CP 1.2 Producer of the plant protection product and the active substances

Manufacturer of BAS 500 06 F (legal entity):

BASF SE
67056 Ludwigshafen
Germany
Crop Protection Division:
P.O. Box 120
67114 Limburgerhof
Germany

Contact person: Please refer to CP 1.1 Applicant.

Location of the manufacturing site of BAS 500 06 F:

Confidential information - data provided in Document J.

Manufacturer of pyraclostrobin (legal entity):

BASF SE
67056 Ludwigshafen
Germany
Crop Protection Division:
P.O. Box 120
67114 Limburgerhof
Germany

Contact person: Please refer to CP 1.1 Applicant.

Location of the manufacturing site of pyraclostrobin:

Confidential information - data provided in Document J.

CP 1.3 Trade names or proposed trade name and producer's development code number of the plant protection product if appropriate

Code number: BAS 500 06 F

Trade Names: BAS 500 06 F, Comet 20 EC, Comet 200, Comet Pro, Modem 200, Platoon, Retengo, Retengo New, Solaram 200

CP 1.4 Detailed quantitative and qualitative information on the composition of the plant protection product

Pyraclostrobin pure active substance:

Minimum purity: 975 g/kg

CP 1.4.1 Composition of the plant protection product

Pure active substance

content of pure active substance:	**200.0 g/L**	**(19.16% w/w)**
limits:	188.00 – 212.00 g/L	(18.01 – 20.31% w/w)

Technical active substance [1)]

content of technical active substance:	**205.13 g/L**	**(19.65% w/w)**
limits:	192.82 – 217.44 g/L	(18.47 – 20.83% w/w)

[1)] at a minimum purity of technical pyraclostrobin of 97.5%

Safeners, synergists and co-formulants

Confidential information - data provided in Document J.

CP 1.4.2 Information on the active substances

Type	Name/Code Number
ISO common name	pyraclostrobin
CAS No	175013-18-0
EC No	n.a.
CIPAC No	657
salt, ester anion or cation present	none

CP 1.4.3 Information on safeners, synergists and co-formulants

Confidential information - data provided in Document J.

CP 1.5 Type and code of plant protection product

Nature: Emulsifiable concentrate [Code: EC]

CP 1.6 Function

Fungicide

Table of Contents

CP 2 PHYSICAL AND CHEMICAL PROPERTIES OF THE PLANT PROTECTION PRODUCT

BAS 500 06 F is a new representative formulation, which has not been evaluated during the previous Annex I inclusion process.

All tests have been performed in GLP-certified laboratories.

Test or study & Data point	Guideline and method	Test material purity and specification	Findings	GLP Y/N	Reference
CP 2.1 Appearance	Visual assessment and organoleptic determination	8241 205.04 g/L	BAS 500 06 F is a dark yellow liquid with a moderate naphthalene-like odour (remains unchanged after accelerated storage test).	Y	[see 2004/1010381 Kaestel R. 2004 a]
CP 2.2 Explosive and oxidising properties	UN test O.2 OECD 113	8241 200 g/L	The test substance is not considered to be an oxidising substance according to the UN recommendations on the Transport Of Dangerous Goods (Division 5.1). The test EEC A 14 has been omitted, because the exothermic decomposition energy determined by a DSC is less than 500 J/g.	Y	[see 2004/1004104 Loeffler U. 2004 a]
CP 2.3 Flammability and self-heating	EEC A9.1.6.3.2 EEC A15	8241 205.04 g/L 8241 200 g/L	The flash point of BAS 500 06 F is 104°C. Auto-flammability: 450°C (self-ignition temperature)	Y Y	[see 2004/1010381 Kaestel R. 2004 a] [see 2004/1004104 Loeffler U. 2004 a]
CP 2.4 Acidity/alkalinity and pH value	CIPAC MT 75	8241 205.04 g/L	The pH of BAS 500 06 F was determined to be 6.5 (1% in CIPAC water D) and 6.1 (1% in pure water). The values do not change throughout the storage period.	Y	[see 2004/1010381 Kaestel R. 2004 a]

</table>
After 7 days at 0°C, no separated material could be observed. The sample remained homogenous.
The product is stable for all tested storage intervals and temperatures.

<u>Content of dimethyl sulfate:</u>
Dimethyl sulfate could not be detected in BAS 500 06 F (see M-CP 5.1.1). Furthermore, it is not formed during the production process of the formulation and its content in formulation does not increase during storage, because it is a molecule with a high energy content.
No significant changes of the physical properties: appearance, odour, pH-value, density and emulsion stability (see corresponding Annex points) were found after the accelerated storage stability test in glass bottles.

09-June-2015	The document according to SANCO/2012/11251 (following data point 3.8) was revised in order to a) better reflect the applicant's intention to achieve the renewal of approval for both, the use as fungicide and the use as plant growth regulator b) have the complete information for the representative uses in this document instead of referring to M-CA, section 3 c) shorten table 2 (critical uses only instead of all registered uses). New or changed text is marked in yellow.	BASF DocID 2015/1106131 (version 2)

[1] It is suggested that applicants adopt a similar approach to showing revisions and version history as outlined in SANCO/10180/2013 Chapter 4 How to revise an Assessment Report

Table of Contents

CP 3 DATA ON APPLICATION

BAS 500 06 F is a new representative formulation, which has not been evaluated during the previous Annex I inclusion process.

CP 3.1 Field of use envisaged

Please see below efficacy information according to SANCO/2012/11251 (chapter 3).

CP 3.2 Effects on harmful organisms

Please see below efficacy information according to SANCO/2012/11251 (chapter 8).

CP 3.3 Details of intended use

Please see below Table 2 in the efficacy information according to SANCO/2012/11251 (following chapter 8).

CP 3.4 Application rate and concentration of active substance

Please see below Table 2 in the efficacy information according to SANCO/2012/11251 (following chapter 8).

CP 3.5 Method of application

Please see below efficacy information according to SANCO/2012/11251 (chapter 7).

CP 3.6 Number and timing of applications and duration of protection

Please see below for general information M-CP 3.8 and for detailed information Table 2 (following chapter 8) of the efficacy information given according to SANCO/2012/11251.

BAS 500 06 F can provide control for up to seven weeks after application when applied before the start of foliar disease attack.

CP 3.7 Necessary waiting periods or other precautions to avoid phytotoxic effects on succeeding crops

Pyraclostrobin has been applied since many years with a several different formulations across a wide range of crops without any reports of a phytotoxic effects on succeeding crops. Due to the broad range of crops in which the product has been used, most rotational crop possibilities have been appeared in practise. Therefore no negative impact on succeeding crops is to be expected. Consequently, there is no necessity for restrictions in the choice of following crops, even in the event of crop failure on a field which has been treated with BAS 500 06 F.

CP 3.8 Proposed instructions for use

BAS 500 06 F is a fungicide with protectant and curative properties for disease control in winter and spring wheat, winter and spring barley, oats, rye and triticale and with protectant properties for disease control in maize (forage and grain). Details are shown in the efficacy information according to SANCO/2012/11251 (chapter 8).

Time of application

Cereals
Apply BAS 500 06 F at the start of foliar disease attack. A maximum of two applications can be made, starting from mid tillering (BBCH 25) until end of flowering (latest application at BBCH 69). The described application window can be more limited in specific countries or for specific uses. The recommended spray interval is 21 days depending on disease pressure and the general spray program strategy.

Maize (forage and grain)
Best results are achieved by an application of BAS 500 06 F before the start of foliar disease attack or at very early signs of infection. Once disease is established in the crop, BAS 500 06 F can stop or reduce the development of the disease. Application can be made after beginning of stem elongation (earliest application at BBCH 30) and up to and including mid-flowering (BBCH 65).

Number and rate of application

Cereals
Apply maximum 2 times per season up to 1.25 L BAS 500 06 F in 100 – 400 L of water per ha.

Maize (forage and grain)
Apply maximum once per season up to 1.0 L BAS 500 06 F in 100 – 400 L of water per ha.

On the specific country labels additional detailed guidance for the use of the product e.g. with regard to filling and application, tank cleaning and field use are given considering the local requirements. These instructions will be covered by the dRRs to be submitted for the re-registration of the plant protection product BAS 500 06 F following the renewal of approval for the active substance pyraclostrobin.

Further information can be found in Document C.

Efficacy Information

Active Substance: Pyraclostrobin

Product Code: BAS 500 06 F
200 g/L EC

Applicant: BASF SE
Date: 09/June/2015

Statement

Pyraclostrobin, the active substance contained in the plant protection product BAS 500 06 F, has been tested in field development trials which demonstrated efficacious activity against a broad range of fungal diseases. It was included in Annex I of Directive 91/414/EEC on 1 June 2004 (entry into force) under Inclusion Directive 2004/30/EC for the use as fungicide. This use was amended on 22 April 2009 (entry into force) by Inclusion Directive 2009/25/EC to the use as fungicide or plant growth regulator.

BAS 500 06 F is registered in many EU countries (for details please see Table 1) based on detailed national assessments of the efficacy data package in compliance with Regulation (EC) No 545/2011 and according to the Uniform Principles as given in Regulation (EC) No 546/2011.

1. INTRODUCTION

This document summarises the information related to the efficacy of the representative formulation BAS 500 06 F containing pyraclostrobin as active substance for which a dossier has been submitted for the renewal of approval.

2. FUNCTION

BAS 500 06 F is used as a fungicide to control harmful diseases in cereals, maize and other crops. It shows local systemic and translaminar activity and can be used for preventative and curative treatments. In addition to the fungicidal effects, plant physiology can be also affected by the application of BAS 500 06 F, e.g. reduction of nonparasitic leaf spots in cereals or yield increase in the absence of fungal diseases. Pyraclostrobin is registered as fungicide and as plant growth regulator.

3. FIELD OF USE

BAS 500 06 F is used in agriculture in several crops for the control of a broad range of harmful and economically important pathogens. In addition it is applied due to its physiological effects.

4. SUPPORTED USES

BAS 500 06 F in cereals and maize had been identified as representative uses to support the renewal of approval for the active substance pyraclostrobin (for details see Tables 1 and 2).

These uses are representative because of

- their wide geographical distribution covering the Southern, Central and Northern Zone
- their broad range of controlled diseases
- their different application timings
- their agricultural importance in the EU
- their importance in the human diet (including their huge importance as feedstuff being the basis for food of animal origin)

BAS 516 07 F in potatoes had been identified as an additional representative use to support the renewal of approval for the active substance pyraclostrobin (for details see separate dossier for BAS 516 07 F).

5. OVERVIEW OF CURRENT REGISTRATIONS

Current registrations of BAS 500 06 F in the EU for the representative uses (cereals and maize) are shown in Table 1.
Besides the use of BAS 500 06 F in cereals and maize, many other uses of pyraclostrobin containing plant protection products are registered covering all EU member states and most of the crops professionally cultivated (further information on these additional uses can be found in M-CA 3.5). In addition to various solo formulations other active substances such as boscalid, dimethomorph, dithianon, epoxiconazole, fenpropimorph, fluxapyroxad, folpet and metiram are used in pyraclostrobin containing mixture formulations (further information on these uses can be found in document D2).

6. HARMFUL ORGANISMS CONTROLLED AND CROPS TREATED

Harmful organisms controlled by BAS 500 06 F in cereals and maize are given in chapter 8 below.
An overview on additional harmful organisms controlled by pyraclostrobin and on additional crops treated in the EU with pyraclostrobin-containing formulations can be found in M-CA 3.5.

7. METHOD OF APPLICATION

BAS 500 06 F is applied in cereals and maize by broadcast foliar spraying using water as carrier. The water volume varies between 100 – 400 L/ha.

8. MODE OF ACTION - EFFECTS ON HARMFUL ORGANISMS

The **mode of action** for the active substance pyraclostrobin is described below for the use as fungicide and the use as plant growth regulator.

Use as fungicide

Pyraclostrobin belongs to the QoI group of fungicides. The mode of action is the inhibition of mitochondrial respiration resulting from a blockage of the electron transport from ubihydroquinone to cytochrome c by means of a binding to the ubihydroquinone oxidation centre (Qo) of the cytochrome bc1 complex (Complex III). This disrupts the mitochondrial electron transport chain, thus blocking phosphorylation further down in the respiratory chain. In consequence, this leads to a reduction of energy-rich ATP which is required to support a range of essential processes in the fungal cell such as maintenance of membrane potentials and concentration gradients up to DNA, RNA and protein biosynthesis. In the end, the various fungal development processes of spore germination, formation of infection structures, mycelium growth and sporulation are permanently disrupted.

Use as plant growth regulator

In addition to the effects on yield through inhibition of fungal pathogens, pyraclostrobin also delivers a positive effect on yield through influence on the plant metabolism and physiology.
A decrease in ethylene levels has been demonstrated in several lab studies after treatment with pyraclostrobin. This can explain the observed delay in senescence. The reduction in ethylene levels can result in a variety of cellular changes being involved in yield gain (e.g. by an increased and longer photosynthetic performance during the vegetation period of a treated crop):

- enhancement of cytokinin levels resulting in increased chlorophyll concentrations in the leaves
- higher catalase and superoxide dismutase (SOD) activities reducing reactive $O_2^{\cdot}$-levels producing e.g. H_2O_2, resulting in reduced chlorophyll degradation

Furthermore, studies demonstrated that pyraclostrobin increases nitrate reductase, improving nitrogen assimilation and nitrogen use efficiency.

In the following, information on the **foliar uptake** of pyraclostrobin and a description of its **general effects on harmful organisms** are given.

After application to the plant, the active ingredient is taken up via the leaf and then translocated at low rates via the transpiration flow. Due its relatively low mobility, it shows local systemic and translaminar activity. Because of its very high intrinsic activity, pyraclostrobin has been observed to have systemic effects in a number of authorized uses. By that, it can control fungal stages which have already become established in deeper tissue layers. Pyraclostrobin is thus suitable for preventative and curative treatments. Since the vapour pressure of pyraclostrobin is very low, a marked gas phase activity was not observed.

Pyraclostrobin is active against different fungal stages on and in the plant. When applied protectively, pyraclostrobin prevents not only the germination of fungal spores landing on the plant surface but also re-infection, since during these extremely energy-consuming phases fungi react very sensitively to disturbances of their mitochondrial respiratory chain. Due to its ability to penetrate into the leaf and its further translocation as well as its high intrinsic activity, it can also control fungal stages which have already become established in deeper tissue layers.

BAS 500 06 F is a fungicide with protectant and curative properties for disease control in winter and spring wheat, durum, spelt, winter and spring barley, oats, rye and triticale and with protectant properties for disease control in maize (forage and grain).

Details are summarized in the table below:

	Winter wheat	Spring wheat	Winter barley	Spring barley	Oats	Rye	Triticale	Maize (forage and grain)
Septoria spp.	X	X					X	
Yellow rust	X	X	X	X		X	X	
Brown rust	X	X	X	X		X	X	
Crown rust					X			
Net blotch			X	X				
Rhynchosporium			X	X		X		
Kabatiella zea								X
Puccinia sorghi								X
Exserohilum turcicum								X
Cochliobolus carbonum								X

In addition to its fungicidal effects, plant physiology is also effected by the application of BAS 500 06 F.

In cereals a reduction of nonparasitic leaf spots have been observed and a yield response may be obtained in the absence of visual disease.

In maize BAS 500 06 F can delay senescence and can improve the total greenness of the crop towards the end of the growing season. In addition, a grain yield response may be obtained in the absence of visual disease.

Table of Contents

CP 4 FURTHER INFORMATION ON THE PLANT PROTECTION PRODUCT

BAS 500 06 F is a new representative formulation, which has not been evaluated during the previous Annex I inclusion process.

CP 4.1 Safety intervals and other precautions to protect humans, animals and the environment

Pre-harvest interval (in days) for each relevant crop:
For cereals maximum two applications are intended at growth stages BBCH 25-69 corresponding to an approximate pre-harvest interval of 35 to 42 days.
For maize including sweet corn one application is intended at growth stages BBCH 30-65. The pre-harvest interval is defined by the growth stage at latest application.

Re-entry period (in days) for livestock, to areas to be grazed:
Because pyraclostrobin is not intended to be used in areas to be grazed, no re-entry period for livestock has to be defined.

Re-entry period (in hours or days) for man to crops, buildings or spaces treated:
The re-entry assessment is discussed in M-CP 7.2. Re-entry is possible after the spray deposits on the crops have dried given the worker is wearing adequate work clothing.

Withholding period (in days) for animal feeding stuffs:
In order to avoid residues above the MRL values proposed for products of animal origin, a withholding period of 35 days (after application) for cereal grains and 21 days for other cereal plant parts to be used as feeding stuff is recommended. In general, maize is fed at different growth stages to livestock. For ripe maize grain, the waiting period is given by the use directions. Green material can be fed to livestock about 1 to 2 weeks after application without exceedance of any MRL in milk or animal tissues. The same period is also applying for cobs with husks.

Waiting period (in days) between application and handling of treated products:
This is not relevant here since a post-harvest treatment is not intended for cereals and maize.

Waiting period (in days) between last application and sowing or planting succeeding crops:
No minimum waiting periods needs to be considered for phytotoxicity or for residues in follow-crops.

Information on specific conditions under which the preparation may or may not be used:
Not relevant

CP 4.2 Recommended methods and precautions

Report:	CP 4.2/1 Anonymous, 2015 a Safety data sheet - Retengo 2015/1280947
Guidelines:	EEC 1907/2006
GLP:	no

Precautions for safe handling

No special measures necessary if stored and handled correctly. Ensure thorough ventilation of stores and work areas. When using do not eat, drink or smoke. Hands and/or face should be washed before breaks and at the end of the shift.

Protection against fire and explosion:
Vapours may form ignitable mixture with air. Prevent electrostatic charge. Sources of ignition should be kept well clear. Fire extinguishers should be kept handy.

Conditions for safe storage including any incompatibilities

Segregate from foods and animal feeds.
Further information on storage conditions:
Keep away from heat. Protect from direct sunlight. Store protected against freezing.

Storage stability:
Storage duration: 60 months
Protect from temperatures below 0 °C and above 40 °C.
Changes in the properties of the product may occur if the product is stored below or above the indicated temperatures for extended periods of time.

Exposure controls

Personal protective equipment

Respiratory protection:
Suitable respiratory protection for higher concentrations or long-term effect: Combination filter for gases/vapours of organic, inorganic, acid inorganic and alkaline compounds (e.g. EN 14387 Type ABEK).

Hand protection:
Suitable chemical resistant safety gloves (EN 374) with prolonged, direct contact. Recommended is protective index 6 corresponding to > 480 minutes of permeation time according to EN 374, e.g. nitrile rubber (0.4 mm), chloroprene rubber (0.5 mm), butyl rubber (0.7 mm) etc.

Eye protection:
Safety glasses with side-shields (frame goggles), e.g. EN 166

Body protection:
Body protection must be chosen depending on activity and possible exposure, e.g. apron, protecting boots, chemical-protection suit (according to EN 14605 in case of splashes or EN ISO 13982 in case of dust).

General safety and hygiene measures
The statements on personal protective equipment in the instructions for use apply when handling crop-protection agents in final consumer packing. Wearing of closed work clothing is recommended. Store work clothing separately. Keep away from food, drink and animal feeding stuffs.

Waste treatment methods

Must be sent to a suitable incineration plant observing local regulations.

Contaminated packaging:
Contaminated packaging should be emptied as far as possible and disposed of in the same manner as the product.

Report: CP 4.2/2
Nolte M., 2010a
BAS 500 06 F: Effectiveness of Procedures for cleaning application equipment and protective clothing
2010/1048392
Guidelines: none
GLP: no

Note: This study was erroneously not contained in the application. It needs to be submitted, because BAS 500 06 F is a new representative formulation, which has not been evaluated during the previous Annex I inclusion process.

Any surplus spray solution containing BAS 500 06 F should be diluted with water at a ratio of 1:10 and sprayed onto the previously treated area according to the use instructions.

The spray equipment should be cleaned thoroughly immediately after use by draining the system completely and by rinsing spray tank, boom and nozzles two to three times with clean water, so that foam and remainders of BAS 500 06 F will be sufficiently removed. No plant damage can be caused when the equipment is used subsequently for other applications.

Protective clothing will be cleaned effectively when washed with usual laundry detergents.

CP 4.3 Emergency measures in the case of an accident

Report:	CP 4.3/1 Anonymous, 2015 a Safety data sheet - Retengo 2015/1280947
Guidelines:	EEC 1907/2006
GLP:	no

First aid measures

First aid personnel should pay attention to their own safety. If the patient is likely to become unconscious, place and transport in stable sideways position (recovery position). Immediately remove contaminated clothing.

If inhaled:
Keep patient calm, remove to fresh air, seek medical attention.

On skin contact:
Immediately wash thoroughly with soap and water, seek medical attention.

On contact with eyes:
Wash affected eyes for at least 15 minutes under running water with eyelids held open, consult an eye specialist.

On ingestion:
Immediately rinse mouth and then drink 200-300 ml of water, seek medical attention. Do not induce vomiting due to aspiration hazard.

Most important symptoms and effects, both acute and delayed
The most important potential symptoms are skin irritation or allergic skin reactions caused by skin contact, or eye irritation caused by eye contact. Furthermore, local irritation of the olfactory epithelium might be caused after repeated inhalation. BAS 500 06 F is classified as harmful if inhaled or swallowed.

Indication of any immediate medical attention and special treatment needed
Treat according to symptoms (decontamination, vital functions), no specific antidote known.

Fire-fighting measures

Suitable extinguishing media
Water spray, carbon dioxide, foam, dry powder

Special hazards arising from the product
The following substances or groups of substances can be released in case of fire:
Carbon monoxide, hydrogen chloride, carbon dioxide, nitrogen oxides, sulphur oxides, organochloric compounds

Advice for fire-fighters
Special protective equipment:
Wear self-contained breathing apparatus and chemical-protective clothing.
Further information:
In case of fire and/or explosion do not breathe fumes. Keep containers cool by spraying with water if exposed to fire. Collect contaminated extinguishing water separately, do not allow to reach sewage or effluent systems. Dispose of fire debris and contaminated extinguishing water in accordance with official regulations.

Accidental release measures

Personal precautions, protective equipment and emergency procedures
Do not breathe vapour or spray. Use personal protective clothing. Avoid contact with the skin, eyes and clothing.

Environmental precautions
Do not discharge into subsoil or soil. Do not discharge into drains, surface waters or ground-water.

Methods and material for containment and cleaning up
For small amounts:
Pick up with suitable absorbent material (e.g. sand, sawdust, general-purpose binder, kieselguhr).
For large amounts:
Dike spillage. Pump off product. Dispose of absorbed material in accordance with regulations. Collect waste in suitable containers, which can be labeled and sealed. Clean contaminated floors and objects thoroughly with water and detergents, observing environmental regulations. Cleaning operations should be carried out only while wearing breathing apparatus.

CP 4.4 Packaging, compatibility of the plant protection product with proposed packaging materials

BAS 500 06 F is marketed in high-density polyethylene containers with an inner barrier, e.g. polyamide (PA/PE). They are sealed by foil seals or by polyamide laminated PE-foam gaskets, protected by screw caps of polyethylene.

0.15 litre bottle	material:	PA/PE (Coex)
	shape/size:	cylindrical / approx. 63 mm diameter x 92 mm
	opening:	42 mm inner diameter
	closure:	polyethylene screw cap
	seal:	HF-seal
0.25 litre bottle	material:	PA/PE (Coex)
	shape/size:	cylindrical / approx. 63 mm diameter x 126 mm
	opening:	42 mm inner diameter
	closure:	polyethylene screw cap
	seal:	HF-seal
0.5 litre bottle	material:	PA/PE (Coex)
	shape/size:	cylindrical / approx. 69 mm diameter x 185.5 mm
	opening:	42 mm inner diameter
	closure:	polyethylene screw cap
	seal:	HF-seal
1 litre bottle	material:	PA/PE (Coex)
	shape/size:	cylindrical / approx. 88.5 mm diameter x 234 mm
	opening:	42 mm inner diameter
	closure:	Polypropylene/Polyethylene screw cap
	seal:	Induction sealed
1 litre eco-bottle	material:	PA/PE (Coex)
	shape/size:	cylindrical / approx. 88.5 mm diameter x 234 mm
	opening:	54 mm mm inner diameter
	closure:	Polypropylene/Polyethylene screw cap
	seal:	gasket
3 litre container	material:	PA/PE (Coex)
	shape/size:	rectangular / approx. 190 mm x 140 mm x 241 mm
	opening:	54 mm inner diameter
	closure:	polypropylene screw cap
	seal:	Induction sealed
5 litre container	material:	PA/PE (Coex)
	shape/size:	rectangular / approx. 190 mm x 140 mm x 313 mm
	opening:	54 mm inner diameter
	closure:	polypropylene screw cap
	seal:	HF-seal
5 litre eco-container	material:	PA/PE (Coex)
	shape/size:	rectangular / approx. 185 mm x 136 mm x 313 mm
	opening:	54mm inner diameter
	closure:	polypropylene screw cap
	seal:	gasket

10 litre container	material:	PA/PE (Coex)
	shape/size:	rectangular / approx. 230 mm x 165 mm x 375 mm
	opening:	54 mm inner diameter
	closure:	polypropylene screw cap
	seal:	Induction sealed
10 litre eco-container	material:	PA/PE (Coex)
	shape/size:	rectangular / approx. 230 mm x 187 mm x 358 mm
	opening:	54mm inner diameter
	closure:	polypropylene screw cap
	seal:	gasket

Report:	CP 4.4/1 Schreiner B., 2005a EU performance tests of BAS 500 06 F (Standard-Coex-Bottle, 1 L, Spec.-No. 775 5108) 2005/1025057
Guidelines:	none
GLP:	no

ADR-test 6.1.5.3 was performed for drop resistance. In this test, the tightness of the bottles was successfully tested. The leak test and the hydrostatic test (ADR 6.1.5.3 and 6.1.5.4) were also done. The stacking test (ADR 6.1.5.6) was not applicable (bottles are part of combination packaging). The permeation test according to ADR 6.1.5.8 showed an acceptable value of <0.008 g/Lh. Packagings are supplied in UN-approved combination packs (ADR 6.1.4.21).

