed by decapitation under carbon dioxide anesthesia. Five centimeter of duodenum were removed for a possible PCNA examination and fixed for 24 hours in 4% formaldehyde. The caudal part was cut for identification.

II. RESULTS AND DISCUSSION

A. TEST SUBSTANCE ANALYSES

See Section B 3. above

B. OBSERVATIONS

1. Clinical signs of toxicity

There was nothing abnormal detected in all animals.

2. Mortality

No animal died during the study.

3. Ophthalmoscopy

Not performed in this study.

C. BODY WEIGHT AND BODY WEIGHT GAIN

An overall body weight loss was observed in both male and female rats at the high dose [see Figure 5.8.2-1 and Table 5.8.2-2]. In mid dose males, effects on body weight and body weight gain were observed, too.

Figure 5.8.2-1: Body weight development of rats administered pyraclostrobin for 14 days

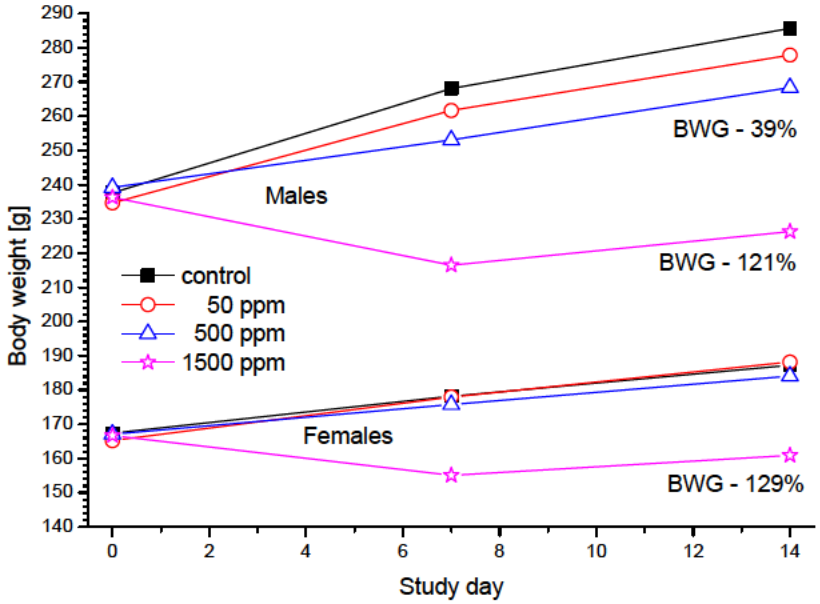

Table 5.8.2-2: Mean body weight of rats administered pyraclostrobin for 14 days

	Males			Females		
day	0	7	14	0	7	14
Dose level [ppm]						
0	237.6 ± 9.3	268.1 ± 13.9	285.7 ± 18.0	167.4 ± 5.4	178.2 ± 8.7	187.2 ± 8.4
50	234.7 ± 7.2	261.7 ± 10.5	277.9 ± 15.1	165.2 ± 5.6	178.0 ± 10.1	188.2 ± 11.1
Δ% (compared to control)#	-1.2	-2.4	-2.8	-1.3	-0.1	0.5

*: p = 0.05, **: p = 0.01 (Dunnett's test, two-sided)

D. FOOD CONSUMPTION AND COMPOUND INTAKE

Food consumption was significantly decreased in high and mid dose males and females during the study [see Table 5.8.2-3].

The approximate mean daily test substance intake was calculated to be 3.8, 33.9 and 73.9 mg/kg bw/day in males and 4.1, 37.4 and 78.3 mg/kg bw/day in females at dietary dose levels of 50, 500, and 1500 ppm, respectively.

Table 5.8.2-3: Mean food consumption of rats administered pyraclostrobin for 14 days

	Males		Females	
day	7	14	7	14
Dose level [ppm]				
0	21.8±1.2	20.1±1.4	15.6±1.0	14.9±0.7

Values may not calculate exactly due to rounding of mean values (values given in the table are based on unrounded means)
*: p = 0.05, **: p = 0.01 (Dunnett's test, two-sided)

E. BLOOD ANALYSIS

1. Serotological findings

In males a dose and time dependent decrease of serum iron levels was observed [see Table 5.8.2-4]. Even though not statistically significant, the decrease in mid dose males after 7 days was considered to be treatment-related. In females no consistent (dose-dependent) effect on iron levels was observed after 7 days. However, the 14 day data indicated a dose-dependent decrease of iron serum levels, which was however less pronounced when compared to males.

Table 5.8.2-4: Iron concentration (µmol/L) in the serum of male and female rats after 7 and 14 days of pyraclostrobin administration

Sex	Blood sampling		0 ppm	50 ppm	500 ppm	1500 ppm
Males	Day 7	Mean % Dev.	47.01 ± 13.51	44.84 ± 6.66 -5	**36.61 ± 5.27** **-22**	**34.85 ± 3.10*** **-26**
	Day 14	Mean % Dev.	54.54 ± 9.83	46.71 ± 6.57 -14	**37.72 ± 5.21**** **-31**	**27.41 ± 4.36**** **-50**
Females	Day 7	Mean % Dev.	59.07 ± 8.47	60.09 ± 14.11 2	46.48 ± 6.38** -21	57.49 ± 15.62 -3
	Day 14	Mean % Dev.	53.61 ± 4.16	58.31 ± 12.22 9	**45.55 ± 9.03*** **-15**	**41.97 ± 9.94**** **-22**

* p ≤ 0.05; ** p ≤ 0.01 (Kruskal Wallis + Wilcoxon-test)

There were no treatment-related changes in the serum transferrin levels of either sex at both time intervals.The slight decrease in transferrin concentration in the serum of the high-dose group males on day 7 was not consistent over time and was regarded to be incidental and not toxicologically relevant [see Table 5.8.2-5].

Table 5.8.2-5: Transferrin concentration (g/L) in the serum of male and female rats after administration of pyraclostrobin for 7 and 14 days

Sex	Blood sampling		0 ppm	50 ppm	500 ppm	1500 ppm
Males	Day 7	Mean % Dev.	5.50 ± 0.34	5.34 ± 0.38 -3	5.45 ± 0.42 -1	4.74 ± 0.37** -14
	Day 14	Mean % Dev.	6.38 ± 0.77	5.80 ± 0.60 -9-	6.07 ± 0.79 -5	5.85 ± 0.47 -8
Females	Day 7	Mean % Dev.	5.40 ± 0.67	5.23 ± 0.27 -3	5.62 ± 0.52 4	4.92 ± 0.39 -9
	Day 14	Mean % Dev.	5.86 ± 0.72	5.68 ± 0.65 -3	6.13 ± 0.56 5	5.63 ± 0.67 -4

* p ≤ 0.05; ** p ≤ 0.01 (Kruskal Wallis + Wilcoxon-test)

2. Clinical chemistry findings

Not performed in this study.

3. Urinalysis

Iron levels in urine were not affected by treatment. The observed numerical differences displayed no statistical significance and were not dose related [see Table 5.8.2-6].

Table 5.8.2-6: Iron concentration (nmol) in the serum of male and female rats after administration of pyraclostrobin for 14 days

Sex	Urine sampling		0 ppm	50 ppm	500 ppm	1500 ppm
Males	Day 15	Mean % Dev.	3.97 ± 1.40	3.27 ± 1.49 -17.6	2.69 ± 1.18 -32.1	3.60 ± 4.39 -9.1
Females	Day 15	Mean % Dev.	2.61 ± 0.90	2.44 ± 1.14 -6.5	2.78 ± 1.48 6.3	2.89 ± 1.17 10.7

* p ≤ 0.05; ** p ≤ 0.01 (Kruskal Wallis + Wilcoxon-test)

B) F. NECROPSY

No gross necropsy observations were made at sacrifice.

III. CONCLUSION

Dietary administration of pyraclostrobin to rats at dose levels of 0, 50, 500 and 1500 ppm over a period of 14 days resulted in a decrease of serum iron concentrations in mid and high dose animals of either sex 14 days after start of treatment. Serum transferrin und urinary iron excretions were not affected by treatment. No treatment-related effects were seen in the low-dose animals.

Thus, regarding the decrease of serum iron concentration, the no observed effect level was 50 ppm (3.8 mg/kg bw/day in males, 4.1 mg/kg bw/day in females).

Immunotoxicity studies (CA 5.8.2/2 – CA 5.8.2/5)

Report: CA 5.8.2/2
[redacted] 2011a
A 28 day oral (dietary) range finding study of BAS 500 F in B6C3F1 mice
2011/1194286
Guidelines: none
GLP: no

Executive Summary

As a range finding study for a subsequent short term studies to determine the immunotoxicological potential of pyraclostrobin, pyraclostrobin (batch: COD-001236; purity: 99.02%) was administered to $B_6C_3F_1$ mice at dietary dose levels of 0, 500, and 1500 ppm for 28 days. The high dose treatment resulted in poor clinical condition and body weight loss within 3 days. As a consequence, the high dose level was terminated after 3 days. Treatment was tolerated at 500 ppm with moderate effects on food consumption and body weight development. Minimal hyperplasia of the duodenal mucosa was observed in both sexes at 500 ppm whereas a minimal decrease of cytoplasmic vaculation in the liver was only observed in 500 ppm males. Lower hemoglobin, hematocrit, mean corpuscular volume, and mean corpuscular hemoglobin values were observed in the 500 ppm group males and females. These changes were of minimal degree and thus not considered to be of adverse nature.

The LOEL was identified as 500 ppm, which is equivalent to mean daily doses of about 121 mg/kg bw/day in male and 139 mg/kg bw/day in female mice.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Pyraclostrobin (96/0494-11)

Description:	semi-solid / orange
Lot/Batch #:	COD-001236
Purity:	99.02%
Stability of test compound:	Stable: Expiry date 01.10.2015

2. Vehicle and/or positive control: Diet was used as vehicle for admistration

3. Test animals:

Species:	Mouse
Strain:	B6C3F1
Sex:	Male and female
Age:	approx. 52 days at start of administration
Weight at dosing:	♂: 22.1 - 25.7 g, ♀ 19.6 - 22.8 g
Source:	Charles River Laboratories, Inc., Raleigh, NC
Acclimation period:	10 days
Diet:	PMI Nutrition International, LLC, Certified Rodent LabDiet® 5002 (meal), ad libitum
Water:	Reverse osmosis-treated (on-site) drinking water, delivered by an automatic watering system, ad libitum
Housing:	Clean, stainless steel, wire-mesh cages suspended above cage-board

Environmental conditions:

Temperature:	22±3°C
Humidity:	50±20%
Air changes:	10 / hour
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 22-Feb-2011 to 27-May-2011
In life dates: 04-Mar-2011 (start of administration) to 01-Apr-2011 (necropsy), 27-May 2011 (last histopathological examination)

2. Animal assignment and treatment:

Pyraclostrobin was administered to groups of 8 male and 8 female mice at dietary concentrations of 0, 500 (low dose), and 1500 (high dose) ppm for up to 28 days, including the day of euthanasia, except for the 1500 ppm group animals which were killed after 4 days of treatment. The animals were assigned to the treatment groups by means of a computer generated randomization list based on body weights.

3. Test substance preparation and analysis:

The diets were prepared by mixing weighed amounts of the pulverized test substance with 100 mL of acetone, which was then completely dissolved in an ultrasonic bath. The resulting solution was sprayed onto a portion of food and mixed. For the control group 100 mL acetone were mixed with the food. Acetone was completely removed at 40°C at 900 mbar. To obtain the appropriate dietary concentration, the premix was mixed with the remaining amount of feed in a laboratory mixer. The test diet formulations were prepared approximately weekly for each of the designated concentrations.

Analyses performed prior to the start of the administration period revealed that the test-substance was stable in the diet for at least 43 days at room temperature.

Samples for homogeneity determination were collected each day of diet preparation. According to the SOP three randomly sampled specimen of the low and high dose level were analyzed. The samples were also used for determination of the test-article concentration. For the control diets a single sample was analyzed.

Analysis of diet preparations for homogeneity and test-item content

Dose level [ppm]	Sampling	Analysis	Concentration [ppm] Mean ± SD[#]	Relative standard deviation [%]	Mean % of nominal concentration
500 ppm	03.03.11	21.-22.03.11	498.1 ± 2.3	0.5	99.6
500 ppm	10.03.11	21.-22.03.11	488.9 ± 1.7	0.3	97.8
500 ppm	14.03.11	05.05.11	507.0 ± 9.4	1.9	101.4
500 ppm	24.03.11	05.-06.05.11	505.2 ± 10.4	2.1	101.0
1500 ppm	03.03.06	21-22.03.11	1498.7 ± 4.0	0.3.	99.9

[#] based on mean values of the three individual samples

Relative standard deviations of the homogeneity samples in the range of 0.3 to 2.1% indicate the homogenous distribution of pyraclostrobin in the diet preparations. The actual average test-substance concentrations were in the range of 97.5 to 103.5% of the nominal concentrations.

4. Statistics:

Means, standard deviations (S.D.), and standard errors (S.E.) of each test group were calculated for several parameters. All statistical tests were performed using WTDMS^{TM} unless otherwise noted. Further statistical analyses were performed according to following table:

Statistics of clinical examinations, clinical pathology and pathology

Parameter	Statistical test
food consumption, body weight, body weight change, clinical pathology parameters, weight parameters	A parametric one-way ANOVA to determine intergroup differences. If the ANOVA revealed statistically significant intergroup variance, Dunnett's test (two-sided) was used to compare the test-substance-treated group with the control group.

C. METHODS

1. Observations:

The animals were examined for moribundity or mortality twice daily. Observations for overt clinical signs of toxicity were performed at least once daily.

Detailed physical observations were performed in all animals prior to the start of the administration period and weekly thereafter. For this the animals were transferred to a standard arena. The findings were ranked according to the degree of severity, if applicable.

2. Body weight:

The body weight of the animals was determined approximately one week prior to test substance administration, on the day of randomization, at the start of the treatment (day 0), and twice weekly thereafter. Furthermore, body weight was determined prior to euthanasia *in extremis*, and at the scheduled necropsy.

3. Food consumption and compound intake:

Individual food consumption was determined twice weekly (according to body weight) and calculated as mean food consumption in grams per animal and day.

The mean daily intake of test substance (group means) was calculated based upon individual values for body weight and food consumption.

4. Water consumption:

Not performed in this study.

5. Ophthalmoscopy:

Not performed in this study.

C) 6. Hematology and clinical chemistry:

Blood samples were withdrawn from all animals at the scheduled necropsy (study day 28). Blood was collected at the time of euthanasia via the vena cava of animals euthanized by inhalation of carbon dioxide. The blood sampling procedure and the subsequent analysis of the blood and serum samples were carried out in a randomized sequence.

The following hematological and clinical chemistry parameters were determined for all animals:

Hematology:					
	Red blood cells		*White blood cells*		*Clotting Potential*
✓	Erythrocyte count (RBC)	✓	Total leukocyte count (WBC)		Prothrombin time
✓	Hemoglobin (Hb)	✓	Neutrophils (percent and absolute)	✓	Platelet count
✓	Hematocrit (Hct)	✓	Eosinophils (% and abs.)		Activated partial thromboplastin time (APPT)
✓	Mean corp. volume (MCV)	✓	Basophils (% and abs.)	✓	Platelet estimate
✓	Mean corp. hemoglobin (MCH)	✓	Lymphocytes (% and abs.)		
✓	Mean corp. Hb. conc. (MCHC)	✓	Monocytes (% and abs.)		
✓	Reticulocyte count	✓	Large unstained cells (% and abs.)		
✓	Red cell morphology (RBC Morphology)				

Clinical chemistry:					
	Electrolytes		*Metabolites and Proteins*		*Enzymes:*

II. RESULTS AND DISCUSSION

A. TEST SUBSTANCE ANALYSES

See Section B 3. above

B. OBSERVATIONS

1. Clinical signs of toxicity

There were test substance-related clinical observations in the 1500 ppm group males and females and 500 ppm group males.

Clinical observations detected in the 1500 ppm group males and/or females included intermittent tremors, dermal atonia, body cool to touch, decreased respiration rate, labored respiration, and yellow material on the urogenital area, anogenital area, ventral trunk, and/or hindlimb(s).

The 500 ppm group males were noted with yellow material on the urogenital area sporadically during the detailed clinical observation. The toxicological relevance of this finding remains unclear. There were no test substance-related clinical observations in the 500 ppm group females.

2. Mortality

All 1500 ppm group males and females were euthanized in extremis on study day 3 due to substantial body weight loss [see Figure 5.8.2-2] and poor physical state. All control and 500 ppm animals survived to the scheduled necropsy.

3. Ophthalmoscopy

Not performed in this study.

C. BODY WEIGHT AND BODY WEIGHT GAIN

High dose (1500 ppm) mice experienced a marked body weight loss of up to 19.5% of the initial weight within 3 days after commencement of treatment [see Table 5.8.2-7 and Figure 5.8.2-2]. Together with the poor clinical condition this was the reason to terminate this dose level pre-term.

Low dose (500 ppm) mice likewise suffered from an initial body weight loss, which was however less pronounced (up to 6.2% of the initial weight). From day 3 onwards, body weight development was roughly comparable to controls, however the initial body weight loss could not be recovered.

Figure 5.8.2-2: Body weight development of mice administered pyraclostrobin for up to 28 days

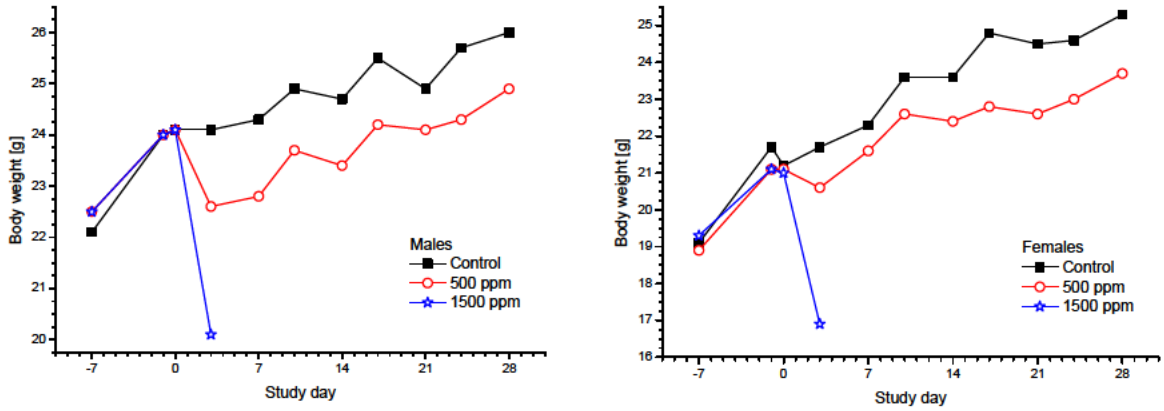

Table 5.8.2-7: Mean body weight of mice administered pyraclostrobin for up to 28 days

	Males			Females		
Dose level [ppm]	0	500	1500	0	500	1500

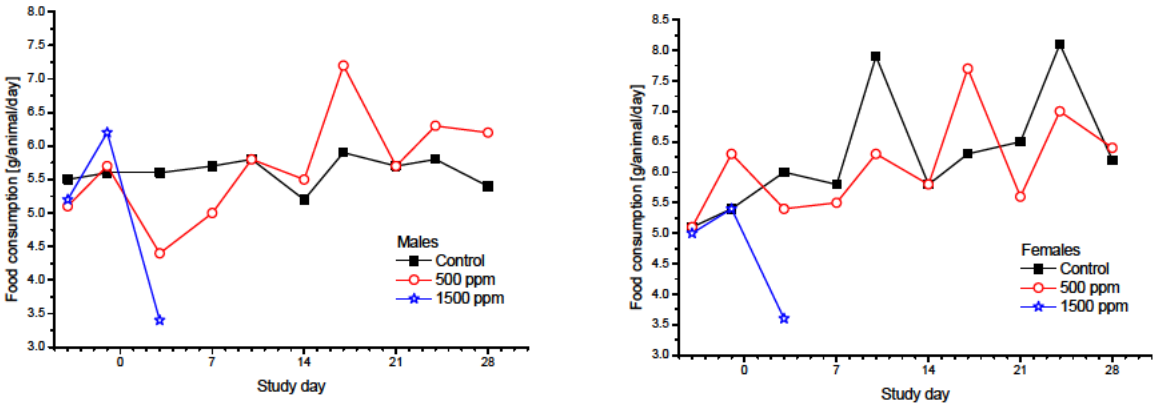
Values may not calculate exactly due to rounding of mean values (values given in the table are based on unrounded means)

NA not applicable

D. FOOD CONSUMPTION AND COMPOUND INTAKE

In the high dose group a treatment-related statistically significant lower food consumption was noted from study day 0 to 3 [see Figure 5.8.2-3]. Slightly lower food consumption in the 500 ppm groups were noted up through study day 7 in males. Even though the study director considered the food consumption in mid dose females to be slightly affected, there is considerable variability in the food consumption of control and high dose females and a clear treatment-related effect is difficult to determine.

Figure 5.8.2-3: Mean daily food consumption in mice administered pyraclostrobin for up to 28 days



The approximate mean daily test substance intake was calculated to be 121, and 231 mg/kg bw/day in males and 139, and 287 mg/kg bw/day in females at dietary dose levels of 500, and 1500 ppm, respectively.

E. BLOOD ANALYSIS

1. Hematological findings

Statistically significant differences of red blood cell parameters were noted at 500 ppm [see Table 5.8.2-8]. These treatment-related changes were generally of minor degree (max 5.8% difference) and thus not considered to be of adverse nature. Red and white blood cell counts were not affected by treatment. Likewise, the differential blood count did not reveal treatment-related effects.

Table 5.8.2-8: Selected hematology findings in mice administered pyraclostrobin for 28 days

		Males		Females	
Dose	[ppm]	0	500	0	500
Hemoglobin	[mmol/L]	17.2 ± 0.25	**16.2 ± 0.61****	16.5	**15.9****
Hematocrit	[L/L]	54.7	**52.2***	51.9	**50.1****

* $p \leq 0.05$; ** $p \leq 0.01$ (Dunnett's test, two sided)

2. Clinical chemistry findings

Statistically significant decreased of mean alkaline phosphatase (ALP) and alanine aminotransferase (ALT) values was observed in females or males, respectively [see Table 5.8.2-9]. Both changes were not considered to be of toxicological relevance.

Table 5.8.2-9: Selected clinical chemistry findings in mice administered pyraclostrobin for 28 days

		Males		Females	
Dose	[ppm]	0	500	0	500
ALP	[U/l]	103	104	129	108**
ALT	[U/l]	36	30*	35	27

* $p \leq 0.05$; ** $p \leq 0.01$ (Dunnett's test, two sided)

3. Urinalysis

Not performed in this study.

F. NECROPSY

1. Gross and histopathology

There were no treatment-related macropathological findings at 500 ppm. In fact, the only finding was observed in a control female (dark red area(s) in the spleen).

In 1500 ppm animals killed pre-term, macroscopic findings were restricted to one female with a dark red discoloration of the adrenal gland(s) and two females with pale livers. As no histopathological evaluation of high dose animals was performed, the toxicological significance of these macroscopic findings remains open.

2. Organ weight

Terminal body weights in 500 ppm female mice were significantly reduced [see Table 5.8.2-10]. A number of statistically significant differences of absolute and/or relative organ weights were observed in both sexes. The study director considered the changes of kidney and seminal vesicle weights in males to be treatment-related. However, no histopathology was performed on these organs and accordingly the presence of corroborative histopathological changes is unknown. Furthermore, the kidney weight changes in females, being of similar degree, were not considered to be related to treatment. Thus the basis for the former conclusion is unknown. The fact that other statistically significant changes of mainly absolute organ weights were attributed to the lower terminal body weights sheds additional doubt regarding the interpretation of the kidney and seminal vesicle weight changes.

Table 5.8.2-10: Selected mean absolute and relative organ weights of mice administered pyraclostrobin for 28 days (500 ppm, control) and 3 days (1500 ppm) (group means)

Sex		Males				Females

Values may not calculate exactly due to rounding of figures

3. Histopathology

Test substance-related mucosal hyperplasia in the duodenum was noted in the 500 ppm group males and females characterized by bigger crypts lined by large, cuboidal epithelial cells with increased numbers of mitotic figures and larger, wider villi lined by large, columnar epithelium. In the liver, there was minimal decreased cytoplasmic vacuolation of the centrilobular hepatocytes in the 500 ppm group males [see Table 5.8.2-11].

Table 5.8.2-11: Incidence of histopathological lesions in mice administered pyraclostrobin for 28 days

	Male		Female	
Dose [ppm]	0	500	0	500
Animals in group	8	8	8	8
Duodenum # examined	8	8	8	8
- Hyperplasia, mucosal minimal		8		8
Liver # examined	8	8	8	8
- Infiltrate, mononuclear, minimal	2	2	6	5
- Vacuolation, cytoplasmic, decreased , minimal		8		
Spleen # examined	8	8	8	8
- Hyperplasia, white pulp minimal		2	1	
Urinary Bladder # examined	8	8	8	8
- Infiltrate, mononuclear minimal	4	1	2	5

All other histopathological findings were considered incidental as they were evenly distributed or observed in single incidences only.

III. CONCLUSION

Dietary administration of pyraclostrobin to mice at dose levels of 0, 500, and 1500 ppm for 28 days resulted in poor clinical condition and body weight loss within 3 days at 1500 ppm. As a consequence, the high dose level was terminated after 3 days. Treatment was tolerated at 500 ppm with moderate effects on food consumption and body weight development. Minimal hyperplasia of the duodenal mucosa was observed in both sexes at 500 ppm, whereas a minimal decrease of cytoplasmic vaculation in the liver was only observed in 500 ppm males. Lower hemoglobin, hematocrit, mean corpuscular volume, and mean corpuscular hemoglobin values were observed in the 500 ppm group males and females. These changes were of minimal degree and thus not considered to be of adverse nature.

The LOEL was determined as 500 ppm, which is equivalent to mean daily doses of about 121 mg/kg bw/day in male and 139 mg/kg bw/day in female mice.

Supplemental information: BASF performed another 28-day subchronic toxicity study in C57BL/6 J Rj at a similar dose range as the study above. However, as the entire pyraclostrobin toxicological data base in mice was developed in B6C3F1 mice, and the laboratories, which finally conducted the immune tox studies described below, use B6C3F1 mice, it was decided not to further pursue testing in C58BL/6 J Rj mice. The findings observed in this 28-day study in C57BL/6 J Rj mice were similar to those observed in the 90-day study in B6C3F1 mice [BASF DocID 1998/11345] and in the above described 28-day study in B6C3F1 mice [BASF DocID 2011/1194286]. Following, this study is not submitted within this dossier.

Report:	CA 5.8.2/3 [redacted] 2012f A 28-day oral (dietary) natural killer cell immunotoxicity study of BAS 500 F in female B6C3F1 mice 2011/1035857
Guidelines:	EPA 870.7800
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

The ability of pyraclostrobin (BAS 500 F; batch: COD-001236; purity: 99.02%) to affect the natural killer cell mediated immune response was investigated in female B6C3F1 mice at dietary dose levels of 0, 50, 200 and 750 ppm (corresponding to mean intake levels of 13, 50 and 165 mg/kg body weight/day, respectively) in a 28 day study.

Treatment with pyraclostrobin resulted in systemic toxicity as assessed by clinical signs, food consumption and body weight development at the high dose (750 ppm). Furthermore, a statistically significant reduction of absolute and relative spleen and thymus weights by 40 to 50% was observed. No effect on natural killer cell activity was observed at any dose level. Concurrent treatment with positive control substance, anti asialo GM1 induced clear signs of immunotoxicity, demonstrating the reliability of the test system under the study conditions employed.

Therefore, the no observed adverse effect level (NOAEL) for systemic toxicity was 200 ppm, whereas the NOAEL for cellular mediated immunity as assessed by the functional NKC assay was 750 ppm.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Pyraclostrobin

Description:	Semi-solid / orange
Lot/Batch #:	COD-001236
Purity:	99.02%
Stability of test compound:	Stable: Expiry date Oct. 1, 2015

2. Vehicle control/Carrier: Rodent diet

3. Positive control: Anti Asialo GM1

Description:	Not available due to container type
Lot/Batch #:	AGH5324
Purity:	100.5% (according to supplier)
Stability of test compound:	According to the supplier the positive control substance was stable over the study period (Expiry date July 30, 2011).
Vehicle for Anti Asialo GM1:	Sterile water for injection and 0.9% sodium chloride for injection, pharmaceutical grade (USP)

4. Test animals:

Species:	Mouse
Strain:	B6C3F1
Sex:	Female
Age:	Approx. 38 days at receipt; approx. 51 days at start of administration
Weight at dosing:	17.0 - 20.2 g
Source:	Charles River Laboratories, Inc., Raleigh, NC, USA
Acclimation period:	13 days
Diet:	PMI Nutrition International, LLC, Certified Rodent LabDiet® 5002 (meal), ad libitum
Water:	Reverse osmosis-treated (on-site) drinking water, ad libitum
Housing:	Single housing in clean, stainless steel, wire-mesh cages suspended above cageboard
Environmental conditions:	
Temperature:	71 ± 5°F (22 ± 3°C)
Humidity:	50 ± 20%
Air changes:	10/hour
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN

1. Dates of experimental work: 07-Jun-2011 to 19-Jul-2011
(In life dates: 20-Jun-2011 (start of administration) to 18-Jul-2011 (necropsy))

The in-life part of the study was performed at WIL Research, Ashland, OH, USA. The spleens sampled at necropsy were shipped packed in ice to ImmunoTox® Inc, Richmond, VA, USA for the conduct of the NK-cell Assay.

2. Animal assignment and treatment:

Pyraclostrobin was administered to groups of 10 female mice at dietary concentrations of 0, 200 and 750 ppm ad libitum for 28 consecutive days, including the day of the scheduled euthanasia (The first day of diet administration was study day 0.).

Additionally, 10 female mice were administered anti asialo GM1 (positive control substance) via single intravenous injection (0.2 mL/animal) on study day 27, the day prior to scheduled necropsy.

The animals were assigned to the treatment groups by means of computer generated randomization list based on body weights.

Following 28 consecutive days of dose administration, all animals were euthanized.

3. Test substance preparation and analysis:

For the vehicle and positive control groups (groups 1 and 5), the same volume of acetone/kg of diet used for preparation of the test diets was added to a predetermined amount of basal diet and mixed for 5 minutes using a Hobart mixer.

For the test diets (groups 2-4), a sufficient amount of test substance was placed in a metal container and covered, frozen (approximately -20ºC), and then pulverized into a powder and placed in jars. An appropriate amount of acetone was then added to the pulverized test substance and the mixture was sonicated until the test substance was dissolved. The dissolved test substance was then added to a predetermined amount of basal diet and mixed for approximately 10 minutes using a Hobart mixer. The remaining basal diet was added to the pre-mixture to bring the batch size to the final weight and was mixed in a V-blender for approximately 15 minutes using an intensifier bar during the first and last 5 minutes. Diet preparations were performed approx. weekly and stored at room temperature.

The control and test diets were placed in storage containers which remained open for approximately 18-24 hours with the exhaust system on to allow venting off of the acetone in the diet.

Analyses performed using a comparable batch prior to the start of the administration period revealed that the test-substance was stable in the diet over a period of 10 days at ambient temperature (see Appendix C of the study report).

Homogeneity and concentration analyses of the diet preparations were performed twice by sampling diet from the top, middle and bottom of the diet containers prepared for use during study weeks 0 and 3 (i.e. the first and last week of treatment).

Nominal Dose level [ppm]	Sampling	Concentration [ppm] Mean ± SD[#]	Relative standard deviation [%]	Mean % of nominal concentration
50	Jun. 15, 2011	46.6 ± 1.4	3.1	93.1
200	"	187.5 ± 3.5	1.8	93.7
750	"	758.2 ± 18.1	2.4	101.1
50	Jul. 06, 2011	47.6 ± 1.4	2.9	95.2
200	"	191.1 ± 2.1	1.1	95.5
750	"	746.2 ± 4.5	0.6	101.9

Values may not calculate exactly due to rounding of figures

Relative standard deviations of the homogeneity of the pyraclostrobin samples were in the range of 0.6 to 3.1% indicating the homogenous distribution of pyraclostrobin in the diet preparations. The actual (mean) average test-substance concentrations were in the range of 93.1 to 101.9% of the nominal concentrations.

One vial of the positive control substance, anti asialo GM1, administered to group 5 was reconstituted in 1 mL of sterile water for injection and diluted 1:10 with 0.9% sodium chloride for injection. The solution was prepared once and stored refrigerated at approximately 2ºC to 8ºC until use.

4. Statistics:

Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to following tables:

Statistics of clinical examinations

Parameter	Statistical test
food consumption, body weight, body weight change (Analyses performed by WIL Research)	For test substance and the vehicle control groups: Body weight, body weight change, and food consumption were subjected to a parametric one-way ANOVA (Snedecor and Cochran, 1980) to determine intergroup differences. If the ANOVA revealed statistically significant ($p<0.05$) intergroup variance, Dunnett's test (Dunnett, 1964) was used to compare the test substance-treated groups to the control group. For the positive control groups: The positive control data were evaluated using the Student's t-Test (Sokal and Rohlf, 1981) and were compared to the vehicle control group

Statistics of clinical pathology

Parameter	Statistical test
NKC assay parameters Weight parameters (terminal body weight, spleen and thymus organ weight) (Analyses performed at ImmunoTox® Inc)	Data were first tested for homogeneity of variances using the Bartlett's Chi Square test (Bartlett, 1937). Homogeneous data were evaluated using a parametric one-way ANOVA (Kruskal and Wallis, 1952). When significant differences occurred, the treatment groups were compared to the vehicle control group using Dunnett's test (Dunnett, 1955; Dunnett, 1964). Non-homogenous data was evaluated using a nonparametric ANOVA (Wilson, 1956). When significant differences occurred, the treatment groups were compared to the vehicle control group using the Gehan-Wilcoxon test, when appropriate (Gross and Clark, 1975). The Jonckheere's test (Hollander and Wolfe, 1973) was used to test for dose-related trends across the vehicle control and treatment groups. The positive control data was evaluated using the Student's t-Test (Sokal and Rohlf, 1981) and compared to the vehicle control group

C. METHODS

1. Observations:

The animals were examined for morbidity or mortality twice daily. Observation for overt clinical signs of toxicity was performed at least once daily.

Detailed clinical observations were performed in all animals approximately weekly, beginning at least 1 week prior to randomization and on the day of the scheduled necropsy.

2. Body weight:

The body weight of the animals was determined before the start of the administration period (approx. 1 week before in order to randomize the animals), at the start of the treatment (day 0), and once weekly thereafter, ending just prior to the scheduled necropsy.

3. Food consumption and compound intake:

Individual food consumption was recorded approximately weekly, beginning approximately 1 week prior to randomization and ending on the day of the scheduled necropsy. Food intake was calculated as g/animal/day for the corresponding body weight intervals.

The mean daily intake of test substance (mg/kg/day, group means) was calculated based upon individual values for body weight and food consumption (g/kg/day) and the appropriate target concentration of test substance in the food (ppm).

4. Water consumption:

Not performed in the study.

5. Sacrifice and pathology:

The animals were sacrificed by decapitation under carbon dioxide anesthesia. The exsanguinated animals were necropsied. The following tissues and organs were collected and –except for spleen - placed in 10% neutral-buffered formalin for potential further histopathology):

- Spleen
- Thymus
- Lymph nodes (mandibular, mesenteric)
- Peyer's Patches

Individual spleens were placed into individual tubes containing EBSS with 15 mM HEPES and supplemented with gentamicin as a bacteriostat. After weighing the spleen samples were placed on crushed ice and shipped to ImmunoTox®, Inc. for NKC analysis.

6. Natural Killer Cell (NKC) assay:

The ability of NK cells (effector cell) to detect and destroy tumor cells was performed ex-vivo. Briefly, splenocytes of all animals from the study were isolated and adjusted to six concentrations ($2x10^7$ cells/mL, $1x10^7$ cells/mL, $5x10^6$ cells/mL, $2.5x10^6$ cells/mL, $1.25x10^6$ cells/mL, $0.625x10^6$ cells/mL) to obtain effector-to-target ratios of 200:1, 100:1, 50:1, 25:1, 12.5:1 and 6.25:1, respectively. YAC-1 tumor cells (target cell) were adjusted to a concentration of $1.5x10^7$ cells/30 mL, labeled by incubation with 500 µCi of ^{51}Cr and then adjusted to $5x10^4$ cells/mL nucleated cells/mL. To determine the maximum release of ^{51}Cr 0.1 mL were incubated with 0.1 ml Triton X-100. For determination of NK cell activity 0.1 ml of the $5x10^4$ YAC-1 cells/mL were incubated for 4 hours with the spleen cells (0.1 mL; effector cells) in 96-well microtiter plates at each effector concentration. Quadruplicate wells were used per effector concentration. Following incubation, the plates were centrifuged and 0.1 mL of the supernatant was removed from each well and counted. The percent cytotoxicity at each effector concentration was determined for each treatment group and compared to the respective values for the vehicle control.

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

1. Clinical signs of toxicity

Treatment-related clinical signs were observed at the high dose (750 ppm) and consisted of decreased defecation and feces smaller than normal. These observations were related to the reduced food consumption. Yellow material on various body surfaces were found in all groups including positive and negative control starting on study day 3 and continuing sporadically until the end of the study. The incidence was slightly increased incidence at 750 ppm. At 50 and 200 ppm no dose-response was noted. Furthermore, the incidence of this finding at 50 and 200 ppm was well comparable to the incidence observed in control animals of the parallel conducted study investigating the humoral immune response [see below 2012/1020986].

A single 750 ppm group animal (#6403) had clinical observations of hypoactivity and dermal atonia on study day 2; however, the relationship of these findings to the test substance was uncertain given the isolated occurrence.

2. Mortality

No mortality was observed in this study.

B. BODY WEIGHT AND BODY WEIGHT GAIN

Treatment-related effects on body weight development were restricted to the high dose. During the first week of treatment a body weight loss was observed. During the following 3 weeks, high dose animals gained weight again, however at a lower rate than in control and treated groups at ≤ 200 ppm [see Table 5.8.2-12, Figure 5.8.2-4].

Statistically significant effects on body weight change in the positive control group were considered to be of incidental nature due to biologically variability.

Figure 5.8.2-4: NK cell assay: Body weight development of female mice administered pyraclostrobin for 28 days

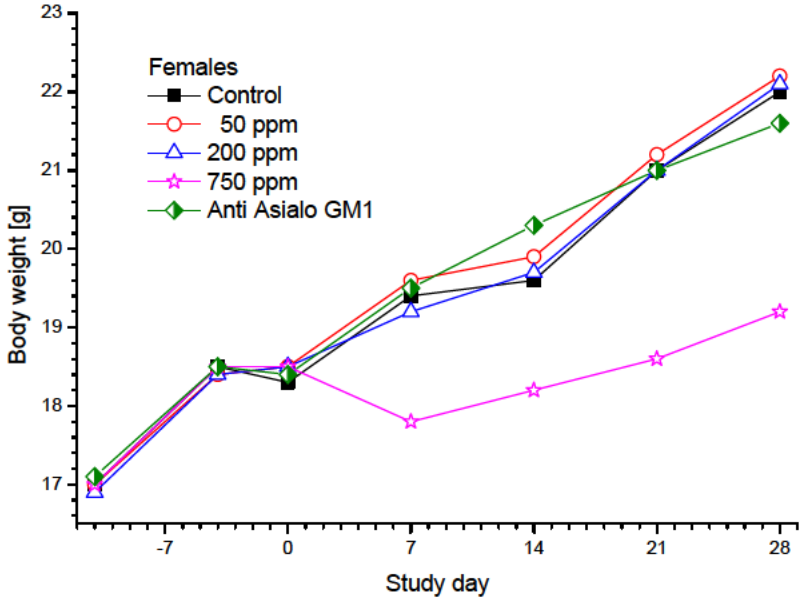

Table 5.8.2-12: Mean body weight of mice administered BAS 500 F or Anti Asialo GM1 for 28 days

Treatment	BAS 500 F				Anti Asialo GM1
Dose level	0 ppm	50 ppm	200 ppm	750 ppm	
Body weight [g]					
- Day -11	17.0	17.0	16.9	17.0	17.1

Δ% (compared to control) #		-2.6	-5.3	-78.4	-15.8

Values may not calculate exactly due to rounding of figures
* $p \leq 0.05$, ** $p \leq 0.01$ (Dunnett's test)

C. FOOD CONSUMPTION AND COMPOUND INTAKE

Test substance-related lower food consumption was observed in the 750 ppm group animals throughout the study except for study day 21 to 28 compared to the vehicle control [see also Table 5.8.2-13]. There were no test substance-related effects on food consumption in the 50 and 200 ppm groups.

The approximate mean daily test substance intake in the groups with a diet containing 50, 200 and 750 ppm test substance corresponded to 13, 50 and 165 mg/kg bw/day, respectively.

Table 5.8.2-13: Mean cumulative food consumption of mice administered BAS 500 F or Anti Asialo GM1 for 28 days

Treatment	BAS 500 F				Anti Asialo GM1
Dose level	0 ppm	50 ppm	200 ppm	750 ppm	
Daily mean food consumption [g/animal]					
- Day 0 to 7	4.8	4.8	4.9	**3.0****	5.0

D. NECROPSY

1. Terminal body and organ weight

A treatment-related decrease of absolute and relative spleen and thumus weights was noted at the high dose level [see Table 5.8.2-14]. The lower spleen weights correlated with the lower number of spleen cells. No histopathological evaluation of the thymus was performed. However, based on the substantial effect on body weight, a stress related reduction of thymus weights can be assumed. In a subchronic toxicity a similar decrease of thymus weights was associated with thymus atrophy.

Table 5.8.2-14: Spleen and thymus weights in mice treated with pyraclostrobin for 28 days

Organ weight [mg]	Dose [ppm]	Absolute weight [mg]	Δ%	Relative weight [% of bw]	Δ%	H/NH
Terminal weight. [g]	0	22.0	-			H
	50	22.2	(0.9)			
BAS 500 F	200	22.1	(0.5)			
	750	**19.2****	(-12.7)			
Spleen	0	60.6	-	0.27	-	NH
	50	70.4	(16.2)	0.32	(18.5)	
BAS 500 F	200	57.4	(-5.3)	0.26	(-3.7)	
	750	**33.1****	(-45.4)	**0.17****	(-37.0)	
Thymus	0	49.1	-	0.22	-	H
	50	50.9	(3.7)	0.23	(4.5)	
BAS 500 F	200	46.7	(-4.9)	0.21	(-4.5)	
	750	**25.0****	(-49.1)	**0.13****	(-40.9)	

** $p \leq 0.01$ (Dunnett's Test for homogenous data (H), Wilcoxon Rank Test for non-homogenous data (NH)
Values may not calculate exactly due to rounding of figures

2. Gross pathology

The only treatment-related necropsy finding was a smaller thymus in two 750 ppm females (#6412 and #6443).

All other gross necropsy findings occurred in single cases and without relation to dose and thus were considered to be of incidental nature.

E. IMMUNOLOGICAL ANALYSES

There was no test substance-related effect on Natural Killer Cell activity at any dose level [see Table 5.8.2-15]. However, in line with the lower spleen weights a lower number of spleen cells was noted at the high dose.

The significantly higher (25%) spleen cell numbers at the low dose level were not test substance-related due to lack of an effect in the 200 ppm group.

For the positive control (anti asialo GM1) a statistically significant decrease in the NKC activity was observed at effector target ratios of ≥ 50:1.