These packagings meet the requirements for packaging group III as specified by the ADR/RID regulations for the transport of hazardous goods.

Report:	CP 4.4/2 Kroehl T., 2006a Shelf life at 23°C in original container of the formulation BAS 500 06 F, 24 month storage, analytical results and physical properties 2006/1019717
Guidelines:	OECD Principles of Good Laboratory Practice,GLP Principles of the German Chemikaliengesetz (Chemicals Act),GIFAP Technical Monograph No. 17 (May 1993),EEC 91/414 Annex III 2.7.3
GLP:	yes (certified by Landesamt fuer Umweltschutz und Gewerbeaufsicht, Mainz, Germany)

Note: In the application this study was only mentioned in section 2.

The study results prove that the original container material and the closure/seal resists to the product BAS 500 06 F. No corrosion of the container could be observed during the storage time.

CP 4.5 Procedures for the destruction or decontamination of the plant protection product and its packaging

CP 4.5.1 Neutralisation procedure

The pH of BAS 500 06 F is in a range between 5.6 and 6.8 in aqueous solution. Therefore, the proposal of a neutralisation procedure is not considered to be necessary. Any spilled product and contaminated soil or water has to be absorbed and disposed according to the use instructions.

CP 4.5.2 Controlled incineration

For purposes of disposal, combustion of BAS 500 06 F at a licensed incinerator is recommended. This method of disposal applies also to contaminated packages, which cannot be cleaned or reused.

Although it is possible to incinerate the product at lower temperatures, combustion at approximately 1100°C with a residence time of about 2 seconds is advised. By doing so, i.e. operating the incinerator according to the conditions laid down in council directive 94/67/EEC resp. directive 2000/76/EC of the European Parliament, one will achieve complete combustion and minimize the formation of undesired by-products in the off-gases.

Users are requested to triple rinse empty primary packages as described in the ECPA "Guidelines for the rinsing of agrochemical containers", 1993.

Pressure rinsing or integrated pressure rinsing of the packaging material achieves a similar or even better result. The rinsing water must be added to the spray liquid.

To minimize waste of packages it is recommended that empty and rinsed containers are delivered to local container collection stations. If these do not exist, empty and rinsed containers must be rendered unusable and disposed according to local regulations.

CP 5 ANALYTICAL METHODS

BAS 500 06 F is a new representative formulation, which has not been evaluated during the previous Annex I inclusion process.

CP 5.1 Methods for the generation of pre-authorisation data

CP 5.1.1 Analysis of the plant protection product

(a) Methods for the determination of the active substance and/or variant in the plant protection product

Report: CP 5.1.1/1
Ziegler H., Machauer B., 2003a
Analytical method CF-A 669: Quantitative determination of the active ingredient Pyraclostrobin in BAS 500 06 F by HPLC
2003/1022228
Guidelines: none
GLP: no

The method CF-A 669 is applicable for the determination of pyraclostrobin in the EC formulation BAS 500 06 F. A reversed phase HPLC method is used, utilizing a 4µm J'sphere ODS-H80 column. Detection is done by a UV detector at 230 nm, quantification is made by external standard.

Report:	CP 5.1.1/2 Ziegler H., 2004a Validation of the analytical method CF-A 669: Determination of the active ingredient Pyraclostrobin in BAS 500 06 F by HPLC 2004/1004041
Guidelines:	OECD Principles of Good Laboratory Practice, GLP Principles of the German Chemikaliengesetz (Chemicals Act)
GLP:	yes (certified by Landesamt fuer Umweltschutz und Gewerbeaufsicht, Mainz, Germany)

Report:	CP 5.1.1/3 Siebecker M., 2016 a BAS 500 06 F - additional document to the validation of the analytical method AFL0669/01 (formerly CF-A 669) 2016/1299807
Guidelines:	none
GLP:	no

Note:
Document BASF DocID 2016/1299807 provides readable chromatograms for the existing HPLC-method. The chromatograms contained in the validation report (BASF DocID 2004/1004041) on page 16 to 18 are unfortunately not well readable and had therefore to be provided in a better quality.

Method principle The active ingredient is dissolved from the samples of BAS 500 06 F by water and acetonitrile. The solution is chromatographed on an HPLC reversed phase system and pyraclostrobin is analyzed by means of UV detection using external calibration.

Findings The validation data of method CF-A 669 with respect to precision, accuracy, linearity and specificity prove that the method is suitable to determine the active ingredient in formulations of the type EC, e.g. in BAS 500 06 F.

Specificity The specificity was demonstrated by:
a) The retention times of the peaks of pyraclostrobin in BAS 500 06 F and the reference items are observed of the same value.
b) Identical UV-spectra of the compound peaks in the preparation and the reference items were measured.
c) The chromatogram of the blank formulation showed no interference with the active ingredient peak.

Linearity The linearity of response to the analyte was determined in a concentration series. The weights amounted to about 0.5, 0.75, 1.0, 1.25 and 1.5 times of the measured concentration. The test demonstrated linearity of response to the analyte concentration over the practical range of the method.

Slope (m): 67609
y axis intercept (b): -2845
Correl. coeff. (r^2): 1.0000

Accuracy Based on six replicates of a sample of blank formulation of BAS 500 06 F fortified with reference grade pyraclostrobin (BAS 500 F), the mean recovery has been determined to be 100.27%. The deviation of the values is given by the analysis errors and errors from preparing the test mixtures. Outliers or stragglers had not been identified.

Repeatability A production sample BAS 500 06 F was weighed six times and the active ingredient pyraclostrobin has been determined from this in accordance with the present analytical method.

Results for the formulation BAS 500 06 F:

Weight % (min, max)	Mean %	RSD %
19.138 – 19.230	19.19	0.194

It is situated in a range which can be expected by the used equipment and the analytical method in general. The RSD values meet the requirements given by the modified Horwitz equation.
Outliers or stragglers had not been identified.

Conclusion **The fortification experiments demonstrate that analytical method CF-A 669 is applicable to determine the content of pyraclostrobin in formulations of the type EC, e.g. in BAS 500 06 F.**

(b) Methods for determination of relevant impurities identified in the technical material or which may be formed during manufacture of the plant protection product or from degradation of the plant protection product during storage

Pyraclostrobin contains < 1mg/kg dimethyl sulfate. Information on the analytical method for determination of this impurity in the technical material can be found in M-CA 4.1.1. In the following, the method for determination of dimethyl sulfate in BAS 500 06 F is outlined.

Report: CP 5.1.1/4
Stegmaier W., 2011a
Gas chromatographic determination of dimethyl sulfate in BAS 500 06 F
2011/1009063
Guidelines: none
GLP: no

The method of analysis was developed in order to determine dimethyl sulfate in BAS 500 06 F. The method applied is a Headspace GC method with quantification by means of standard addition. The method was developed and validated in accordance with current GLP regulations.

Report: CP 5.1.1/5
Stegmaier W., 2011b
Validation of an analytical method for the determination of dimethyl sulfate in BAS 500 06 F
2011/1009064
Guidelines: OECD Principles of Good Laboratory Practice, GLP Principles of the German Chemikaliengesetz (Chemicals Act)
GLP: yes

Apparatus

- Capillary gas chromatograph (HP 6890, Agilent) equipped with headspace autosampler (HS 40 XL, Perkin Elmer) and mass spectrometer detector (MSD, HP 5975A, Agilent), connected to a chromatography data system (ChemStation, Agilent)
- Analytical balance (AT 250 and AT 261, Mettler)

Reagents and reference materials

- Dimethyl sulfate, purity ≥99peak area-% (GC), Merck
- Toluene, purity ≥99.9%, Merck
- "BAS 500 06 F batch 991017", blank formulation, identical with the test item but without active substance, supplied by the sponsor.

All samples, stock solutions and calibration standards were dissolved in toluene.

Headspace conditions

Temperature of equilibration:	90°C
Duration of equilibration:	60 min
Transfer line temperature:	150°C
Duration of pressurization:	0.3 min
Final headspace pressure:	2 bar
Duration of injection:	0.75 min

GC conditions

- Column

Fused silica capillary:	Rtx-1701 (Restek)
Length:	30 m
Internal diameter:	0.25 mm
Film thickness:	0.25 µm

- Carrier gas

Helium	
Column head pressure:	0.9 bar
Splitless injection	
Septum purge:	3 mL/min

- Temperatures

Oven:	50°C isothermal for 1 min 50°C → 160°C, 15 K/min 160°C → 270°C, 35 K/min 270°C isothermal for 22 min
Injector:	210°C

- Detector

MSD	
Acquisition mode:	SIM
EMV:	2435 V
Detection of selected ions:	**m/z = 95.0**, m/z=96.0, m/z=125.0
Temperature of source:	230°C
Temperature of quadrupole:	150°C

Validation

Specificity

Peaks in the gas chromatogram are assigned to the analyte dimethyl sulfate by comparison of retention times and by the selection of characteristic ions in MS-detection. Constituents of the sample which coelute with the analyte which yield the same ions as selected for dimethyl sulfate give rise to excessively high mass fractions.

Linearity

Linearity was tested in the case of external calibration without the influence of the sample matrix and for standard additions to the test item (with influence of active substances) and to the blank formulation “BAS 500 06 F batch 991017” (without influence of active substances).

Linearity (calibration solutions): Verified on 6 concentration levels in the range of 0.0872 mg/kg to 4.42 mg/kg:

Slope (m):	442815
y axis intercept (b):	68561
Correlation coefficient (r^2):	0.9993

Linearity (standard addition to test item): Verified on 7 concentration levels in the range of 0.0428 mg/kg to 4.35 mg/kg:

Slope (m):	454303
y axis intercept (b):	-2106
Correlation coefficient:	0.9991

In principle determinations are possible starting from 0.0428 mg/kg to higher concentrations. However, in order to be compliant to SANCO/3030/99 rev.4 the linear range was limited to a concentration range of 0.189 mg/kg to 4.35 mg/kg with a resulting coefficient of determination of 0.9989.

Linearity (standard addition to blank formulation): Verified on 6 concentration levels in the range of 0.0437 mg/kg to 4.50 mg/kg:

Slope (m):	553206
y axis intercept (b):	-19248
Correlation coefficient:	0.9997

Accuracy

Fortifications of approximately 0.2 and 0.8 mg/kg dimethyl sulfate were added to each - the test item BAS 500 06 F (batch 0003223026) and the blank formulation "BAS 500 06 F batch 991017".

Results:

The mean recovery value for dimethyl sulfate in the test item was 110%, RSD = 15.5% (0.2 ppm fortification) and 107%, RSD = 3.9% (0.8 ppm fortification).

The mean recovery value for dimethyl sulfate in the blank formulation was 99%, RSD = 7.6% (0.2 ppm fortification) and 102%, RSD = 4.3% (0.8 ppm fortification).

Precision	Precision was deduced from the standard deviation of the recoveries of 6 samples spiked with approximately 0.2 and 0.8 mg/kg each. The standard deviation for the 0.2 ppm fortification yielded 17.1% and for the 0.8 ppm fortification 4.2%.
Recovery	Recoveries were almost quantitative (see accuracy data). There is no significant difference in recoveries between the test item and the blank formulation indicating that there are no adverse effects of the active substances on the quantification of the analyte.
Conclusion	**The described method is a valid method for quantification of dimethyl sulfate in EC formulations, e.g. in BAS 500 06 F. Dimethyl sulfate could not be detected in the product.**

(c) Methods for the determination of relevant co-formulants or components of co-formulants, where required by the national competent authorities

Currently not required by EU legislation

CP 5.1.2 Methods for the determination of residues

Methods for the determination of residues are submitted and summarized in M-CA 4.1.2.

CP 5.2 Methods for post-authorisation control and monitoring purposes

Methods for the determination of residues in or on plants, plant products, processed food commodities, food and feed of plant and animal origin

Monitoring methods for plant and animal matrices are discussed in M-CA 4.2.

Methods for the determination of residues in body fluids and tissues

Monitoring methods for body fluids are discussed in M-CA 4.2.

Methods for the determination of residues in soil

Monitoring methods for soil are discussed in M-CA 4.2.

Methods for the determination of residues in water

Monitoring methods for water are discussed in M-CA 4.2.

Methods for the determination of residues in air, unless the applicant shows that exposure of operators, workers, residents or bystanders is negligible

As pyraclostrobin has a very low vapour pressure of 2.6×10^{-8} Pa (for details see M-CA 2.2), it is considered to be non-volatile. Consequently, inhalation exposure of operators, workers, residents or bystanders to vapours of pyraclostrobin is negligible. Further information can be found in M-CP 7.2.

CP 7 TOXICOLOGICAL STUDIES ON THE PLANT PROTECTION PRODUCT

BAS 500 06 F is a new representative formulation, which has not been evaluated during the previous Annex I inclusion process.

This document reviews the toxicological studies for BAS 500 06 F, an EC solo formulation containing 200 g/L pyraclostrobin. In addition, a full risk assessment is provided, which shows that BAS 500 06 F is safe for operators, workers, bystanders and residents (for details please see M-CP 7.2). Information on the detailed composition of BAS 500 06 F can be found in the confidential part of the dossier (Document J).

CP 7.1 Acute toxicity

The acute toxicity of BAS 500 06 F is assessed using the studies listed below in Table 7.1-1. BAS 500 06 F is moderately toxic by the oral and inhalation route of exposure and non-toxic by the dermal route. It is irritant to the skin and the eye and may cause skin sensitization.

Table 7.1-1: Summary of acute toxicity studies conducted with BAS 500 06 F

Type of study	Result Classification	Reference (BASF DocID)
Oral route - rat	LD_{50} ~ 500 mg/kg bw EU classification: Xn, R22 CLP classification: Cat. 4, H302	CP 7.1.1/1 (2007/1053390)
Dermal route - rat	LD_{50} > 5000 mg/kg bw EU classification: not required CLP classification: not required	CP 7.1.2/1 (2009/1084157)
Inhalation route - rat	LC_{50} = 4.48 mg/L (both sexes) LC_{50} = 4.78 mg/L (males) LC_{50} = 4.55 mg/L (females) EU classification: Xn, R20 CLP classification: Cat. 4, H332	CP 7.1.3/1 (2009/1122167)
Skin irritation - rabbit	Irritating to rabbit skin EU classification: Xi, R38 CLP classification: Cat. 2, H315	CP 7.1.4/1 (2009/1100358)
Eye irritation - rabbit	Irritating to rabbit eye EU classification: not required CLP classification: Cat. 2, H 319	CP 7.1.5/1 (2009/1100359)
Skin sensitization - LLNA-Assay	Sensitizing EU classification: Xi, R43 CLP classification: Cat. 1, H317	CP 7.1.6/1 (2007/1053391)
Skin sensitization – Maximization Test		CP 7.1.6/2 (2009/1018498)

CP 7.1.1 Oral toxicity

Report: CP 7.1.1/1
[redacted] 2008a
BAS 500 06 F: Acute oral toxicity study in rats
2007/1053390
Guidelines: OECD 423, EEC 2004/73 B.1 tris, EPA 870.1100
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In an acute oral toxicity study groups of 3 fasted female Wistar rats were administered single doses of 2000, 500 and 300 mg/kg bw of BAS 500 06 F. The high dose was administered undiluted at a volume of 1.92 mL/kg bw. The lower dose levels were administered as diluted emulsion in bidistilled water at a volume of 2 mg/kg bw. The observation period was 14 days.
Administration of 2000 mg/kg bw of BAS 500 06 F resulted in the death of all animals at day 1 (i.e. the day after administration). Whereas the first administration of a dose of 500 mg/kg bw did not result in mortality, the second administration of this dose resulted in the death of 2 animals within 2 hours after administration, i.e. 2 of 6 animals died at 500 mg/kg bw. No mortality was observed after administration of 300 mg/kg bw in two independent experiments. Accordingly, the oral LD_{50} was about 500 mg/kg bw.

oral LD_{50} ~ 500 mg/kg bw

Treatment-related gross necropsy findings were restricted to animals which died. These consisted of lung edema at 500 mg/kg bw and of red and black discoloration of the contents of the small intestines at 2000 mg/kg bw.

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 500 06 F is to be classified as "harmful if swallowed" (Xn, R22 and Cat. 4, H302).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 06 F

Description:	liquid
Density:	1.044 g/mL
Lot/Batch #:	8265
Purity/content:	Pyraclostrobin (= BAS 500 F): 202.7 g/L
Stability of test compound:	Stable (Expiry date: 31-Jan-2008; see Analytical Certificate)

2. Vehicle and/or positive control: bidistilled water

3. Test animals:

Species:	Rat
Strain:	Wistar, HanRcc:WIST(SPF)
Sex:	female
Age:	8 - 12 weeks
Weight at dosing (mean):	184.3 ± 6.7 g
Source:	RCC Ltd Laboratory Animal Services, CH-4414 Füllinsdorf, Switzerland
Acclimation period:	At least 5 days
Diet:	Kliba Laboratory Diet (Maus / Ratte Haltung "GLP"), Provimi Kliba SA, Kaiseraugst, Switzerland, ad libitum
Water:	Tap water, ad libitum
Housing:	Single housing in Makrolon cages, type III; Bedding: Lignocel FS14; SSNIFF; Environmental enrichment: Wooden gnawing blocks (Type NGM E-022); Abedd® Lab. and Vet. Service GmbH Vienna, Austria

Environmental conditions:

Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	Fully air-conditioned rooms; number of air-changes not indicated in the report
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 19-Jun-2007 to 22-Oct-2007
20-Jun-2007 to 14-Aug-2007 (in-life phase)

2. Animal assignment and treatment:
Groups of 3 female rats received single doses of 2000 mg/kg bw, 500 mg/kg bw (2 groups) and 300 mg/kg bw (2 groups) of the formulation by oral gavage. Prior to administration the animals were deprived of food for 16 hours, however had free access to water.
The top dose was administered undiluted (1.92 mL/kg bw) whereas the lower doses were administered as aqueous dilutions (25 and 15 g/100 mL) at a volume of 2 mg/kg bw. The aqueous dilutions were prepared shortly before administration. Homogeneity was ensured by constant stirring with a magnetic stirrer.
Animals were observed for signs of toxicity and behavioral changes several times on the day of administration, and at least once each workday for the remainder of the 14-day observation period. A check for mortality/morbidity was performed twice each workday and once on Saturdays, Sundays and on public holidays.
Body weights were recorded at day 0 (prior to dosing), weekly thereafter and at the end of the observation period. Additionally, body weights were determined when animals died or were sacrificed moribund.
Necropsy with gross-pathology examination was performed on the last day of the observation period. The animals were sacrificed by CO_2-inhalation. For animals that died prior to the scheduled study termination, necropsy was performed as early as possible.

II. RESULTS AND DISCUSSION

A. MORTALITY

Administration of 2000 mg/kg bw of BAS 500 06 F resulted in the death of all animals at day 1 (day after administration). Whereas the first administration of a dose of 500 mg/kg did not result in mortality, the second administration of this dose resulted in the death of 2 animals within 2 hours after administration. No mortality was observed after administration of 300 mg/kg bw in two independent experiments (see Table 7.1.1-1).

Table 7.1.1-1: Mortality of rats administered BAS 500 06 F by the oral route

Sex	Dose [mg/kg bw]	No. of administration	Cumulative mortality	Time of deaths
Female	2000	1st	3/3	d1 (3x)
	500	1st	0/3	-
	500	2nd	2/3	h2 (2x)
	300	1st	0/3	-
	300	2nd	0/3	-

h = hour after administration, d1 = day after administration

B. CLINICAL OBSERVATIONS

Clinical signs of toxicity were observed at all dose levels. The type, incidence and duration of clinical signs are given in Table 7.1.1-2.

Table 7.1.1-2: Clinical signs in rats administered BAS 500 06 F by the oral route (incidence / duration)

Dose [mg/kg bw]	300	300	500	500	2000
Total number of animals	**3**	**3**	**3**	**3**	**3**
Administration	**1st**	**2nd**	**1st**	**2nd**	**1st**
- Impaired general state	3 / h2 - h4	-	2 / h3 - h4	3 / h1 - h5	3 / h1 - h5

C. BODY WEIGHT

The mean body weights of all surviving animals increased throughout the study period.

D. NECROPSY

Treatment-related gross necropsy findings were restricted to animals which died. These consisted of lung edema at 500 mg/kg bw and of red and black discoloration of the contents of the small intestines at 2000 mg/kg bw (see Table 7.1.1-3).

Table 7.1.1-3: Necropsy findings in rat administered BAS 500 06 F by the oral route

Dose [mg/kg bw]	**300**	**300**	**500**	**500**	**2000**
Administration	**1st**	**2nd**	**1st**	**2nd**	**1st**
Number of affected animals	-	1	-	2	3
Lung:					
- edema in all lobes	-	-	-	2	-
Small intestine:					
- discoloration of contents, black	-	-	-	-	3
- discoloration of contents, red	-	-	-	-	3
Mammary gland:					
- mass, 30 mm diameter, red/beige	-	1	-	-	-

- not observed

One low dose animal (# 701, 2nd administration) displayed a red/beige mass at a mammary gland. Histopathological examination revealed an adenocarcinoma in the mammary gland. This finding is considered to be spontaneous and not related to treatment.

III. CONCLUSION

Under the conditions of this study the oral LD_{50} in rats for BAS 500 06 F was determined to be about 500 mg/kg bw.

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 500 06 F is to be classified as "harmful if swallowed" (Xn, R22 and Cat. 4, H302).

CP 7.1.2 Dermal toxicity

Report: CP 7.1.2/1
[redacted] 2009a
BAS 500 06 F: Acute dermal toxicity study in rats
2009/1084157

Guidelines: OECD 402, EPA 870.1200, JMAFF No 12 Nosan No 8147, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. L 142

GLP: yes
(certified by Umweltministerium Baden-Wuerttemberg, Stuttgart)

Executive Summary

In an acute dermal toxicity study groups of 5 male and 5 female Wistar rats were administered a single dose of 5000 mg/kg of BAS 500 06 F to the clipped skin under semi-occlusive conditions for 24 hours. The liquid formulation was applied undiluted (4.8 mL/kg bw). The animals were observed for 14 days after administration. Based on the absence of mortality in this study the acute dermal LD_{50} was determined to be

dermal LD_{50} > 5000 mg/kg bw

No clinical observations of systemic toxicity were made. However, local signs of dermal irritation consisting of erythema up to grade 3, edema up to grade 2, scaling, incrustations and severe scaling were observed on study day 1 until day 12. At necropsy no deviations from normal morphology were observed.