Table 5.8.2-15: Natural Killer Cell Activity in female mice treated for 28 days with pyraclostrobin at the indicated doses or anti asialo GM1 as positive control

Treatment	Pyraclostrobin				AAGM1
Dose	0 ppm	50 ppm	200 ppm	750 ppm	1:10
Effector:Target Ratio					
200:1	6.2 ± 0.5	5.3 ± 0.4	6.0 ± 0.5	6.3 ± 1.1	**1.1± 0.6****
100:1	2.0 ± 0.2	1.9 ± 0.3	1.8 ± 0.3	1.4 ± 0.5	**0.1 ± 0.4****
50:1	1.2 ± 0.3	0.9 ± 0.3	1.2 ± 0.3	0.6 ± 0.3	**0.1 ± 0.3***
25:1	1.1 ± 0.4	0.8 ± 0.4	0.9 ± 0.3	0.6 ± 0.3	0.4 ± 0.3
12.5:1	1.1 ± 0.3	1.1 ± 0.3	0.9 ± 0.3	0.8 ± 0.3	0.5 ± 0.3
6.25:1	0.8 ± 0.3	0.8 ± 0.1	0.3 ± 0.3	0.7 ± 0.3	0.5 ± 0.2
Spleen Cells (x 10^7)	9.5 ± 0.6	11.9 ± 0.9*	9.1 ± 0.5	**5.3 ± 0.4****	10.0 ± 0.4

* $p \leq 0.05$,** $p \leq 0.01$ (Dunnett's Test for homogenous data, Wilcoxon Rank Test for non-homogenous data, the positive control was compared to the vehicle control using Student's t Test)

III. CONCLUSION

Dietary administration of pyraclostrobin to female B6C3F1 mice for 28 consecutive days resulted in impaired body weight development, lower food consumption and reduced absolute and relative spleen and thymus weights at the high dose of 750 ppm. No adverse effects were noted at 50 and 200 ppm. There was no effect on the NKC assay at any dose level.

Therefore, the no observed adverse effect level (NOAEL) for systemic toxicity was 200 ppm (approx. 50 mg/kg body weight/day), and the no-observed-effect level (NOEL) for the functional NKC assay for cellular mediated immunity was 750 ppm (approx. 165 mg/kg body weight/day).

Report: CA 5.8.2/4
[redacted] 2012e
A 28-day oral (dietary) antibody forming cell immunotoxicity study of BAS 500 F in female B6C3F1 mice
2012/1020986
Guidelines: EPA 870.7800
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The immunotoxic potential of pyraclostrobin (BAS 500 F; batch: COD-001236; purity: 99.02%) in female B6C3F1 mice was analyzed using dietary dose levels of 0, 50, 200 and 750 ppm (corresponding to mean intake levels of 13, 50 and 202 mg/kg body weight/day, respectively) for 28 days.

Dietary administration of pyraclostrobin to female B6C3F1 mice for 28 consecutive days resulted in decreased body weight gain and 30 to 40% reduced absolute and relative spleen and thymus weights at the highest dose of 750 ppm. No adverse effects were noted at 50 and 200 ppm.

Test substance-related lower spleen cell numbers were noted in the 750 ppm group (-45%). An apparent suppression of the humoral component of the immune system was noted in all test substance-treated groups when evaluated using the concurrent control of this AFC assay. However, the functional response of the vehicle control was substantially above the historical control mean and the pyraclostrobin-exposed groups were within or close to the historical control range of the same sex and strain of mice.

Treatment with the positive control substance cyclophosphamide (CPS), administered once daily at 50 mg/kg/day on study day 24-27 by intraperitoneal injection resulted in decreased thymus and spleen weights, reduced number of spleen cells and a complete suppression of the humoral immune response.

Based on the increased humoral immune response in control animals, the results of this study are not conclusively interpretable. Thus, the test needed to be repeated [see BASF DocID 2012/1084176].

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Pyraclostrobin
Description: Semi-solid / orange
Lot/Batch #: COD-001236
Purity: 99.02%
Stability of test compound: Stable: Expiry date Oct. 1, 2015

2. Vehicle control: Rodent diet

3. Positive control: Cyclophosphamide monohydrate (CPS)
Description: Solid / white
Lot/Batch #: 079K1569
Purity: 100.5% (according to supplier)
Stability of test compound: Stable: Expiry date July 01, 2012
Vehicle for CPS: Phosphate buffered saline (PBS); sterile water for injection

4. Antigen used for immunization: Sheep red blood cells (sRBC) -Prepared by ImmunoTox® and shipped to WIL Research

5. Test animals:
Species: Mouse
Strain: B6C3F1
Sex: Female
Age: Approx. 37 days at receipt; approx. 51 days at start of administration
Weight at dosing: 16.8 - 20.5 g
Source: Charles River Laboratories, Inc., Raleigh, NC, USA
Acclimation period: 14 days
Diet: PMI Nutrition International, LLC, Certified Rodent LabDiet® 5002 (meal), ad libitum
Water: Reverse osmosis-treated (on-site) drinking water, ad libitum
Housing: Single housing in clean, stainless steel, wire-mesh cages suspended above cageboard.
Environmental conditions:
Temperature: 71 ± 5°F (22 ± 3°C)
Humidity: 50 ± 20%
Air changes: 10/hour
Photo period: 12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN

1. Dates of experimental work: 07-Jun-2011 to 05-Aug-2011
In life dates: 21-Jun-2011 (start of administration) to 19-Jul-2011 (necropsy)

The in-life part of the study was performed at WIL Research, Ashland, OH, USA. The spleens sampled at necropsy were shipped packed in ice to ImmunoTox® Inc, Richmond, VA, USA for the conduct of the SBRC or t-cell dependent antibody response (TDAR) assay.

2. Animal assignment and treatment:

Pyraclostrobin was administered to groups of 10 female mice at dietary concentrations of 0, 200 and 750 ppm for 28 days (The first day of diet administration was study day 0.). Additionally, 10 female mice were administered Cyclophosphamide monohydrate (CPS; positive control substance) via intraperitoneal injection once daily during study days 24-27 at a dose level of 50 mg/kg/day and a dose volume of 10 mL/kg/day.

The animals were assigned to the treatment groups by means of computer generated randomization list based on body weights.

On study day 24 all animals were immunized via an intravenous tail vein injection with 0.2 mL of 7.5 x 10^7 sRBC in EBSS with HEPES (except for a single animal in the 750 ppm group which was immunized via intraperitoneal injection with 0.4 mL of 7.5 x 10^7 sRBC in EBSS with HEPES).

3. Test substance preparation and analysis:

For the test diets (groups 2-4), a sufficient amount of test substance was placed in a metal container and covered, frozen (approximately -20ºC), and then pulverized into a powder and placed in jars. An appropriate amount of acetone was then added to the pulverized test substance and the mixture was sonicated until the test substance was dissolved. The dissolved test substance was then added to a predetermined amount of basal diet and mixed for approximately 10 minutes using a Hobart mixer. The remaining basal diet was added to the pre-mixture to bring the batch size to the final weight and was mixed in a V-blender for approximately 15 minutes using an intensifier bar during the first and last 5 minutes. Diet preparations were performed approx. weekly and stored at room temperature.

For the vehicle and positive control groups (Groups 1 and 5), the same volume of acetone/kg of diet used for preparation of the test diets was added to a predetermined amount of basal diet and mixed for 5 min using a Hobart mixer.

The control and test diets were placed in storage containers which remained open for approximately 18-24 hours with the exhaust system on to allow venting off of the acetone in the diet.

Homogeneity and concentration analyses of the diet preparations were performed twice by sampling diet from the top, middle and bottom of the diet containers prepared for use during study weeks 0 and 3 (i.e. the first and last week of treatment).

Nominal Dose level [ppm]	Sampling	Concentration [ppm] Mean ± SD[#]	Relative standard deviation [%]	Mean % of nominal concentration
50	Jun. 15, 2011	46.6 ± 1.4	3.1	93.1
200	"	187.5 ± 3.5	1.8	93.7
750	"	758.2 ±18.1	2.4	101.1
50	Jul. 06, 2011	47.6 ± 1.4	2.9	95.2
200	"	191.1 ± 2.1	1.1	95.5
750	"	746.2 ± 4.5	0.6	101.9

Values may not calculate exactly due to rounding of figures

Relative standard deviations of the homogeneity of the pyraclostrobin samples were in the range of 0.6 to 3.1% indicating the homogenous distribution of pyraclostrobin in the diet preparations. The actual (mean) average test-substance concentrations were in the range of 93.1 to 101.9% of the nominal concentrations.

The positive control Substance, CPS, was prepared in a PBS solution at a concentration of 5 mg/mL. The solution was prepared once and was stored at approximately -20°C. On each day of dosing (study days 24-27), an aliquot was quickly thawed, kept on ice, and mixed prior to dosing. The formulation was used within approximately 3 hours of thawing.

4. Statistics:

Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to following tables:

Statistics of clinical examinations

Parameter	Statistical test
food consumption, body weight, body weight change (Analyses performed by WIL Research)	For test substance and the vehicle control groups: A comparison of each group with the vehicle control group was performed using DUNNETT's test for the hypothesis of equal means For the vehicle and positive control groups: A comparison of the positive control group with the vehicle control group was performed using the Student's t-test for the hypothesis of equal means

Statistics of clinical pathology

Parameter	Statistical test
AFC assay parameters (Analyses performed at ImmunoTox® Inc)	Data were first tested for homogeneity of variances using the Bartlett's Chi Square test (Bartlett, 1937). Homogeneous data were evaluated using a parametric one-way ANOVA (Kruskal and Wallis, 1952). When significant differences occurred, the treatment groups were compared to the vehicle control group using Dunnett's test (Dunnett, 1955; Dunnett, 1964). Non-homogenous data was evaluated using a nonparametric ANOVA (Wilson, 1956). When significant differences occurred, the treatment groups were compared to the vehicle control group using the Gehan-Wilcoxon test, when appropriate (Gross and Clark, 1975). The Jonckheere's test (Hollander and Wolfe, 1973) was used to test for dose-related trends across the vehicle control and treatment groups. The positive control data was evaluated using the Student's t-Test (Sokal and Rohlf, 1981) and compared to the vehicle control group.

C. METHODS

1. Observations:

The animals were examined for morbidity or mortality twice daily. Observation for overt clinical signs of toxicity was performed at least once daily and included, but were not limited to, changes in the skin, fur, eyes and mucous membranes; respiratory, circulatory, autonomic and central nervous systems function; somatomotor activity and behavior patterns.

Detailed clinical observations were performed in all animals prior to the start of the administration period and weekly thereafter. The findings were ranked according to the degree of severity, if applicable.

2. Body weight:

The body weight of the animals was determined before the start of the administration period (approx. 1 week before in order to randomize the animals), at the start of the treatment (day 0), and once weekly thereafter, ending just prior to the scheduled necropsy.

3. Food consumption and compound intake:

Food consumption was determined once weekly on a cage basis and calculated as mean food consumption in grams per animal and day.

The mean daily intake of test substance (mg/kg/day, group means) was calculated based upon individual values for body weight and food consumption (g/kg/day) and the appropriate target concentration of test substance in the food (mg/kg).

4. Water consumption:

Not performed in the study.

5. Hematology (IgM antibody analysis):

At the scheduled necropsy blood was drawn from carbon dioxide anesthetized animals via the inferior vena cava. Blood was collected into tubes containing no anticoagulant, allowed to clot, and processed to serum. Serum samples were transferred to cryovials and stored frozen at approximately -70°C. Serum samples were not analyzed and were discarded upon issuance of the final report.

6. Sacrifice and pathology:

The animals were sacrificed by decapitation under carbon dioxide anesthesia. The exsanguinated animals were necropsied. The following tissues and organs were collected and –except for spleen - placed in 10% neutral-buffered formalin for potential further histopathology):

- Spleen (placed in EBSS/HEPES buffer)
- Thymus
- Lymph nodes (mandibular, mesenteric)
- Peyer's Patches

Individual spleens were placed into individual tubes containing EBSS with 15 mM HEPES and supplemented with gentamicin as a bacteriostat. After weighing the spleen samples were placed on crushed ice and shipped to ImmunoTox®, Inc. for the conduct of the Splenic antibody-forming cell (AFC) assay assay.

7. Splenic antibody-forming cell (AFC) assay:

The spleen samples were processed into single-cell suspensions. The cell suspensions were centrifuged and resuspended in EBSS with HEPES. Spleen cell counts were performed using a Model Z1 Coulter Counter®. Viability of splenocytes was determined using propidium iodide and the Coulter® EPICS® XL-MCL Flow Cytometer.

The primary IgM response to sheep erythrocytes was measured using a modification of the hemolytic plaque assay. After isolation and resuspension of the spleen cells, 1:30 and 1:120 dilutions were prepared. A 0.1 mL aliquot of spleen cells from each suspension was added to separate test tubes, each containing 25 µL of guinea pig complement, 25 µL of sRBC, and 0.5 mL of warm agar (0.5%). After thoroughly mixing, each test tube mixture was plated onto a separate petri dish, covered with a microscope cover slip, and incubated at approximately 36-38°C for 3 hours. The plaques that developed were counted using a Bellco plaque viewer. A plaque, occurring from the lysis of sRBC, is elicited as a result of the interaction of complement and antibodies (produced in response to the IV immunization of the animals) directed against sRBC. Each plaque is generated from a single IgM antibody-producing B cell (plasma cell), permitting the number of AFC present in the whole spleen to be calculated. The data are expressed as Specific Activity (AFC/10^6 Spleen Cells) and Total Spleen Activity (AFC/Spleen).

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

1. Clinical signs of toxicity

Treatment-related clinical signs were restricted to the high dose level (750 ppm) and consisted of decreased defecation, feces smaller than normal and yellow material around the urogenital area.

Additionally, on study day 1, due to poor body condition and/or body weight loss, all high dose mice were given a water bottle.

2. Mortality

No mortality was observed in this study.

B. BODY WEIGHT AND BODY WEIGHT GAIN

Statistically significant and treatment-related effects on body weight development were only observed at the high dose level. During the first week of treatment a body weight loss was observed. During the following 3 weeks, high dose animals gained weight again [see Table 5.8.2-16, Figure 5.8.2-5].

No impaired body weight development was observed in CPA treated mice.

Figure 5.8.2-5: Body weight development of female mice administered pyraclostrobin or cyclophosphamide (CPS) for 28 days

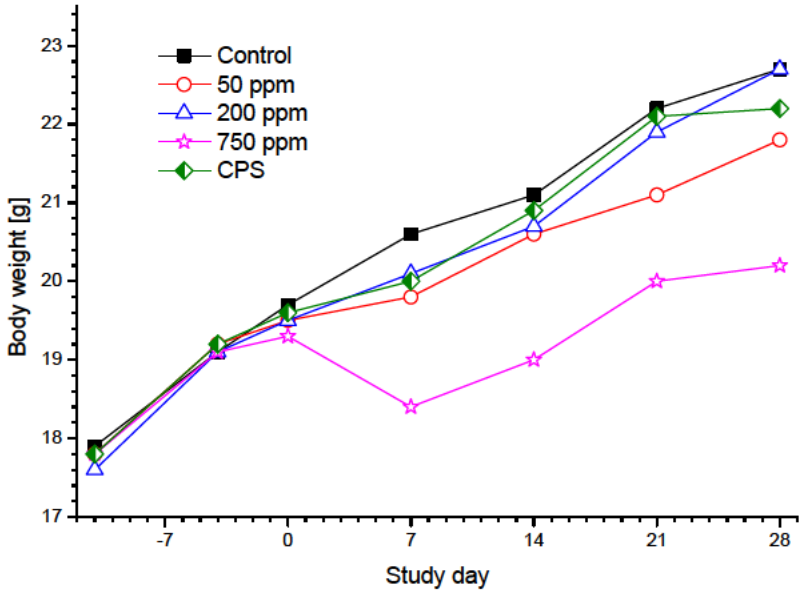

Table 5.8.2-16: Mean body weight of mice administered pyraclostrobin or cyclophosphamide (CPS) for 28 days

Treatment	BAS 500 F				CPS
Dose level	0 ppm	50 ppm	200 ppm	750 ppm	50 mg/kg
Body weight [g]					
- Day -11	17.9	17.8	17.6	17.8	17.8
- Day -4	19.1	19.2	19.1	19.1	19.2
- Day 0	19.7	19.5	19.5	19.3	19.6
- Day 7	20.6	19.8	20.1	**18.4***	20.0
- Day 14	21.1	20.6	20.7	**19.0***	20.9
- Day 21	22.2	21.1	21.9	**20.0***	22.1
- Day 28	22.7	21.8	22.7	**20.2***	22.2
Δ% (compared to control) #		-4.0	0.0	**-11.0***	-2.2
Overall body weight gain [g]	3.0	2.3	3.3	**0.9***	2.6
Δ% (compared to control) #		-23.3	10	-70	13.3

Values may not calculate exactly due to rounding of figures
* $p \leq 0.01$ (Dunnett's test)

Occasionally, statistically significant differences of body weight gain were observed in low dose females. However, these changes were not dose dependent and therefore nor considered to be treatment-related.

C. FOOD CONSUMPTION AND COMPOUND INTAKE

Statistically significant lower food consumption was observed at 200 and 750 ppm for the intervall day 0 to 7. Whereas the decrease at 750 ppm was accompanied by substantial effects on body weight, no such effect was observed at 200 ppm [see Table 5.8.2-17]. Therefore, the effect in mid dose females was not considered to be of adverse nature. Food consumption of CPA treated animals was not significantly altered.

The approximate mean daily test substance intake in the groups with a diet containing 50, 200 and 750 ppm test substance corresponded to 13, 50 and 202 mg/kg body weight/day, respectively.

Table 5.8.2-17: Mean food consumption of mice administered BAS 500 F or cyclophosphamide (CPS) for 28 days

Treatment	BAS 500 F				CPS
Dose level	0 ppm	50 ppm	200 ppm	750 ppm	50 mg/kg
Cumulative food consumption [g/animal]					
- Day 0 to 7	5.6	5.0	4.7*	**4.2****	5.2
- Day 7 to 14	5.4	5.0	4.9	4.9	5.1
- Day 14 to 21	6.7	6.7	5.6	6.9	5.9
- Day 21 to 28	6.1	5.4	5.7	5.0	6.1

* $p \leq 0.05$ (Dunnett's test)
** $p \leq 0.01$ (Dunnett's test)

D. Necropsy

1. Gross pathology

There were no macroscopic findings noted at the scheduled necropsy.

2. Terminal body and organ weight

Treatment-related and statistically significant decreases of absolute and relative terminal body, thymus and spleen weights were observed in the high dose animals [see Table 5.8.2-18]. There were no test substance-related effects on spleen and thymus weights in the 50 and 200 ppm groups. The lower spleen weights correlated with the lower number of spleen cells. No histopathological evaluation of the thymus was performed. However, based on the substantial effect on body weight, a stress related reduction of thymus weights can be assumed. In a subchronic toxicity a similar decrease of thymus weights was associated with thymus atrophy.

Table 5.8.2-18: Selected mean absolute and relative organ weights in mice treated with BAS 500 F or cyclophosphamide for 28 days

Organ weight [mg]	Dose [ppm]	Absolute weight [mg]	Δ%	Relative weight [% of bw]	Δ%
Terminal weight. [g]	0	22.7			
BAS 500 F	50	21.8	(-4.0)		
	200	22.7	(0.0)		
	750	20.2*	(-11.0)		
CPS (pos. control)	50 mg/kg	22.2	(-2.2)		
Spleen	0	92.4		0.41	
BAS 500 F	50	85.2	(-7.8)	0.39	(-4.9)
	200	82.6	(-10.6)	0.37	(-9.8)
	750	**55.4***	**(-40.0*)**	**0.27***	**(-34.1*)**
CPS (pos. control)	50 mg/kg	**46.3***	**(-49.9*)**	**0.21***	**(-48.8*)**
Thymus	0	41.3		0.18	
BAS 500 F	50	42.1	(1.9)	0.19	(5.6)
	200	39.9	(-3.4)	0.18	(0.0)
	750	**25.5***	**(-38.3*)**	**0.12***	**(-33.3*)**
CPS (pos. control)	50 mg/kg	**13.1***	**(-68.3*)**	**0.06***	**(-66.7*)**

* $p \leq 0.01$ (Dunnett's test)
Values may not calculate exactly due to rounding of figures

No decrease of terminal body weight was observed in the animals treated with the positive control substance CPA [see Table 5.8.2-18]. However, absolute and relative spleen and thymus weights were significantly decreased within this group.

E. IMMUNOLOGICAL ANALYSES

Test substance-related significantly lower spleen cell numbers (-45%) were noted in the 750 ppm dose group compared to the vehicle control. As expected, a statistically significant decrease in the spleen cell number (-64%) was observed in the positive control group (CPS) [see Table 5.8.2-19].

An apparent, statistically significant suppression of the humoral immune response was observed in all treated groups when evaluated as Specific Activity (AFC/10^6 Spleen Cells) or total Spleen Cell Activity (AFC/Spleen) [see Table 5.8.2-19].

However, the overall functional responses of the vehicle control and the pyraclostrobin-exposed groups were enhanced compared to historical control data from vehicle animals of the same sex and strain. In the vehicle animals from the pyraclostobin study, the Specific Activity was more than twice the mean of 1206 AFC/10^6 Spleen Cells observed in the historical control data. Similarly, the mean responses of all of the pyraclostobin-exposed animals ranged from 1210-1559 AFC/10^6 Spleen Cells, while historical control values averaged 1206 AFC/10^6 Spleen Cells (historical control minimum/maximum of study means: 1116/1499 AFC/10^6 Spleen Cells), i.e. the responsed of the pyraclostrobin treated animals were well within the historical control range. The reason for the increased AFC activity in controls could not be determined. Thus, the results of this assay can not be conclusively interpreted.

The positive control group displayed statistically significant decreases in specific activity (-100%) and total spleen activity (-100%), when compared to the vehicle control group.

Table 5.8.2-19: Spleen Antibody-Forming Cell responses to the T-dependent antigen, Sheep Erythrocytes, in female mice treated for 28 days with pyraclostrobin or cyclophosphamid

	pyraclostrobin				CPS
Dose	0 ppm	50 ppm	200 ppm	750 ppm	50 mg/kg bw
Spleen Cells (x 10^7)	14.03 ± 0.86	12.32 ± 0.54	12.12 ± 0.60	**7.71 ± 0.35****	**5.07 ± 0.16****
IgM AFC/10^6 Spleen Cells	2939 ± 343	**1559 ± 219****	**1523 ± 94***	**1210 ± 126***	**0 ± 0****
IgM AFC/Spleen (x 10^3)	419 ± 47	**189 ± 24****	**184 ± 14****	**93 ± 9****	**0 ± 0****

* $p \leq 0.05$, ** $p \leq 0.01$ (Dunnett's Test for homogenous data, the positive control was compared to the vehicle control using Student's t Test)

III. CONCLUSION

Dietary administration of pyraclostrobin to female B6C3F1 mice for 28 consecutive days resulted in decreased body weight gain and reduced absolute and relative spleen and thymus weights at the highest dose of 750 ppm. No adverse effects were noted at 50 and 200 ppm.
Test substance-related lower spleen cell numbers were noted in the 750 ppm group (-45%). An apparent suppression of the humoral component of the immune system was noted in all test substance-treated groups when evaluated using the concurrent control of this AFC assay. However, the functional response of the vehicle control was substantially above the historical control mean and the pyraclostrobin-exposed groups were within or close to the historical control range of the same sex and strain of mice. Therefore, the results of the humoral immune response of this study are not conclusively interpretable. Thus, the test needed to be repeated [see BASF DocID 2012/1084176].

Report:	CA 5.8.2/5 [redacted] 2012d A 28-day oral (dietary) antibody forming cell immunotoxicity study of BAS 500 F in female B6C3F1 mice 2012/1084176
Guidelines:	EPA 870.7800
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

The immunotoxic potential of pyraclostrobin (batch: COD-001236; purity: 99.02%) in female B6C3F1 mice was analyzed using dietary dose levels of 0, 50, 200 and 750 ppm (corresponding to mean intake levels of 14, 55 and 191 mg/kg body weight/day, respectively) for 28 days. This is the second assay to assess the IgM mediated immune response, as the first assay [see BASF DocID 2012/1035857] was not interpretable as to immunotoxicity due to a higher activity of the vehicle control, which exceeded the historical control control range by a factor of two.

Treatment-related signs of systemic toxicity were restricted to the high dose level (750 ppm) as assessed by clinical signs, reduced food consumption and impaired body weight development. Furthermore, a statistically significant reduction of absolute and relative spleen and thymus weights and spleen cell numbers were observed. However, the number of antibody forming cells (AFC) per spleen was not affected in high dose animals or at lower dose levels. To the contrary, the specific AFC activity (AFC/10^6 spleen cells) was statistically significant increased at the high dose level, while it was comparable to the control at the lower dose levels. In the positive control a total loss of IgM mediated immune response was noted.

While a decrease in the AFC response has been recognized as an indicator that a test substance has the potential of being immunosuppressive; at the present time, the consequences of an increase in the specific AFC response have not been established and thus the adversity of this change cannot be assessed.

Based on the results of this study, the NOEL (No Observed Effect Level) for general toxicity and overall effect on the various parameters of the immune system was 200 ppm.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Pyraclostrobin

Description:	Semi-solid / orange
Lot/Batch #:	COD-001236
Purity:	99.02%
Stability of test compound:	Stable: Expiry date Oct. 1, 2015

2. Vehicle control: Rodent diet

3. Positive control: Cyclophosphamide monohydrate (CPS)

Description:	Solid / white
Lot/Batch #:	079K1569
Purity:	100.5% (according to supplier)
Stability of test compound:	Stable Expiry date July 01, 2012).
Vehicle for CPA:	Phosphate buffered saline (PBS); sterile water for injection

4. Test animals:

Species:	Mouse
Strain:	B6C3F1
Sex:	Female
Age:	Approx. 38 days at receipt; approx. 51 days at start of administration
Weight at dosing:	18.0 - 21.4 g
Source:	Charles River Laboratories, Inc., Raleigh, NC, USA
Acclimation period:	13 days
Diet:	PMI Nutrition International, LLC, Certified Rodent LabDiet® 5002 (meal), ad libitum
Water:	Reverse osmosis-treated (on-site) drinking water, ad libitum
Housing:	Single housing in clean, stainless steel, wire-mesh cages suspended above cageboard.
Environmental conditions:	
Temperature:	71 ± 5°F (22 ± 3°C)
Humidity:	50 ± 20%
Air changes:	10/hour
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN

1. Dates of experimental work: 01-Nov-2011 - 09-Feb-2012
In life dates: 14-Nov-2011 (start of administration) to 12-Dec-2011 (necropsy)

The in-life part of the study was performed at WIL Research, Ashland, OH, USA. The spleens sampled at necropsy were shipped packed in ice to ImmunoTox® Inc, Richmond, VA, USA for the conduct of the SBRC or t-cell dependent antibody response (TDAR) assay.

2. Animal assignment and treatment:

Pyraclostrobin was administered to groups of 10 female mice at dietary concentrations of 0, 200 and 750 ppm for 28 days (the first day of diet administration was study day 0.). Additionally, 10 female mice were administered cyclophosphamide monohydrate (CPS; positive control substance) via intraperitoneal injection once daily during study days 24-27 at a dose level of 50 mg/kg/day and a dose volume of 10 mL/kg/day.

The animals were assigned to the treatment groups by means of computer generated randomization list based on body weights.

On study day 24 all animals were immunized via an intravenous tail vein injection with 0.2 mL of 7.5 x 10^7 sRBC in EBSS with HEPES (If an intravenous injection could not be administered, the volume of sRBC antigen was adjusted and an intraperitoneal injection was performed).

3. Test substance preparation and analysis:

For the test diets (groups 2-4), a sufficient amount of test substance was placed in a metal container and covered, frozen (approximately -20ºC), and then pulverized into a powder and placed in jars. An appropriate amount of acetone was then added to the pulverized test substance and the mixture was sonicated until the test substance was dissolved. The dissolved test substance was then added to a predetermined amount of basal diet and mixed for approximately 10 minutes using a Hobart mixer. The remaining basal diet was added to the pre-mixture to bring the batch size to the final weight and was mixed in a V-blender for approximately 15 minutes using an intensifier bar during the first and last 5 minutes. Diet preparations were performed approx. weekly and stored at room temperature.

For the vehicle and positive control groups (Groups 1 and 5), the same volume of acetone/kg of diet used for preparation of the test diets was added to a predetermined amount of basal diet and mixed for 5 min using a Hobart mixer.

The control and test diets were placed in storage containers which remained open for approximately 18-24 hours with the exhaust system on to allow venting off of the acetone in the diet.

The positive control substance, CPS, was prepared in a PBS solution at a concentration of 5 mg/mL. The solution was stored in aliquots at approximately -20°C. On each day of dosing (study days 24-27), an aliquot was quickly thawed, kept on ice, and mixed prior to dosing. The formulation was used within 3 hours of thawing.

The stability of the test item in the diet for 10 days was proven prior to the start of the study Homogeneity and concentration analyses of the diet preparations were performed twice by sampling diet from the top, middle and bottom of the diet containers prepared for use during study weeks 0 and 3 (i.e. the first and last week of treatment).

Nominal Dose level [ppm]	Sampling	Concentration [ppm] Mean ± SD[#]	Relative standard deviation [%]	Mean % of nominal concentration
50	Nov. 11, 2011	43.3 ± 3.8	8.8	86.5
200	"	181.6 ± 5.6	3.1	90.8
750	"	801.5 ± 0.5	0.1	106.9
50	Dec. 02, 2011	44.4 ± 3.4	7.6	88.8
200	"	181.9 ± 9.8	5.4	90.0
750	"	812.7 ± 8.8	1.1	108.4

Values may not calculate exactly due to rounding of figures

Relative standard deviations of the homogeneity of the pyraclostrobin samples were in the range of 0.1 to 8.8%, which indicate the homogenous distribution of pyraclostrobin in the diet preparations (RSD ≤ 10%). The actual (mean) average test-substance concentrations were in the range of 86.5 to 106.9% and 88.8 to 108.4% of the nominal concentrations. For the lowest concentration these values were slightly below the specification limit of 90%, but mean found concentrations within ± 15% of the target concentration can be regarded acceptable for complex matrices like diet. Furthermore, as the mid dose was identified as NOAEL in this study, the slighty lower dietary concentration does not affect the validity of the study.

The positive control Substance, CPS, was prepared in a PBS solution at a concentration of 5 mg/mL. The solution was prepared once and was stored at approximately -20°C. On each day of dosing (study days 24-27), an aliquot was quickly thawed, kept on ice, and mixed prior to dosing. The formulation was used within approximately 3 hours of thawing.

4. Statistics:

Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to following tables:

Statistics of clinical examinations

Parameter	Statistical test
food consumption, body weight, body weight change (Analyses performed by WIL Research)	For test substance and the vehicle control groups: A comparison of each group with the vehicle control group was performed using DUNNETT's test for the hypothesis of equal means For the vehicle and positive control groups: A comparison of the positive control group with the vehicle control group was performed using the Student's t-test for the hypothesis of equal means

Statistics of clinical pathology

Parameter	Statistical test
AFC assay parameters (Analyses performed at ImmunoTox® Inc)	Data were first tested for homogeneity of variances using the Bartlett's Chi Square test (Bartlett, 1937). Homogeneous data were evaluated using a parametric one-way ANOVA (Kruskal and Wallis, 1952). When significant differences occurred, the treatment groups were compared to the vehicle control group using Dunnett's test (Dunnett, 1955; Dunnett, 1964). Non-homogenous data was evaluated using a nonparametric ANOVA (Wilson, 1956). When significant differences occurred, the treatment groups were compared to the vehicle control group using the Gehan-Wilcoxon test, when appropriate (Gross and Clark, 1975). The Jonckheere's test (Hollander and Wolfe, 1973) was used to test for dose-related trends across the vehicle control and treatment groups. The positive control data was evaluated using the Student's t-Test (Sokal and Rohlf, 1981) and compared to the vehicle control group.

C. METHODS

1. Observations:

The animals were examined for morbidity or mortality twice daily. Observation for overt clinical signs of toxicity was performed at least once daily and included, but were not limited to, changes in the skin, fur, eyes and mucous membranes; respiratory, circulatory, autonomic and central nervous systems function; somatomotor activity and behavior patterns.

Detailed clinical observations were performed in all animals prior to the start of the administration period and weekly thereafter. The findings were ranked according to the degree of severity, if applicable.

2. Body weight:

The body weight of the animals was determined before the start of the administration period (approx. 1 week before in order to randomize the animals), at the start of the treatment (day 0), and once weekly thereafter, ending just prior to the scheduled necropsy.

3. Food consumption and compound intake:

Food consumption was determined once weekly on a cage basis and calculated as mean food consumption in g/animal/day.

The mean daily intake of test substance (mg/kg/day, group means) was calculated based upon individual values for body weight and food consumption (g/kg/day) and the appropriate target concentration of test substance in the food (mg/kg).

4. Water consumption:

Not performed in the study.

5. Hematology (IgM antibody analysis):

At the scheduled necropsy blood was drawn from carbon dioxide anesthetized animals via the inferior vena cava. Blood was collected into tubes containing no anticoagulant, allowed to clot, and processed to serum. Serum samples were transferred to cryovials and stored frozen at approximately -70°C. As the serum samples were not analyzed they were discarded upon issuance of the final report.

6. Sacrifice and pathology:

The animals were sacrificed by decapitation under carbon dioxide anesthesia. The exsanguinated animals were necropsied. The following tissues and organs were collected and –except for spleen - placed in 10% neutral-buffered formalin for potential further histopathology):

- Spleen (placed in EBSS/HEPES buffer)
- Thymus
- Lymph nodes (mandibular, mesenteric)
- Peyer's Patches

Individual spleens were placed into individual tubes containing EBSS with 15 mM HEPES and supplemented with gentamicin as a bacteriostat. After weighing the spleen samples were placed on crushed ice and shipped to ImmunoTox®, Inc. for the conduct of the Splenic antibody-forming cell (AFC) assay.

7. Splenic antibody-forming cell (AFC) assay:

Spleen samples from Group 1-4 animals were randomized and coded for AFC analysis. The spleen samples were processed into single-cell suspensions. The cell suspensions were centrifuged and resuspended in EBSS with HEPES. Spleen cell counts were performed using a Model Z1 Coulter Counter®. Viability of splenocytes was determined using propidium iodide and the Coulter® EPICS® XL-MCL Flow Cytometer.

The primary IgM response to sheep erythrocytes was measured using a modification of the hemolytic plaque assay. After isolation and resuspension of the spleen cells, 1:30 and 1:120 dilutions were prepared. A 0.1 mL aliquot of spleen cells from each suspension was added to separate test tubes, each containing 25 µL of guinea pig complement, 25 µL of sRBC, and 0.5 mL of warm agar (0.5%). After thoroughly mixing, each test tube mixture was plated onto a separate petri dish, covered with a microscope cover slip, and incubated at approximately 36-38°C for 3 hours. The plaques that developed were counted using a Bellco plaque viewer. A plaque, occurring from the lysis of sRBC, is elicited as a result of the interaction of complement and antibodies (produced in response to the IV immunization of the animals) directed against sRBC. Each plaque is generated from a single IgM antibody-producing B cell (plasma cell), permitting the number of AFC present in the whole spleen to be calculated. The data are expressed as Specific Activity (AFC/10^6 Spleen Cells) and Total Spleen Activity (AFC/Spleen).

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

1. Clinical signs of toxicity

No clinical signs indicative of toxicity were observed throughout the study. Secondary to the decreased food consumption the hig dose animals showed decreased defecation, which was observed most frequently beginning on study day 5 and continued throughout the remainder of the study.

2. Mortality

No test-substance related lethality was observed during this study. Two unscheduled deaths of 200 ppm animal # 2509 and 750 ppm animal #2493 were considered to be accidental. Gross necropsy of the former animal revealed no cause of death, whereas the latter animal displayed a fractured mandible.

B. BODY WEIGHT AND BODY WEIGHT GAIN

Statistically significant and treatment-related effects on body weight development were only observed at the high dose level. During the two weeks of treatment a body weight loss was observed. During the following 2 weeks, high dose animals gained weight at a rate comparable to the other groups [see Table 5.8.2-20, Figure 5.8.2-6].

Figure 5.8.2-6: Body weight development of female mice administered pyraclostrobin or cyclophosphamide (CPS) for 28 days

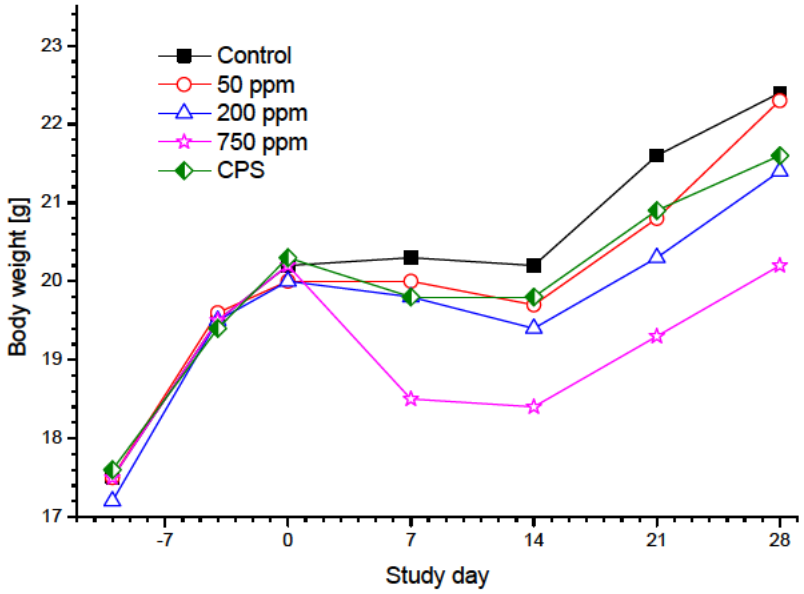

Table 5.8.2-20: Mean body weight of mice administed BAS 500 F or cyclophosphamide (CPS) for 28 days

Treatment	BAS 500 F				CPS
Dose level	0 ppm	50 ppm	200 ppm	750 ppm	50 mg/kg
Body weight [g]					
- Day -10	17.5	17.5	17.2	17.5	17.6
- Day -4	19.5	19.6	19.5	19.5	19.4
- Day 0	20.2	20.0	20.0	20.2	20.3
- Day 7	20.3	20.0	19.8	**18.5****	19.8
- Day 14	20.2	19.7	19.4	**18.4****	19.8
- Day 21	21.6	**20.8***	**20.3****	**19.3****	20.9
- Day 28	22.4	22.3	**21.4***	**20.2****	21.6
Δ% (compared to control) #		-0.4	-4.5	-9.8	-3.6
Overall body weight gain [g]	2.2	2.3	1.3	**0.2****	1.3
Δ% (compared to control) #		4.5	-40.9	-90.9	-40.9

Values may not calculate exactly due to rounding of figues
* $p \leq 0.05$; ** $p \leq 0.01$ (Dunnett's test)

Statistically significant decreases of absolute body weights and body weight gain were also occasionally observed at 50 and 200 ppm. This was however not considered to be treatment-related, but rather an expression of biological variability. This is because in the two previously conducted immunotoxicity studies [see BASF DocID 2012/1020986 and 2012/1035857] no effects on body weight development were observed at these dose levels. Furthermore, body weight gain in control and in the - at that time still untreated - positive control animals was zero respectively -0.5 grams. This is in contrast to the above mentioned studies where a body weight gain of 0.9 to 1.4 grams was observed during the first two study weeks. No impaired body weight development was observed in CPA treated mice.

C. FOOD AND COMPOUND INTAKE

Test substance-related lower food consumption was observed in the 750 ppm group throughout the study compared to the vehicle control, reaching statistical significance from study days 7 to 14 [see Table 5.8.2-21].

Table 5.8.2-21: Mean food consumption of mice administed BAS 500 F or cyclophosphamide (CPS) for 28 days

Treatment	BAS 500 F				CPS
Dose level	0 ppm	50 ppm	200 ppm	750 ppm	50 mg/kg
Mean food consumption [g/animal]					
- Day 0 to 7	4.6	4.8	4.7	3.8	4.7
- Day 7 to 14	5.4	4.9	5.2	**4.4***	5.3
- Day 14 to 21	5.7	5.8	5.5	5.1	5.4
- Day 21 to 28	7.6	7.2	6.6	6.2	**6.2****

* $p \leq 0.05$ (Dunnett's Test)
** $p \leq 0.05$ (Student's t Test)

The approximate mean daily test substance intake in the groups with a diet containing 50, 200 and 750 ppm test substance corresponded to 14, 55 and 191 mg/kg body weight/day, respectively.

D. NECROPSY

1. Gross pathology

There were no test substance-related macroscopic findings noted at the scheduled necropsy. The only finding was a small thymus in a Cyclophosphamid treated animal. In addition to the fracuted mandible, the high dose animal displayed red discolored skin (nasal buccal) and muscle(s) (neck), which were probably secondary to the fracture.

2. Terminal body and organ weight

Treatment-related and statistically significant decrease of absolute and relative terminal body, thymus and spleen weights were observed in the 750 ppm group animals [see Table 5.8.2-22]. The statistically lower terminal body weight of mid dose (200 ppm) animals was considered incidental for the reasons discussed above. There were no test substance-related effects on spleen and thymus weights in the 50 and 200 ppm groups.

The lower spleen weights correlated with the lower number of spleen cells. No histopathological evaluation of the thymus was performed. However, based on the substantial effect on body weight, a stress related reduction of thymus weights can be assumed. In a subchronic toxicity a similar decrease of thymus weights was associated with thymus atrophy.

No statistically significant decrease of terminal body weight was observed in the animals treated with the positive control substance Cyclophosphamid [see Table 5.8.2-22]. However, absolute and relative spleen and thymus weights were significantly decreased.

Table 5.8.2-22: Mean absolute and relative organ weights in mice treated with pyraclostrobin or cyclophosphamide for 28 days

Organ weight [mg]	Dose [ppm]	Absolute weight [mg]	Δ%	Relative weight [% of bw]	Δ%
Terminal weight. [g]	0	22.4			
BAS 500 F	50	22.3	(-0.4)		
	200	**21.4***	(-4.5)		
	750	**20.2****	(-9.8)		
CPS (pos. control)	50 mg/kg	21.6	(-3.6)		
Spleen	0	94.1		0.42	
BAS 500 F	50	89.4	(-5.0)	0.40	(-4.8)
	200	87.5	(-7.0)	0.41	(-2.4)
	750	**67.5****	**(-28.3**)**	**0.33****	**(-21.4**)**
CPS (pos. control)	50 mg/kg	**44.7****	**(-52.5**)**	**0.21****	**(-50.0**)**
Thymus	0	45.0		0.20	
BAS 500 F	50	46.0	(2.2)	0.21	(5.0)
	200	43.6	(-3.1)	0.20	(0.0)
	750	**29.1****	**(-35.3**)**	**0.14***	**(-30.0*)**
CPS (pos. control)	50 mg/kg	**15.6****	**(-65.3**)**	**0.07****	**(-65.0**)**

* $p \leq 0.05$; ** $p \leq 0.01$ (Dunnett's test)
Values may not calculate exactly due to rounding of figures

E. IMMUNOLOGICAL ANALYSES

A treatment-related lower number of spleen cells (-40%) was noted at the high dose level (750 ppm). An even more pronounced decrease (-74%) was noted for the Cyclophosphamid treated positive control group (CPS).

The statistically significant lower spleen cell number at the low dose level (50 ppm; -17%) was not considered treatment related, because the values were identical to those of the 200 ppm group and statistical significance was most likely due to the decreased variability within the group [see Table 5.8.2-23].