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 500 06 F is not to be classified for acute dermal toxicity.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 06 F

Description:	liquid, orange, clear
Lot/Batch #:	8265
Purity/content:	Pyraclostrobin 202.7 g/L
Density:	1.042 g/mL
Stability of test compound:	The stability was guaranteed for the duration of the study

2. Vehicle and/or positive control: none

3. Test animals:

Species:	Rat
Strain:	Wistar, Crl:WI (Han) SPF
Sex:	male and female
Age:	young adult (male animals approx. 8 weeks, female animals approx. 12 weeks)
Weight at dosing (mean):	males: 236.6 ± 7.2 g; females: 200.4 ± 5.13 g
Source:	Charles River Wiga GmbH, Sandhofer Weg 7, 97633 Sulzfeld, Germany
Acclimation period:	At least 5 days
Diet:	VRF1(P); SDS Special Diets Services, 67122 Altrip, Germany), ad libitum
Water:	Tap water, ad libitum
Housing:	Single housing in Makrolon cages, type III with enrichment
Temperature:	20 - 26°C
Humidity:	20 - 80%
Air changes:	Fully air-conditioned rooms; number of air-changes not indicated in the report
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 04-Aug-2009 to 14-Sep-2009

2. Animal assignment and treatment:
Five male and five female rats were given a single application of the undiluted test substance to the clipped epidermis (dorsal and dorsolateral parts of the trunk; about 40 cm^2, corresponding to at least 10% of the body surface area) for 24 hours. The clipping was performed about 24 hours before administration. The application volume was 4.80 mL/kg bw. The application site was covered with a semi-occlusive dressing (bandage consisting of four layers absorbent gauze, Ph. Eur. Lohmann GmbH & Co. KG and Fixomull stretch (adhesive fleece), Beiersdorf AG). After the exposure period, the dressing was removed and the application site was rinsed with warm water.
Rats were observed for signs and symptoms several times on the day of administration and thereafter at least once each workday. A check for any dead or moribund animals was also made at least once each workday. Individual body weights were recorded shortly before application (day 0), weekly thereafter and on the last day of observation. Skin findings were scored individually 30 – 60 minutes after removal of the semi-occlusive dressing (day 1) and several times until the last day of observation. The skin findings were assessed according to the Draize scheme. Necropsy with gross-pathology examination was performed on the last day of the observation period after sacrifice with CO_2.

II. RESULTS AND DISCUSSION

A. MORTALITY
No mortality was observed in this study.

B. CLINICAL OBSERVATIONS
No clinical signs of systemic toxicity were observed throughout the study. Skin effects at the application site comprising erythema (grade 1 to 3), edema (grade 1 or 2), scaling and incrustations were observed from study day 1 until day 12 after application.

C. BODY WEIGHT
The mean body weight of the animals increased throughout the study period.

D. NECROPSY
Gross necropsy revealed no abnormal findings in any of the animals.

III. CONCLUSION

Under the conditions of this study the dermal LD_{50} for BAS 500 06 F in rats was determined to be greater than 5000 mg/kg bw.

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 500 06 F is not to be classified for acute dermal toxicity.

CP 7.1.3 Inhalation toxicity

Report:	CP 7.1.3/1 [redacted], 2010a BAS 500 06 F - Acute inhalation toxicity study in Wistar rats - 4-Hour liquid aerosol (head-nose only) 2009/1122167
Guidelines:	OECD 403 (2009), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.2, EPA 870.1300
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In an acute inhalation toxicity study, groups of 5 male and 5 female Wistar rats were exposed to liquid aerosols of BAS 500 06 F at actual concentrations of 1.04 ± 0.18 mg/L, 2.02 ± 0.07 and 4.68 ± 0.33 mg/L for 4 hours. The animals were observed for 14 days after exposure.
One of five males and no females died at 1.04 mg/L. No mortality occurred at 2.02 mg/L. At 4.68 mg/L three of five female and three of five male animals died or were sacrificed in a moribund state. Accordingly, the acute inhalation LC_{50} was determined to be

LC_{50} (both sexes combined)	**about 4.48 mg/L**
LC_{50} (male rats)	**about 4.78 mg/L**
LC_{50} (female rats)	**about 4.55 mg/L**

Clinical signs of toxicity in animals exposed to the test substance comprised abdominal, accelerated, depressed, gasping or labored respiration, respiratory sounds, reduced attention, encrusted eyes and nose, semiclosed eylids, contaminated fur, hunched posture, piloerection and/or reduced nutritional conditions. Gross necropsy of animals dying revealed the following findings in the lung: focal dark-red discoloration of all lobes and surface partly sunken (1 female group 3), diffuse dark-red discoloration of lobus dexter cranialis, lobus medialis and pulmo sinister (1 male group 1), focal dark-red discoloration lobus dexter cranialis and pulmo sinister (1 male, group 3) or several red foci of all lobes (1 female, group 3). One female of group 3 showed few black erosion/ulcer in the glandular stomach und one male and one female of group 3 showed furthermore moderated dilation with gaseous content in the jejunum. Necropsy of the animals at termination of the post exposure periods revealed findings only in the lung: in one male animal of test group 1 few red foci in all lobes and in one female animal of test group 3 few red foci, dexter caudalis lobe and pulmo sinister were seen.

The mass mean aerodynamic diameters (MMAD) were in the range of 2.8 to 3.3 µm with geometric standard deviations (GSD) between 2.2 and 2.5. Depending on the concentration 46 to 53% of the particles had a diameter of ≤ 3.0 µm and thus may have reached the alveolar space of the lung.

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 500 06 F is to be classified as "harmful by inhalation / harmful if inhaled" (Xn, R20 and Cat. 4, H332).

Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 26-Oct-2009 to 22-Jan-2009

2. Animal assignment and treatment:
For determination of the acute inhalation toxicity (single 4-hour-exposure) groups of five male and five female rats were exposed to liquid aerosols of BAS 500 06 F at three concentrations. The animals were randomly selected from a pool of animals.

3. Clinical examinations:
For each test group, the body weight of the animals was determined just prior to exposure (day 0), on study days 1, 3, and 7 and weekly thereafter and at the end of the observation period. A check for overt clinical signs of toxicity or mortality as well as a check for the presence of feed and drinking water was made twice a day on workdays and once daily on weekends and public holidays. Detailed clinical observations were recorded for each animal separately several times during exposure and at least once on each workday of the observation period.

4. Pathology:
At the end of the 14-day observation period the surviving animals were sacrificed with CO_2 and were subjected to gross-pathological examination like those performed for animals which had died prematurely.

5. Statistics/Calculations:
The statistical evaluation of the concentration-response relationship was carried out using a computer program. Depending on the data of the concentration-response relationship obtained by the experiment, this program is used to estimate the LC_{50} or to perform a Probit analysis[1].
The calculation of the particle size distribution was carried out in the inhalation laboratory on basis of mathematical methods for evaluating particle measurements[2].

[1] FINNEY, D.J. (1971): "Probit Analysis" Cambridge University Press, pp. 1 - 50

[2] DIN 661 41: Darstellung von Korngrößenverteilungen, DIN 661 61: Partikelgrößenanalyse (Beuth-Vertrieb GmbH, Berlin 30, FRG und Köln 1, FRG)

6. Generation of the test atmosphere / chamber description:
A head-nose inhalation system INA 20 (glass-steel construction, BASF SE, volume V ≈ 55 L) was used. The animals were restrained in glass tubes and their snouts projected into the inhalation system.

The exposure system was located inside an exhaust cabin in an air-conditioned laboratory. A supply airflow (compressed air) of 0.5 m³/h was used for the exposure. The exhaust airflow was set at 1.35 m³/h for groups 1 and 2 and at 1.00 m³/h for group 3. An air change of about 27 times per hour can be calculated by dividing the supply air flow by the volume of the inhalation system. The lower amount of exhaust air, which was adjusted by means of a separate exhaust air system, achieved a positive pressure inside the exposure system. This ensured that the mixture of test substance and air was not diluted with laboratory air in the breathing zones of the animals.

The animals were exposed to the inhalation atmosphere for 4 hours plus an equilibration time for the inhalation system of about 10 minutes.

7. Analytical investigation:

The flows of supply and exhaust air were adjusted and continuously measured with a flow meter. Air flows, the temperature and the humidity in the exposure system measured were at about 1-hour intervals.
The oxygen content in the inhalation system was not measured. The air change was judged to be sufficient to prevent oxygen depletion by the breathing of the animals, and the concentrations of the test substance used could not have a substantial influence on oxygen partial pressure.

The nominal concentration was calculated from the amount of substance dosed and the supply airflow.

The sampling for determination of the actual aerosol concentration was performed with 3 impingers connected in series and filled with a sorption solvent (acetonitrile) using a sampling probe (diameter 7 mm, with quartz wool). By means of the vacuum pump metered volumes of the inhalation atmospheres were drawn through the impingers.

- Sampling position: immediately adjacent to the animals' noses
- Sampling flow: 3 L/min
- Sampling velocity: 1.25 m/s
- Sampling frequency: 4 samples at about hourly intervals
- Sample volume: Test group 1: 30 L; Test group 2: 15 L; Test group 3: 6 L

The sampling volumes were adjusted to achieve suitable amounts of test substance for analysis.

The quartz wool and the first 2 impingers were analyzed for each sample. The third impinger was used to control the effectiveness of the sorption for all samples of a test group and was analyzed separately at the end of the sampling campaign.

The quantitative determination of the aerosol concentrations were performed by HPLC analysis using the following parameters:

- Column: Gemini 5µ C28, 50 mm x 3 mm
- Injection volume: 10 µL
- Column temperature: ambient
- Mobile phase: 50% A: acetonitrile + HCOOH (1000 mL + 1 mL)
  50% B: highly deionized water + HCOOH (1000 mL + 1 mL)
- Flow rate: 0.6 mL/min
- Detection: UV 274 nm

The particle size analysis was done using a Stack Sampler Mark III (Andersen) and a vacuum pump (Millipore). The sampling probe had an internal diameter of 6.9 mm.
Before sampling, the impactor was assembled with metal collecting discs and a backup filter. The impactor was connected to the vacuum pump and for each test group two samples were taken from the breathing zone of the animals starting not earlier than 30 minutes after the beginning of the exposure. The sample volumes were 36, 15 and 6 L for test groups 1, 2 and 3, respectively.
After sampling the impactor was taken apart. The impactor stages and the backup particle filter were eluted with acetonitrile. The obtained samples were analyzed by HPLC. Additionally, material absorbed on the walls of the impactor and the sampling probe (wall losses) were also determined quantitatively.

II. RESULTS AND DISCUSSION

A. MORTALITY

Mortality was observed for one of five animals in test group 1 and three of five males and three of five females in test group 3. No lethality was observed in test group 2. Details are given in Table 7.1.3-1.

Table 7.1.3-1: Mortality of rats exposed for 4 hours to a liquid aerosol of BAS 500 06 F

Test group	Concentration [mg/L]	Cumulative mortality		Time of deaths
		Male	Female	
1	1.04	1/5	0/5	d0
2	2.02	0/5	0/5	-
3	4.68	3/5	3/5	d0 – d1

d0: post exposure on the day of exposure

Based on the observed mortality the following LC_{50} values were determined:

- LC50 (both sexes combined) about 4.48 mg/L
- LC50 (male rats) about 4.78 mg/L
- LC50 (female rats) about 4.55 mg/L

B. CLINICAL OBSERVATIONS

Clinical signs observed consisted of abdominal, accelerated, depressed, gasping or labored respiration, respiratory sounds, reduced attention, encrusted eyes and nose, semiclosed eylids, contaminated fur, hunched posture, piloerection and/or reduced nutritional conditions. The maximum incidence and duration of the observations are indicated in Table 7.1.3-2.

Table 7.1.3-2: Clinical signs in rats exposed for 4 hours to a liquid aerosol of BAS 500 06 F (incidence/duration)

Dose [mg/L]	1.04	2.02	4.68	1.04	2.02	4.68
Sex	**Males**			**Females**		
- Total number of animals	5	5	5	5	5	5

hn = hour n of exposure; d0 = day of exposure; dn = day n after exposure

C. BODY WEIGHT

In test group 1 and 3 the mean body weight of the surviving animals decreased during the first post exposure observation week, but increased during the second week. In the second test group the mean body weights of the animals did not increase adequately during the first post exposure observation week, but increased during the second week.

D. NECROPSY

Gross necropsy of one male animal exposed to 1.04 mg/L (group 1) that died on study day 0 after exposure revealed diffuse dark-red discoloration of the dexter cranialis lobe, medialis lobe and the pulmo sinister. The following gross pathological abnormality was noted in one male animal necropsy at termination of the post exposure observation period, few red foci in all lung lobes (Ø 2 mm). The remaining animals showed no gross pathological abnormalities.
No gross pathological abnormalities were noted during the necropsy at the termination of the post exposure observation period in animals exposed to 2.02 mg/L (group 2).
Necropsy of one male and one female animal exposed to 4.68 mg/L (group 3) that died on study day 0 during exposure showed no gross pathological abnormality. The female animal that died on study day 1 after exposure showed partly sunken surface and focal dark-red discoloration of the lung and few black erosion/ulcer (Ø 2 mm) in the glandular stomach. From the animals, which were sacrificed in a moribund state on study day 1, two of three animals showed the following findings: in one male animal focal dark-red discoloration in the dexter cranial lobe and the pulmo sinister, in one female animal several red foci in all lobes (Ø 2 mm). Both animals showed additionally a moderate dilation of the jejunum with gaseous content. The third animal (male) showed no gross pathological abnormality. The following gross pathological abnormality was noted in one female animal necropsy at termination of the post exposure observation period, few red foci in the dexter cranial lobe and the pulmo sinister (Ø 2 mm). The remaining animals showed no gross pathological abnormalities.

E. ATMOSPHERE ANALYSIS

The exposure conditions are summarized in Table 7.1.3-3.

Table 7.1.3-3: Exposure conditions

Test group	Supply air (compressed) [m³/h]	Exhaust air [m³/h]	Temp. [°C]	Relative humidity [%]
1	0.5	1.35	20.5 ± 0.0	51.4 ± 0.6
2	0.5	1.35	21.0 ± 0.1	52.2 ± 1.0
3	0.5	1.00	21.0 ± 0.1	52.4 ± 1.6

The results of the concentration measurements (mean of 4 measurements) are presented in Table 7.1.3-4.

Table 7.1.3-4: Measurement of concentrations (4 hourly measurements)

Test group	Mean concentration [mg/L]	Standard deviation	Nominal concentration [mg/L]
1	1.04	0.18	8.8
2	2.02	0.07	20.9
3	4.68	0.33	100.9

The measurements of particle-size distribution revealed mass mean aerodynamic diameters (MMAD) in the range of 2.8 to 3.3 µm with geometric standard deviations in the range of 2.2 to 2.5 (see Table 7.1.3-5).

Depending on the concentration 46 to 53% of the particles had a diameter of ≤ 3.0 µm and thus may have reached the alveolar space of the lung.

Table 7.1.3-5: Particle size measurements

Test group / Sample	% ≤ 3 µm	MMAD [µm]	Geometric standard deviation
1 / 1	52.4	2.9	2.3
1 / 2	53.4	2.8	2.4
2 / 1	51.8	2.9	2.3
2 / 2	46.4	3.3	2.5
3 / 1	49.1	3.1	2.5
3 / 2	51.4	2.9	2.2

III. CONCLUSION

Under the conditions of this study the 4 hour inhalation LC_{50} for BAS 500 06 F was estimated to be

- LC_{50} (both sexes combined) 4.48 mg/L
- LC_{50} (male rats) 4.78 mg/L
- LC_{50} (female rats) 4.55 mg/L

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 500 06 F is to be classified as "harmful by inhalation / harmful if inhaled" (Xn, R20 and Cat. 4, H332).

CP 7.1.4 Skin irritation

Report: CP 7.1.4/1
[redacted] 2010a
BAS 500 06 F - Acute dermal irritation / corrosion in rabbits
2009/1100358

Guidelines: OECD 404 (2002), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. L 142, EPA 870.2500, JMAFF No 12 Nosan No 8147

GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a primary dermal irritation study the skin irritation/corrosion potential of BAS 500 06 F was tested. An area of 6.25 cm² of clipped skin of 3 New Zealand White rabbits was exposed to 0.5 mL of the test-substance for 4 hours under semi-occlusive conditions. The rabbits were observed for 14 days after removal of the dressings. Signs of skin irritation were scored using the Draize scheme according to guideline requirements.
Administration of BAS 500 06 F to the skin of rabbits caused up to grade 3 (slight to marked) erythema and grade 2 (slight to moderate) edema. The cutaneous reaction was not reversible in all animals within 14 days after removal of the patch. Slight to moderate erythema and scaling, both extending beyond the area of exposure, were still observed in all animals at study termination on day 14. The overall 24 to 72 hour skin irritation scores were 2.8 for erythema and 1.0 for edema.

Based on the findings of this study the formulation BAS 500 06 F has to be classified as "Irritating to skin" (Xi, R38) according to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC). According to Regulation (EC) 1272/2008 (CLP), BAS 500 06 F has to be classified as "Causes skin irritation" (Cat. 2, H315).

2. In-vitro pre-test:
No in-vitro pre-test was performed.

3. Animal assignment and treatment:
The potential of BAS 500 06 F to cause acute dermal irritation or corrosion was assessed by a single topical application of 0.5 mL of the test substance for 4 hours to the intact skin of two male and one female New Zealand White rabbits.

At least 24 hours before treatment, the dorsolateral part of the trunk of the animals was clipped. Only animals without obvious signs of skin irritation were used in the study. A dose of 0.5 mL of the unchanged liquid formulation was applied to a 2.5 x 2.5 cm test patch and applied to the flank for 4 hours. The gauze patch was held in place by means of an adhesive semi-occlusive dressing (Idealbinde, Pfaelzische Verbandstoff-Fabrik, Kaiserslautern and Fixomull® adhesive fleece, Beiersdorf AG, Germany). After a 4 hour exposure period the patch was removed and the application area was washed with Lutrol® (PEG 400) and Lutrol®/water (1:1).
The cutaneous reactions were assessed immediately after removal of the patch, approximately 1, 24, 48 and 72 hours as well as 7 and 14 days after removal of the patch.
Body weights were measured shortly prior to application and after the last reading. The animals were checked for mortality, morbidity and clinical signs twice on working days and once on weekends and public holidays.

II. RESULTS AND DISCUSSION

Administration of BAS 500 06 F to the skin of rabbits caused moderate or marked erythema (grade 2 or 3), observed in all animals immediately after removal of the patch up to day 7, and decreased to slight or moderate (grade 1 or 2) in all animals until 14 days after removal of the patch. Moderate edema (grade 2) was noted in all animals immediately after removal of the patch up to 1 hour and persisted in one animal until 24 hours. Slight edema (grade 1) was observed in two animals after 24 hours and in all animals at the 48-hour reading. Slight edema persisted in two animals from 72 hours up to day 7. Additionally, erythema and edema were extended beyond the area of exposure in all animals during the observation period. Scaling extending beyond the area of exposure was noted in all animals on study days 7 and 14 (see Table 7.1.4-1). The cutaneous reactions were not reversible in all animals within 14 days after removal of the patch. Slight or moderate erythema and scaling, both extending beyond the area of exposure, were still observed in all animals at study termination on day 14.
Mean scores over 24, 48 and 72 hours for each animal were 2.3, 3.0 and 3.0 for erythema and 1.3, 0.7 and 1.0 for edema.

III. CONCLUSION

Based on the findings of this study the formulation BAS 500 06 F has to be classified as "Irritating to skin" (Xi, R38) according to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC). According to Regulation (EC) 1272/2008 (CLP), BAS 500 06 F has to be classified as "Causes skin irritation" (Cat. 2, H315).

CP 7.1.5 Eye irritation

Report: CP 7.1.5/1
[redacted] 2010b
BAS 500 06 F - Acute eye irritation in rabbits
2009/1100359

Guidelines: OECD 405 (2002), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. L 142, EPA 870.2400, JMAFF No 12 Nosan No 8147

GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a primary eye irritation study, the eye irritation/corrosion potential of BAS 500 06 F was determined by instillation of 0.1 mL of the test substance into the conjunctival sac of the right eye of three rabbits (stepwise procedure starting with one animal and supplementing two additional animals). The left eye, which remained untreated, served as a control. The eyes were rinsed 24 hours after administration of the test substance.
The ocular reactions were assessed approximately 1, 24, 48 and 72 hours as well as 7 and 14 days after the administration of the test substance.
Signs of ocular irritation consisted of up to grade 2 corneal opacity, up to grade 1 iritis, up to grade 3 conjunctival redness and up to grade 3 chemosis. All signs of ocular irritation were reversible within 14 days. The mean scores calculated for all animals over 24, 48 and 72 hours were 1.2 for corneal opacity, 0.7 for iris lesions, 2.3 for redness of the conjunctiva and 1.8 for chemosis.

Based on the results of the study no classification as to eye irritation is warranted according to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC). In contrast, according to Regulation (EC) No 1272/2008 (CLP), the formulation has to be classified as an eye irritant ("Causes serious eye irritation", Cat. 2, H319).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 06 F
Description: liquid, orange, clear
Lot/Batch #: 8265
Purity/content: BAS 500 F / pyraclostrobin: 202.7 g/L
Stability of test compound: The stability was guaranteed for the duration of the study.

2. Vehicle and/or positive control: none

3. Test animals:
Species: Rabbit
Strain: New Zealand White, A 1077 INRA (SPF)
Sex: male and female
Age: 6 – 7 month (animal 01)
ca. 4 months (animals 02 and 03)
Weight at dosing
(mean): 2.86 to 3.82 kg
Source: Centre Lago S. A., 01540 Vonnas, France
Acclimation period: At least 5 days
Diet: Kliba Laboratory Diet, Provimi Kliba SA, Kaiseraugst, Basel, Switzerland (approx.. 130 g/day)
Water: Tap water, ad libitum
Housing: Single housing in stainless steel wire mesh cages with grating, floor area 3000 cm²

Environmental conditions:
Temperature: 20 - 24°C
Humidity: 30 - 70%
Air changes: Fully air-conditioned rooms; number of air-changes not indicated in the report
Photo period: 12 h light / 12 h dark
(06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 03-Aug-2009 and 09-Sep-2009

2. In-vitro pre-test:
No in-vitro pre-test was performed.

3. Animal assignment and treatment:
The potential of BAS 500 06 F to cause acute eye irritation was assessed by instillation of 0.1 mL of the unchanged test substance into the conjunctival sac of the right eye. The left eye, which remained untreated, served as a control. The eyes were rinsed with tap water 24 hours after administration of the test substance.
The ocular reactions were assessed approximately 1, 24, 48 and 72 hours as well as 7 days and 14 days after the administration of the test substance.
Body weights were measured shortly prior to application and after the last reading. The animals were checked for mortality, morbidity and clinical signs twice on working days and once on weekends and public holidays.

II. RESULTS AND DISCUSSION

Slight corneal opacity (grade 1) was observed in all animals 24 hours after application and persisted in two animals up to 72 hours. Slight corneal opacity increased to moderate (grade 2) in one animal at the 48-hour reading up to 72 hours. Moderate iritis (grade 1) was observed in two animals 24 and 48 hours after application and persisted in one of these animals up to 72 hours. Another animal showed moderate iritis at the 72-hour reading, only. Moderate or severe conjunctival redness (grade 2 or 3) were noted in all animals from 1 hour up to 72 hours after application. Slight conjunctival redness (grade 1) was observed in one animal on day 7. Moderate or marked conjunctival chemosis (grade 2 or 3), noted in all animals 1 hour after application up to 24 hours, persisted in one animal up to 48 or 72 hours, respectively. Slight conjunctival chemosis (grade 1) was observed in one animal after 48 hours and in two animals at the 72-hour reading. Severe discharge (grade 3) was noted in all animals 1 hour and 24 hours after application and persisted in two animals up to 48 hours. Slight discharge (grade 1) was seen in one animal after 48 hours and in two animals after 72 hours after application. Additional findings like suppuration, contracted pupil and injected scleral vessels in a circumscribed area or circular were noted in the animals during the observation period. The ocular reactions were reversible in two animals within 7 days and in one animal within 14 days after application. The mean 24 to 72 hour scores for corneal opacity, iritis, conjunctival redness and chemosis were 1.2, 0.7, 2.3 and 1.8, respectively (see Table 7.1.5-1).

SD = study discontinued because the animals was free of findings

III. CONCLUSION

Based on the findings of this study a classification of the formulation BAS 500 06 F as an eye irritant is not required according to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC). In contrast, according to Regulation (EC) No 1272/2008 (CLP), the formulation has to be classified as an eye irritant ("Causes serious eye irritation", Cat. 2, H319).

CP 7.1.6 Skin sensitization

Report: CP 7.1.6/1
[redacted] 2008b
BAS 500 06 F: Murine local lymph node assay (LLNA)
2007/1053391
Guidelines: OECD 429, EEC 2004/73 B.42, EPA 870.2600
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

For the determination of potential sensitizing properties of the formulation BAS 500 06 F a mouse local lymph node assay (LLNA) was conducted.
Topical application of the formulation to the ears of groups of 5 female mice at 3 different concentrations (3, 10 and 30% (w/w) in acetone) for three consecutive days resulted in a biologically significant increase of the stimulation indices (SI) for lymph node cell count, ^{3}H-thymidine incorporation into the lymph node cells and lymph node weights, when assessed approximately 2 days after the last application.
A slight increase in ear weights was observed at all concentrations (max SI: 1.47). This may have been caused by a slight irritation of the ears.