In contrast to the lower spleen cell number, the number of antibody forming cells (AFC) per spleen was not affected by treatment. Accordingly, at the high dose level a statistically significant higher (47%) specific activity (AFC/10^6 spleen cells) was noted when compared with the vehicle control group. There were no effects on the absolute and specific activity at the mid and low dose level.

As anticipated, in the positive control group the total absence of antibody forming cells (AFC) resulted in a 100% decrease of total and specific AFC activity.

Table 5.8.2-23: Spleen Antibody-Forming Cell responses to the T-dependent antigen, Sheep Erythrocytes, in female mice treated for 28 days with pyraclostrobin or cyclophosphamid

	BAS 500 F				CPS
Dose	0 ppm	50 ppm	200 ppm	750 ppm	50 mg/kg bw
Spleen Cells (x 10^7)	15.01 ± 0.92	12.52 ± 0.48*	12.54 ± 0.71	**9.01 ± 0.64****	**3.85 ± 0.22****
IgM AFC/10^6 Spleen Cells	990 ± 66	1003 ± 84	1001 ± 75	**1459 ± 132****	**0 ± 0****
IgM AFC/Spleen (x 10^3)	148 ± 13	125 ± 11	122 ± 5	129 ± 11	**0 ± 0****

* $p \leq 0.05$, ** $p \leq 0.01$ (Dunnett's Test for homogenous data, the positive control was compared to the vehicle control using Student's t Test)

III. CONCLUSION

Dietary administration of pyraclostrobin to female B6C3F1 mice for 28 consecutive days resulted in decreased body weight and body weight gain and - secondary to the lower food consumption - a decreased defecation at the high dose level (750 ppm). Furthermore, reduced absolute and relative spleen and thymus weights were observed. Secondary to the lower spleen weight / size a lower number of spleen cells was recorded, which however did not result in a decrease in the number of antibody forming cells (AFC). To the contrary, the specific AFC activity was statistically significant increased. No adverse effects were noted at the lower dose levels, whereas the positive control resulted in a total loss of IgM mediated immune response.

While a decrease in the AFC response has been recognized as an indicator that a test substance has the potential of being immunosuppressive; at the present time, the consequences of an increase in the AFC response have not been established and thus the adversity of this change cannot be assessed.

Based on the results of this study, the NOEL (No Observed Effect Level) for general toxicity and overall effect on the various parameters of the immune system was 200 ppm.

Additional toxicological information found in public literature (CA 5.8.2/6 - CA 5.8.2/9)

Report: CA 5.8.2/6
Houck K.A. et al., 2009a
Profiling Bioactivity of the ToxCast Chemical Library Using BioMAP Primary Human Cells
2009/1130882
Guidelines: none
GLP: no
(literature study; part of the ToxCast Program)

Executive Summary

The authors use the BioMAP human cell system to characterize effects relevant to human tissue and inflammatory disease biology as part of EPA's ToxCast program. They show a similar pattern for pyraclostrobin, trifloxystrobin and a reference compound for mitochondrial activity, myxathiazol. As the fungicidal mode of action for stobilurins is on mitochondria activity, this is to be expected. Interestingly the underlying data indicates significant mitochondrial toxcicities with AC_{50}'s for different endpoint of 0.39 to 49.6 µM. Mitochondrial mass and membrane potential are discussed to be hallmarks of cytotoxicity, which is in indeed observer at an AC_{50} of 3.32 µM at the 72 hour time point.

Thus the described data confirm the pesticidal mode of action of pyraclostrobin.

Using nuclear receptors activity to stratify hepatocarcinogens
2011/1295091
Guidelines: none
GLP: no
(literature study; part of the ToxCast Program)

Executive Summary

This study is part of the EPA ToxCast program. The authors investigated the effects of 309 environmental pesticides on nuclear receptors using primary human hepatocytes, HepG2 cells transfected with a multiple reporter transcription unit (MRTU) library consisting of 48 transcription factor binding sites, cis reporter gene assays and cell free and cell based cytochrome P450 assays. This data was used to calculate an aggregate scaled activity scores for different nuclear receptors (CAR, PXR, PPAR, AhR, SR, RXR), which was then correlated to lesion progression data extracted from EPA's pesticide database.
Pyraclostrobin, together with cyprodinil, etoxazole, flumetralin, haxaconazole, methoxyfenozide, phosalone, and tebufenozide was grouped into category VIII A. Group A indicated, that the compound can activate the nuclear receptor AhR, and PXR and to a lesser degree CAR. The rationale for this grouping is largely based on the activation of the reporter genes. In case of AhR these are Cyp1a1 genes in various forms and Cyp1b1. For PXR this consists of the PXR gene, several variants of Cyp3a4, PXRE_Cis, nPXR, human PXR agonist and PXR trans. For CAR the situation gets even more complex, with single target genes in cis and trans form and CAR itself in CIS and trans form as reporter gene assays.

It is interesting to note, that for AhR association the actual AhR is not part of the group, although there are numerous publications indicating that also AhR expression can be regulated by prototypical AhR activators like dioxin and beta naphthoflavone, albeit on a small scale (2-3 fold), not involving binding to the AhR binding site. Also Cyp1b1 transcript changes have been reported in numerous studies without accompanying transcription of Cyp1a1, indicating further regulatory mechanisms at least for this cyp. Also, numerous other known hepatic target genes for each of the receptors have been neglected in the choice for target genes of this assay. Additionally, it is important to note that for example the AhR has a very broad ligand range with more than 400 known endogeneous and exogeneous known ligands. Often AhR activitation is seen at high doses for prototypical ligands for other nuclear receptor agonists. The same holds true for other nuclear receptors, like PXR or PPAR.

It is also important to note that many of the Cyps have a all or nothing or at least a very steep dose response curve. E.g. Cyp1a1 is often considered to be a switch gene with binding of an AhR ligand inducing > 100-fold gene expression changes. In case of pyraclostrobin only a 1.5-fold increase (50%) of activity is seen for one of the multiple Cyp1a1 reporter gene transcripts. This indicates that the apparent AhR activation is only weak in comparison to strong AhR ligands.

When looking at the AC_{50} values for nuclear receptor activation that is scored with a positive association for pyraclostrobin (active activity call; taken from the concurrent EPA dashboard), they are in the range of 0.54 to 2.48, with NVS_MP_hPBR activity at 0.9 and NVS_MP_rPBR at 1.5 µM at the low end and NVS_ENZ_hBACE at 13.6 µM at the upper end of the scale. Apart from PBR, all activity calls fall well within the range of cytotoxicity indicated by Houck et al (see CA 5.8.2/6) and other available data from mammalian cells (e.g. Orton EC_{20} = 0.089 µM; see CA 5.8.3/1) or in vitro mutagenicity assays. Recent presentations by EPA indicate that positive associations from any of the ToxCast assays derived at cytotoxic concentration can be at best used as supplementary information.

Association to group VIII is indicative of a lack of cancer lesion progression and indeed pyraclostrobin shows indications of hepatic enzyme induction (increased liver weight, and hepatocyte hypertrophy) but no progression to neoplastic lesions in mice or rats.

It is interesting to note, that other ADME assays within the ToxCast program do not show an activation of any phase I enzymes, including the ones identified in this publication. Therefore, this study can only be viewed as supplemental information.

Report: CA 5.8.2/8
Kleinstreuer N.C., 2011a
Environmental impact on vascular development predicted by high-throughput screening
2011/1296591
Guidelines: none
GLP: no
(literature study; part of the ToxCast Program)

Executive Summary

This study is part of the EPA ToxCast program. The authors investigated the effects of 309 chemicals using 467 high-throughput screening tests (HTS). The assays measured direct interactions between chemicals and molecular targets (receptors, enzymes), as well as downstream effects on reporter gene activity or cellular consequences. From this assays individual bioactivity scores were determined. Primary pathways of interest, associated to these scores, were inflammatory chemokine signaling, the vascular endothelial growth factor pathway, and the plasminogen-activating system. Figure 2 of the publication shows ToxPi visualizations for the 50 top ranking chemicals in the assay. The visualization is based on the activity on the assay for µPAR up- or down-regulation, PAI-1 up- or down regulation, CCL2 down-regulation, CXCL10 up-regulation, TIE2 binding and VEGFR2 down regulation. It is interesting to note that for µRAR and PAI-1 the direction of regulation was not taken into account, albeit an up-regulation is likely based on fundamentally different molecular events than a down-regulation. Also consequences will marketly differ as shown for multiple signaling pathways.

Pyraclostrobin is depicted to regulate PAI-1 (without direction of change), weak to medium regulation of µPAR (without direction of change) and to down-regulate CCL2. Please note that the original assay database contains assays for rats and humans, and that from this visualization it is not clear, whether the human or rat assay is investigated. This is also not indicated in the text.
We have querried the values for each of the implicated assays in the concurrent version of the data on EPA's dashboard (http://actor.epa.gov/dashboard/). Pyraclostrobin is scored negative for each of the implicated assays, be it in the rodent or human version. The actual AC_{50} values are 1000 µM each. It is interesting to note, that indeed none of the genes/assay implied in the above pathways, including many additional cytokines and chemokines, as well as numerous other factors were not positively associated with pyraclostrobin up to 1000 µM each. Therefore, we consider that pyraclostrobin is not positively correlated with any of the risk factors for vascular development.

Report: CA 5.8.2/9
Sipes N.S. et al., 2013a
Profiling 976 toxcast chemicals across 331 enzymatic and receptor signaling assays
2013/1371960
Guidelines: none
GLP: no

Executive Summary of the Literature

Summary report on the ToxCast program. The publication makes some general statements on the progress of the ToxCast program. The data provided for pyraclostrobin is the same as in Shah et al. (see CA 5.8.2/7). No linkage between pyraclostobin and other endpoints is provided.

Classification of study: Supplementary information

General comment to the evaluation of the ToxCast literature:

ToxCast was originally designed to evaluate more than 600 in vitro and cell free assays for their potential of hazard identification, respectively prioritarization for further testing of chemicals. The initial expectation was very high, in particular due to the massive number of test systems and due to the fact that multiple assays were targeting similar endpoints. The underlying principle was that one could combine the information from multiple members of a pathway, use a weight of evidence approach and give a reasonably precise prediction for hazard identification.

This expectation however was not met. In a seminal effort Russel Thomas et al (2012, Toxicological Science 128(2); 398-417), working for the Hamner Institute at that time, did a comprehensive statistical analysis of the whole ToxCast database. For this he teamed up with the statistical software company SAS and more than 300 prediction models were generated, in particular comparing the predictivity of the in vitro approaches with in silico prediction models. In general, the balanced accuracy of the prediction was <0.55 or smaller than 55%. This is largely based on two influencing factors. 1. Better values for more balanced endpoints and due to the high specificity associated with low sensitivity or high sensitivity with low specificity for each endpoint. The only assay with a predictivity > 0.8 or 80% was cholinesterace inhibition, both for QSAR and in vitro. The underlying database is very data rich for this endpoint as carbamate and organophosphate insecticides make up a significant amount of the 309 ToxCast chemicals. Therefore, it was to be expected, that respective high quality in vitro and QSAR assays would be available.

For the rest of the > 600 assays, the predictivity is little better than tossing a coin. This publication had significant impact on the ToxCast program and indeed Russel Thomas has meanwhile been named the new lead scientist for it.

In a personal presentation given by Richard Judson at BASF, EPA stated that they currently plan to use the ToxCast data only in a weight of evidence approach. The underlying decision tree will consist of the formulation of adverse outcome pathways (AOP). The ToxCast data will be projected onto the AOP and EPA will use the spatial information in the pathway, as well as the order of events to characterize, whether any given chemical will be associated with a pathway. For example, if a chemical is implicated in one pathway a single hit anywhere in the pathways will not be sufficient. However, if a chemical is associated with multiple endpoints in the pathway, this will give the prediction a higher status. E.g., a chemical that hits nuclear receptor binding, receptor localization to the nucleus, receptor transactivation, and target gene expression will be considered positive for this pathway. Currently EPA has not yet published a list of AOPs and assays associated with AOPs. Respective scoring systems for the positive or negative association to any given pathways are also still lacking.

When one applies this AOP principle to the data presented above on pyraclostrobin, it is nonetheless obvious, that no positive assotiation to any given tox endpoint can be drawn.

In the same presentation Judson stated that positive activity calls seen in any given assay have to be evaluated with great care if the concentration range with the positive association is withing the range of the cytotoxicity of the compound. Most assays were no longer predictive at cytotoxic concentration and gave multiple false associations due to e.g. endogeneous substances released from the damaged cells. One could argue, that for most of the assay systems cytotoxicity information is laking. In such cases the mean cytotoxic concentration of a compound should be taken into account, unless the cytotoxicity is mediated by a cell type specific mode of action. In case of pyraclostrobin the cytotoxicity is expected to be based on the mitochondrial activity. As mitochondrial signaling pathways are evolutionary conserved, it is to be expected that mitochondrial toxicity will be similar in most test systems. Therefore, a mean cytotoxicity can be assumed. Positive activity calls as taken from the concurrent version of the data accessible in the EPA dashboard are mostly seen at cytotoxic concentrations or above.

In summary,

1) The balanced accuracy for ToxCast endpoints is < 0.55.
2) Pyraclostrobin in not positively associated with any known AOP, with the exception of hepatic enzyme induction.
3) Most activity calls seen in the ToxCast dataset occure at cytotoxic concentration, reducing the predictivity of the respective assays.
4) No positive association of pyraclostrobin to any endpoint has been raised in the public literature apart from the ToxCast database.

No further point of concern was raised from the public literature. Pyraclostrobin has been adequately tested.

CA 5.8.3 Endocrine disrupting properties

The evaluation of potential endocrine disruption was not a data-requirement at the time of Annex I inclusion of pyraclostrobin. However, this endpoint is considered to be intrinsically covered by the respective pivotal toxicity studies on pyraclostrobin.

The data package of pyraclostrobin neither indicate a potential to affect the estrogen or androgen system nor the pituitary-thyroid axis.

The organ weight changes of male (testes, epididymis (dogs only)), and female sexual organs (ovaries) and endocrine glands (adrenals, thyroid (dogs only)) observed in subchronic studies at higher dose levels were secondary to the observed decrease of terminal body weights and typically not accompanied by histopathological findings. The decrease of absolute and relative adrenal weights in female mice was accompanied by a decrease of lipid deposition in the x-zone, which is specific to mice and of unknown function. The decreased lipid content is considered secondary to the impaired body weight development. No histopathological effects on the thyroid were observed in rodents and dogs. Likewise, long-term administration of pyraclostrobin did not indicate treatment-related effects on neoplastic or non-neoplastic findings in sexual organs or endocrine tissues. In the 2-generation study administration of pyraclostrobin had no effect on the estrous cycle; the number, morphology and motility of sperm as well as on male or female fertility.

The only potential indication for a sex-hormone mediated effect is the slight delay of vaginal opening in the 2-generation study (BASF DocID 1999/11869). In this study a slight, but statistically significant delay of vaginal opening was observed. The mean time of vaginal opening was 31.7, 32.1, 32.4 and 33.3** ($p < 0.01$) days at 0, 25, 75 and 300 ppm. However, the mean day of vaginal opening at the high dose level was well within the historical control range of 29.9 to 34.9 days (see Table 5.8.3-1). There is only a limited number of studies (4) in the historical control because a) determination of vagnial opening was only started in 1998 and b) the (sub-) strain and source of rats used in the laboratory was changed from Boehringer Ingelheim, Biberach/Riss, Germany (Chbb.THOM(SPF)) to Charles River Laboratories, Sulzfeld, Germany (CrlCLxBrHan:WI) in the year 2000. Nonetheless, it is interesting to note that for animals delivered to the laboratory within a 3 week period, the mean day of vaginal opening in control females varied between 31.7 days (study 93175 (pyraclostrobin)) and 34.9 days (study 96173), indicating a relatively high biological variability of this parameter.

Table 5.8.3-1: Historical control data base for vaginal opening in Chbb.Thom Wistar rats

Delivery date of animals	Study identification	Mean day of vaginal opening
16.03.1998	98010	33.0
26.05.1998	96172 (BAS 500 F)	31.7
16.06.1998	96173	34.9
01.09.1998	97136	30.6
22.09.1998	97139	29.9

As already discussed in the study report as well as in the 2003 DAR, the slight delay in vaginal opening (VO) is most probably related to the slight delay in physical development secondary to the slightly lower body weights observed at weaning (45.2 g ± 3.04 vs. 51.3 g ± 3.99 in controls; -11.9%, $p < 0.01$) and in F1 parental females at week 0 (73.4 g ± 7.67 vs. 80.9 g ± 7.50; - 9.3%, $p < 0.05$), week 1 (111.4 g ± 9.16 vs. 118.5 g ± 9.71; - 6.0%, $p < 0.05$) and week 2 (140.9 g ± 9.64 vs. 145.5 g ± 10.22; -3.2%, n.s.).

This becomes even more evident if one compares the mean weight of high dose and control females at VO (103.0 g ± 9.3 g vs. 103.0 g ± 10.9 g in control females), which is identical in both groups. As the body weights at VO were not recorded in this study, the body weights were extrapolated for the day of VO by linear extrapolation from the body weight curve in the period of interest for each individual animal.

Overall, there is no indication that pyraclostrobin has a human relevant endocrine related effect. Thus, the conclusion for relevant endpoints for the current renewal was amended as follows:

Other toxicological studies (SANCO/11802 data point 5.8)

Endocrine disrupting properties	No endocrine effects on the oestrogen, androgen or thyroid hormone system.

In addition to the pivotal toxicity studies the following literature was taken into consideration.

Literature data

As many other pesticides and chemicals, pyraclostrobin is part of the US ToxCast program. Several assays react to varying doses of pyraclostrobin, however, no conclusive picture has emerged. In the following two publications related to endocrine effects are discussed.

Report: CA 5.8.3/1
Orton F. et al, 2011a
Widely used pesticides with previously unknown endocrine activity revealed as in vitro antiandrogens
2011/1291251
Guidelines: none
GLP: no

Executive Summary of the Literature

This publication investigated the antiandrogenic activity of pesticides based on the heights of exposure and known or QSAR predicted interaction with the androgen receptor. A total of 37 pesticides were tested in the MDA-kb2 assay using MDA-kb2 human breast cancer cells transfected with a fire-fly kuciferase reporter gene that is driven by an androgen-response element-containing promoter. Selected pesticides were also tested in the YAS-assay.

The QSAR analysis of pyraclostrobin was 'out of domain', i.e. no predicition with regard to anti-androgenic activity was possible. The MDA-kb2 assay was negative, indicating the absence of antiandrogenic activity. The cytotoxicity in the MDA.kb2 assay was relatively high with an EC_{20} of 0.089 µM. This confirms the high cytotoxicity also seen in other assays (e.g. BASF DocID 1998/11421). No YAS assay was performed with pyraclostrobin.

Classification of study: Supplementary information

Report: CA 5.8.3/2
Reif D.M. et al., 2010a
Endocrine profiling and prioritization of environmental chemicals using ToxCast data
2010/1231552
Guidelines: none
GLP: no

Executive Summary of the Literature

This publication illustrates a profiling tool developed on the ToxCast database to prioritize chemicals with regard to endocrine disruption evaluation/testing as a decision support tool. Thus this priorization tool was applied also to pyraclostrobin being part of the ToxCast program. The priorization tool focused on estrogen, androgen and thyroid pathways and thus incorporated those screening assays of the ToxCast program considered relevant for putative endocrine profiles. In addition, it incorporated external molecular pathway databases i.e. Kyoto Encyclopedia of Genes and Genomes (KEGG), Ingenuity software and the Online Mendelian Inheritance in Men repository. The tests in which pyraclostrobin showed an activity are the same as described in the publication of Shah et al. 2011 (see M-CA 5.8.2/7). The current evaluation of the results can be seen on EPA's dashboard (http://actor.epa.gov/dashboard/). The so-called ToxPi profile for pyraclostrobin (supplementary information) indicates medium activity in LogP and KEGG path, and weak activity for Ingenuity path, other NR, other XME/ADME and TR. The publication does not provide an absolute ranking but in visual comparison to activity alerts for other compound the ranking of activities for pyraclostrobin is low. No linkage between pyraclostrobin and other endpoints is provided.

It is important to note that both Ingenuity Pathways and KEGG rely on literature data often generated in completely different cellular setting. In particular Ingenuity pathways are highly curated and quality controlled. However, genes/proteins have linkage to multiple pathways. An estimation from Lockhart et al (Nature 405, 827-836, (15 June 2000)) indicated that a typical protein is associated to 7 other proteins. This is much more profound in key cellular regulators or chaperones (e.g. heat shock proteins). Those are implicated in multiple pathways and often regulation on gene expression level is not associated to any functional change in the pathway, as cells have large pools for those protein and can compensate for changes. A regulation of such an accessory protein thus will indicate a positive association to multiple pathways, without giving any information on a functional change. Current approaches in bioinformatics therefore apply a weight of evidence approach, which means that multiple parameters within a pathway need to be regulated, before this is considered to be affected. Please also note that neither KEGG nor Ingenuity pathway analysis takes the direction of the regulation into account. This is an important limitation, as an up regulation can have fundamentally different consequences than a down regulation. A really meaningful prediction using either KEGG or Ingenuity would require a detailed evaluation of the affected network and prior knowledge of the regulation of this network in the used cell system. On their own, KEGG or Ingenuity pathways can only be seen as indicator or roadsigns pointing a researcher into a direction.

Another factor which needs to be taken into account, is the level of complexity for each pathway. A gouping according to nuclear receptor regulation does not provide any information, which receptor is regulated. The same is true for a group like KEGG path: Which of the more than 500 KEGG pathways is regulated? What does it mean?

Also this analysis does not take into account that multiple assays exist for the same pathway or endpoint within the ToxCast program. In principle a chemical acting on any given pathway should score at multiple assays associated with that endpoint. Individual hits should be disregarded in the context of a weight of evidence. Another factor not taken into account is that assay results achieved at cytotoxic concentrations have low reliability (please see discussion in M-CA 5.8.2). Using the EPA dashboard it is apparent, that positive activity calls were largely seen at cytotoxic concentration. Furthermore, different assays for the indicated outcome did not show concordance. Therefore, we consider this information to be supplementary only.

Classification of study: Supplementary information

CA 5.9 Medical Data

Information evaluated in the draft monograph of Rapporteur Member State Germany of Sep. 12, 2000:

Since pyraclostrobin is a new compound, no data and medical experience regarding possible health effects in humans are available to the rapporteur. All information provided by the sole notifier is presented here.

Thus, the following conclusion was given in the list of endpoints for Annex I listing of pyraclostrobin:

Medical data (SANCO/1420, 8. Sept. 2004, data point 5.9**)**

Medical data	Limited data (new compound); no human health problems identified

Information on medical data obtained since then has been collected and evaluated. In order to extend the evaluation basis a search in the literature and internet databases listed below - restricted to "pps=human" and "ct d human" - has been performed on May 5, 2014 via DIMDI-host for the following terms:
Pyraclostrobin* or F500
CAS 175013-18-0

Literature data basis:
Medline 66 (NLM)
Medline alert (NLM)
Embase 74 (Elsevier)
Embase alert (Elsevier)
Cochrane Library-Central
Biosys (Thomson Reuters)
gms (German Medical Science)
IPA International Pharmaceutical Abstracts (Thomson Reuters)
Deutsches Aerzteblatt (Aerzteverlag)

Internet available databases:
CHEMID (http://chem2.sis.nlm.nih.gov/chemidplus/chemidlite.jsp)
PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi)
Toxnet (http://toxnet.nlm.nih.gov/)

These searches revealed one relevant document, which is summarized in M-CA 5.9.3.

Considering all available information, the conclusion for relevant endpoints for the current renewal remains as follows:

Medical data	Exposure to humans may result in irritation of skin and eyes. Accidental inhalation of pyraclostrobin containing products was reported to result in symptoms of respiratory irritation.

CA 5.9.1 Medical surveillance on manufacturing plant personnel and monitoring studies

All persons handling crop protection products are surveyed by regular medical examinations. There are no specific parameters available for effect monitoring of pyraclostrobin. Thus, the medical monitoring program is designed as a general health check-up, with special interest in the primary target organs presumed to be relevant by analogy from animal experiments.
The surveillance program includes a general physical examination including neurological status, red and white blood cell counts and liver enzymes. Adverse health effects suspected to be related to pyraclostrobin exposure have not been observed and no monitoring studies are known to the applicant.

CA 5.9.2 Data collected on humans

Some cases of eye irritation deriving from pyraclostrobin in combination with other substances in the course of production, transportation, formulation and packaging have been reported to BASF SE.

CA 5.9.3 Direct observations

Some cases of slight irritation of the skin and mouth and/or intoxication (indisposition, headache, ague, fatigue, aching muscles, vomiting, drowsiness, dizziness, adynamic feet, breathing difficulties) have been registered in the internal clinical incident log at BASF SE in Ludwigshafen for persons exposed to pyraclostrobin containing products in combination with other active ingredients and/or products. It is not clear whether pyraclostrobin was the cause for these effects and whether exposure was according to good agricultural practice.

Gergely et al. described 5 events. All cases were categorized as being of low to moderate severity. The patients had irritation and pain of the upper respiratory tract as well as nausea, headache, eye pain, weakness, dizziness, chest pain. More details are shown below.

Report: CA 5.9.3/1
Gergely R.M. et al., 2008a
Acute pesticide poisoning associated with Pyraclostrobin fungicide - Iowa, 2007
2008/1102036
Guidelines: none
GLP: no

Executive Summary

The information was published in the Morbidity and Mortality Weekly Report (MMWR) series of the US Centers for Disease Control and Prevention (CDC). The MMWR series is the CDC's "primary vehicle for scientific publication of timely, reliable, authoritative, accurate, objective, and useful public health information and recommendations". The data are based on reports sent by state health departments to CDC.
The authors reported 5 events, which were reported to the Iowa Departement of Public Health. 33 persons were exposed to pyraclostrobin. All cases were categorized as being of low to moderate severity.
In all but one incidents the exposure was to spray drift from aerial application. The most severe incident pertained 27 Hispanics. They were exposed to off-target drift from a nearby field while detasseling corn (i.e., removing tassels from corn plants to prevent auto-pollination and enable hybridization). Some workers reported feeling wet droplets on their skin and seeing mist coming from the aircraft. All workers received skin decontamination on-site by a hazardous materials team before being transported to an emergency department for observation until their symptoms resolved. All cases were categorized as being of low severity. According to NIOSH classifications low severity illness or injury includes "illnesses manifested by skin, eye, or upper respiratory irritation". These illnesses might also include fever, headache, fatigue or dizziness. Typically, the illness or injury resolves without treatment, and time lost from work or normal activities is < 3 days.
The most common symptom was upper respiratory tract pain or irritation (26 patients), followed by chest pain (20 patients). Three patients had nausea, and one patient each had pruritis, skin redness, eye pain, weakness, headache, dizziness, and chest pain.
The other incidents pertained single cases with off-target drift of pyraclostrobin from nearby aerial applications. They were exposed by riding a motorcycle near a field or by spray drifting to their home yard. Symptoms reported were headache, eye pain partially associated with conjunctivitis and dizziness. The last case was from a crop-duster pilot who – when his plane crashed during take-off – was exposed to spilling of the liquid fungicide. In this case of moderate severity (non-life-threatening health effects that generally are systemic and require medical treatment), the pilot reported no respiratory symptoms.

Classification of study: Additional information

Based in the above described observations, the known irritant potential of pyraclostrobin as well as the supportive evidence for respiratory irritation observed in subchronic inhalation studies (see M-CA 5.3.3/1 and 5.3.3/2) BASF self-classified pyraclostrobin with STOT SE Category 3 (H335, May cause respiratory irritation).

CA 5.9.4 Epidemiological studies

Data on exposure of the general public or epidemiologic studies are not available to the applicant and no epidemiologic studies performed by third parties are known**.**

CA 5.9.5 Diagnosis of poisoning (determination of active substance, metabolites), specific signs of poisoning, clinical tests

Specific signs of toxicity or specific clinical test methods are not known to the applicant.

CA 5.9.6 Proposed treatment: first aid measures, antidotes, medical treatment

Supportive treatment should be done according to symptoms. No specific antidote is known. Further information can be found in M-CA 3.10, which is reflecting the information given in the safety data sheet.

CA 5.9.7 Expected effects of poisoning

Effects of poisoning are not known. Expected effects may be derived from acute and subacute studies in animals.

CA 6 RESIDUES IN OR ON TREATED PRODUCTS, FOOD AND FEED AND PLANT METABOLISM

Pyraclostrobin (BAS 500 F), a fungicide for use in cereals, maize, potatoes, legumes, fruits, vegetables and various other crops, is registered in Europe since many years. It was fully reviewed under Directive 91/414/EEC and included in Annex I by Commission Directive No 2004/30/EC and 2009/25/EC. Inclusion entered into force on 10 March 2004. The approval was transferred to the new Regulation (EC) No 1107/2009 in Commission Implementing Regulation (EU) No 540/2011. Approval extension was granted until 31 January 2017 by Regulation No 823/2012/EU.

All relevant information on the first Annex I review and the endpoints used in consumer dietary assessments can be found in the monograph of pyraclostrobin and in the SANCO/1420/2001-Final document (EU Review Report).

For the current renewal of approval under Regulation 1107/2009, a data gap analysis according to new guidelines, new guidance documents and new policies in exposure assessments was performed. New studies / evaluations were initiated where considered necessary. Furthermore, a literature search was performed and scientific publications were evaluated for their endpoint relevance and quality.

Although titles and abstracts of several publications indicated a potential connection to respective consumer safety chapters of this dossier, the detailed evaluation of these publications showed no endpoint of sufficient reliability which could be used for the required risk assessments. Consequently, for consumer safety only a summary of public literature data on pyraclostrobin is provided in this supplemental dossier. Further information on the literature assessment and respective justifications can be found in M-CA 9.

An overview of metabolites identified during consumer safety studies is given below. In addition, two metabolites being identified in the aerobic soil metabolism studies (500M01, 500M02) are included in Table 6-1. Their potential uptake behavior into succeeding crops will be discussed in M-CA 6.7 and M-CA 6.9. The list of metabolites occurring in rats (limited to in-vivo investigations of BASF DocID 1999/11781) is not complete; the complete list can be found in M-CA 5.1. The information in the table allows a comparison between the pathways in different test systems.

The metabolite overview below is including the different code numbers that are available for each metabolite. Due to historic reasons (e.g. use of different metabolite codes in different study reports), it is unfortunately not possible to use always only one and the same metabolite code for a certain metabolite. In the following chapters and study summaries synonym metabolite codes are given in brackets where deemed to be helpful.

CA 6.1 Storage stability of residues

Stability of residues during storage of samples

The stability of residues was reviewed during the previous Annex I inclusion process (Annex II, section 4, point 6.1) and no further data are required.

For pyraclostrobin in **plant** matrices, only an interim report was available at the time point of DAR preparation. The storage stability study in plant matrices covering a period of 18 to 25 months is summarised below. It has already been submitted several times during the past years in context of national and zonal registrations, but is not considered as peer reviewed. In order to fulfil the reporting needs of the OECD Guideline 506, the results of the study are additionally presented as measured and not recovery corrected.

In case of **animal** matrices, storage stability data exists covering the period between sample generation and analysis. They were submitted and evaluated during the previous Annex I inclusion process.

The following information is copied from the Draft Assessment Report prepared by RMS Germany (Vol. 1, list of endpoints, 2001):

Stability of residues (Annex IIA, point 6 introduction, Annex IIIA, point 8 introduction)

Food of animal origin: pyraclostrobin stable for 8 month Metabolite BF 500-10 (model compound) with slow degradation but stable enough to evaluate the submitted feeding study (analysed within 6 month). Plant (peanut nutmeat, peanut oil, wheat grain, wheat straw, sugar beet tops, sugar beet roots, tomatoes, grape juice): pyraclostrobin, metabolite BF 500-3 stable for 18 month

Note: This study was erroneously not contained in the application. The reason for submission is described above.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: active ingredient pyraclostrobin and its metabolite BF 500-3
Description: pyraclostrobin; BF 500-3
Lot/Batch #: 00937-128, BAS 500 F; 00937-272, BF 500-3
Purity: 99.8%, BAS 500 F; 99.0% BF 500-3
CAS#: 175013-18-0, BAS 500 F
Development code: BAS 500 F; BF 500-3 (synonym : 500M07)
Spiking level: 1 mg/kg

2. Test Commodity: peanut, wheat, sugar beet, tomato, grape
Crop: oilseed, cereals, root crop, fruiting vegetables, berries & other small fruit
Type: n/a
Variety: n/a
Botanical name: *Arachis hypogeae, Triticum vulgare, Beta vulgaris, Lycopersicon esculentum, Vitis vivifera*
Crop parts(s) or processed
Commodity: peanut nutmeat, wheat grain, sugar beet tops, sugar beet roots, tomatoes, wheat straw, peanut oil, grape juice
Sample size: 20 g (peanut oil 10 g)

B. STUDY DESIGN AND METHODS

1. Test procedure

The freezer stability of pyraclostrobin and its metabolite BF 500-3 (synonym: 500M07) were determined in a diverse set of commodities. The materials were an oilseed (peanut nutmeat; OECD: high oil content), a non-oily grain (wheat grain; OECD: high starch content) a leafy vegetable (sugar beet tops; OECD: high water content), a root crop (sugar beet roots; OECD: high starch content), a fruit/fruiting vegetable (tomatoes; OECD: high water content), and a dry feed item (wheat straw). In addition, the unique processed commodities of oil (peanut) and juice (grape; OECD: high acid content) are also represented. Control samples of each matrix were fortified at a level of 1.0 mg/kg with each pyraclostrobin and its metabolite BF 500-3. Samples were analysed for recoveries initially after fortification and after 1, 3, 6, 14, 18 - 19 and 25 months frozen storage (< -10°C). The maximum frozen storage interval used for all matrices was 25 months, with the exception of peanut nutmeat and peanut refined oil, which were held a maximum of 19 months. The samples were analysed by method number D9908 (421/0). The limit of quantitation (LOQ) of the method is 0.02 mg/kg for each analyte.

2. Description of analytical procedures

Method Number D9908 (421/0) was used for the analyses of this study. Pyraclostrobin and its metabolite BF 500-3 are extracted from plant matrix samples with a methanol/water/HCl mixture (70/25/5). A 0.5% aliquot of the extract is removed and cleaned by liquid/liquid partition with cyclohexane. For wheat and sugar beet matrices, the extracts are further purified on a Silica Gel Speedisk® column. The final chromatography analysis of pyraclostrobin and its metabolite BF 500-3 are determined by LC/MS-MS. The limit of quantitation (LOQ) for pyraclostrobin and BF 500-3 residues is 0.02 mg/kg for each analyte. The ranges of the procedural recoveries at typically 1 mg/kg are shown in Table 6.1-1.

Table 6.1-1: Ranges of procedural recoveries

Matrix	Storage intervals [months]	Range of mean procedural recoveries [%]	
		BAS 500 F	BF 500-3 (500M07)
Peanut nutmeat	0, 1, 3, 6, 14, 19	65 – 101	59 – 104
Peanut oil	0, 1, 3, 6, 14, 19	77 – 107	72 – 107
Wheat grain	0, 1, 3, 6, 14, 19, 25	74 – 100	66 – 99
Wheat straw	0, 1, 3, 6, 14, 19, 25	82 – 112	73 – 111
Sugar beet tops	0, 1, 3, 6, 14, 19, 25	80 – 105	64 – 119
Sugar beet roots	0, 1, 3, 6, 14, 19, 25	56 – 109	50 – 137
Tomatoes	0, 1, 3, 6, 14, 19, 25	80 – 107	72 – 101
Grape juice	0, 1, 3, 6, 14, 19, 25	75 – 125	71 – 110

II. RESULTS AND DISCUSSION

The results obtained from the stored fortified samples indicate that pyraclostrobin and BF 500-3 residues are stable when frozen in peanut nutmeat and oil for at least 19 months and in wheat (grain and straw), sugar beets (tops and roots), tomatoes and grape juice for at least 25 months. The table below presents a summary of the recoveries from the stored fortified samples, corrected for procedural recoveries. A comparison between the recovery corrected and the uncorrected values indicate that lower recoveries in stored samples are rather caused by variability of the method than actual instability of pyraclostrobin residues in sample matrices.

Table 6.1-2: Storage stability of BAS 500 F and BF 500-3 in plant matrices

[1)] For peanut nutmeat and oil samples, the longest storage interval used was 19 months.

III. CONCLUSION

This storage stability study demonstrates that residues of pyraclostrobin and BF 500-3 are stable for up to 25 months in the following frozen raw agricultural and processed commodities: wheat grain and straw, sugar beet roots and tops, tomatoes and grape juice. In addition, the frozen stability of pyraclostrobin and its metabolite have been demonstrated for up to 19 months in peanut nutmeat and oil; peanut matrices were not analysed at the 25-months sampling interval. The pyraclostrobin and BF 500-3 residues remained consistent from time 0 up to the last analysis time period in all plant matrices.

Stability of residues in sample extracts

For the active substance pyraclostrobin, investigations were performed using sample extracts out of ^{14}C-metabolism studies and fortified samples during the validation of the residue analytical methods. In none of the extracts investigated any degradation was observed. From the data available it can be concluded that pyraclostrobin is stable in sample extracts or solutions when stored during residue analysis.

CA 6.2 Metabolism, distribution and expression of residues

CA 6.2.1 Metabolism, distribution and expression of residues in plants

In context of the previous submission for Annex I inclusion, plant metabolism studies have been submitted in grapes, potatoes and wheat covering the crop categories of fruits, root & tuber vegetables and cereals (all foliar application).

According to the results of these studies, pyraclostrobin is intensively metabolized by mainly three key transformation steps:

- N-Desmethoxylation and O-desmethylation of the side chain
- Hydroxylation of the aromatic ring systems
- Cleavage between the ring systems

The contribution of these reactions followed by subsequent conjugation leads to a large number of metabolites. The studies are considered as suitable and valid for describing the degradation behaviour of pyraclostrobin in plants.

The assessment was recently confirmed by EFSA during the re-evaluation of the established MRLs according to Reg. 396/2005, Art. 12.

The following conclusion is directly copied from the Reasoned Opinion (see: EFSA Journal 2011;9(8):2344):
The relevant residue in grapes consisted of parent pyraclostrobin (55.7 - 66% TRR) and its desmethoxy metabolite 500M07 (11.2 - 15.3% TRR). In potatoes the highest TRR was identified in green matter (41.2 - 57.9 mg/kg) in both studies. Parent pyraclostrobin was the main component of the TRR in green matter and potato tubers in studies with [chlorophenyl-U-14C]-pyraclostrobin, amounting for 55% and 29.4% of the TRR, respectively. In the green matter desmethoxy metabolite 500M07 was identified in levels > 20% of the TRR in both studies. In the tolyl study the major component of the TRR in potato tubers was identified as natural amino acid L-tryptophan (29.2% TRR). In cereals, the lowest TRR was found in grains, varying between 0.098 mg/kg in the chlorophenyl labelled and 0.441 mg/kg in the tolyl labelled matrix. The highest TRR was identified in wheat straw, amounting for up to 37.76 mg/kg (chlorophenyl study) and 40.46 mg/kg (tolyl study). The major component of the TRR in straw and grain in the chlorophenyl study was parent pyraclostrobin and its desmethoxy metabolite (500M07). In the tolyl study the major component of the TRR in grain was L-tryptophan (23% TRR), any other components being below 10% of the TRR. L-tryptophan is an essential natural amino acid therefore it is of no toxicological relevance (EFSA, 2010).
Generally it was concluded in the peer review (EC, 2002) that the metabolic pathway is similar in all crop groups investigated. Results from the supervised residue trials indicated that desmethoxy metabolite 500M07 occurs in crops in small amounts compared to parent pyraclostrobin; therefore in the peer review it was concluded that a general residue definition for risk assessment and enforcement should be set as parent pyraclostrobin.

For covering a broader use spectrum and a different application type, two new crop metabolism studies have been conducted. New crop metabolism studies were performed in wheat (seed treatment application) and in paddy rice. Besides these new studies, a cabbage metabolism study is newly submitted in the EU. This study was performed for achieving the Japanese registration. Furthermore, a supplementary document (non-GLP) to the grape metabolism study was prepared upon request of Japan. Purpose of the document was to clarify the way of metabolite identification which is based on extracts from grape leaves. In order to provide a comprehensive picture in grapes, an overall summary of all relevant documents is provided.

The studies summarized below were performed using the tolyl-^{14}C and chlorophenyl-^{14}C labeled pyraclostrobin.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1.	**Test Material:**	Chlorophenyl-U-C^{14}- pyraclostrobin and tolyl-U-C^{14}
	Description:	Carbon-14 chlorophenyl ring labelled (4.34 MBq/mg) and carbon-14 tolyl ring labelled (4.50 MBq/mg) pyraclostrobin
	Lot/Batch #:	^{14}C-BAS 500 F (chlorophenyl): 579-1017 ^{14}C-BAS 500 F (tolyl): 566-1047
	Purity:	^{14}C-BAS 500 F (chlorophenyl): >99% (radiochemical) ^{14}C-BAS 500 F (tolyl): >99% (radiochemical)
	CAS#:	not applicable
	Development code:	not applicable
	Stability of test Compound:	The residues in grapes, treated with pyraclostrobin were stable under the chosen experimental conditions (-20°C, 188 days).
2.	**Test Commodity**:	Berries & small fruits
	Crop:	Grapevine
	Type:	not reported
	Variety:	Müller-Thurgau
	Botanical name:	*Vitis vinifera L.*
	Crop parts(s) or processed Commodity:	Grapes and leaves
	Sample size:	Grapes: 849 g, leaves: >1507 g
3.	**Soil:**	not reported

B. STUDY DESIGN

1. Test procedure

In the plant-uptake part of the study, ^{14}C-BAS 500 F was applied in the form of a pyraclostrobin EC-formulation to grapevines. In total, six post-emergence applications at an intended use rate of 1.500 kg as/ha and vegetation period were performed. The first application was performed at growth stage BBCH 53 – 55 (inflorescences visible to fully developed). The application was repeated 5 times approximately every 16 to 19 days thereafter. The last application was done at growth stage 81 (beginning of ripening), 40 days before harvest.

Figure 6.2.1-1: Structural formula of ^{14}C-BAS 500 F labelled at the chlorophenyl ring

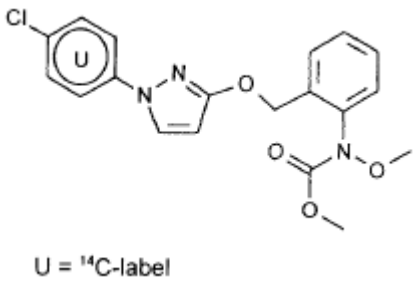

Figure 6.2.1-2: Structural formula of ^{14}C-BAS 500 F labelled at the tolyl ring

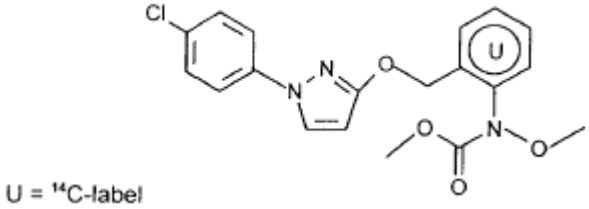

The grapevines were cultivated at a field site which belongs to the BASF Agricultural Center Limburgerhof, BASF Aktiengesellschaft (today: BASF SE). During the study, leaves were sampled to take care for good growing conditions (e.g. high light intensity and low humidity) 12 days after the last application. Brunches were also harvested 12 days after the last application and young brunches were sampled 14 days after the 4th application. At harvest, 40 days after the last application (=PHI), grapes and leaves were harvested. Samples were taken for analysis only at harvest, 40 days after the last application (= PHI).