The threshold concentration for sensitization induction was < 3%. The estimated concentration that leads to the SI of 1.5 for cell count (EC 1.5) and the estimated concentration that leads to the SI of 3.0 for ^{3}H-thymidine incorporation (EC 3) were calculated by linear regression from the results of the control group and the 3% concentration to be 0.9 and 1%, respectively.

Positive control studies performed twice a year with the sensitizer Hexylcinnamaldehyde proved the sensitivity of the method used.

Based on the results of this study it can be concluded that BAS 500 06 F has sensitizing properties under the test conditions chosen. The formulation has to be classified as a sensitizer ("May cause sensitization by skin contact", Xi, R43) according to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC). According to Regulation (EC) 1272/2008 (CLP), the formulation has to be classified as "May cause an allergic skin reaction" (Cat. 1, H317).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 06 F

Description:	liquid
Lot/Batch #:	8265
Purity/content:	BAS 500 F / pyraclostrobin: 202.7 g/L
Stability of test compound:	According to the CoA the formulation was stable until January 31, 2008 when stored at +5 to +30°C.

2. Vehicle and/or positive control: Acetone

3. Test animals:

Species:	Mouse
Strain:	CBA/J
Sex:	20 females
Age:	6 to 12 weeks
Weight at dosing:	20.6 ± 0.8 g
Source:	Charles River Laboratories, Research Models and Services, Germany GmbH, Sandhofer Weg 7, 97633 Sulzfeld
Acclimation period:	at least 5 days
Diet:	Kliba-Labordiät (Maus / Ratte Haltung "GLP"), Provimi Kliba SA, Kaiseraugst, Basel, Switzerland, ad libitum
Water:	tap water ad libitum
Housing:	individual housing in Makrolon Type II cages with Lignocel FS 14 (SSNIFF) bedding. Environmental enrichment: Nest-building material (wood wool) (Type NBF E-011); Abedd® Lab. and Vet. Service GmbH Vienna, Austria

Environmental conditions:

Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	not indicated in the report
Photo period:	12 h light / 12 h dark (06:00 - 18:00/18:00 – 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 28-Aug-2007 to 23-Oct-2007
29-Aug-2007 to 03-Sep-2007 (in life work)

2. Animal assignment and treatment:
The skin sensitizing potential of BAS 500 06 F was assessed using the radioactive Murine Local Lymph Node Assay. For this, female mice were allocated to groups of 5 animals according to the randomization instructions of „Nijenhuis, A. and Wilf, H.S.: Combinatorial Algorithms, Academic Press, New York, San Francisco, London, 1978, pp. 62 – 64".
The groups were treated either with

- the vehicle (acetone),
- a 3% (w/w) dilution in acetone,
- a 10% (w/w) dilution in acetone, or
- a 30% (w/w) dilution in acetone.

The application solutions were prepared shortly before treatment.

3. Analysis of treatment solutions:
The stability of the test substance in the vehicle was determined indirectly by the concentration control or homogeneity analysis. For this purpose, the samples taken were stored at room temperature over the maximum duration of the application period and were subsequently deep-frozen. Afterwards, these samples were analyzed. The homogeneity of the test-substance preparation in the vehicle was not determined since the test-substance was dissolved in the preparation. The actual test substance concentration was determined once for the 3, 10 and 30% dilution.
The correctness of the concentrations of the preparations was confirmed analytically (for details see raw data).

4. Statistics:
Not performed in this study

5. Clinical observation:
Mortality was checked twice daily on working days and once on weekends and public holidays. No detailed clinical examination of the individual animals was performed, but any obvious signs of systemic toxicity and/or local inflammation at the application sites were recorded (see raw data).

6. Body weights:
Individual body weights were determined on day 0 prior to the first application and on day 5 prior to the sacrifice of the animals.

7. Treatment of animals:
The dosing solutions were applied daily to the dorsal part of the ears at a volume of 25 µL per ear for 3 consecutive days. On study day 5, i.e. 66 to 72 hours after the last application, 20 µCi of ^{3}H-thymidine in 250 µL sterile saline was injected into the tail vein of each mouse.

8. Terminal procedures:

Approximately 5 hours after ^{3}H-thymidine injection the animals were killed by cervical dislocation.

Immediately after the death a circular piece of tissue (diameter 0.8 cm) was punched out of the apical part of each ear of all animals. The weight of the pooled punches was determined for each test group. These measurements served for the detection of a potential inflammatory ear swelling.

Immediately after removal of the ear punches the left and right auricular lymph nodes were dissected. The weight of the pooled lymph nodes from both sides was determined for each animal.

After weight determination, a single cell suspension was prepared per test group from the pooled lymph nodes by carefully passing all lymph nodes through an iron mesh (mesh size 200 µm) into 40 mL of phosphate-buffered physiological saline. Subsequently the cell counts were determined with an aliquot of each suspension using a Casy®- Counter.

The remaining cell suspensions were washed twice with phosphate buffered saline (PBS) and precipitated with 5% trichloro-acetic acid. Each precipitate was transferred to scintillation fluid and incorporation of ^{3}H-thymidine into the cells was measured in a β-scintillation counter.

9. Data evaluation and interpretation:

The stimulation indices (SI) of cell count, ^{3}H-thymidine incorporation, lymph node weight and ear weight were calculated as the ratio of the test group values for these parameters divided by those of the vehicle control group.

The lymph node cell count and the ^{3}H-thymidine incorporation into the lymph node cells as well as to a certain extent lymph node weight are used to determine the potential sensitizing properties of a test article. Because not only sensitization but also irritation of the ear skin by the test substance may induce lymph node responses, the weight of ear punches taken from the area of test-substance application is determined as a parameter for inflammatory ear swelling as an indicator for the irritant action of the test substance.

Stimulation indices of >1.5 for cell count and/or of ≥ 3 for ^{3}H-thymidine incorporation are generally considered as indicative for a sensitizing potential of a test substance. If applicable, the EC (estimated concentration) leading to the respective SI values were calculated by linear or semi-logarithmical regression.

If the increase in cell count, ^{3}H-thymidine incorporation and/or lymph node weight is accompanied by a biologically relevant increase in ear weights it cannot be ruled out that the lymph node response was caused by irritation and not by skin sensitization. Depending on the magnitude of lymph node response, based on expert judgment, the evaluation of the sensitizing potential may be modified or additional studies might be necessary.

If a test article – despite of concentration related increase - does not elicit a biological relevant increase in cell count and/or ^{3}H-thymidine incorporation, further investigation of the sensitization potential at higher concentrations may be considered.

10. Positive controls:
A concurrent positive control (reliability check) with a known sensitizer was not included into this study. Studies using the positive control substance Alpha-Hexylcinnamaldehyde are performed twice a year in the laboratory in order to show that the test system is able to detect sensitizing compounds under the test conditions chosen.

II. RESULTS AND DISCUSSION

A. OBSERVATIONS
No clinical observations or mortality were observed.

B. BODY WEIGHTS
Mean body weight gain was observed in control and low dose animals (3% in acetone). However, body weight gain at the low dose level was lower (0.2 ± 0.8 g) than in the controls (1.4 g ± 0.5 g). At the mid dose (10% in acetone; -0.3 ± 0.4 g) and high dose level (30% in acetone; -3.7 ± 1.0 g) body weight loss was observed. This is interpreted as indication for systemic toxicity.

C. STIMULATION INDICES
When applied as 30, 10 and 3% preparations in acetone, the test substance induced a biologically relevant response in the auricular lymph node cell counts and ^{3}H-thymidine incorporation. In addition there was an increase in lymph node weights.

The test-substance preparations caused concentration dependent slight to moderate increases in ear weights as indication of ear skin irritation. Scaling was observed on the day of lymph node removal in all animals applied with the 10% test-substance preparation. Two animals of the 30% test group exhibited scaling and incrustation and slight erythema was noted in all animals.

The irritation probably contributed to the lymph node reaction. However the considerable increase in cell counts and ^{3}H-thymidine incorporation in the 3% test group cannot be fully attributed to the slight ear skin irritation.

The stimulation indices (SI) for lymph node cell counts, ^{3}H-thymidine incorporation and lymph node and ear weights are given in Table 7.1.6-1.

Table 7.1.6-1: Stimulation indices for cell counts, ^{3}H-thymidine incorporation, lymph node and ear weight in mice after treatment with BAS 500 06 F

Test Group	Treatment	Parameter evaluated	Stimulation index (SI)[1]
		Cell count [counts/lymph node pair]	
1	vehicle (acetone)	6085333	1.00
2	3% (w/w) in acetone	16381333	2.69
3	10% (w/w) in acetone	19994667	3.29
4	30% (w/w) in acetone	19416000	3.19
		^{3}H-Thymidine incorporation [DPM/lymph node pair]	
1	vehicle (acetone)	412.5	1.00
2	3% (w/w) in acetone	2839.2	6.88
3	10% (w/w) in acetone	6014.6	14.58
4	30% (w/w) in acetone	6643.4	16.10
		Lymph node weight [mg/lymph node pair]	
1	vehicle (acetone)	4.6	1.00
2	3% (w/w) in acetone	9.2	2.00
3	10% (w/w) in acetone	12.0	2.61
4	30% (w/w) in acetone	11.1	2.39
		Ear weight [mg/animal]	
1	vehicle (acetone)	30.8	1.00
2	3% (w/w) in acetone	36.7	1.19
3	10% (w/w) in acetone	42.2	1.37
4	30% (w/w) in acetone	45.1	1.47

[1] test group x / test group 1 (vehicle control)

The threshold concentration for sensitization induction was < 3%. The estimated concentration that leads to the SI of 1.5 for cell count (EC 1.5) and the estimated concentration that leads to the SI of 3.0 for ^{3}H-thymidine incorporation (EC 3) were calculated by linear regression from the results of the control group and the 3% concentration to be 0.9 and 1%, respectively.

D. POSITIVE CONTROL

The sensitivity of mice (CBA/CaOlaHsd, Harlan Winkelmann GmbH, Borchen, Germany or CBA/J, Charles River Laboratories, Research Models and Services, Germany GmbH, Sandhofer Weg 7, 97633 Sulzfeld) and the reliability of experimental techniques is assessed regularly using a known sensitizer. Positive results were consistently obtained over the years using several variations of the methods and different vehicles. The results of 6 control studies are presented in Table 7.1.6-2.

Table 7.1.6-2: Positive control LLNA studies performed

1 = Borderline SI at 10% in accordance with published results using AOO as the vehicle

III. CONCLUSION

Based on the results of this study it can be concluded that BAS 500 06 F has sensitizing properties under the test conditions chosen.

The formulation has to be classified as a sensitizer (“May cause sensitization by skin contact”, Xi, R43) according to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC). According to Regulation (EC) 1272/2008 (CLP), the formulation has to be classified as "May cause an allergic skin reaction" (Cat. 1, H317).

Report:	CP 7.1.6/2 [redacted] 2009a BAS 500 06 F - Maximization test in guinea pigs 2009/1018498
Guidelines:	OECD 406, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH, EPA 870.2600, JMAFF No 12 Nosan No 8147
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

For the determination of potential sensitizing properties of the formulation BAS 500 06 F a Maximization test based on the method of Magnusson and Kligman was conducted using a control and a treated group of 10 and 20 female Dunkin Hartley (Crl:HA) Guinea pigs, respectively.

The test-substance concentrations for the main test were selected based on the results of the pretests and the result of the first challenge. The intradermal induction was performed with a 5% test-substance preparation in 0.9% aqueous NaCl-solution or 5% test-substance preparation in Freund's complete adjuvant / 0.9% aqueous NaCl-solution (1:1). The epicutaneous induction was conducted with a 50% test-substance preparation in highly deionized water.
The intradermal induction caused intense erythema and swelling at the injection sites of the test-substance preparations in all test group animals. After the epicutaneous induction, incrustation, partially open (caused by the intradermal induction) could be observed in addition to intense erythema and swelling in all test group animals.
For the first challenge, a 25% test-substance preparation in highly deionized water was chosen. Skin reactions were observed in 30% of the control and in 70% treated group animals. Therefore, a second challenge with a concentration of 10% was carried out. The second challenge did not cause any skin findings in control but in 7/20 (35%) of the test group animals.

Based on the results of this study it can be concluded that BAS 500 06 F has sensitizing properties under the test conditions chosen. The formulation has to be classified as a sensitizer ("May cause sensitization by skin contact", Xi, R43) according to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC). According to Regulation (EC) 1272/2008 (CLP), the formulation has to be classified as "May cause an allergic skin reaction" (Cat. 1, H317).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 500 06 F

Description:	liquid
Lot/Batch #:	8265
Purity/content:	BAS 500 F / pyraclostrobin: 202.7 g/L
Stability of test compound:	The stability of the formulation under storage conditions was guaranteed.

2. Vehicle and/or positive control: 0.9% aqueous NaCl-solution for intradermal application and highly deionized water for epidermal application

3. Test animals:

Species:	Guinea pigs
Strain:	Dunkin Hartley, Crl:HA
Sex:	female
Age:	5 to 8 weeks (on day 0)
Weight on day 0:	417 to 510 g; 467.1 ± 24.4 g
Source:	Charles River Laboratories, Research Models and Services, Germany GmbH, 88353 Kisslegg
Acclimation period:	at least 5 days
Diet:	Kliba-Labordiät (Kaninchen & Meerschweinchenhaltung "GLP"), Provimi Kliba SA, Kaiseraugst, Basel, Switzerland, ad libitum
Water:	tap water ad libitum
Housing:	groups of 5 animals housed in plastic cages from Tecniplast Deutschland GmbH (Type 3020W009) with perforated base; floor area: 4000 cm^2. Environmental enrichment: Wooden gnawing blocks (Type NGM E-022); Abedd® Lab. and Vet. Service GmbH Vienna, Austria

Environmental conditions:

Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	not indicated in the report
Photo period:	12 h light / 12 h dark (6:00 a.m. - 6:00 p.m. / 6:00 p.m. – 6:00 a.m.)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 22-Dec-2008 to 09-Feb-2009
22-Dec-2008 to 06-Feb-2009 (in life work)

2. Animal assignment and treatment:
The skin sensitizing potential of BAS 500 06 F was assessed using the Guinea Pig Maximization Test. This test consists of a pretest for the determination of suitable induction and challenge concentrations and the Maximization Test itself.
For this, female Guinea pigs were allocated to groups according to the randomization instructions of „Salfi, R.: A Long-Period Random Number Generator with Application to Permutation, Compstat 1974, pp. 28 – 35".

For the intradermal and epicutaneous application, animal fur was clipped at least 2 hours before each test-substance application at the appropriate treatment sites. If necessary, additional hair clipping was performed 2 hours prior to the evaluation of skin reactions.

Evaluations of the skin reactions were performed according to the grading scale of Magnusson and Kligman (The Identification of Contact Allergens by Animal Assay. The Guinea Pig Maximization Test. J. Invest. Dermatol. 52, 268 - 276 (1969)).

Individual body weights were determined on study day 0 and on the last day of observation. Mortality was checked twice daily on working days and once on weekends and public holidays.

A: Preliminary tests
Two animals per test substance concentration received six intradermal injections (see below) in groups of two at the neck region in order to determine a test substance concentration that is well-tolerated locally and systemically for the intradermal induction treatment in the main test. The evaluation of the skin reactions was performed 24 h after application.

Intradermal injections:

A) front row: 2 injections each of 0.1 mL Freund's complete adjuvant without test substance emulsified with 0.9% aqueous NaCl-solution in a ratio of 1:1 (w/w)
B) middle row: 2 injections each of 0.1 mL of a test- substance preparation in an appropriate vehicle at the selected concentration
C) back row: 2 injections each of 0.1 mL Freund's complete adjuvant / 0.9% aqueous NaCl-solution (1:1 w/w) with test substance at the selected concentration.

Additionally, for the dermal induction treatment the highest concentration of the test substance that causes slight to moderate irritation and for the challenge the maximum non-irritant concentration was determined. The test-design took into account the possible influence of a previous intradermal treatment with Freund's complete adjuvant on irritating effects. For this, animals were used that received dermal injections of 0.1 mL Freund's complete adjuvant / 0.9% aqueous NaCl-solution at a ratio of 1:1 (w/w) three weeks prior to the epidermal pretest.

Skin reactions were determined by dermal application of 0.5 mL of the test-substance preparations under occlusive conditions to groups of 3 animals for 24 hours. The patch consisted of 6 layers of surgical gauze (2 x 2 cm) covered by patches of rubberized linen (4 x 4 cm) and Idealbinde (5 x 5 cm) which were held in place by Fixomull® adhesive fleece. One hour, 24 and 48 hours after removal of the patch evaluations of the skin reactions were performed.

B: Main study - Induction

The intradermal induction consisted of 6 intradermal injections in groups of two into the neck of the animals according to the scheme given above. Control animals received for the mid row injections of 0.1 mL of 0.9% aqueous NaCl and for back row injections of 0.1 mL of a 50% formulation of 0.9% aqueous NaCl with Freund's complete adjuvant / 0.9% aqueous NaCl-solution (1:1 w/w). Skin reactions were assessed 24 hours after injection. The treated and the control groups consisted of 20 and 10 females, respectively.

Epidermal induction was performed one week after intradermal induction. For this 1 mL of the test substance preparation was applied under occlusive conditions to the neck region previously used for intradermal induction. The patch consisted of 6 layers of surgical gauze (2 x 4 cm) covered by patches of rubberized linen (4 x 6 cm) which was held in place by Fixomull® adhesive fleece for 48 hours. One hour, 24 and 48 hours after removal of the patch evaluations of the skin reactions were performed.

C: Challenge

The 1st challenge was carried out 14 days after epidermal induction. A 2nd challenge was performed one week after the first. For this 0.5 mL of the test substance preparation was applied under occlusive conditions to the intact flank for 24 hours. The patches were prepared as described above for the epidermal pretest. Skin reactions were determined 24 and 48 hours after removal of the patches.

D: Positive controls

A positive control (reliability check) with a known sensitizer was not performed in this study. However, positive control studies are performed twice a year in the laboratory. The positive control with alpha-Hexylcinnamaldehyde techn. 85% showed that the test system was able to detect sensitizing compounds under the laboratory conditions chosen.

E: Evaluation of results

The number of animals with skin findings at 24 and/or 48 hours after the removal of the patch was taken into account for the determination of the sensitization rate. If at least 30% of the test animals exhibit skin reactions in this adjuvant test, the result of the evaluation is "sensitizing".
The evaluation is based on the criteria of the Commission Directive 67/548/EEC and the OECD Harmonized Integrated Classification System that were in place on the date of report signature.

3. Analysis of treatment solutions:

The stability of the test-substance preparations for intradermal induction was not determined, because the preparations using Freund's complete adjuvant + physiological saline (paraffin oil/water emulsion) are required by the test method and impaired stability of the test substance in the preparations, including test substance in the vehicle, is without influence on the procedure of intradermal induction.

The stability of the test substance in highly deionized water was confirmed indirectly by the concentration control or homogeneity analysis. For this purpose, the samples taken were stored at room temperature over the maximum duration of the application period and were subsequently deep-frozen. Afterwards, these samples were analyzed. The results of this analysis are available in the raw data.

The homogeneity of the test-substance preparation used for the first challenge application was confirmed indirectly by the concentration control analysis. The results of this analysis are available in the raw data.

4. Statistics:

Not performed in this study.

II. RESULTS AND DISCUSSION

A. Pre-Test

A first intradermal injection of 1% BAS 500 06 F in 0.9% aqueous NaCl caused only moderate and confluent erythema with swelling (see Table 7.1.6-3).

Table 7.1.6-3: Skin irritation scores 24 hours after intradermal injection - 1st and 2nd preliminary intradermal test

1st preliminary intradermal test				
Animal #	Application site	A) Freund's adjuvant / 0.9% aqueous NaCl-solution (1 : 1)	B) 1% BAS 500 06 F preparation in 0.9% aqueous NaCl-solution	C) 1% BAS 500 06 F in A)
208	left	3	2 E	3
	right	3	2 E	3
209	left	3	2 E	3
	right	3	2 E	3
2nd preliminary intradermal test				
Animal #	Application site	A) Freund's adjuvant / 0.9% aqueous NaCl-solution (1 : 1)	B) 5% BAS 500 06 F preparation in 0.9% aqueous NaCl-solution	C) 5% BAS 500 06 F in A)
203	left	3	3	3
	right	3	3	3
207	left	3	3	3
	right	3	3	3

Grading: 2: moderate and confluent erythema
E: swelling
3: intense erythema and swelling

Therefore, a second intradermal pretest was performed using a 5% BAS 500 06 F preparation in 0.9% aqueous NaCl. This time intradermal injection caused intense erythema and swelling at the injection site. Injection of Freund's adjuvant caused intense erythema and swelling irrespective of mixing with 0.9% aqueous NaCl or BAS 500 06 F at concentrations of 1 and 5%.

The dermal irritation scores observed 1, 24 and 48 hours after a 48-hour epidermal exposure of 10, 25 and 50% dilutions in highly deionized water and in undiluted BAS 500 06 F are given in Table 7.1.6-4.

Table 7.1.6-4: Skin irritation scores after epidermal application - Preliminary test

Animal #	Readings 1 hour after removal of the patch		Readings 24 hours after removal of the patch		Readings 48 hours after removal of the patch	
Application site	Right flank middle	Left flank middle	Right flank middle	Left flank middle	Right flank middle	Left flank middle
1st Pretest (conducted 15-Dec-2008)						
BAS 500 06 F in highly deionized water	100%	50%	100%	50%	100%	50%
4	1	1	0	0	0	0
5	1	1	1	1	1	0
6	1	1	1	1	1	1
2nd Pretest (conducted 12-Jan-2009)						
BAS 500 06 F in highly deionized water	25%	10%	25%	10%	25%	10%
83	1	1	0	0	0	0
84	0	0	0	0	0	0
85	0	0	0	0	0	0

Grading: 0: no visible change 1: discrete or patchy erythema

Based on the data from the pre-test a 5% dilution of BAS 500 06 F in 0.9% aqueous NaCl-solution or in Freund's complete adjuvant / 0.9% aqueous NaCl-solution (1:1) was used for intradermal induction, whereas a 50% dilution in highly deionized water was used for epidermal induction. As no skin findings were observed 24 and 48 hours after dermal administration of a 25 and 10% aqueous dilution, a 25% dilution was used for the 1st challenge. Since this concentration caused skin findings in 30% of the control and 70% treated animals (see below), the second challenge was performed with a 10% dilution.

B. Induction reactions
Intradermal injection of

- Freund's adjuvant / 0.9% aqueous NaCl-solution (1 : 1) in control and treated animals,
- 5% BAS 500 06 F preparation in 0.9% aqueous NaCl-solution in treated animals,
- 5% BAS 500 06 F in Freund's adjuvant / 0.9% aqueous NaCl-solution (1 : 1) in treated animals, and
- 50% formulation of 0.9% aqueous NaCl-solution with Freund's complete adjuvant / 0.9% aqueous NaCl-solution (1 : 1) in control animals

caused intense erythema and swelling (grade 3) in all animals. No skin reactions were observed in control animals at the mid row injections of 0.9% NaCl-solution (see Table 7.1.6-5).

Table 7.1.6-5: Skin irritation scores 24 hours after intradermal injection - Main test

Control animals				
Animal #	Application site	A) Freund's adjuvant / 0.9% aqueous NaCl-solution (1 : 1)	B) 0.9% aqueous NaCl-solution	C) 50% formulation of 0.9% aqueous NaCl-solution with Freund's complete adjuvant / 0.9% aqueous NaCl-solution (1 : 1)
all animals	left	3	0	3
	right	3	0	3
Treated animals				
Animal #	Application site	A) Freund's adjuvant / 0.9% aqueous NaCl-solution (1 : 1)	B) 5% BAS 500 06 F preparation in 0.9% aqueous NaCl-solution	C) 5% BAS 500 06 F in A)
all animals	left	3	3	3
	right	3	3	3

Grading: 3: intense erythema and swelling

The epicutaneous induction with a 50% test-substance preparation in highly deionized water led to incrustation, partially open (caused by the intradermal induction) in addition to intense erythema and swelling (grade 3) in all test group animals.

C. Challenge

Epidermal challenge with a 25% aqueous dilution of BAS 500 06 F in highly deionized water caused grade 1 (discrete or patchy erythema) or Grade 2 skin reactions (moderate and confluent erythema) in certain control and treated animals (see Table 7.1.6-6). Therefore, a second challenge using a 10% aqueous dilution of BAS 500 06 F was performed. This time no skin reactions were observed in control animals whereas grade 1 or grade 2 skin reactions were observed in a total of 7 animals. One of the animals displaying moderate and confluent erythema also displayed skin swelling.