2. Description of analytical procedures

Grape and leaf samples were extracted three times with methanol. The extractable radioactivity was characterized and quantified by HPLC and radio-assayed by LSC. In addition, liquid/liquid partitioning experiments using cyclohexane and ethyl acetate were carried out. The metabolites were identified by comparison with reference substances. If possible, they were isolated by HPLC and their structures elucidated by LC-MS/MS.

For characterisation of the Residual Radioactive Residue (RRR) after solvent extraction, the radioactive residues were further extracted with ammonia solution (tolyl-label) or water (chlorophenyl-label), followed by an extraction step (reflux) with NaOH.

In order to get information on the storage stability of the grape fruit samples, the extractability and the HPLC metabolite profiles were investigated at the beginning and at the end of the study.

The residual radioactive residue of grape leaf sampled was determined by combustion analysis.

II. RESULTS AND DISCUSSION

A. TOTAL RADIOACTIVE RESIDUES (TRRs)

Grapes:

The total radioactive residues (TRRs) from the grape samples at harvest time (40 DALA) treated either with [tolyl-label]- or [chlorophenyl-label]- labelled pyraclostrobin are shown in Table 6.2.1-1. Due to the high water content of the samples, TRRs were calculated from the sum of ERRs and RRRs. In spite of 6 applications with a total application amount of 1.500 kg/ha, the total radioactive residue level in the fruits from both labels is relatively low. It ranges from 0.951 mg/kg (chlorophenyl-label) to 1.559 mg/kg (tolyl-label). One reason for this low residue level could be that fruits are partly protected by the leaf canopy.

Table 6.2.1-1: Total radioactive residues (TRR) after treatment of grape fruits with ^{14}C-BAS 500 F

Total radioactive residues (TRR)[1] [mg/kg]		
Label position	**Tolyl label**	**Chlorophenyl label**
Grape fruits (at harvest)	1.559	0.951

[1] Calculation as sum of ERR+RRR

Leaves:

The total radioactive residues (calc.) were almost identical for both labels. A TRR of 40.029 mg/kg was found for the chlorophenyl label whereas 41.243 mg/kg were detected in the tolyl label.

The total radioactive residue data in grape leaves are shown in Table 6.2.1-2.

Table 6.2.1-2: Total radioactive residues (TRR) after treatment of grape leaves with ^{14}C-BAS 500 F

Total radioactive residues (TRR)[1] [mg/kg]		
Label position	**Chlorophenyl label**	**Tolyl label**
Grapes leaves (at harvest)	40.029	41.243

[1] Calculation as sum of ERR+RRR

B. EXTRACTION, CHARACTERIZATION AND IDENTIFICATION OF RESIDUES

1. Extraction of residues

Grapes:

In grape samples, the extractability with methanol was high; it ranged from 84 to 88% of the TRR. To increase the extractability, ammonia/water extraction was applied.

Extractability in grapes is shown in Table 6.2.1-3.

Table 6.2.1-3: Extraction of radioactivity after treatment of grapes with ^{14}C-BAS 500 F

Extraction of radioactivity [mg/kg] (% TRR)	
Solvent	**Grapes**
Tolyl label	
Methanolic extract	1.314 (84.3)
Residue after solvent extraction (RRR)	0.245 (15.7)
Ammonia extract	0.023 (1.5)
Chlorophenyl label	
Methanolic extract	0.835 (87.8)
Residue after solvent extraction (RRR)	0.166 (12.2)
Aqueous extracts	0.006 (0.6)

In order to classify metabolites into organo-soluble and water-soluble compounds, the methanolic extracts of the tolyl- and the chlorophenyl-label were partitioned. In Table 6.2.1-4 the values are summarized. In all samples, the organo-soluble metabolites significantly predominated. Their amounts ranged from 73% TRR (tolyl-label) to 78% TRR (chlorophenyl-label).

Table 6.2.1-4: Partition characteristics of Extractable Radioactivity (grape fruit samples)

Label	Cyclohexane/water Partition				Ethyl acetate/water Partition				Sum			
	organo-soluble		water-soluble		organo-soluble		water-soluble		organo-soluble		water-soluble	
	[mg/kg]	[%TRR]	[mg/kg]	[%TRR]	[mg/kg]	[%TRR]	[mg/kg]	[%TRR]	[mg/kg]	[%TRR]	[mg/kg]	[%TRR]
Chlorophenyl	0.663	69.7	-	-	0.077	8.1	0.075	7.8	**0.740**	**77.8**	**0.075**	**7.8**
Tolyl	1.011	65.5	-	-	0.119	7.7	0.096	6.2	**1.130**	**73.2**	**0.096**	**6.2**

Leaves:

Both labels showed comparable extraction behaviour. Around 70% of the TRR could be extracted with methanol. Around 30% of the TRR remained in the residual radioactive residue.

Extractability data in grape leaves are shown in Table 6.2.1-5.

Table 6.2.1-5: Total radioactive residue and extraction behaviour in grape leaves, 40 DAT

Matrix	Label	TRR combusted	ERR		RRR	TRR[1] calc.
		[mg/kg]	[mg/kg]	[%TRR]	[mg/kg]	[mg/kg]
Leaves (at harvest)	Chlorophenyl label	49.673	28.327	70.8	11.702	40.029
	Tolyl label	40.266	28.866	70.0	12.377	41.243

[1] Calculation as sum of ERR+RRR

The methanol extract of the chlorophenyl label was partitioned between organic solvents and water. Most of the radioactivity was found to be organo-soluble. About 14% of the TRR was detected in the aqueous phase.

Partition behaviour data in grape leaves are shown in Table 6.2.1-6.

Table 6.2.1-6: Partition behaviour of the MeOH extract (Chlorophenyl label) - grape leaves

Matrix	ERR		Cyclohexane phase[1]		Ethyl acetate phase		Aqueous phase		Recovery
	[mg/g]	[%TRR]	[mg/g]	[%TRR]	[mg/g]	[%TRR]	[mg/g]	[%TRR]	[%]
Leaves	28.327	70.8	12.326	30.8	9.086	22.8	5.615	14.1	95

[1] Calculation as sum of ERR+RRR

2. Identification, characterization and quantitation of extractable residues

Grapes:

Extractable radioactive residues:
In the methanol extracts only parent (56-62% TRR) and one main metabolite, 500M07 or synonym BF 500-3 (11% - 17% TRR) could be isolated and analyzed (LC-MS).
Three minor metabolites could be further characterized by co-chromatography with isolated and identified metabolites from leaves, designated as 500M54, 500M55 and 500M56 (each single peak was less or equal to 4.01% TRR). Their concentrations in the berries were < 0.05 mg/kg. Compound 500M54 is a derivative of the desmethoxy metabolite BF 500-3 and the two other metabolites are glycosides of the chlorophenyl-OH-pyrazol.

Residual radioactive residues:
Approximately half of the Residual Radioactive Residues (RRR) after solvent extraction could be characterized as bound to or associated to cellulose and lignin. The rest of the RRR was not further characterized because of low concentrations. It is postulated that the remaining residues are likely to be also lignins of a lower molecular weight.

The quantification of the individual metabolites present in grapes fruits is summarized in Table 6.2.1-7.

Table 6.2.1-7: Summary of identified components in grape fruit samples after treatment with ^{14}C-BAS 500 F

Metabolite code (Reg. No. of reference substance)	Metabolite structure	Grape fruits	
		Tolyl label mg/kg (% TRR)	Chlorophenyl label mg/kg (% TRR)
BAS 500 F (304428)		0.860 **(55.7)**	0.588 **(61.79)**
500M07 (BF 500-3) (340266)		0.170 **(11.02)**	0.159 **(16.68)**
500M54 (not assigned)		0.045 **(2.9)**	0.015 **(1.55)**
500M55 (not assigned)		n.d.	0.038 **(4.01)**
500M56 (not assigned)		0.048 **(3.11)**	0.016 **(1.69)**

n.d. not detected

Leaves:

Pyraclostrobin and its desmethoxy metabolite **500M07** (BF500-3) formed the major part of the radioactivity in the MeOH extracts. Additionally, some polar and medium polar peaks were detected. Since in case of the tolyl labelled sample, the individual metabolites were only present in trace amounts, no additional work-up was performed. The MeOH extract of the chlorophenyl label was partitioned between water and organic solvents. Despite no HPLC quantitation was performed, the amounts can be roughly estimated by considering the radioactivity being present in the relevant partition phases.

The **cyclohexane phase** containing 12.326 mg/kg (corresponding to 30.8% TRR) consisted of pyraclostrobin and 500M07; only one minor additional peak was detected. The radioactivity present in the **ethyl acetate phase** (corresponding to 9.086 mg/kg, 22.8% TRR) was distributed among at least 10, partly overlapping metabolites. The ethyl acetate phase was fractionated and the individual fractions passed to MS for structural identification. Fraction 2 consisted at least of three metabolites. One of them was characterized as saccharose conjugate of the hydroxy parent molecule. Based on its fragmentation pattern, hydroxylation and subsequent conjugation is more likely in the chlorophenyl-pyrazole moiety. In fraction 4, two metabolites were detected. The first one was characterized as saccharose conjugate; according to the fragmentation pattern, hydroxylation and subsequent conjugation took place in the pyrazole ring system. The second peak was identified as 500M56. Further fractionation of fraction 5 resulted in two samples. In one sample, four metabolites were found. For none of them a clear identification was possible. In the other sample, the metabolite present was identified as 500M04. Fraction 6 consisted of at least three metabolites. One of them was characterized as glucose conjugate of the desmethoxy metabolite. Most likely, hydroxylation and conjugation took place in the tolyl ring system resulting in structure 500M71. In fraction 8, a glucose conjugate was present. Based on the fragmentation pattern, hydroxylation and subsequent conjugation is more likely in the chlorophenyl pyrazole moiety. In fraction 9, MS was identified as 500M54.

The remaining **aqueous phase** containing 5.615 mg/kg and 14.1% TRR is containing one predominant peak plus 4 additional components in very low amounts. The peak was identified as the metabolite 500M55. It is clearly present in amounts greater than 10% TRR.

The structure of the metabolites present in grapes leaves is summarized in Table 6.2.1-8.

Table 6.2.1-8: Summary of components in grape leaf samples after treatment with ^{14}C-BAS 500 F

Metabolite code (Reg. No. of reference substance)	Structure
BAS 500 F (304428)	500M07 (BF 500-3) (340266)	500M54 (not assigned)	500M55 (not assigned)	500M56 (not assigned)	500M04 (BF 500-5) (not assigned)	 500M04
500M71 (not assigned)	 500M71or isomer

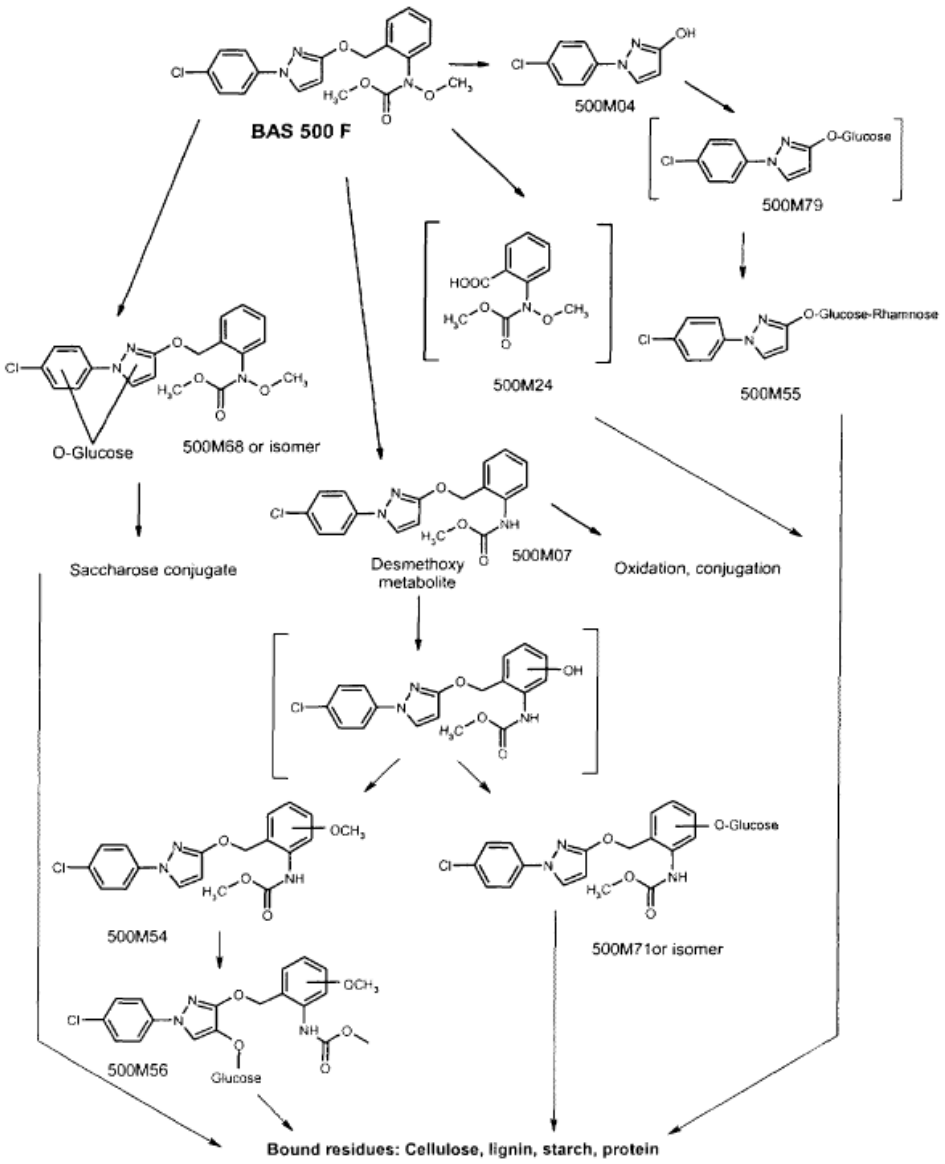
3. Proposed metabolic pathway

The metabolic pathway, presented in Figure 6.2.1-3, shows that the metabolization takes places on two sites of the molecule. One is the tolyl-moiety, were a desmethoxylation takes place in the side chain and a methoxylation in the aromatic ring. At the second site, the chlorophenyl-pyrazol, a glucosidation after hydroxylation takes place. Later, this molecule moiety is cleaved from the tolyl-moiety. In the next step a glycosidation by scillabiose (disaccharide of glucose and rhamnose) is performed. Only smaller amounts of the radioactivity could be found in the bound residues (RRR). They could be assigned to the biopolymers lignin and cellulose.

In grapes, ^{14}C- pyraclostrobin is metabolized by three key transformation steps:

(1) desmethoxylation at the oxime ether bond,
(2) hydroxylation of the tolyl and the chlorophenyl ring systems followed by glucosylation or methylation, and
(3) cleavage between both ring systems and subsequent transformation of the resulting intermediates by glucosylation.

Figure 6.2.1-3: Metabolic pathway of BAS 500 F in grapes



4. Storage stability

In order to examine the storage stability, samples were triple extracted with methanol at the beginning of the metabolism work and at the end of the study. The methanol extracts were analyzed by Radio-HPLC, and both resulting metabolic patterns compared with each other.

An estimate of the storage stability of the metabolite pattern was carried out with MeOH extracts of grapes treated with both ^{14}C-labels of pyraclostrobin and stored at about -20°C until further work up. The MeOH extracts from the first and the last extraction were compared by radio-HPLC.
At the end of the study, 97 days after the 1st extraction, the chromatogram from the tolyl-label corresponds considerably with that of the 1st extraction. Only a slight change from 74.1% TRR to 73.5% TRR for pyraclostrobin and from 19.5% to 20.7% for the metabolite 500M07 (BF 500-3) could be observed. Grapes which were stored at -20°C for 188 days were extracted three times with MeOH. By HPLC analysis, the resulting extract was compared with the 1st extract, which had been stored for the same time at -20°C. The results showed that in the MeOH extract pyraclostrobin slightly decreased when compared to the active substance content in the stored grapes (73% TRR to 70% TRR). The concentration of the metabolite 500M07 slightly increased from 17 to 19% TRR in the MeOH extract within the same time interval.

These results indicate that the residues in grapes, treated with pyraclostrobin were stable under the chosen experimental conditions.

III. CONCLUSION

The investigation of the metabolism of pyraclostrobin in grapes using material labelled either in the tolyl or the chlorophenyl ring leads to the conclusion that the predominant residue in grapes consists of the parent compound pyraclostrobin and its desmethoxy metabolite 500M07 (BF 500-3). Some other compounds were identified as products formed by cleavage of the molecule. The cleavage reaction resulting in the metabolites 500M04 (BF 500-5) and 500M55 is more expressed in leaves than in fruits. The metabolization by O-glucosylation or methoxylation is a minor degradation pathway; the metabolites 500M54, 500M56 and 500M71 are present in amounts clearly below 10% of the TRR.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: chlorophenyl-U-C14-BAS 500 F, tolyl-U-C14-BAS 500 F, pyrazole-3-C13-BAS 500 F

Description:	carbon-14 chlorophenyl ring labelled (5.06 MBq/mg) carbon-14 tolyl ring labelled (6.79 MBq/mg)
Lot/Batch #:	^{14}C-BAS 500 F (chlorophenyl): 579-2012 ^{14}C-BAS 500 F (tolyl): 566-3016
Purity:	^{14}C-BAS 500 F (chlorophenyl): >99% (radiochemical), >98% (chemical) ^{14}C-BAS 500 F (tolyl): >99% (radiochemical), >97% (chemical)
CAS#:	175013-18-0
Stability of test compound:	not reported

2. Test Commodity: Leafy brassica

Crop:	Chinese cabbage
Type:	not reported
Variety:	Shin-Kyoto No. 3
Botanical name:	*Brassica campestris L.*
Crop parts(s) or processed Commodity:	outer leaves, leaf balls (edible portion)
Sample size:	not reported

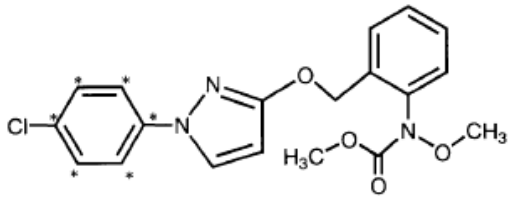
3. Soil: Tachikawa soil

B. STUDY DESIGN AND METHODS

1. Test procedure

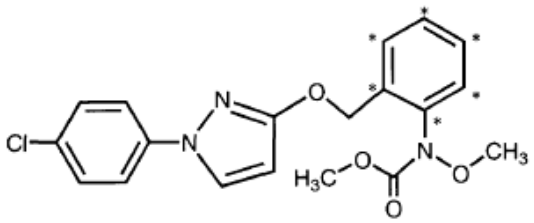
Two different ^{14}C-radiolabeled test items of pyraclostrobin uniformly labelled at either chlorophenyl ring (C-ring label) or tolyl ring (T-ring label) were formulated as 18.8% DF, and then diluted 3000 times with water to prepare a spray solution of each label. Three potted Chinese cabbage plants were treated three times with either radiolabeled test substance by a spray application on the day of 17, 10 and 3 days before mature harvest at a nominal rate of ca. 0.130 kg as/ha. Three days after the final application, the treated Chinese cabbage plants were harvested and separated to a leaf-ball (as edible portion) and outer leaves.

Figure 6.2.1-4: Structural formula of ^{14}C-BAS 500 F labelled at the chlorophenyl ring (C-ring)



* Labeling position

Figure 6.2.1-5: Structural formula of ^{14}C-BAS 500 F labelled at the tolyl ring (T-ring)



* Labeling position

The cabbage plants were grown in pots filled with Tachikawa soil to which small amounts of calcium hydroxide and commercially available fertilizer (N:P:K = 8:8:8) were added. Physical and chemical properties of Tachikawa soil are given in Table 6.2.1-9.

Table 6.2.1-9: Physical and chemical properties of Tachikawa soil

Information from Agricultural Experimental Station of Tokyo Megalopolis	
Type	Volcanic ash
Dominant clay mineral	Allophane
Classified by ISSA method	
Texture	CL
Soil parameters	
Clay content [%]	18.2
pH (H_2O)	5.7
pH (KCl)	5.2
Organic carbon content [%]	5.58
CEC [meq/100g dry soil]	34.7

2. Description of analytical procedures

Leaf-ball and outer leaves samples of both labels were mainly extracted with methanol. The extractable radioactivity was characterized and quantified by radio HPLC. In addition, liquid/liquid partitioning experiments using benzene and methanol were carried out. The metabolites were identified by comparison with reference substances. Where possible, they were isolated by HPLC and their structures elucidated by LC-MS/MS.

The residual radioactive residue (RRR) after extraction was air-dried at ambient temperature (ca. 25°C) for more than 1 day and then weighed. Triplicate aliquots of the dried residues were then subjected to oxidative combustion.

II. RESULTS AND DISCUSSION

A. TOTAL RADIOACTIVE RESIDUES (TRRs)

The outer leaves or the leaf ball of Chinese cabbage was pulverized and then the TRR in each sample was determined by oxidative combustion. The results are reported in Table 6.2.1-10. The TRR levels of chlorophenyl ring label in the outer leaves and the leaf ball were 2.75 and 1.12 mg/kg, respectively. The TRR levels of tolyl ring label in the outer leaves and the leaf ball were 3.72 and 1.20 mg/kg, respectively. There was no significant difference for the TRR levels in plant samples between both labels. The distributions of radioactive residues among the outer leaves and the leaf-ball of Chinese cabbage plants were approximately 60% and 40%, respectively. There was also no significant difference for the distributions of radioactive residues between the labels indicating that cleavage of the molecule is not an important degradation pathway.