Table 7.1.6-6: Challenge skin reaction scores 24 hours after intradermal injection - Main test

	1st challenge		2nd challenge	
	Test substance 25% in highly deionized water		Test substance 10% in highly deionized water	
	24 h	48 h	24 h	48 h
Control group				
- Grade 1	2 / 10	1 / 10	-	-
- Grade 2	1 / 10	-	-	-
Test group				
- Grade 1	11 / 20	5 / 20	-	1 / 20
- Grade 2	3 / 30	3 / 20	5 / 20	6 / 20
- Swelling	-	-	-	1 / 20

x/y: number of positive reactions/number of animals tested (reading at 24 h and/or 48 h after the removal of the patch)

D. Observations

No clinical signs of systemic toxicity or mortality were observed.

E. Body weights

The expected body weight gain was generally observed in the course of the study.

F. Positive control

The sensitivity of Harlan Guinea pigs (Hsd Poc: DH (SPF), Harlan Winkelmann GmbH, Borchen, Germany) or Charles River Guinea pigs (Dunkin Hartley, Crl:HA, Charles River Laboratories, Research Models and Services, Germany GmbH, 88353 Kisslegg) and the reliability of experimental techniques is assessed regularly using a known sensitizer as recommended by the test guidelines.

The study procedures were based on the methods of Magnusson and Kligmann (1969) (Maximization Test) and Buehler, E.V. (1965) (Buehler Test) and are summarized below.

Name of test substance:	alpha-Hexylcinnamaldehyde, techn. 85%
CAS number:	101-86-0
Substance number:	98/0288-3
Concentrations:	
Maximization Test:	
Intradermal induction:	Test substance 5% in paraffin oil Test substance 5% in Freund's complete adjuvant / 0.9% aqueous NaCl solution (1:1)
Epicutaneous Induction:	Test substance 10% in Lutrol® E 400
Challenge:	Test substance 5% in Lutrol® E 400
Buehler Test:	
Induction:	Test substance 25% in Lutrol® E 400
Challenge:	Test substance 15% in Lutrol® E 400

As evident from Table 7.1.6-7 the test system and the used procedures were capable to detect the sensitizing properties of alpha-Hexylcinnamaldehyde.

Table 7.1.6-7: Positive control studies - Number of animals with skin findings after the challenge in control studies with the test-substance alpha-Hexylcinnamaldehyde (techn. 85%)

				Challenge

x/y: number of positive reactions/number of animals tested (reading at 24 h and/or 48 h after the removal of the patch)

III. CONCLUSION

Based on the results of this study it can be concluded that BAS 500 06 F has sensitizing properties under the test conditions chosen.

The formulation has to be classified as a sensitizer ("May cause sensitization by skin contact", Xi, R43) according to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC). According to Regulation (EC) 1272/2008 (CLP), the formulation has to be classified as "May cause an allergic skin reaction" (Cat. 1, H317).

CP 7.1.7 Supplementary studies on the plant protection product

No supplementary studies on the plant protection product were deemed necessary and thus none were conducted.

CP 7.1.8 Supplementary studies for combinations of plant protection product

No studies for combinations of BAS 500 06 F with other plant protection products were deemed necessary and thus none were conducted.

CP 7.2 Data on exposure

Exposure assessments and risk evaluations for operators, workers, bystanders and residents are presented below for the new representative formulation BAS 500 06 F, which has not been evaluated during a previous Annex I inclusion process.

CP 7.2.1 Operator exposure

The plant protection product BAS 500 06 F is already registered for the use as fungicide in the representative crops cereals and maize. Among these crops, cereals are the critical use based on the higher application rate (i.e. 250 g/ha per application in cereals versus 200 g/ha in maize) and number of applications (i.e. 2 per season in cereals versus 1 per season in maize). Information on the critical use pattern relevant for operator exposure is summarized in Table 7.2.1-1.
The formulation is an emulsifiable concentrate (EC) containing 200 g/L pyraclostrobin and is mainly commercialized in 5 and 10 L containers.

Table 7.2.1-1: Summary of critical use pattern

Crop (indoor / field)	**Application rate** (g as/ha)		**Spray dilution** (L/ha)	**Application equipment**	**Number of applications**
Cereals (field)	Pyraclostrobin	250	100	Tractor mounted boom sprayers	2

The critical use pattern has been defined based on the already registered uses in cereals and maize (for details see M-CP 3 Table 2).

Estimations of potential operator exposure have been undertaken for BAS 500 06 F using the intended use shown above and the following predictive models:

- Uniform Principles for Safeguarding the Health of Applicators of Plant Protection Products (Uniform Principles for Operator Protection), Mitteilungen aus der Biologischen Bundesanstalt, Heft 277, Berlin 1992 ("German model").

- Revised UK POE Model, as available on http://www.pesticides.gov.uk/uploadedfiles/Web_Assets/PSD/UK_POEM1.xls [UK Predictive Operator Exposure Model (POEM): Estimation of Exposure and Absorption of Pesticides by Spray Operators, Scientific subcommittee on Pesticides and British Agrochemical association Joint Medical Panel Report (UK MAFF), 1986 and the Predictive Operator Exposure Model (POEM) V 7 of 2008, (UK MAFF), 1992 ("UK Model").

Risk assessment for operator

The toxicological reference value (Acceptable Operator Exposure Level) for pyraclostrobin and dermal absorption values appropriate for BAS 500 06 F, which were used in the operator risk assessment are shown in Table 7.2.1-2 below.

Table 7.2.1-2: Endpoints for pyraclostrobin used in operator risk assessment

Endpoint	Value	Reference
Dermal penetration - Concentrate - Spray dilutions	3% 7%	BASF DocIDs 2010/1059865 and 2014/1001501 (for details see M-CP 7.3 of this dossier)
$AOEL_{systemic}$	0.015 mg/kg bw/day	EU Review Report SANCO/1420/2001-Final, 8. September 2004

The estimated operator exposure to pyraclostrobin for the use of BAS 500 06 F in cereals is shown in Table 7.2.1-3 below.

Table 7.2.1-3: Estimated operator exposure to pyraclostrobin in BAS 500 06 F

Model data	Level of PPE	Total absorbed dose (mg/kg bw/day)[1]	% of AOEL[2]	Reference in Appendix
outdoor tractor operated boom sprayer application with hydraulic nozzles to field crops 1.25 L BAS 500 06 F/ha corresponding to 250 g pyraclostrobin per ha				
German Model - 20 ha/day - 70 kg operator	Gloves during mixing/loading and gloves, coverall and sturdy footwear during application	0.0009	6	**7.2-3**
UK POEM - 50 ha/day - 60 kg operator	Gloves during mixing/loading and gloves during application	0.025	169	**7.2-4**

[1] systemic exposure based on dermal absorption of 3% for mixing/loading and 7% for application for pyraclostrobin
[2] based on a systemic AOEL of 0.015 mg/kg bw/day

For operators exposed to pyraclostrobin when applying BAS 500 06 F to cereals no safe use could be demonstrated based on UK POEM. Therefore a refined risk assessment is presented in M-CP 7.2.1.2. Results are summarised below.

Table 7.2.1-4: Refined assessment: Estimated operator exposure to pyraclostrobin in BAS 500 06 F based on field exposure data

Model data	Level of PPE	Total absorbed dose (mg/kg bw/day)[1]	% of AOEL[2]	Reference in Appendix
outdoor tractor operated boom sprayer application with hydraulic nozzles to field crops 1.25 L BAS 500 06 F/ha corresponding to 250 g pyraclostrobin per ha				
Refined assessment based on field exposure data - 50 ha/day	Coverall and gloves during mixing/loading and application	0.000047	0.31	**7.2-9**

[1] systemic exposure based on dermal absorption of 7% for both mixing/loading and application for pyraclostrobin as a worst case
[2] based on a systemic AOEL of 0.015 mg/kg bw/day

Results and discussion

Following the operator exposure and risk evaluation based on models a safe use could be shown for the BBA model estimates. For UK POEM adequate operator safety could not be demonstrated if PPE is considered. However, refined exposure assessments based on surrogate data, which reflect today's application equipment, have shown that the predicted systemic exposure is within the acceptable limit.

In conclusion operators when exposed to pyraclostrobin under the use conditions of BAS 500 06 F in cereals and maize are considered to be at acceptable risk.

CP 7.2.1.1. Estimation of operator exposure

BAS 500 06 F is applied in field crops (cereals and maize), which is professional use only. The relevant application scenario is outdoor tractor operated boom sprayer with hydraulic nozzles. Risk assessments are presented based on the BBA model and the UK POEM with consideration of the following input parameters.

Table 7.2.1.1-1: German model input parameters for tractor mounted boom sprayer application in cereals

Application method:	tractor-mounted boom sprayers with hydraulic nozzles, field crop
Treated area:	20 ha/day
Max. dose rate:	1.25 L BAS 500 06 F/ha
	corresponding to: 0.25 kg pyraclostrobin/ha
Operator body weight:	70 kg

Table 7.2.1.1-2: UK POEM input parameters for tractor mounted boom sprayer application in cereals

Application method:	Tractor-mounted/trailed boom sprayer: hydraulic nozzles
Treated area:	50 ha/day
Max. dose rate:	1.25 L BAS 500 06 F/ha
	corresponding to: 0.25 kg pyraclostrobin/ha
Spray volume:	100 L/ha
Duration:	6 h
Container:	10 litres 63 mm closure
Operator body weight:	60 kg

Estimation of operator exposure <u>without personal protective equipment</u>

Exposure predictions for operators using no protective equipment (PPE) are summarized in Table 7.2.1.1-3.

Table 7.2.1.1-3: Estimated operator exposure to pyraclostrobin in BAS 500 06 F without using PPE

Model data	Level of PPE	Total absorbed dose (mg/kg bw/day)[1]	% of AOEL[2]	Reference in Appendix
outdoor tractor operated boom sprayer application with hydraulic nozzles to field crops 1.25 L BAS 500 06 F/ha corresponding to 250 g pyraclostrobin per ha				
German Model - 20 ha/day - 70 kg operator	None	0.016	103	**7.2-1**
UK POEM - 50 ha/day - 60 kg operator	None	0.159	1058	**7.2-2**

[1] systemic exposure based on dermal absorption of 3% for mixing/loading and 7% for application for pyraclostrobin
[2] based on a systemic AOEL of 0.015 mg/kg bw/day

A safe use could not be shown for operators without personal protective equipment with any of the models chosen. Detailed information is presented in Appendix 7.2-1 and 7.2-2.

Estimation of operator exposure <u>with personal protective equipment</u>

Exposure predictions for operators using protective equipment (PPE) are summarized in Table 7.2.1.1-4.

Table 7.2.1.1-4: Estimated operator exposure to pyraclostrobin in BAS 500 06 F with using PPE

Model data	Level of PPE	Total absorbed dose (mg/kg bw/day)[1]	% of AOEL[2]	Reference in Appendix
outdoor tractor operated boom sprayer application with hydraulic nozzles to field crops 1.25 L BAS 500 06 F/ha corresponding to 250 g pyraclostrobin per ha				
German Model - 20 ha/day - 70 kg operator	Gloves during mixing/loading and gloves, coverall and sturdy footwear during application	0.0009	6	**7.2-3**
UK POEM - 50 ha/day - 60 kg operator	Gloves during mixing/loading and gloves during application	0.025	165	**7.2-4**

[1] systemic exposure based on dermal absorption of 3% for mixing/loading and 7% for application for pyraclostrobin
[2] based on a systemic AOEL of 0.015 mg/kg bw/day

For operators exposed to pyraclostrobin when applying BAS 500 06 F in cereals no safe use could be demonstrated based on UK POEM. Detailed information is presented in Appendix 7.2-3 and 7.2-4.
Therefore a refined risk assessment is presented which considers higher tier data on the basis of two field exposure studies performed by the applicant.

CP 7.2.1.2. Measurement of operator exposure

Since the risk assessments performed indicate that the health-based limit value (AOEL) for pyraclostrobin will be exceeded under practical conditions of use, two surrogate studies to provide field data on operator exposure to BAS 500 06 F are used, for which study summaries are shown below.

Report:	CP 7.2.1.2/1 Stadler R., 2007a Determination of dermal and inhalation operator exposure for mixing/loading and application of BAS 601 KD F in cereals 2007/1033389
Guidelines:	OECD Series on Testing and Assessment No. 9 - Guidance document on the conduct of studies of occupational exposure to pesticides during agricultural application (Paris 1997)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Note: This study was erroneously not contained in the application. It needs to be submitted, because it is the basis for the refined risk assessment.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1.	**Test Material:**	Epoxiconazole formulated in the preparation BAS 601 KD F
	Description:	Experimental suspension concentrate (SC) formulation containing nominal 100 g/L epoxiconazole
	Batch/purity #:	batch no. 2032: 91.0 g epoxiconazole/L batch no. 2036: 92.2 g epoxiconazole/L batch no. 2037: 94.5 g epoxiconazole/L mean epoxiconazole content: 92.6 g/L
	Stability of test compound:	The stability of the formulation was guaranteed by the sponsor Expiry date (Certificates of Analysis): 30 September 2008

B. STUDY DESIGN AND METHODS

Dates of work: 06-Sep-2006 to 27-Feb-2007

The measurement of operator exposure was conducted with a surrogate formulation (BAS 601 KD F) under field crop conditions. Unlike assessments to the current available models (BBA-model, UK POEM or EUROPOEM), where the data base was generated by means of studies performed before 1990, the existing operator exposure study was performed with application machinery that is more appropriately reflecting the present standard of application technology. Tractors with closed cabins, large sprayers for water volumes in the range of 2000 to 5200 L thus allowing less mixing/loading operations and large spray booms with a spray boom width in the range of 18 to 36 m allowing reduce the time needed for spray operations. The combination of these technical features has been considered to show an operator exposure pattern that is more accurately addressing today's conditions of use.
This operator exposure study was conducted at 10 locations in the Southwest and East of Germany during September and October 2006. The applied product BAS 601 KD F was an experimental suspension concentrate (SC) containing nominal 100 g/L epoxiconazole.
Analytical evaluation of the product revealed, however, that the actual concentration was lower, the mean concentration of the used batches being 92.6 g/L. Therefore the actual mean concentration was used for the calculations. The product was applied at a rate of 1.25 L/ha. The treated daily area per operator was about 50 ha with a range of 48.0 to 53.5 ha. The applications were performed with conventional tractor-mounted or tractor-drawn boom sprayers fitted with hydraulic nozzles. Typical water volumes were used (water rates were in a range of 100 – 200 L/ha with a mean of about 142 L/ha). Water volumes thus appropriately reflect spray practices in Western and Central Europe.
Meteorological conditions were monitored during all workdays. Air temperatures ranged from 12 to 32°C, the range of soil temperatures was 11 to 25°C. A relative humidity of 55–100% was measured, the wind speed ranged from 0 to 4 m/s.
A total of 10 operators were monitored during mixing/loading and application of the spray solution. No differentiation in exposure monitoring between mixing/loading and application was done. The whole study was divided in subset A and B characterised as follows:

A) Mixing/loading was performed as standard procedure to assess operator exposure when handling conventional containers of the product (operator 1B, 2A-10A. Note: In the study conduct the subset designation for operator No 1 was mixed up thus showing the exposure data for the standard mixing/loading process under 1B instead of 1A, and vice-versa. In this subset commercial 5 L containers were used. A summary of the relevant application equipment parameters is provided in Appendix 7.2-5.
B) Mixing/loading was performed with a closed transfer system for the mixing/loading process (operator 1A, 2B-10B). In this subset two closed transfer systems were used: Nine operators used the ECOMATIC system with 50 L product containers. The tenth operator used the CONNECTA system which allowed the transfer of the product from 5 L standard containers into the spray tank under controlled exposure conditions. Subset B was chosen in addition to demonstrate additional operator protection by testing a closed transfer system for the product containers in comparison to standard Mixing/Loading (M/L) [subset B].

   These data were, however, not included into the surrogate database.

Each operator performed two treatments. One treatment was performed according to the conditions of "subset A", the other according to "subset B", about 50 ha having been treated each time. The operator used the same sprayer when performing the two applications.
Operators were considered experienced in pesticide application. Their age was in the range of 32 to 57 years. Their body weight was in the range of 85 kg to 110 kg with a mean of about 93 kg.

Dosimeter

Dermal dosimeter
The exposure was measured by whole body dosimetry for the dermal exposure. Hand exposure was assessed by means of a hand wash procedure following the back rinse method [Durham, W.F. and Wolfe, H.T., 1962: Measurement of the exposure of workers to pesticides, Bull. WHO 26, 75-91]. The operators were equipped with two layers of whole body dosimeters consisting of outer dosimeters and inner dosimeters. A standard work clothing of cotton/polyester fabric was chosen as outer dosimeter. The inner dosimeters consisted of whole cotton underwear with long arms and legs. The hand exposure was assessed by analysis of nitrile protective gloves (outer dosimeter) and hand wash samples (inner dosimeter). Hand wash samples were taken at times when the worker normally washed his hands for reasons such as eating or using the toilet and at the end of the work period when it was reasonable to expect workers to wash hands. The operators were advised to use the protective gloves only for the mixing/loading process. For the application the operator did not need to wear protective gloves as long as he was not doing maintenance works at the sprayer where he could get into contact with spray liquid. In cases where the applicator was likely to get into contact with spray-liquid he wore protective gloves. Right and left gloves used per operator on a working day were pooled and subjected to a common analysis of the active substance contained. Hand wash samples were pooled as well in order to assess the actual hand exposure. Head exposure was measured by face/neck wipes with 100% cotton gauze. Face/neck wipes were taken at the end of the work period. Face and neck wipe samples were performed with 2 pads of cotton gauze wetted with liquid soap solution. If the operator wished to wear a hat or a cap for sun protection or any other reason he was allowed to do so. The hat or a cap was not taken as a dosimeter. At the end of the monitoring period outer and inner dosimeters were separated and sectioned into individual parts as follows for the subsequent analysis.

Outer dosimeter	**Inner dosimeter**
Both lower arms	Both lower arms
Both upper arms	Both upper arms
Chest	Chest
Back	Back
Both lower legs	Both lower legs
Both upper legs	Both upper legs
Protective gloves (right and left pooled)	Hand wash samples (right and left one pooled)
	Face/neck wipes

The potential dermal exposure (PDE) was calculated from residues on the work jacket, the pair of trousers, the underwear (vest & long-johns), face/neck wipes, the hand-wash samples and the protective gloves. The actual dermal exposure (ADE) was calculated from the residues detected on/in the underwear (long sleeved vest & long-johns), the faces/neck wipes and the hand-wash samples.

Inhalation dosimeters

Operators were equipped with personal air sampling pumps (TENAX adsorption tubes) combined with an inhalable fraction sample collector located in the operator's breathing zone. The limit of quantification (LOQ) was 1 ng (0.001 µg). The air pump flow was calibrated to 2 L/min. For a sampling interval of one hour this corresponds to a total air volume of 120 L. For an operator engaged in moderate physical labour a breathing volume of 14 L/min or 840 L/hour was considered. Thus, a conversion factor of 7 [14 : 2 = 7] was used to derive an estimate of inhalation exposure for the operators.

Storage of dosimeters

At the end of the treatment, the body dosimeters were removed and sectioned on site prior to storage in a cool box for the transport to the laboratory. Samples were subsequently stored deep-frozen until analysis. Air samplers were stored in darkness at ambient temperatures until analysis.

Field recoveries and analytical procedures

The stability of the test item under field, storage and transport conditions in or on the sampling materials (coverall, inner dosimeters, facial swabs, protective gloves if necessary and air sampling filters) was assessed for field fortifications, for storage and for transport conditions. For this purpose, the test item was applied under laboratory and under field conditions onto the different sampling materials at two different concentrations (i.e. at the 10-fold and 100-fold of the LOQ) and the recoveries were analytically determined.

Inner and outer dosimeters as well as protective gloves were extracted with methanol. Aliquots of the extract were diluted with equal volumes of water for LC/MS/MS injection. Hand wash solution aliquots were diluted with equal volumes of methanol for LC/MS/MS analysis. Face/Neck wipes were extracted with methanol. Aliquots of the extract were diluted 1: 9 with water : methanol (1:1) for LC/MS/MS injection. The Tenax absorber was extracted with acetone. Extracts were reduced to dryness and subsequently diluted in methanol : water (1:1) for LC/MS/MS analysis.

II. RESULTS AND DISCUSSION

Field and concurrent laboratory fortifications

The results of field, transport and concurrent laboratory fortification analyses demonstrated the storage and transport stability of the test item. Field recovery and lab recovery data for body dosimeters were in the range of 74 to 99% of the test substance initially applied. For air sampler units, recoveries were between 95 to 102%. A short summary of the recovery results is given in Table 7.2.1.2-1 below.

Table 7.2.1.2-1: Field and concurrent laboratory fortifications

Matrix	Field recovery [%]	Lab recovery [%]	Correction factor[1]
Inner dosimeter	74	78	1.35
Face wipe	98	99	n n.
Hand wash solution	92	99	n n.
Outer dosimeter	92	95	n n.
Gloves	88	87	n n.
Air sampler	95	102	n n.

[1] According to guidelines a correction factor needs not be applied if the recovery values are within the 70 - 120% range.

Based on the obtained recovery data a correction factor of 1.35 was applied to account for incomplete field and laboratory recoveries for inner body dosimeters. For all other matrices no correction factor was employed.

Analytical confirmation of the test substance in BAS 601 KD F

Three different batches of BAS 601 KD F were used in the study. The analytical confirmation of test substance control gave the following results (Table 7.2.1.2-2).

Table 7.2.1.2-2: Analytical results of used BAS 601 KD F batches

Batch-No.	Nominal content (epoxiconazole) [g/L]	Analyzed content (epoxiconazole) [g/L]
2032	100	91
2036	100	92.2
2037	100	94.5

The mean analytical recovery was 92.6 g epoxiconazole/L. An additional correction factor was therefore used to account for the difference found in regard to the nominal test substance concentration of 100 g/L. A summary of the obtained exposure levels for outer and inner body dosimeters, hand wash and glove exposure, face and neck wipes as well as inhalation exposure is given in Table 7.2.1.2-3.

Table 7.2.1.2-3: Summary of operator exposure to epoxiconazole when mixing/loading and spraying BAS 601 KD F to field crops

Note: This study was erroneously not contained in the application. It needs to be submitted, because it is the basis for the refined risk assessment.

Executive Summary

I. MATERIAL AND METHODS

A. MATERIALS

1.	**Test Material:**	Epoxiconazole formulated in the preparation BAS 480 31 F
	Description:	Suspension concentrate (SC) formulation containing nominal 125 g/L epoxiconazole
	Batch/purity #:	batch L72-185, epoxiconazole: 126.1 g/L
	Stability of test compound:	The stability of the formulation was guaranteed by the sponsor Expiry data (certificate of analysis): April 01, 2010

B. STUDY DESIGN AND METHODS

Dates of work: 19-May-2008 to 07-August-2008 (experimental data),
30-April-2010 (study completion date)

This operator exposure study was conducted at 13 locations in Germany and the United Kingdom during May and June 2008. At two locations 2 individual operators each were monitored on separate dates. Thus, in total 15 operators were monitored for all tasks related to application of the product BAS 480 31 F in cereals i.e. mixing/loading the appropriate amounts and application to a daily work area of about 50 ha. The applied product BAS 480 31 F was a commercial suspension concentrate (SC) containing nominal 125 g/L epoxiconazole.
In addition to the subset of 15 operators conducting all tasks (mixing/loading and application) a second subset of 14 operators was monitored separately for mixing/loading activities only. Within these two subsets (mixing/loading/application versus mixing/loading 9 operators were members of both subsets, but monitored on separate dates to allow a better comparison.
Although summarized below, the result of the second subset (mixing/loading activity only) will not be taken into consideration for the risk assessment purposes of this dossier.
Meteorological conditions were monitored during all workdays. Air temperatures ranged from 11 to 32°C. A relative humidity of 23–80% was measured, the wind speed ranged from 0 to 2.5 m/s.
A total of 15 operators were monitored during mixing/loading and application of the spray solution. In addition, a total of 14 operators were monitored during mixing/loading only. The subsets were defined as follows.

A) The activities mixing/loading and application were conducted in order to perform an application of BAS 480 31 F according to the recommended GAP of 1 L/ha to an approximate area of 50 ha. Mixing/loading was assessed when handling conventional 5 L containers of the product. Application was performed using conventional boom sprayer equipment with either standard or drift reduced nozzles. A summary of the relevant application equipment parameters is provided in Appendix 7.2-5.
B) For the mixing/loading activity the amount of product handled was intended to cover a daily application area. While 8 operators mixed an amount necessary for application of 50 ha, i.e. 10 containers of product during 1-2 mixing/loading activities corresponding to about 6.25 kg epoxiconazole, the remaining 6 operator mixed 3.75 to 5.63 kg epoxiconazole. Conventional 5 L containers of the product were used.

Operators were considered experienced in pesticide application. Their body weight was in the range of 72 kg to 145 kg with a mean of about 104 kg.

Dosimeter

Dermal dosimeter

The exposure was measured by whole body dosimetry for the dermal exposure. Hand exposure was assessed by means of a hand wash with 2 x 500 ml soap solution (2.5 mL liquid soap in 500 mL water).

The operators were equipped with two layers of whole body dosimeters consisting of outer and inner dosimeters. A standard work coverall of cotton/polyester fabric was chosen as outer dosimeter. The inner dosimeters consisted of whole cotton underwear with long arms and legs.

The hand exposure was assessed by analysis of nitrile protective gloves (outer dosimeter) and hand wash samples (inner dosimeter). Hand wash samples were taken at the end of the monitoring period for each operator prior to removing the body dosimeters. The operators were advised to use the protective gloves only for the mixing/loading process. For the application the operator did not need to wear protective gloves as long as he was not doing maintenance works at the sprayer where he could get into contact with spray liquid. In cases where the applicator was likely to get into contact with spray-liquid he wore protective gloves. Right and left gloves used per operator on a working day were pooled and subjected to a common analysis of the active substance contained. Hand wash samples were pooled as well in order to assess the actual hand exposure. Head exposure was measured by face/neck wipes with 100% cotton gauze. Face/neck wipes were taken at the end of the monitoring period prior to removing of the body dosimeters. Face and neck wipe samples were performed with 2 pads of cotton gauze wetted with 4 mL liquid soap solution. If the operator wished to wear a hat or a cap for sun protection or any other reason he was allowed to do so. The hat or a cap was not taken as a dosimeter. Other protective measures like face shield or mask were allowed at the discretion of the operator and not taken into account as dosimeter.

At the end of the monitoring period outer and inner dosimeters were separated and sectioned into individual parts as follows for the subsequent analysis.

Outer dosimeter	**Inner dosimeter**
Both lower arms	Both lower arms
Both upper arms	Both upper arms
Chest	Chest
Back	Back
Both lower legs	Both lower legs
Both upper legs	Both upper legs
Protective gloves (right and left pooled)	Hand wash samples (right and left one pooled)
	Face/neck wipes

The potential dermal exposure (PDE) was calculated from residues of the coverall, the underwear (vest & long-johns), faces/neck wipes, the hand-wash samples and the protective gloves. The actual dermal exposure (ADE) was calculated from the residues detected on/in the underwear (long sleeved vest & long-johns), the faces/neck wipes and the hand-wash samples.

Inhalation dosimeters

Operators were equipped with personal air sampling tubes (TENAX adsorption tubes) combined with a personal air sampling pump located in the operator's breathing zone. The limit of quantification (LOQ) was 1 ng (0.001 µg). The air pump flow was adjusted to 1.5 L/min and the pumps were calibrated prior and after use. The total volume of air sampled was calculated based on the mean calibration data in conjunction with the total run time. For an operator engaged in moderate physical labour a breathing volume of 14 L/min or 840 L/hour was considered.

Storage of dosimeters

At the end of the treatment, the body dosimeters were removed and sectioned on site prior to storage in a freezer or freezer truck for the transport to the laboratory. Samples were subsequently stored deep-frozen until analysis. Air samplers were stored in darkness at ambient temperatures until analysis.

Field recoveries and analytical procedures

The stability of the test item under field, storage and transport conditions in or on the sampling materials (coverall, inner dosimeters, facial swabs, protective gloves if necessary and air sampling filters) was assessed for field fortifications, for storage and for transport conditions. For this purpose, the test item was applied under laboratory and under field conditions onto the different sampling materials at two different concentrations and the recoveries were analytically determined.

Inner and outer dosimeters as well as protective gloves were extracted with methanol. Aliquots of the extract were diluted with equal amounts of water for LC/MS/MS injection. Hand wash solution aliquots were diluted with equal volumes of methanol for LC/MS/MS analysis. Face/Neck wipes were extracted with methanol. Aliquots of the extract were diluted 1: 9 with water : methanol (1:1) for LC/MS/MS injection. The Tenax absorber was extracted with acetone. Extracts were reduced to dryness and subsequently diluted in methanol : water (1:1) for LC/MS/MS analysis.

II. RESULTS AND DISCUSSION

Field and concurrent laboratory fortifications

The results of field, transport and concurrent laboratory fortification analyses demonstrated the storage and transport stability of the test item. Field recovery and lab recovery data for body dosimeters were in the range of 74 to 99% of the test substance initially applied. For air sampler units, recoveries were between 95 to 102%. A short summary of the recovery results is given in Table 7.2.1.2-4 below.

Table 7.2.1.2-4: Mean field and concurrent laboratory fortifications

Matrix	Field recovery [%]	Lab recovery [%]	Correction factor[2]
Inner dosimeter	100.0 ± 5.5	97.5 ± 8.6	n.n.
Face/Neck wipe	105.7 ± 20.6	93.0 ± 6.0	n.n.
Hand wash solution	109.8 ± 13.4	98.3 ± 8.2	n.n.
Outer dosimeter	93.9 ± 6.1	99.1 ± 7.8	n.n.
Gloves[1]	72.8 ± 19.8	86.6 ± 8.3	Mean of field fortification levels except invalid values
Gloves except field fortification considered invalid	77.5 ± 14.5		1.29
Air sampler	98.3 ± 16.9	106.0 ± 4.3	n.n.

[1] The field fortifications for gloves were in the range of 68 to 89% except for one specific day. The lower values of this day (mean 32%) were considered invalid as the fortified specimens were blown from the table by a sudden wind gust.

[2] According to guidelines a correction factor needs not be applied if the recovery values are within the 70 - 120% range. However, no correction was applied in cases were the upper range was exceeded as the uncorrected values would result in a conservative overestimation of exposure

Based on the obtained recovery data a correction factor of 1.29 was applied to account for field recoveries for gloves. For all other matrices no correction factor was employed.

The occasionally higher field recoveries for face/neck wipes and air samplers were not considered for correction as the uncorrected values would result in an overestimation of exposure.

Analytical confirmation of the test substance in BAS 480 31 F

One batch of BAS 480 31 F was used in the study. The analytical confirmation of test substance control gave the following results (Table 7.2.1.2-5).

Table 7.2.1.2-5: Analytical results of used BAS 480 31 F batch

Batch-No.	Nominal content (epoxiconazole) [g/L]	Analyzed content (epoxiconazole) [g/L]
L72-185	125	126.1

A summary of the obtained exposure levels for outer and inner body dosimeters, hand wash and glove exposure, face and neck wipes as well as inhalation exposure is given in Table 7.2.1.2-6.

Table 7.2.1.2-6: Summary of operator exposure to epoxiconazole when mixing/loading and spraying BAS 480 31 F to field crops

Study	Total Inner Body Dosimeter	Hand Wash	Face/Neck Wipe	Actual Dermal Exposure	Total Outer Body Dosimeter	Glove	Potential Dermal Exposure	Inhalation Exposure

The results of the two field exposure studies, which are summarized above, will be further discussed in the following chapters.

General conclusion on the applicability of the surrogate studies to assess operator exposure under the proposed use conditions of BAS 500 06 F

The surrogate field exposure studies conducted used liquid formulations applied to field crops using ground-boom sprayers with hydraulic nozzles. In the studies the exposure during mixing/loading and application was monitored together. The results are considered representative of equipment intended for large areas, i.e. corresponding to the data used in the UK agronomic parameters (50 ha/day). The application rate was 125 g a.s./ha with application volumes of 100 to 200 L/ha. The exposure data were generated using current standards of application equipment (e.g. tractors with cabins in combination with large-tank ground-boom sprayers and wide spray booms (for details see Appendix 7.2-5). Thus, the use conditions of the field exposure study is representative for the use conditions of BAS 500 06 F as it is applied today.

Methodology

In the studies the operator exposure was investigated using the whole body dosimetry method, which is considered to be more reliable than the patch method. In all cases, the inhalation exposure was measured by means of pumps connected to suitable filters or cartridges. The pumps were adjusted to an air volume that allowed capturing airborne particles in the respirable range. The exposure of the hands was measured by performing hand washing with an appropriate solution after taking off the protective gloves. Gloves were worn in all the cases during the mixing/loading phase. During the application phase protective gloves were worn when operators identified the need (e.g. during operations like fixing blocked nozzles). Therefore, since gloves were not worn throughout the application phase, it is not possible to evaluate a transfer through gloves from the available data.

Agronomic parameters

Treated areas were in the range of 48.0 to 55.4 ha for operators (details are shown in Appendix 7.2-5). The geometric mean and the 75th percentile is about 50 ha which corresponds to the recommended area of the UK-POEM and EUROPOEM. Treated areas are thus well representing agricultural practice in European countries, where treated areas have increased since the time when the BBA model was developed. On the other hand, for these areas the average duration of application was only 3.8 hours, which is about half the duration recommended in the agronomic parameter guide in UK-POEM or BBA.

The agricultural equipment was of a size suitable to spray large areas and all the tractors were equipped with cabins (open or closed). Application rates were defined in the protocol of the studies being 0.125 kg a.s./ha, respectively. Water application volumes were variable and comprised between 90 and 180 L/ha, which corresponds to the current standards. Therefore, this exposure database is considered to be representative for the uses on large field crop areas with modern application equipment.

Standardisation and adjustment of surrogate data

The data obtained from the operator exposures studies were standardized in order to simplify the extrapolation of surrogate data to application rates of other products or of other conditions of use.

Normalisation of the application rate

Data generated in the studies were normalized to an application of 1 g active substance per 1 ha allowing subsequent adoption to product specific application. Furthermore adjustments were made to work rates of 50 ha per day and to exposure per kg operator body weight to meet the respective input data for standard model assessments (e.g. UK POEM). A summary of the normalized study data is presented in Table 7.2.1.2-7; details are given in Appendix 7.2-6.

Table 7.2.1.2-7: Extrapolated dermal and inhalation exposure of recently conducted operator exposure studies with ground boom sprayers standardized for a work rate of 50 ha/day and for 1 g a.s./ha and normalized to the individual body weight

	Dermal exposure		Inhalative exposure
	no PPE	**complete PPE**	**no PPE**
	Potential dermal exposure	**Actual dermal exposure**	
	Sum of inner + outer body dosimeter + hand (inner) + gloves (outer) + head	Sum of inner body dosimeter + hand (inner) + head	
	[µg/kg bw/day when applying 1 g a.s./ha to 50 ha/day]		
Geometric Mean	**0.2903**	**0.0016**	**0.0000177**
75th Percentile	**0.4778**	**0.0032**	**0.0000289**

Personal protective equipment

For the evaluation below two scenarios with regard to different levels of personal protective equipment (PPE) were taken into consideration:

"no PPE":

It is assumed that operators completely neglect the label advice on protective equipment. The potential dermal exposure reflects the sum of total outer and inner body dosimeters, the head and hands including gloves. The “no PPE” scenario assumes permeation of 50% of the findings on dosimeters of outer clothing. Dermal exposure estimates thus have been based on the aggregation of findings on inner dosimeters including hand wash and face/neck wipes (head), findings on gloves plus 50% of findings on outer clothing dosimeters. Individual results and percentile values over the data set are presented as ‘Scenario 1’ in Appendix 7.2-7.

"complete PPE":

Complete protective equipment as used in the operator exposure study (standard protective working clothing during mixing/loading and application and protective gloves during mixing/loading). Dermal exposure estimates thus have been based on the aggregation of findings on inner dosimeters including hand wash and face/neck wipes (head). Individual results and percentile values over the data set are presented as ‘Scenario 2’ in Appendix 7.2-7.

Note: In the studies, operators wore protective gloves during mixing/loading and usually no gloves during spray application, except when performing maintenance work that would likely result in contact with the spray liquid.

Operator body weight

The individual operator body weights determined in the exposure study clearly indicate that the standard value used in the UK model is at the low end of distribution for actual operator weights. The exposure levels are thus normalized to µg a.s. per kg bodyweight on an individual basis (see Appendix 7.2-6).

Conclusion on the surrogate data of the two operator exposure studies in field crops

Exposure data points from two field studies comprising 25 operators on 23 farms were generated. State-of-the-Art technology of application equipment was used and individual work rates appropriately reflect today's agronomic conditions for field crop growers. The data are therefore considered to provide an adequate data base for the assessment of operator exposure during mixing/loading of liquid formulations and spray applications with field crop sprayers. Therefore, this database can be regarded as well adapted for extrapolation to other active substances applied within liquid formulations on field crops.

Exposure estimates and risk assessment for pyraclostrobin when used in BAS 500 06 F based on the surrogate operator exposure data

The following parameters were used for the estimations of operator exposure from the product BAS 500 06 F (see Table 7.2.1.2-8).

Table 7.2.1.2-8: Product specific parameters

	Pyraclostrobin
Application rate (kg a.s./ha)	0.25
Systemic AOEL (mg/kg bw/day)	0.015
Dermal penetration (%)	7

The normalized surrogate data were adjusted to account for the maximum recommended application rate of 250 g pyraclostrobin/ha. Furthermore a daily work rate of 50 ha/day was taken into account. The obtained dermal and inhalation exposure values (75th percentile estimates) are presented in Table 7.2.1.2-9 below. Detailed information is presented in Appendix 7.2-8 for the scenario "no PPE" and in Appendix 7.2-9 for the scenario "complete PPE".

Table 7.2.1.2-9: Operator risk assessment for the product BAS 500 06 F based on surrogate operator exposure data adapted to a work rate of 50 ha/day

Level of personal protection	Active ingredient	Systemic exposure[1]			Total systemic exposure	Account of AOEL[2]	Reference Appendix
		Dermal	Inhalation	Total			
		mg/kg bw/d			mg/kg bw/d		
75th percentile							
no PPE [3]	pyraclostrobin	0.0084	0.0000073	5.362	0.00841	56%	7.2-8
complete PPE [4]	pyraclostrobin	0.00004	0.0000073	0.000047	0.000045	0.31%	7.2-9

[1] systemic exposure based on dermal absorption for both mixing/loading and application of 7% for pyraclostrobin as a worst case
[2] total systemic exposure x 100 / systemic AOEL (AOEL for pyraclostrobin = 0.015 mg/kg bw/d)
[3] scenario 1, 50% permeation of outer body dosimeters
[4] scenario 2, actual dermal exposure
Note: Calculations were made using non rounded values, therefore deviations may occur when calculating with rounded values as shown above

Following the concept of the UK POEM with a work rate of 50 ha/day, the 75th percentile exposure values derived for pyraclostrobin correspond to about 56% of the AOEL and is thus within the acceptable range for an operator not being adequately dressed and not applying PPE.

The exposure values derived for pyraclostrobin for a protected operator wearing gloves during mixing/loading and adequate working clothing correspond to about 0.31% of the respective AOEL.

Conclusion

A generic data base consisting of recently generated field exposure data was set up and adjusted to the conditions of use for the formulation BAS 500 06 F (200 g pyraclostrobin/L). The basis for the generic data has been formed by two operator exposure field studies performed by BASF and described above. The studies were conducted under the current conditions of field crop applications using fungicide formulations.

In conclusion, operators are considered to be at acceptable risk when exposed to pyraclostrobin under the use conditions of BAS 500 06 F in cereals.

CP 7.2.2. Bystander and resident exposure

The plant protection product BAS 500 06 F is already registered for the use as fungicide in the representative crops cereals and maize. Information on the formulation and the critical use pattern relevant for the bystander and resident risk assessment can be found in chapter 7.2.1. The critical GAP is summarized in Table 7.2.1-1.

Exposure assessments and risk evaluations for bystanders and residents for the representative formulation BAS 500 06 F are presented below. According to the EU requirements they have been based on the following model:

- Martin S. et al. (2008): Guidance for Exposure and Risk Evaluation for Bystanders and Residents exposed to Plant Protection Products during and after Application. J. Verbr. Lebensm., drift distances adopted according to the recommendation published by the German BVL: B. Nolting (2012) Bekanntmachung ueber Mindestabstaende, die bei der Anwendung von Pflanzenschutzmitteln zum Schutz von Umstehenden und Anwohnern einzuhalten sind. Bundesanzeiger 2012 No. 4 Pp. 75-76 for the bystander and resident.

Risk assessment for bystander and resident

A summary of the bystander risk assessment is provided in Table 7.2.2-1.

Table 7.2.2-1: Summary of bystander exposure during application of BAS 500 06 F in cereals

	Active ingredient	Estimated bystander exposure[1] (mg/kg bw/day)	% of AOEL[2]	Reference in Appendix
Adults	pyraclostrobin	0.000813	5.42	7.2-10
Children		0.000635	4.23	

[1] according to the German model for bystander and resident exposure assessment; Martin S. et al. (2008)
[2] based on a systemic AOEL of 0.015 mg/kg bw/day for pyraclostrobin

A summary of the risk assessment for residents is provided in Table 7.2.2-2.

Table 7.2.2-2: Summary of residential exposure during application of BAS 500 06 F in cereals

	Active ingredient	Estimated residential exposure[1] (mg/kg bw/day)	% of AOEL[2]	Reference in Appendix
Adults	pyraclostrobin	0.0001	0.7	7.2-11
Children		0.00022	1.5	

[1] based on the German model for bystander and resident exposure assessment; Martin S. et al. (2008)
[2] based on a systemic AOEL of 0.015 mg/kg bw/day for pyraclostrobin

Conclusion
It is concluded that there is no unacceptable risk to bystanders or residents after accidental exposure of BAS 500 06 F under the use conditions in cereals and maize.

CP 7.2.2.1. Estimation of bystander and resident exposure

Bystanders and residents are not involved in application or handling of plant protection products or the professional handling of treated crops. Therefore, exposure differs significantly from operator exposure levels. The exposure assessment presented below is based on the German guidance paper for evaluation of bystander and resident exposure (Martin S. et al., 2008) with adopted drift distances (B. Nolting, 2012).

A. Bystander exposure

The presence of bystanders is incidental within or directly adjacent to an area where plant protection products are applied. A situation in which bystander exposure could occur would be a person walking alongside an area being treated at the same time. Under these conditions the bystander would never walk directly next to the outer spraying nozzle. A distance of some meters from the spraying device can always be expected. It can further be assumed that any bystander, as soon as becoming aware of an exposure will leave the spraying area. Therefore, bystander exposure is of short duration, typically a matter of minutes. Thus, the exposure duration of 5 minutes is assumed.

Bystander exposure results from spray drift that deposits on the body surface or passes the breathing zone. Assuming that bystanders wear only light clothing (i.e. short-sleeved shirt and shorts), the exposed, uncovered body surface of an adult (head, face, neck front and back, forearms, half upper arms, hands, lower half of thighs, lower legs and feet) is amounting to about 1 m². For children the exposed body surface with the same level of clothing amounts to 0.21 m².

For the scenario of professional agricultural use it is assumed that the bystander is located at a distance of 1 m, downwind from the spraying source. The extent of spray drift and the consequent deposition depends on the plant protection product application rate, the particular crop being treated and the method of application. Measurements of spray drift following different crop/equipment combinations are available from Rautmann D. et al., 2001: New basic drift values in the authorisation procedure for plant protection products. In: Forster, B. and Streloke, M. (eds.), Workshop on Risk Assessment and Risk Mitigation Measures (WORMM). 27–29 September 1999, Mitteilungen aus der Biologischen Bundesanstalt für Land- und Forstwirtschaft, booklet 383, 2001; actual version of 27th March 2006: Rautmann, D., 2006: Aktuelle Abdrifteckwerte (Current Drift Values). http://www.jki.bund.de/cln_045/nn_926124/SharedDocs/10_FA/Publikationen/Pflanzenschutzgeraete/abdrifteckwerte_xls.html.
Thus, for the corresponding application scenario in cereals the proposed drift value at 1 m distance of 2.77% (90th percentile value) is used for estimations of dermal exposure. However, the drift deposition data by Rautmann D. et al., 2001 cannot easily be transposed into airborne concentrations and consequent inhalation exposure values. Therefore, to ensure a conservative evaluation, measured inhalation exposure data for the unprotected operator during spray applications (Lundehn J.R. et al., 1992, German BBA model) are used for the bystander inhalation exposure estimation.

The parameters used for bystander exposure calculations are summarized in Table 7.2.2.1-1.

Table 7.2.2.1-1: Parameters used for bystander exposure calculations

	Parameter	**Pyraclostrobin**	
AR	Maximum application rate (kg a.s./ha)	0.25	
ar	Maximum application rate (mg a.s./m²)	25	
DA	Dermal absorption (%)	7	
IA	Inhalation absorption (%)	100	
		Default values	
D	Drift at 1 meter distance for field crop (% of application rate)	2.77	
TB	Exposure duration bystander (minutes)	5	
TO	Exposure duration operator (hours)	6	
TF	Exposure duration factor (TB / TO) [1]	0.0139	
A	Area treated (ha/day)	50	
		Adults	Children
BSA	Exposed body surface (m²)	1	0.21
IA	Specific inhalation exposure (mg a.s./kg a.s. handled) [2]	0.001	0.00057
BW	Bystander body weight (kg)	60	16.15

[1] since the German model values are based on an application period of 6 hours/day, adjustment to 5 minutes is required for exposure calculations.
[2] based on geometric mean values proposed by the German BBA Model (Lundehn et al., 1992) and inhalation rates of 1.74 and 1.0 m³/h for adults and children, respectively

Bystander exposure for adults and children is estimated according the following equations:

Systemic dermal exposure $$SDE_B = \frac{ar \times D \times BSA \times DA}{BW}$$

Systemic inhalation exposure $$SIE_B = \frac{I_A \times AR \times A \times TF \times IA}{BW}$$

Total systemic exposure $$SE_B = SDE_B + SI_B$$

Assessment

For the exposure of a bystander passing by the field treated with BAS 500 06 F the systemic exposure to pyraclostrobin was assessed based on 5 minutes exposure applying generic spray drift deposits of 2.77% of the application rate at 1 meter distance and air borne spray concentrations of 0.001 and 0.00057 mg/kg a.s./person for adults and children, respectively.

The result of the bystander exposure estimation is presented in Table 7.2.2.1-2. Details of the estimations are presented in Appendix 7.2-10.

Table 7.2.2.1-2: Estimated bystander exposure to pyraclostrobin and % of the AOEL

	Active Substance	
	Pyraclostrobin	
	AOEL = 0.015 mg/kg bw/day	
	Adults	**Children**
Systemic exposure via dermal route (mg/kg bw/day)	0.00081	0.00063
Systemic exposure via inhalation (mg/kg bw/day)	0.000003	0.000006
Total systemic exposure [1] (mg/kg bw/day)	**0.000813**	**0.000635**
% of AOEL [2]	**5.42**	**4.23**

[1] according to the German model for bystander and resident exposure assessment; Martin S. et al. (2008)
[2] based on a systemic AOEL of 0.015 mg/kg bw/day for pyraclostrobin

This estimate results in 5.4 and 4.2% usage of the AOEL for pyraclostrobin for adults and children, respectively. Thus, the exposure of adult and child bystanders passing by a field treated with BAS 500 06 F is considered to be safe.

In conclusion, bystanders are not considered to be at risk when exposed to spray drift of pyraclostrobin under the use conditions of BAS 500 06 F in cereals and maize.

B. Resident exposure

Residents are persons who live, work or attend any institution adjacent to an area that has been treated with a plant protection product. Possible situations are persons who are standing, working, or sitting in a garden in the vicinity of the application. They may be exposed to the plant protection products mainly via the dermal route from spray drift deposits and by inhalation of vapour drift depending on the vapour pressure of the active substances. For infants and toddlers oral exposure via hand-to-mouth transfer or object-to-mouse transfer has to be considered, too.
As for the bystander it can be assumed that residents are unlikely to take actions to avoid or control exposure, and they wear only light clothing and no protective equipment. In addition, as conservative approach it is assumed that residents are located directly downwind of the centre of the treatment area from the point of spray emission caused by professional agricultural uses.
The field crop application is here considered to represent the worst case scenario for which a distance of 1 m from the spraying device is taken into consideration.

It can be assumed that the exposure duration of residents being in a garden is longer than the exposure duration of bystanders. Therefore, the default exposure duration of 2 hours is adopted for risk evaluations.

According to the German model for bystander and resident exposure assessments, inhalation exposure has only to be considered for semi-volatile and volatile active substances (vapour pressures of 1×10^{-5} – 5×10^{-3} Pa and $> 5 \times 10^{-3}$ Pa, respectively). As pyraclostrobin has a vapour pressure of 2.6×10^{-8} it is considered non-volatile. Consequently, inhalation exposure to vapours is not taken into account.