Table 6.2.1-10: Total radioactive residues (TRR) after treatment of Chinese cabbage with ^{14}C-BAS 500 F

Total radioactive residues (TRR) [mg/kg]		
Label position	**Chlorophenyl label**	**Tolyl label**
Outer leaves*	2.7484	3.7219
Leaf-ball*	1.1161	1.2013

* determined by direct combustion analysis

B. EXTRACTION, CHARACTERIZATION AND IDENTIFICATION OF RESIDUES

1. Extraction of residues

In outer leaves and leaf ball samples, the solvent extractability was high; it ranged from 89 to 109% of the TRR. In outer leaves, no difference between the extractabilities of the two labels could be observed with values of 106% (chlorophenyl label) and 109% (tolyl label). In leaf ball samples, a slight difference between the extractabilities of the two labels could be observed. In the case of the tolyl label, 109% of the TRR could be extracted whereas the extractable portion from the leaf ball samples treated with the chlorophenyl label was lower (89%).
Residues after solvent extraction were less than 5% of the TRR, indicating that there was no appreciable formation of unextractable bound residues.

The extraction behaviour is summarized in Table 6.2.1-11.

Table 6.2.1-11: Extraction of radioactive residues after treatment of Chinese cabbage with ^{14}C-BAS 500 F

Extraction of radioactivity [mg/kg] (% TRR)		
Solvent	**Outer leaves**	**Leaf ball**
Tolyl label		
ERR	4.0166 **(109.40)**	1.2911 **(108.95)**
RRR	0.1551 **(4.22)**	0.0414 **(3.49)**
TRR	4.1716 **(113.63)**	1.3324 **(112.44)**
Chlorophenyl label		
ERR	2.9260 **(106.46)**	0.9889 **(88.60)**
RRR	0.0978 **(3.56)**	0.0284 **(2.54)**
TRR	3.0238 **(110.02)**	1.0172 **(91.14)**

In order to classify the metabolites into organo-soluble and water-soluble ones, solid phase extraction (SPE) experiments were carried out. In the case of the samples treated with the chlorophenyl and tolyl label most of the radioactivity was found in the benzene eluate (81.5% - 102%). The polar components in the methanol eluate amounted for only 6.0-8.8% of the TRR. The amounts of highly polar fractions eluted in aqueous eluate were negligible (less than 0.5% of the TRR for all samples).
For both labelled samples, the behavior of outer leaves and leaf ball was very similar. The solid phase extraction behavior is summarized in Table 6.2.1-12.

Table 6.2.1-12: Solid phase extraction of radioactive residues in extract after treatment of Chinese cabbage with ^{14}C-BAS 500 F

Partition of radioactivity [mg/kg] (% TRR)		
Solvent	**Outer leaves**	**Leaf ball**
Tolyl label		
Initial ^{14}C in extract	4.0166 **(109.40)**	1.2911 **(108.95)**

Total recovery	4.0587 **(110.55)**	1.2674 **(106.95)**
Chlorophenyl label		
Initial ^{14}C in extract	2.9260 **(106.46)**	0.9889 **(88.60)**
Aqueous eluate	0.0046 **(0.17)**	0.0030 **(0.27)**
Benzene eluate	2.6982 **(98.17)**	0.9097 **(81.51)**
Methanol eluate	0.2421 **(8.81)**	0.0672 **(6.02)**
Total recovery	2.9448 **(107.15)**	0.9798 **(87.79)**

2. Identification, characterization and quantitation of extractable residues

Unchanged pyraclostrobin was the principal radioactive component in both outer leaves and the leaf-ball. This compound accounted for 82.9% (2.28 mg/kg) and 82.5% (3.03 mg/kg) of the TRR in outer leaves of C-ring label and T-ring label treated plants, respectively. For the leaf-ball, BAS 500 F represented 74.2% (0.83 mg/kg) and 85.1% (1.01 mg/kg) of the TRR in the C-ring label and the T-ring label treated plants, respectively. The principal metabolite was found to be 500M07 (BF 500-3). The residue levels of this metabolite in the outer leaves of the C-ring label and the T-ring label treated plants was 8.5% (0.23 mg/kg) and 11.9% (0.44 mg/kg), respectively. The metabolite also accounted for 5.6% (0.06 mg/kg) and 10.6% (0.13 mg/kg) of the TRR in the leaf-ball of the C-ring label and the T-ring label treated plants, respectively.
In addition to metabolite 500M07, several minor radioactive metabolites were found in the extracts of the C-ring label and/or the T-ring label treated plants. None of these metabolites, however, matched with available reference standards by HPLC and TLC co-chromatography. Two minor metabolites were found to contain only C-ring label, whereas other several minor metabolites contained both C-ring moiety and T-ring moiety. The residue levels of these minor metabolites were extremely low. For example, the most abundant minor metabolite, Unknown CT1, accounted for only 2.6% (0.07 mg/kg) and 3.7% (0.13 mg/kg) of the TRR in the outer leaves of the C-ring label and the T-ring label treated plants, respectively. For the leaf-ball, this metabolite represented 1.6% (0.02 mg/kg) and 1.7% (0.02 mg/kg) of the TRR in the C-ring label and the T-ring label treated plants, respectively.

The quantification of the individual metabolites present in the different plant matrices is summarized in Table 6.2.1-13 (^{14}C-tolyl-BAS 500 F) and Table 6.2.1-14 (^{14}C-chlorophenyl-BAS 500 F).

Table 6.2.1-13: Summary of identified components in Chinese cabbage samples after treatment with ^{14}C-tolyl-BAS 500 F

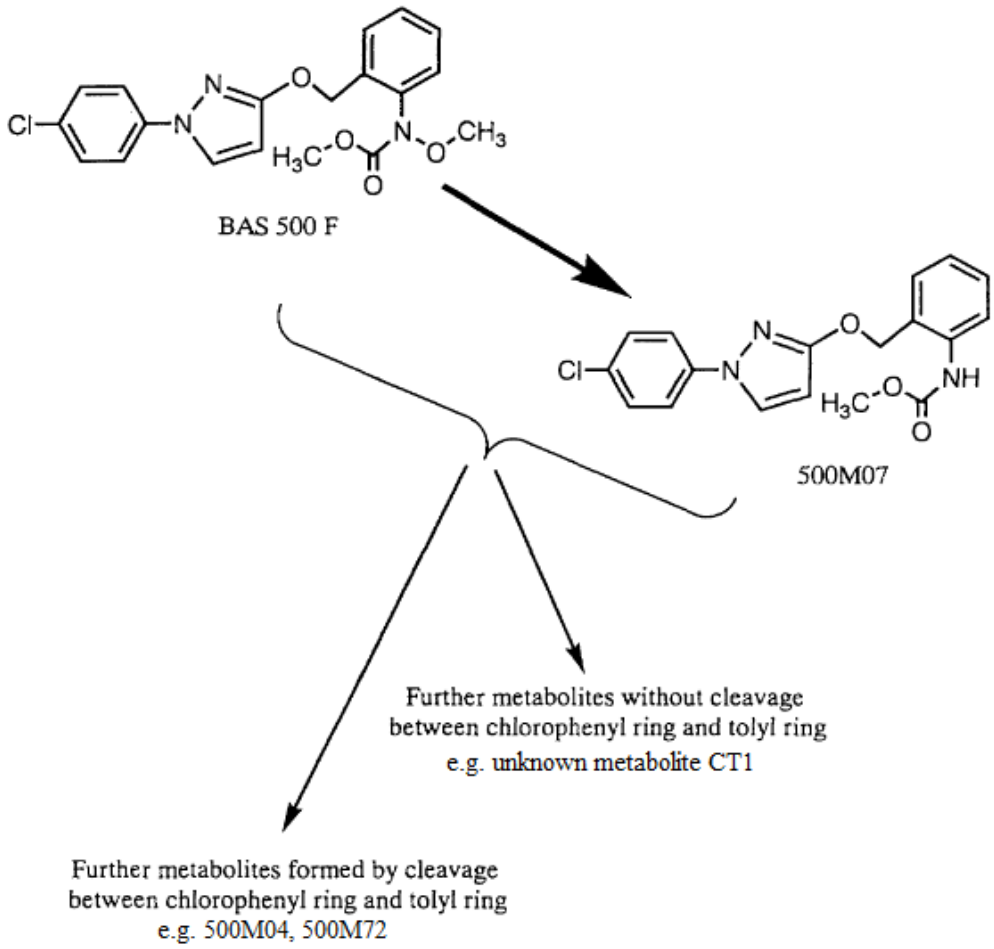
3. Proposed metabolic pathway

In Chinese cabbage, pyraclostrobin is metabolized by desmethoxylation which resulted in the formation of the metabolite 500M07 (BF 500-3). Cleavage of the molecule resulting in the metabolites 500M04 (BF 500-5) and 500M72 (tryptophan) is occurring to a minor extent. Besides these reactions, metabolites being considerably more polar than parent / 500M07 were found in both labels, but in low amounts (clearly below 5% TRR). No incorporation into bound residues was observed.

Figure 6.2.1-6: Proposed metabolic pathway of BAS 500 F in Chinese cabbage



III. CONCLUSION

The proposed metabolic pathway of pyraclostrobin in Chinese cabbage is presented in Figure 6.2.1-6**. The investigation of the metabolism of BAS 500 F in Chinese cabbage using material labeled in either the tolyl or the chlorophenyl ring leads to the conclusion that the predominant residue in outer leaves and leaf ball consists of the parent compound pyraclostrobin and its metabolite 500M07. Some other components which were identified as products formed by cleavage of the molecule, O-glucosylation or methoxylation turned out to be of minor importance, because their respective amount is far below 10% of the TRR (amounts ranged between <0.16 and 3.65% of the TRR).**

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: chlorophenyl-U-C14-BAS 500 F, tolyl-U-C14-BAS 500 F, pyrazole-3-C13-BAS 500 F

Description:	carbon-14 chlorophenyl ring labelled (6.57 MBq/mg) carbon-14 tolyl ring labelled (7.32 MBq/mg) carbon-13 pyrazole labelled pyraclostrobin
Lot/Batch #:	^{14}C-BAS 500 F (chlorophenyl): 579-6103 ^{14}C-BAS 500 F (tolyl): 566-4201 ^{13}C-BAS 500 F (pyrazole): 1026-1018
Purity:	^{14}C-BAS 500 F (chlorophenyl): 98.3% (radiochemical), 97.6% (chemical) ^{14}C-BAS 500 F (tolyl): 99.4% (radiochemical), 97.8% (chemical) ^{13}C-BAS 500 F (pyrazole): 99.8% (chemical)
CAS#:	175013-18-0
Stability of test compound:	The test item was stable for at least 11 month

2. Test Commodity: Cereals

Crop:	Rice
Type:	Paddy rice
Variety:	Thaibonnet
Botanical name:	*Oryza sativa L.*
Crop parts(s) or processed Commodity:	Forage, spelts & straw (combined), grain
Sample size:	Forage: 673.1 g (chlorophenyl) and 792.4 g (tolyl) Straw: 1675.7 g (chlorophenyl) and 1576.0 g (tolyl) Grain: 945.4 g (chlorophenyl) and 974.3 g (tolyl)

3. Soil: A sandy loam soil was used. The soil physicochemical properties are described below (see Table 6.2.1-15).

B. STUDY DESIGN AND METHODS

1. Test procedure

Two different application solutions were used for the investigations. For the chlorophenyl label chlorophenyl-U-C14-labelled and pyrazole-3-C13-labelled test item were mixed in a ratio of 2:1. The tolyl label comprised a mixture of tolyl-ring-U-C14-labelled, pyrazole-3-C13-labelled and unlabelled test item in a ratio of 50:33:17 (14C:13C:12C).

Figure 6.2.1-7: Structural formula of ^{14}C-BAS 500 F labelled at the chlorophenyl ring

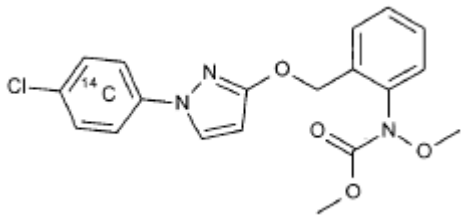

Figure 6.2.1-8: Structural formula of ^{14}C-BAS 500 F labelled at the tolyl ring

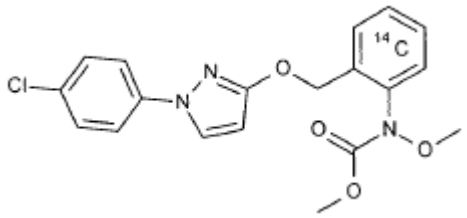

Figure 6.2.1-9: Structural formula of pyrazole-3-C13-labelled pyraclostrobin

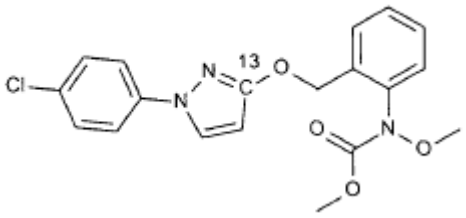

Figure 6.2.1-10: Structural formula of unlabelled pyraclostrobin

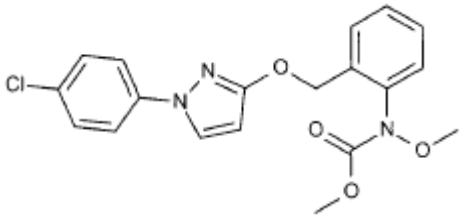

For each test item mixture, two foliar spray applications were performed with BAS 500 GG F (CS formulation), each with a nominal application rate of 100 g a.s./ha. The first application was carried out at growth stage BBCH 39, the second at BBCH 69. Forage samples of both labels were taken one day before the second application. Straw, grain and spelts were sampled from mature rice plants at BBCH 89. The spelts were combined with straw.
All samples were stored at -18°C or below until analysis. Subsamples of rice straw and grain were extracted with methanol and water 69 - 71 days after sampling, forage samples were extracted 126 / 127 days after sampling.

The rice was sown into two multicells filled with sandy loam soil. Physical and chemical properties of sandy loam soil are given in Table 6.2.1-15.

Table 6.2.1-15: Soil characteristics: soil used for sowing

USDA classification	
clay	9.3%
silt	20.6%
sand	70.1%
soil class	sandy loam
DIN classification

max. water holding capacity	27.7 g/100 g dry soil
microbial biomass	38.7 mg C/100 g dry soil
microbial C / organic C	2.8%
bulk density	1269 g/L
dry matter	91.9%

2. Description of analytical procedures

All samples (forage, straw and grain) were homogenized with a knife mill along with dry ice. After sublimation of the dry ice, the samples were weighed, mixed, divided into aliquots and radioassayed.
The total radioactive residues (TRR) were determined by direct combustion analysis of small aliquots of homogenized sample material. The sample material was combusted by means of an automatic sample oxidizer. The $^{14}CO_2$ was trapped by an absorption and scintillation liquid, and the collected radioactivity was measured by liquid scintillation counting.
Aliquots of liquid samples were mixed with a sufficient volume of a suitable scintillator prior to measurement.

The homogenized samples (rice forage, straw and grain) were extracted with methanol and water. *Methanol extracts* were concentrated and investigated by radio HPLC. The column used was a Phenomenex Synergi Polar RP, the eluent system consisted of 2 mobile phases (A: water/acetonitrile/formic acid, 950/50/2.5, v/v/v & B: water/acetonitrile/formic acid, 50/950/2.5, v/v/v) which were used applying gradient elution. *Water extracts* were concentrated, centrifuged and also investigated by HPLC.

The residual radioactive residue (RRR) after solvent extraction was extracted with ammonia and successively solubilized with mixtures of macerozyme / cellulase and tyrosinase / laccase and for grain also with amylase / amyloglucosidase. Residues in solubilizates of the straw specimens (both labels) were concentrated, if necessary centrifuged and analyzed by HPLC using method LC05. Due to the low residue levels, the solubilizates of the grain and forage specimens (both labels) were not analyzed by HPLC.

In case of the tolyl label, after extraction with cyclohexane, some further purification steps were applied using acetonitrile. Finally, the sample was resuspended in water/acetonitrile and subsequently fractionated by HPLC. The fractions were concentrated and analyzed by HPLC-MS.

In case of the chlorophenyl label, after extraction with cyclohexane, some further purification steps were applied using SPE (MegaBondElut, C18) and an eluent system consisting of water and methanol with increasing concentration of methanol. Finally, the obtained sample was fractionated. The fractions were concentrated and analyzed by HPLC-MS.

The active substance pyraclostrobin (BAS 500 F) and its desmethoxy metabolite 500M07 were identified by HPLC-MS analysis of purified fractions from rice grain methanol extracts (both labels). Peak assignment in forage, straw and grain methanol extracts was additionally supported by HPLC co-chromatography experiments and retention time comparison with reference items of BAS 500 F and 500M07 or well-characterized extracts.

II. RESULTS AND DISCUSSION

A. TOTAL RADIOACTIVE RESIDUES (TRRs)

Aliquots of the homogenized samples were successively extracted with methanol and water. The Total Radioactive Residues (TRR) was determined by summarizing the Extractable Radioactive Residues (ERR) and the Residual Radioactive Residues (RRR) after solvent extraction. The total radioactive residues in forage sampled 1 day before the second treatment accounted for 1.924 mg/kg and 1.622 mg/kg (chlorophenyl label and tolyl label, respectively). The highest radioactive residues were found in rice straw samples accounting for 8.564 mg/kg (chlorophenyl label) and 10.503 mg/kg (tolyl label). In rice grain, lower residue levels were found for both labels (chlorophenyl label: 1.948 mg/kg, tolyl label: 2.112 mg/kg).

Additionally, the TRR was measured by direct combustion analysis of homogenized sample material. The measured TRR showed no major differences to the calculated TRR values. Slightly larger deviations found for rice straw of the chlorphenyl label may be caused by inhomogeneity of the sample material and the low amounts used for combustion.

The levels of total radioactive residues (TRR) of pyraclostrobin found in rice forage, straw and grain are reported in Table 6.2.1-16.

Table 6.2.1-16: Total radioactive residues in rice samples

Rice matrix	Sampling Interval (DAT[1])	TRR determined by direct combustion [mg/kg]	TRR calculated[2] [mg/kg]
Chlorophenyl Label			
Forage[3]	-1	2.021	1.921
Straw	57	7.271	8.564
Grain	57	2.075	1.948
Tolyl Label			
Forage[3]	-1	1.557	1.622
Straw	57	10.776	10.503
Grain	57	2.031	2.112

[1] DAT = Days After Treatment
[2] TRR was calculated as the sum of ERR + RRR
[3] Forage was sampled one day before the second application, thus the samples of forage had received only one application

B. EXTRACTION, CHARACTERIZATION AND IDENTIFICATION OF RESIDUES

1. Extraction of residues

For the investigations of metabolic patterns, subsamples of forage, straw and grain were extracted with methanol and water. The extractability with methanol and water was high in rice forage (chlorophenyl label: 86.5% TRR, tolyl label: 83.5% TRR). For rice straw, the extractability was lower with 68.5% TRR (chlorophenyl label) and 64.8% TRR (tolyl label). From rice grain 75.6% TRR (chlorophenyl label) and 71.4% TRR (tolyl label) were extracted by solvent extraction. The major part of the radioactivity was extracted with methanol, while water released only minor portions (1.9 – 7.8% TRR) from rice forage, straw and grain.

Table 6.2.1-17: Extractability of radioactive residues in rice samples

Matrix	TRR Calculated [1] mg/kg	Combined Methanol Extract		Combined Water Extract		ERR [2]		RRR [3]	
		mg/kg	% TRR	mg/kg	% TRR	mg/kg	% TRR	mg/kg	% TRR
Chlorophenyl Label									
Forage [4]	1.921	1.604	83.5	0.058	3.0	1.662	86.5	0.259	13.5
Straw	8.564	5.193	60.6	0.672	7.8	5.865	68.5	2.699	31.5

[1] TRR was calculated as the sum of ERR + RRR (ERR and RRR see below)
[2] ERR = Extractable Radioactive Residue (extraction with methanol and water)
[3] RRR = Residual Radioactive Residue (after solvent extraction with methanol and water)
[4] Forage was sampled one day before the second application, thus the samples of forage had received only one application

2. Identification, characterization and quantitation of extractable residues

The active substance pyraclostrobin (BAS 500 F) and its desmethoxy metabolite 500M07 (BF 500-3) were identified by HPLC-MS, co-chromatography and retention time comparison.
The results of the analysis of rice forage, straw and grain are summarized in Table 6.2.1-18 to Table 6.2.1-23.

TRR in rice forage (chlorophenyl label) accounted for 1.921 mg/kg, whereby pyraclostrobin and metabolite 500M07 were identified in ERR with 1.165 mg/kg (60.7% TRR) and 0.312 mg/kg (16.3% TRR), respectively. In total, 1.960 mg/kg were identified and characterized (ERR and RRR, including the final residue), representing 102.0% of TRR.
Further components in the methanol and water extracts were characterized by their chromatographic properties which each single peak less or equal to 5.9% TRR. The solubilization steps released altogether further portions of 4.9% from forage.

Table 6.2.1-18: Summary of identified and characterized residues of rice forage (chlorophenyl label)

TRR in rice forage (tolyl label) accounted for 1.622 mg/kg, whereby pyraclostrobin and metabolite 500M07 were identified in ERR with 1.189 mg/kg (73.3% TRR) and 0.140 mg/kg (8.6% TRR), respectively. In total, 1.648 mg/kg were identified and characterized (ERR and RRR, including the final residue), representing 101.6% of TRR.
Further components in the methanol and water extracts were characterized by their chromatographic properties which each single peak less or equal to 1.7% TRR. The solubilization steps released altogether further portions of 6.7% from forage.

TRR in rice straw (chlorophenyl label) accounted for 8.564 mg/kg, whereby pyraclostrobin and metabolite 500M07 were identified in ERR with 3.794 mg/kg (44.3% TRR) and 1.477 mg/kg (17.3% TRR), respectively. In total, 8.067 mg/kg were identified and characterized (ERR and RRR, including the final residue), representing 94.2% of TRR.
Further components in the water extracts were characterized by their chromatographic properties which each single peak less or equal to 2.8% TRR.
The solubilization steps released altogether further portions of 14.9% from straw.