For assessment of the oral exposure of children and toddlers in a first-tier approach the default values proposed by the German model for bystander and resident exposure assessments are used (Martin S. et al. (2008) as derived from a US-EPA policy paper). Table 7.2.2.1-3 summarizes the parameters used for resident exposure of adults and children.

Table 7.2.2.1-3: Parameters used for resident exposure estimations

	Parameter	Pyraclostrobin	
	Vapour pressure (Pa)	2.6×10^{-8}	
	Volatility	non-volatile	
	Maximum application rate (kg a.s./ha)[1]	0.25	
	Maximum number of applications	2	
AR	Application rate relevant for resident (kg a.s./ha)	0.50	
Ar	Maximum application rate (mg a.s./cm²)	0.005	
DA	Dermal absorption (%)	7	
IA	Inhalation absorption (%)	100	
OA	Oral absorption (%)	50	
ACV	Airborne concentration of vapour (mg/m³) [2]	-	
		Default values	
D	Drift (%) at 1 m distance - 90th percentile values[3] for field crop	2.77	
H	Duration (hours)	2	
		Adults	Children
TTR	Turf transferable residues hand (%)	5	5
TC	Transfer coefficient (cm²/hour)	7300	2600
IR	Inhalation rate (m³/day)	16.57	8.31
SE	Salivation extraction factor (%)		50
SA	Surface area of hands (cm²)		20
Freq	Frequency of hand-to-mouth events (events/hour)		20
DFR	Dislodgeable foliar residue object to mouth (%)		20
IgR	Ingestion rate for mouthing of grass (cm²)		25
BW	Resident body weight (kg)	60	16.15

[1] As BAS 500 06 F will be applied twice per season at maximum, the double application rate is considered relevant for residential exposure according to the German model for bystander and resident exposure assessment.

[2] Since pyraclostrobin is non-volatile, i.e. the vapour pressure is 2.6×10^{-8} Pa, the ACV value is 0.0 mg/m³.

[3] 90th percentile of drift recommended for one application, 82nd percentile of drift for double application rate recommended for more than one application according to Martin S. et al. (2008)

Resident exposure for adults and children is estimated according the following equations:

Systemic dermal exposure

$$SDE_R = \frac{AR \times D \times TTR \times TC \times H \times DA}{BW}$$

Systemic inhalation exposure

$$SIE_R = \frac{AC \times IR \times IA}{BW}$$

Systemic exposure due to hand-to-mouth transfer (children only)

$$SOE_H = \frac{AR \times D \times TTR \times SE \times SA \times F \times H \times OA}{BW}$$

Systemic exposure due to mouthing (children only)

$$SOE_O = \frac{AR \times D \times DFR \times IgR \times OA}{BW}$$

Total systemic exposure (adults)

$$SE_R = SDE_R + SIE_R$$

Total systemic exposure (children)

$$SE_R = SDE_R + SIE_R + SOE_H + SOE_O$$

The resulting predicted exposures are summarized below.

Assessment

For the exposure of a resident located next to a field treated with BAS 500 06 F the systemic exposure to pyraclostrobin was assessed based on 2 hour exposure to spray drifts via dermal and oral route. Exposure to airborne concentration of vapour for non-volatile compounds such as pyraclostrobin is not considered.

The results of the resident exposure calculations are summarized in Table 7.2.2.1-4 below. Details of the estimations are presented in Appendix 7.2.11.

Table 7.2.2.1-4: Estimated resident exposure to pyraclostrobin and % of the AOEL for the use of BAS 500 06 F in cereals

	Active Substance	
	Pyraclostrobin	
	AOEL = 0.015 mg/kg bw/day	
	Adults	**Children**
Systemic exposure via dermal route (mg/kg bw/day)	0.0001	0.00013
Systemic exposure via inhalation (mg/kg bw/day)	-	-
Systemic exposure via oral route (mg/kg bw/day)	-	0.000094
Total systemic exposure[1] (mg/kg bw/day)	**0.0001**	**0.00022**
% of AOEL[2]	**0.7**	**1.5**

[1] based on the German model for bystander and resident exposure assessment; Martin S. et al. (2008)
[2] based on a systemic AOEL of 0.015 mg/kg bw/day for pyraclostrobin

The estimate results for adults in 0.7 and for children in 1.5% of the AOEL for pyraclostrobin. Thus, the exposure of adult and child residents living next to a field treated with BAS 500 06 F is considered to be safe.

In conclusion, residents are not considered to be at risk when exposed to spray drift of pyraclostrobin under the use conditions of BAS 500 06 F in cereals.

CP 7.2.2.2. Measurement of bystander and resident exposure

Since the risk assessment performed indicates that the health-based limit values (AOEL) will not be exceeded under practical conditions of use, studies to provide field data on bystander or residential exposure to BAS 500 06 F were not considered to be necessary and were thus not performed.

CP 7.2.3. Worker exposure

The plant protection product BAS 500 06 F is already registered for the use as fungicide in the representative crops cereals and maize. Information on the formulation and the critical use pattern relevant for the re-entry worker risk assessment can be found in chapter 7.2.1. The critical GAP is summarized in Table 7.2.1-1.

Exposure assessments and risk evaluations for re-entry workers for the representative formulation BAS 500 06 F are presented below. Estimations of potential worker exposure have been undertaken applying the following guidance for exposure prediction:

- EUROPOEM - Re-entry exposure model final draft adopted by more specific US EPA agricultural transfer coefficients

Risk assessment for worker

A summary of the worker risk assessment is provided Table 7.2.3-1.

Table 7.2.3-1: Summary of re-entry workers exposure following application of BAS 500 06 F without protective equipment (standard assessment)

	Active ingredient	Estimated worker exposure (mg/kg bw/day)	% of AOEL[1]	Reference in Appendix
2 hour/day scouting and crop inspection in cereals	pyraclostrobin	0.00525	35	**7.2-12**

[1] based on a systemic AOEL of 0.015 mg/kg bw/day for pyraclostrobin

Conclusion
It is concluded that there is no unacceptable risk anticipated for the worker wearing adequate working clothing when re-entering cereal crops treated with BAS 500 06 F after the spray dilute has dried.

CP 7.2.3.1. Estimation of worker exposure

Worker exposure to pyraclostrobin from the product BAS 500 06 F

BAS 500 06 F will be used as a fungicide in cereals during growth stages BBCH 25-69 with a maximum of two applications per season. Thus, the considered reasonable worst case for the maximum applied amount of product per season is 2.5 L/ha corresponding to 0.5 kg pyraclostrobin per ha.

Hand operations in cereals (and maize), which may result in re-entry exposure do not belong to standard growing procedures after the application of the product. Exposure scenarios one may think of as a worst case may be scouting and crop inspection. These operations are considered to be of limited duration and of limited direct contact to the treated plants. For these operations a working period of 2 hours per day is considered a reasonable approach.

Exposure Estimation Models used

The exposure estimation of the re-entry worker presented below is based on the:

- EUROPOEM - Re-entry exposure model final draft adopted by more specific US EPA agricultural transfer coefficients

The default exposure assessment is based on the following assumptions:

- Re-entry exposure is predominantly via the dermal route (contact with the foliage)
- Residues on the foliage depend on:
  - application rate
  - the crop habitat (total size of foliage compared to surface area, Leaf Area Index (LAI))
- Transfer of residues from the foliage to clothes or skin of workers is more or less independent of the product applied, but depend mainly on the intensity of contact with foliage (work activity).
- Activities with a similar pattern can be grouped and generic Transfer Coefficients (TC) can be used for one group.
- Based on the EUROPOEM proposal an Dislodgeable Foliar Residue (DFR) default value of 3 µg a.s./cm² is taken into account.

It is reasonably presumed that workers re-enter the treated crop after the spray has dried.

For pyraclostrobin a cumulated application rate of 0.5 kg a.s./ha is taken into account.

Within the EU, there are no commonly accepted specific transfer coefficients (TC) available to assess scouting and crop inspection activities in cereals. Whereas the RMS widely accepted a TC of 1500 cm²/hour for crop inspection, the EFSA draft guidance on operator, bystander, resident and worker exposure assessment has proposed a transfer coefficient of 1100 cm²/hour for crop inspection activities instead.
Following the US EPA agricultural transfer coefficient, a TC of 1500 cm²/hour based on Central value from ARF021 -- scouting dry peas (range 486 to 2760) has been used in this evaluation as the more conservative approach.

In the following Table 7.2.3.1-1 the parameters used in the re-entry worker risk assessment are presented.

Table 7.2.3.1-1: Parameters used for the worker risk assessment

	Parameter	**Pyraclostrobin**	
MR	Application rate considered for default worker exposure	0.500	kg a.s./ha
DF	Dermal absorption[1]	7	%
DFR	Default dislodgeable foliar residue	3	µg/cm² x kg a.s. applied
		Default values	
BW	Re-entry worker body weight	60	kg
TC	Transfer coefficient[2]	1,500	cm²/h x person
A	Working period	2	h/day
TR	Transmission to skin for unprotected worker	1.00	(factor, equal to 100%)

[1] The given value for dermal absorption of pyraclostrobin represent the estimate for spray dilutes. Exposure during re-entry occurs to dry residues for which it is adequate to expect a very low dermal absorption. Therefore, it is considered to be a conservative approach to use the dermal absorption value determined for the liquid spray dilute.
[2] A TC of 1500 cm²/h x person was used (according to US EPA agricultural transfer coefficients) for activities like scouting and irrigation in cereals and maize based on recommendations for Central value from ARF021 -- scouting dry peas (range 486 to 2760).

Based on the assumptions and consideration made above, worker exposure is calculated as follows:

External dermal exposure ED_W

$$ED_W = MR \times A \times DFR \times TC \times TR$$

Total systemic exposure SE_W

$$SE_W = \frac{ED_W}{BW} \times DF$$

Estimatimation of worker exposure without personal protective equipment

The results of the re-entry worker risk assessment without PPE is presented in Table 7.2.3.1-2 below, details are given in Appendix 7.2-12.

Table 7.2.3.1-2: Estimated worker exposure to pyraclostrobin following application of BAS 500 06 F in cereals (standard assessment)

		Exposure parameter	
Active substance	**AOEL (mg/kg bw/day)**	**Absorbed dose (mg/kg bw/day)**	**% of AOEL**
unprotected worker[1]			
Pyraclostrobin	0.015	0.00525	35

[1] worker wearing working clothing

Based on the proposed exposure estimation, the predicted exposure to pyraclostrobin is 35% of the AOEL. Thus, for a worker performing post-treatment activities (cereals: scouting and crop inspection) without gloves or protective clothing for 2 hours, the estimated worker exposure levels for pyraclostrobin is within the acceptable range.

It is concluded that there is no unacceptable risk anticipated for the worker wearing adequate working clothing when re-entering cereal crops treated with BAS 500 06 F after the spray dilute has dried.

CP 7.2.3.2. Measurement of worker exposure

Since the risk assessment performed indicates that the health-based limit value (AOEL) will not be exceeded under practical conditions of use, studies to provide field data on worker exposure to BAS 500 06 F were not considered to be necessary and were thus not performed.

CP 7.3 Dermal absorption

Report: CP 7.3/1
Fabian E.,Landsiedel R., 2010a
^{14}C-BAS 500 F in BAS 500 06 F - Study of penetration through human skin in vitro
2010/1059865

Guidelines: OECD Guideline for testing of chemicals No. 428 (Skin absorption: In vitro method (2004)), OECD Guidance Document No. 28 for the conduct of skin absorption studies (March 2004)

GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Note: This reference was erroneously not included in the study list of the application. It is submitted, because the proposed dermal absorption value for the formulation concentrate is based on this study.

Executive Summary

In an in-vitro experiment, the dermal penetration of pyraclostrobin (BAS 500 F) formulated as BAS 500 06 F through human skin was determined. For this a high dose (formulation concentrate; nominal dose 2000 µg pyraclostrobin per cm²) and a low dose (1:200 spray dilution; 10 µg pyraclostrobin per cm²) was applied to human dermatomed skin at a volume of 10 µL/cm². The skin was mounted into Franz-type diffusion cells operated in static mode. The exposure of the skin to the test material lasted 6 hours; thereafter the skin was thoroughly washed. Samples of the receptor fluid were taken 0.5, 1, 2, 4, 6, 10 and 24 hours after the start of the exposure in order to determine kinetic parameters (lag phase, absorption rate and permeability constant).

The in-vitro dermal absorption of ^{14}C-pyraclostrobin formulated as BAS 500 06 F through human skin as determined in this study was low. The absorption estimates (sum of the absorbed dose and the remaining dose associated to the skin membrane and the 3rd to 6th tape strip) for pyraclostrobin were 1.64 ± 1.12% for the formulation concentrate and 4.77 ± 1.35% of the 1:200 spray dilution. The dermal penetration estimates to be used for risk assessment are based on the results of this as well as the results of a 2014 study summarized below (M-CP 7.3/2).

Considering both in-vitro dermal penetration studies, the dermal penetration estimates to be used for risk assessment were therefore calculated to be 3 and 7% for the formulation concentrate and the spray dilution (1:400), respectively. The value for the formulation concentrate was derived from this study, whereas the value for the 1:400 spray dilution was derived from the 2014 study (see M-CP 7.3/2).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

	a) ^{14}C-BAS 500 F (chlorophenyl-U-C14)
	b) BAS 500 06 F (formulated BAS 500 F)
Description:	a) not indicated
	b) not indicated
Lot/Batch #:	a) 579-2301
	b) 8265
Purity:	a) radiochemical purity: 99.4%; specific activity: 4.38 MBq/mg
	b) Content: 202.7 g pyraclostrobin per liter
Stability of test compound:	a) The storage stability of the test substance was confirmed by HPLC analysis prior to and after termination of the study
	b) The test substance is stable in the formulation; the expiry date of the formulation: 31-Dec-2010.

2. Vehicle: tap water

3. Human skin preparations:

Source:	BIOPREDIC International, Rennes, France
Preparation:	Dermatomed (split thickness) human skin membranes with a thickness of 390-420 µm were prepared and supplied frozen by BIOPREDIC International.
Storage of skin samples:	Human skin samples were stored vacuum-wrapped at -20°C until use.

4. Reagents:

Receptor fluid:	Ethanol/tap water (1:1 (v/v)) for the high dose (formulation concentrate) Ethanol/tap water (2:8 (v/v)) for the low dose (spray dilution) The solubility of pyraclostrobin was determined analytically in several mixtures of ethanol/tap water. It was for the low dose 8.2 mg/L in ethanol/tap water (2:8 (v/v) and at a maximum of 2710 mg/L in ethanol/tap water (1:1 (v/v)). The maximum solubility of the test substance in water is 0.41 mg/L.
Extraction media:	Soluene®-350 and ethanol
Washing solution:	Texapon® N 70 (sodium-laurylethersulfate), 1:140 w/w in bi-distilled water

5. Preparation of the dosing solutions

High dose (undiluted formulation):
The applied radioactivity was 37 kBq/cm² for the formulation concentrate. This corresponds to a desired specific radioactivity of the test substance preparation of 3.7 MBq/g. To obtain the desired specific activity, a respective aliquot of the radio-labeled stock solution in toluene was taken and the organic solvent was evaporated to dryness. The dried residue was taken up in the required amount of liquid formulation concentrate. The preparations were stirred and sonicated in order to ensure homogeneity.

Low dose (1:200 spray dilution):
Due to the low concentration of active ingredient in the use dilution (1:200 dilution of the formulation concentrate), an applied radioactivity of about 10 kBq/cm² was achieved. This corresponds to a desired specific radioactivity of the test substance preparation of 1 MBq/g. To obtain the desired specific activity, a respective aliquot of the radio-labeled test-substance solution was taken and the organic solvent was evaporated. The required amount of the liquid formulation concentrate was added to the residual radio-labeled test substance. This mixture was filled up to the final volume with the required volume of tap water. The preparations were stirred and sonicated in order to produce homogeneity.

Analyses:
Liquid scintillation counting and/or HPLC verified the homogeneity and accuracy of the test substance preparations. Taking and analyzing samples before and after the application period confirmed the stability of the test-substance in the preparation.

The conditions of the HPLC analysis are described in the table below:

Column:	J'sphere ODS-H80 4µm, 250 mm x 4.6 mm
Eluent:	A: acetonitrile + formic acid (1 mL/L) B: highly de-ionized water + formic acid (1 mL/L)
Gradient:	0 – 10 min: 30% B 10 – 15 min: 30% – 10% B 15 – 25 min: 10% B 25 – 26 min: 30% – 10% B 26 – 35 min: 30% B
Flow:	1.2 mL/min
Wavelength:	230 nm
Detection:	Agilent 1100 with variable wavelength detector, Radioflow Detector Berthold LB 509 (Cell: YG 75 – S6M)

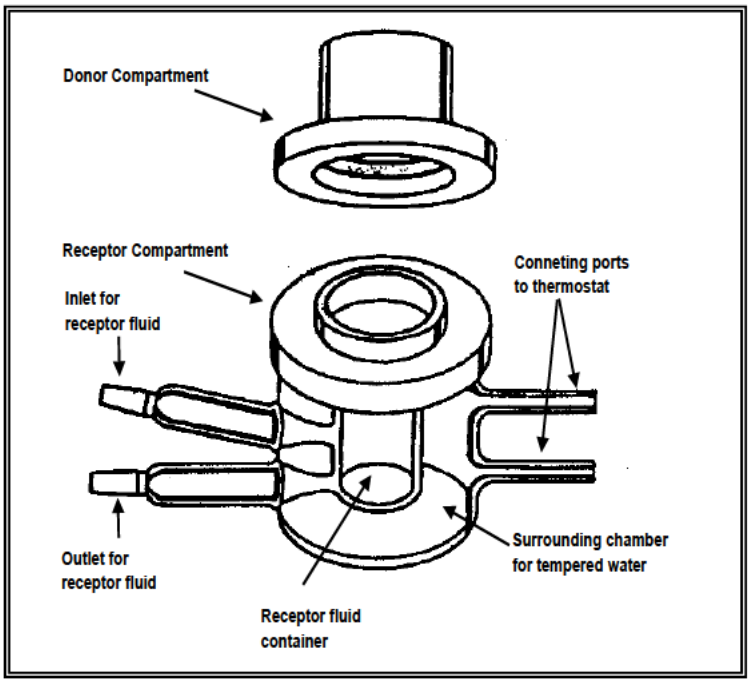
B. TEST PERFORMANCE

1. Dates of experimental work: 23-Mar-2010 - 25-May-2010

2. Study design:

The penetration of pyraclostrobin through human dermatomed skin was determined using a modified Franz cell (see Figure 7.3-1). The study was carried out in consecutive steps using a maximum of 10 skin preparations per step.

Figure 7.3-1: Schematic depiction of a Franz cell



After introducing the skin preparation, the upper donor compartment and the lower receptor compartment were assembled and fixed with a stainless steel clamp and four screws. Specifically, the receptor compartment was filled with the physiological saline (for the assessment of skin integrity). Subsequently, the skin was placed with the external surface of the stratum corneum upmost on the fluid avoiding air bubbles underneath. The donor compartment was carefully placed on top so that the skin sample was stretched between the donor and receptor compartments.

The receptor compartment was jacketed with a second chamber to maintain the receptor fluid at the 32 ± 1°C with the aid of thermostated water circulating in the surrounding second chamber. The exposed skin area was about 1 cm^2 and the receptor volume was about 4 ml. Mixing of receptor fluid was provided by magnetic stirrers.

The diffusion cells were operated in a static mode. Sampling and replacement of removed receptor fluid was carried out by outlet (bottom) and inlet (top) pipe connections. The inlet ports were connected to a receptor fluid stock container, the outlet ports to an automated fraction sampler.

Before the actual penetration experiment, the integrity of the skin preparations was determined by measuring electrical resistance. For intact skin preparations using physiological saline electrical resistances in the range of > 1 kΩ were expected. In addition, the skin preparations integrity was checked by visual inspection. In case of low resistance skin preparations were used unless the visual check revealed any damage.

The following findings were reasons for not using a skin preparation in the study or rejecting results from calculation of the mean penetration parameters:

- A skin preparation showed low resistance and physical damage or leakage of receptor medium to the surface.
- A skin preparation displayed clearly aberrant test substance recovery rates (according to the guidelines of OECD a total recovery per membrane of 100 ± 10% is considered to be acceptable).
- A membrane displayed clearly aberrant penetration kinetics.

The test substance preparation was applied to the skin preparations using a displacement pipette. The exact amount applied per diffusion cell was determined by reweighing the pipette after application, the weight of which had been previously determined after filling. The application time was documented for each cell. The donor compartment was covered with a sheet of semiocclusive adhesive fleece (Fixomull® Stretch, Beiersdorf AG). After 6 hours the skin surface was washed twice using approx. 250 µL Texapon® N70 diluted 1:140 (w/w) in highly de-ionized water and once with 250 µL pure water. The skin was then wiped dry using cotton swabs. The rinsing fluids, the pipette tips and the cotton swabs were stored for analysis. The upper chamber was covered again with the fleece until the end of the run.

Samples of the receptor fluid were taken 0.5, 1, 2, 4, 6, 10 and 24 hours after application. For this a volume of about 0.6 ml was removed from the receptor cell within 60 seconds by means of a peristaltic pump connected to the outlet port of the receptor cell (see above). The removed volume was hydrostatically replaced with fresh receptor fluid from the reservoir via the inlet port.

The sampling was divided into a 30-second flush period to remove receptor medium remaining in the tubes from the previous sampling, and an actual 30-second sampling period for determination of test-substance concentration in the receptor medium. The void volumes were pooled per diffusion cell and the actual sample volumes were collected in separate vessels.

After the last sampling of receptor fluid, the feed of the receptor medium was stopped and the contents of the individual receptor compartments was sampled by emptying the receptor compartments with the fraction collector. The receptor chamber was washed and the skin was removed from the diffusion cell, put onto aluminum foil and pinned onto a Styrofoam support. The skin surface was washed using cotton swabs soaked with afore mentioned washing fluid and dried using an untreated swab. When the skin surface had dried, the stratum corneum was removed by tape stripping. The tapes were pooled into two samples (1st and 2nd tape strip (sample 1) and 3rd to 6th tape strip (sample 2)) for analysis. The remaining skin and the tape strips were analyzed separately.

The diffusion cells were dismantled and all parts (with the exception of the stainless steel clamp and tubes) were extracted in ethanol.

Weighed aliquots of each native receptor fluid sample or of the solvents used for extraction were analyzed by liquid scintillation counting for 10 min.

The cumulative absorbed dose [µg/cm²] was presented graphically over the time. The absorption rate [µg/(cm²·h)] was determined from the slope of the penetration curve in the linear region by means of linear regression, and the lag phase [h] of the test substance penetration was calculated (intersection point of the regression line with the x-axis). The permeability constant Kp [cm/h] was determined by dividing the absorption rate by the concentration of the applied test substance.

In this summary the recovery rate of the test substance applied in the various compartments was determined as non-absorbed fraction (donor compartment wash and the dislodgeable test substance fraction at the first and second skin wash), the dose associated to the skin (1st and 2nd tape strip, 3rd to 6th tape strip and the remaining skin preparation) and the absorbed fraction (contents of the receptor compartment, receptor compartment wash and receptor fluid samples taken).

II. RESULTS AND DISCUSSION

A. STABILITY, HOMOGENEITY AND CONTENT OF PYRACLOSTROBIN IN THE APPLICATION MEDIUM

The stability, homogeneity and content of pyraclostrobin in the application medium were confirmed by analysis. Details are available in the raw-data.

B. APPLIED DOSE AND RECOVERY OF DOSE

The applied doses and the number of usable skin samples per dose group are given in Table 7.3-1.

Table 7.3-1: Applied doses

Dose group	Target dose [µg/cm²]	Actual nominal dose [µg/cm²]
1 (concentrate)	2000	2002 ± 64 (n=4/5) [a]
2 (1:200 spray dilution)	10	10.8 ± 0.2 (n=5/5)

[a] (number of valid cells/total number of cells); cell no 4 was excluded from calculation due to an invalid first skin wash (58.2% recovery compared to 84.6 ±9.9% for the remaining 4 cells)

The mean recoveries were 100.3 and 98.7% for the high and the low dose levels, respectively (see Table 7.3-2). All individual cell recoveries were within the OECD acceptance criteria (100 ± 10%). The individual values ranged between 96.5 and 103.1% for the high dose and 96.7 and 100.9% for the low dose. Furthermore, the group mean total recovery for all groups was > 95%, therefore no adjustment to the dermal penetration values was necessary.

Nearly the entire dose, i.e. 98.7% was recovered from the skin washing, donor chamber and first two tape strips at the high dose. In case of the cells treated with the low dose this value was 93.9%. The amount associated with the skin preparations and the 3rd to 6th skin strip was 1.42% and 3.16% for the high and low dose, respectively.

The absorbed dose, i.e. the sum of receptor samples, the receptor fluid recovered at the end of the experiment as well as the receptor chamber, amounted to 0.22 and 1.61% at the high and low doses, respectively. The absorption estimate, which corresponds to the amount recovered from skin, the tape strips 3-6 and the absorbed dose, thus, sum up to 1.64 and 4.77% for the high and low dose, respectively.

\# values may not calculate exactly due to rounding of figures

[a] Grouping is different than in the report: In accordance with the EFSA Guidance on Dermal Absorption (EFSA Journal 2012;10(4):2665) the radioactivity in the second tape-strip pool (3rd to 6th tape strip) is considered potentially absorbable if less than 75% of the absorption occurred in the first half of the study (see Table 7.3-3). Finally, the skin preparation is also considered potentially absorbable.

[b] Cells with insufficient recovery (<95%) were corrected by normalization of absorption estimate to 100% recovery.

[c] In accordance with the EFSA Guidance on Dermal Absorption (EFSA Journal 2012;10(4):2665) one standard deviation was added to the mean % dermal penetration in cases where the standard deviation was ≥ 25% of the mean value. This value was then rounded to the required number of significant figures.

n.a.: not applicable

The total amount of pyraclostrobin recovered in the receptor fluid after 24 hours was 4.38 and 0.173 µg for the formulation concentrate and the spray dilution, respectively. When compared to the maximum solubilisation capacity in the total receptor medium volume of 8.2 mL of 22222 µg and 67.2 µg, the solubility in the receptor media was ~5000 and ~390 fold higher than actually needed for the formulation concentrate and the spray dilution, respectively. Even if the receptor volume of 4 mL is considered only, the solubility was at least 190-fold higher than actually needed. These results show that the maximum concentration of the test substance in the receptor chamber does not exceed 10% of the saturation concentration as recommended by EFSA.

C. ABSORPTION KINETICS

The mean values of the kinetic parameters determined from the linear region of the cumulative absorbed dose curve are presented in Table 7.3-3. An absorption rate of 0.140 µg/cm²·h and a permeability coefficient (Kp) of $0.069 \cdot 10^{-5}$ cm/h was obtained for the formulation concentrate of BAS 500 06 F. At the approx. 200-fold lower concentration of applied test substance an absorption rate of 0.007 µg/cm²·h and a permeability coefficient of $0.662 \cdot 10^{-5}$ cm/h was determined. A lag time of 8.2 and 1.8 hours was determined for the formulation concentrate and the 1:200 spray dilution, respectively.

III. CONCLUSION

The in-vitro dermal absorption of ^{14}C-pyraclostrobin formulated as BAS 500 06 F through human skin is low. The absorption estimates (sum of the absorbed dose, the remaining dose associated to the skin membrane and the remaining test substance in the 3rd to 6th tape strip) for pyraclostrobin were 1.64 ± 1.12% for the formulation concentrate and 4.77 ± 1.35% for the 1:200 spray dilution.

Report:	CP 7.3/2 Fabian E.,Landsiedel R., 2014a ^{14}C-BAS 500 F in BAS 500 06 F - Study of penetration through human skin in vitro 2014/1001501
Guidelines:	OECD 428, OECD Guidance Document No. 28 for the conduct of skin absorption studies (March 2004)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In an in-vitro experiment, the dermal penetration of pyraclostrobin formulated as BAS 500 06 F through human skin was determined. For this a high dose (formulation concentrate; nominal dose 2000 µg pyraclostrobin per cm²) and a low dose (spray dilution; 5 µg pyraclostrobin per cm²) was applied to human dermatomed skin at 10 µL/cm². The skin was mounted into Franz-type diffusion cells operated in static mode. The exposure of the skin to the test material lasted 8 hours; thereafter the skin was thoroughly washed. Samples of the receptor fluid were taken 1, 2, 4, 6, 8, 12 and 24 hours after the start of the exposure in order to determine kinetic parameters (lag phase, absorption rate and permeability constant).

The in-vitro dermal absorption of ^{14}C-pyraclostrobin formulated as BAS 500 06 F through human skin as determined in this study was low. The absorption estimates (sum of the absorbed dose and the remaining dose associated to the skin membrane) for pyraclostrobin were 0.18 ± 0.14% for the formulation concentrate and 4.13 ± 2.67% of the 1:400 spray dilution. The dermal penetration estimates to be used for risk assessment are based on the results of this as well as the results a 2010 study summarized above (CP 7.3/1).

Considering both in-vitro dermal penetration studies, the dermal penetration estimates to be used for risk assessment were therefore calculated to be 3 and 7% for the formulation concentrate and the spray dilution (1:400), respectively. The value for the formulation concentrate was derived from the 2010 study (see M-CP 7.3/1) whereas the value for the 1:400 spray dilution was derived from this study.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

	a) ^{14}C- pyraclostrobin (tolyl-ring-U-C14)
	b) BAS 500 06 F (formulated pyraclostrobin)
	c) Blank formulation (BAS 500 06 F without pyraclostrobin)
Description:	a) not indicated
	b) not indicated
	c) not indicated
Lot/Batch #:	a) 566-5101
	b) FRE-000904
	c) FD-130726-0004
Purity:	a) radiochemical purity: 99.9%; specific activity: 6.6 MBq/mg
	b) Content: 200.2 g pyraclostrobin per liter
	c) not applicable
Stability of test compound:	a) The storage stability of the test substance was confirmed by HPLC analysis prior to and after termination of the study
	b) The test substance is stable in the formulation; the expiry date of the formulation: 31-May-2015.
	c) expiry date: 23-Jan-2018

2. Vehicle: tap water

3. Human skin preparations:

Source:	BIOPREDIC International, Saint-Grégoire, France
Preparation:	Dermatomed (split thickness) human skin membranes with a thickness of 300-400 µm were prepared and supplied frozen by BIOPREDIC International.
Storage of skin samples:	Human skin samples were stored vacuum-wrapped at -20°C until use.

4. Reagents:

Receptor fluid:	Ethanol/tap water (4:6 (v/v); pyraclostrobin solubility 600 mg/L) for the high dose (formulation concentrate)
	Ethanol/tap water (2:8 (v/v); pyraclostrobin solubility 8.2 mg/L) for the low dose (spray dilution)
Extraction media:	Soluene®-350, ethanol and ethanol/ultrapure water (90%)
Washing solution:	Texapon® N 70 (sodium-laurylethersulfate), 1:140 w/w in tap water

5. Preparation of the dosing solutions

High dose (undiluted formulation):
The applied radioactivity was 37 kBq/cm² for the formulation concentrate. This corresponds to a desired specific radioactivity of the test substance preparation of 3.57 MBq/g. To obtain the desired specific activity, about 162.4 mg of the radio-labeled stock solution in toluene (10.4 mg/g) was taken and the organic solvent was evaporate to dryness. The dried residue (~1.69 mg) was taken up in ~3.1242 g BAS 500 06 F formulation concentrate. The preparation was stirred and sonicated in order to ensure homogeneity.

Low dose (1:400 spray dilution):
Due to the low concentration of active ingredient in the use dilution (1:400 dilution of the formulation concentrate), an applied radioactivity of about 33.7 kBq/cm² was achieved. This corresponds to a desired specific radioactivity of the test substance preparation of 3.30 MBq/g. To obtain the desired specific activity, ~144.3 mg of the radio-labeled test-substance solution was taken (~ 1.5 mg ^{14}C-pyraclostrobin) and the organic solvent was evaporated. Approximate 1 g of the blank formulation was diluted with ~ 399 g tap water. From this dilution ~3.00 g was added to the residual radio-labeled test substance. The preparations were stirred and sonicated in order to ensure homogeneity.

Analyses:
Liquid scintillation counting and/or HPLC verified the homogeneity and accuracy of the test substance preparations. Taking and analyzing samples before and after the application period confirmed the stability of the test-substance in the preparation.

The conditions of the HPLC analysis are described in the table below:

Column:	Ascentis Express C18, 150 mm x 4.6 mm, 2.7µm
Eluent:	A: ultrapure water / formic acid (1 L + 1 mL) B: acetonitrile / formic acid (1 L + 1 mL) isocratic: 70% B
Flow:	0.8 mL/min
Wavelength:	225 nm
Detection:	variable wavelength detector HP 1100 serial, radioflow detector Berthold LB 509 (Cell: YG 75 – S6M)

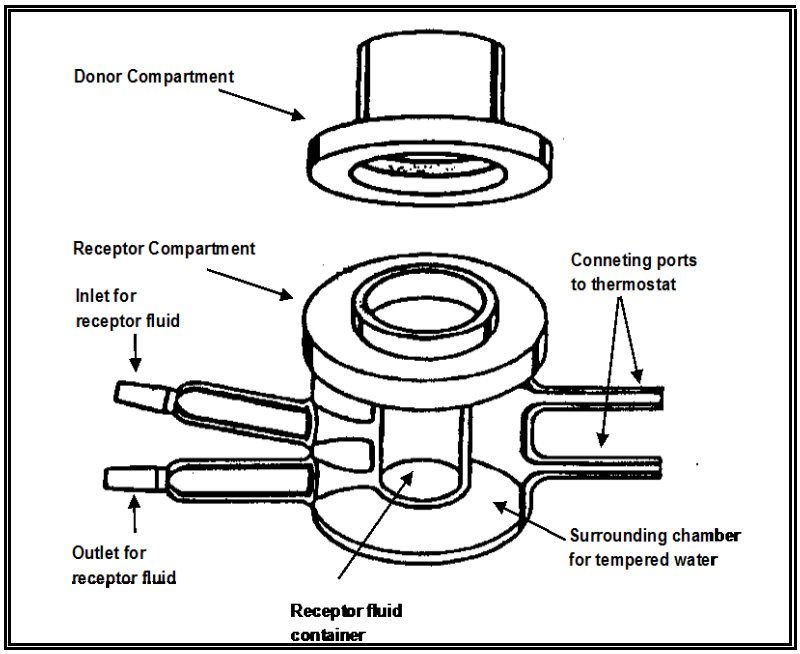
B. TEST PERFORMANCE

1. Dates of experimental work: 14-Jan-2014 - 25-Feb-2014

2. Study design:

The penetration of pyraclostrobin through human dermatomed skin was determined using a modified Franz cell (see Figure 7.3-2). The study was carried out in consecutive steps using 8 skin preparations per step.

Figure 7.3-2: Schematic depiction of a Franz cell



After introducing the skin preparation, the upper donor compartment and the lower receptor compartment were assembled and fixed with a stainless steel clamp and four screws. Specifically, the receptor compartment was filled with the physiological saline (for the assessment of skin integrity). Subsequently, the skin was placed with the external surface of the stratum corneum upmost on the fluid avoiding air bubbles underneath. The donor compartment was carefully placed on top so that the skin sample was stretched between the donor and receptor compartments.

The receptor compartment was jacketed with a second chamber to maintain the receptor fluid at the 32 ± 1°C with the aid of thermostated water circulating in the surrounding second chamber. The exposed skin area was about 1 cm² and the receptor volume was about 4 mL. Mixing of receptor fluid was provided by magnetic stirrers.

The diffusion cells were operated in a static mode. Sampling and replacement of removed receptor fluid was carried out by outlet (bottom) and inlet (top) pipe connections. The inlet ports were connected to a receptor fluid stock container, the outlet ports to an automated fraction sampler.

Before the actual penetration experiment, the integrity of the skin preparations was determined by measuring the transepidermal electrical resistance (TEER) and the transepidermal water loss (TEWL). For intact skin preparations using physiological saline TEER values in the range of > 1 kΩ and TEWL values below 15 g/m² were expected. In addition, the skin preparations integrity was checked by visual inspection. In case of low resistance skin preparations were used unless the visual check revealed any damage.
After the experiment, cells were assessed to be valid, if total recoveries generally fulfilled guideline requirements (according to the guidelines of OECD a total recovery per membrane of 100 ± 10% is considered to be acceptable) and if clearly aberrant penetration kinetics and aberrant skin wash after the 8h exposure period could be excluded.

The test substance preparation was applied to the skin preparations using a displacement pipette. The exact amount applied per diffusion cell was determined by reweighing the pipette after application, the weight of which had been previously determined after filling. In addition, so called exemplary applications were performed in parallel by pipetting 10µl of the preparations directly into scintillation vials. Samples with high specific activity were appropriately diluted. The results of these exemplary applications are not taken into account for calculations unless preliminary results indicate that (depending on e.g. the phys./chem. properties of the test substance preparations) the weights taken as described before may be unacceptable in respect of variability and the there from derived actual doses.
The application time was documented for each cell. The donor compartment was covered with a sheet of semiocclusive adhesive fleece (Fixomull® Stretch, Beiersdorf AG). After 8 hours the skin surface was washed twice using approx. 250 µL Texapon® N70 diluted 1:140 (w/w) in tap water and once with 250 µL tap water. The skin was then wiped dry using cotton swabs. The rinsing fluids, the pipette tips and the cotton swabs were stored for analysis. The upper chamber was covered again with the fleece until the end of the run.

Samples of the receptor fluid were taken 1, 2, 4, 6, 8, 12 and 24 hours after application. For this a volume of about 0.6 mL was removed from the receptor cell within 60 seconds by means of a peristaltic pump connected to the outlet port of the receptor cell (see above). The removed volume was hydrostatically replaced with fresh receptor fluid from the reservoir via the inlet port.
The sampling was divided into a 30-second flush period to remove receptor medium remaining in the tubes from the previous sampling, and an actual 30-second sampling period for determination of test-substance concentration in the receptor medium. The void volumes were pooled per diffusion cell and the actual sample volumes were collected in separate vessels.

After the last sampling of receptor fluid, the feed of the receptor medium was stopped and the contents of the individual receptor compartments was sampled by emptying the receptor compartments with the fraction collector. The receptor chamber was washed and the skin was removed from the diffusion cell, put onto aluminum foil and pinned onto a Styrofoam support. The skin surface was washed using cotton swabs soaked with afore mentioned washing fluid and dried using an untreated swab. When the skin surface had dried, the stratum corneum was removed by tape stripping by using Scotch Crystal Clear Tape 600. The tapes were pooled into two samples (1st and 2nd tape and 3rd to 6th tape) for analysis. The remaining skin and the tape strips were analyzed separately.

The diffusion cells were dismantled and all parts (with the exception of the stainless steel clamp) were extracted in ethanol.

Weighed aliquots of each native receptor fluid sample or of the solvents used for extraction were analyzed by liquid scintillation counting for 10 min.

The cumulative absorbed dose [µg/cm²] was presented graphically over the time. The absorption rate [µg/(cm²·h)] was determined from the slope of the penetration curve in the linear region by means of linear regression, and the lag phase [h] of the test substance penetration was calculated (intersection point of the regression line with the x-axis). The permeability constant Kp [cm/h] was determined by dividing the absorption rate by the concentration of the applied test substance.

In this summary the recovery rate of the test substance applied in the various compartments was determined as non-absorbed fraction (donor compartment wash and the dislodgeable test substance fraction at the first and second skin wash), the dose associated to the skin (1st and 2nd tape strip, 3rd to 6th tape strip and the remaining skin preparation) and the absorbed fraction (contents of the receptor compartment, receptor compartment wash and receptor fluid samples taken).

II. RESULTS AND DISCUSSION

A. STABILITY, HOMOGENEITY AND CONTENT OF PYRACLOSTROBIN IN THE APPLICATION MEDIUM

The stability, homogeneity and content of pyraclostrobin in the application medium were confirmed by analysis. Details are available in the raw-data.

B. APPLIED DOSE AND RECOVERY OF DOSE

The applied doses and the number of usable skin samples per dose group are given in Table 7.3-4.

Table 7.3-4: Applied doses

Dose group	Target dose [µg/cm²]	Actual nominal dose [µg/cm²]
1 (concentrate)	2000	2120 ± 27 (7/8)[a]
2 (spray dilution)	5.0	4.8 ± 0.1 (8/8)

[a] (number of valid cells/total number of cells); cell no 8 was excluded from calculation due to an invalid first skin wash (21.6% recovery compared to 94.3 ± 1.2% for the remaining 7 cells and to an invalid recovery of < 90%, i.e. 88.93%)

The mean recoveries were 94.8 and 103.3% for the high and the low dose levels, respectively (see Table 7.3-5). With regard to the high dose group, the mean total recovery was below 95% (94.80%) with individual values ranging from 93.54 to 98.33%. Six cells which displayed an insufficient recovery of < 95% were corrected by normalization of absorption estimate to 100% recovery. As group mean total recovery for the low dose group (1:400 spray dilution) was 103.32%, no adjustment of the dermal penetration values was necessary. The individual recovery was in the range of 100.23 – 107.17%.

In both dose groups absorption was essentially complete. After 12 hours 80.5 or 89.1% of the total penetrated radioactivity was recovered in the receptor media for the formulation concentrate and the spray dilution, respectively (see Table 7.3-6). Accordingly, neither the first two nor the following four tape strips were added to the absorption estimate.

Nearly the entire dose, i.e. 94.62% was recovered from the skin washing, donor chamber and the first two tape strips at the high dose. In case of the cells treated with the low dose this value was 98.55%. The amount associated with the skin preparations was 0.06 and 2.12% for the high and low dose, respectively.

The absorbed dose, i.e. the sum of receptor samples, the receptor fluid recovered at the end of the experiment as well as the receptor chamber, amounted to 0.13 and 2.65% at the high and low dose, respectively. The total absorption, which corresponds to the amount recovered from skin and the absorbed dose, thus, sum up to 0.18 and 4.13% for the high and low dose, respectively.

The total amount of pyraclostrobin recovered in the receptor fluid after 24 hours was 2.70 µg and 0.13 µg for the formulation concentrate and the spray dilution, respectively. When compared to the maximum solubilization capacity in the total receptor medium volume of 8.2 mL of 4920 µg and 67.2 µg, the solubility in the receptor media was ~1820 and 517 fold higher than actually needed for the formulation concentrate and the spray dilution, respectively. Even if the receptor volume of 4 mL is considered only, the solubility was at least 252-fold higher than actually needed. These results show that the maximum concentration of the test substance in the receptor chamber did not exceed 10% of the saturation concentration as recommended by EFSA.

n.a.: not applicable

C. ABSORPTION KINETICS

The mean values of the kinetic parameters determined from the linear region of the cumulative absorbed dose curve are presented in Table 7.3-6. An absorption rate of 0.49 µg/cm²·h and a permeability coefficient (Kp) of $0.25 \cdot 10^{-5}$ cm/h was observed for the formulation concentrate of pyraclostrobin. At the 400-fold lower amount of applied test substance, the absorption rate was 0.02 µg/cm²·h and an approx. 13-fold higher permeability coefficient of $3.30 * 10^{-5}$ cm/h was determined.

8	0.68	0.03	0.06	1.28
12	1.30	0.06	0.07	1.38
24	1.61	0.08	0.07	1.55
Kp [$*10^{-5}$ cm/h]	0.25		3.30	
Absorption rate [µg/cm²·h]	0.49		0.02	
Lag time [h]	4.73		0.80	
% absorbed within 12 hours	80.5		89.1	

* Mean values for Kp, absorption rate and lag time are calculated from cell 5-7. For cell 1-4, no meaningful kinetic values could be calculated. Cell 8 is not included in statistics due to insufficient first skin and invalid recovery wash.

III. CONCLUSION

The in-vitro dermal absorption of ^{14}C-pyraclostrobin formulated as BAS 500 06 F through human skin is low. The absorption estimates (sum of the absorbed dose and the remaining dose associated to the skin membrane) for pyraclostrobin were 0.18 ± 0.14% for the formulation concentrate and 4.13 ± 2.67% of the 1:400 spray dilution.

Considering both in-vitro dermal penetration studies, the dermal penetration estimates to be used for risk assessment were therefore calculated to be 3 and 7% for the formulation concentrate and the spray dilution (1:400), respectively. The value for the formulation concentrate was derived from the 2010 study (see M-CP 7.3/1), whereas the value for the 1:400 spray dilution was derived from the 2014 study (see M-CP 7.3/2).

Table of Contents

CP 9 FATE AND BEHAVIOUR IN THE ENVIRONMENT

BAS 500 06 F is a new representative formulation, which has not been evaluated during the previous Annex I inclusion process.

CP 9.1 Fate and behaviour in soil

No studies were performed with BAS 500 06 F. The fate and behavior in soil is sufficiently addressed by information given in M-CA 7.1.

CP 9.1.1 Rate of degradation in soil

No studies were performed with BAS 500 06 F. The rate of degradation in soil is sufficiently addressed by information given in M-CA 7.1.2.

CP 9.1.1.1 Laboratory studies

No laboratory studies were performed with BAS 500 06 F. Data for pyraclostrobin and its metabolites are covered by information given in M-CA 7.1.2.1.

CP 9.1.1.2 Field studies

No field studies were performed with BAS 500 06 F. Data for pyraclostrobin and its metabolites are covered by information given in M-CA 7.1.2.2.

CP 9.1.1.2.1 Soil dissipation studies

No soil dissipation studies were performed with BAS 500 06 F. Data for pyraclostrobin and its metabolites are covered by information given in M-CA 7.1.2.2.1.

CP 9.1.1.2.2 Soil accumulation studies

No soil accumulation studies were performed with BAS 500 06 F. Data for pyraclostrobin and its metabolites are covered by information given in M-CA 7.1.2.2.2.

CP 9.1.2 Mobility in the soil

No studies were performed with BAS 500 06 F. The mobility in soil is sufficiently addressed by information given in M-CA 7.1.4.

CP 9.1.2.1 Laboratory studies

No laboratory studies were performed with BAS 500 06 F. Data for pyraclostrobin and its metabolites are covered by information given in M-CA 7.1.4.1.

CP 9.1.2.2 Lysimeter studies

Due to the negligible leaching risk of pyraclostrobin and its metabolites, lysimeter studies are not considered necessary.

CP 9.1.2.3 Field leaching studies

Due to the negligible leaching risk of pyraclostrobin and its metabolites, field leaching studies are not considered necessary.

CP 9.1.3 Estimation of concentrations in soil

Predicted environmental concentrations in soil (PEC_S)

Report: CP 9.1.3/1
Kallweit W., 2014a
Predicted environmental concentrations of BAS 500 F - Pyraclostrobin and its metabolites in soil, groundwater, surface water and sediment following application to cereals, maize and potatoes
2014/1000685

GLP: no

Executive Summary

PEC_{soil} were calculated for worst-case application scenarios of pyraclostrobin and its aerobic soil metabolites BF 500-6 and BF 500-7 applied to cereals and maize. Anaerobic soil metabolites (BF 500-3, BF 500-4 and BF 500-5) are not considered relevant for the assessment in soil, since soil organisms are not viable under these conditions. In addition, the anaerobic soil metabolites are immediately further degraded when aerobic conditions are re-established. Conservative crop interception values were selected in accordance with the guidance of the FOCUS groundwater scenarios workgroup (2012). For cereals, interception values of 50% for the first and 70% for the second application were selected. For the application to maize, a crop interception value of 50% was considered.

A soil bulk density of 1.5 g cm^{-3} and a soil layer depth of 5 cm were assumed for the calculations.

Maximum PEC_{soil} for pyraclostrobin and its soil metabolites were calculated (Table 9.1.3-1). No accumulation is triggered for pyraclostrobin (DT_{90} of trigger endpoints < 365 days). However, $PEC_{soil,plateau}$ and $PEC_{soil,accu}$ of the metabolites were taken into account due to multi-year application of pyraclostrobin to cereals and maize.

Table 9.1.3-1: PEC_{soil} concentrations of pyraclostrobin and its soil metabolites BF 500-6 and BF 500-7 after application to cereals and maize

Compound	Crop	$PEC_{soil,plateau}$ [mg kg^{-1}] in 0 - 20 cm depth	$PEC_{soil,max}$ [mg kg^{-1}] in 0 - 5 cm depth	$PEC_{soil,accu}$ [mg kg^{-1}] (= $PEC_{soil,plateau}$ + $PEC_{soil,max}$) in 0 - 5 cm depth
Pyraclostrobin	Cereals	-	0.228	-
	Maize	-	0.133	-
BF 500-6	Cereals	0.057[a]	0.065[a]	0.121[a]
	Maize	0.028	0.033	0.061
BF 500-7	Cereals	0.034	0.039	0.073
	Maize	0.017[a]	0.019[a]	0.038[a]

[a] Rounded values

I. MATERIAL AND METHODS

Application scenarios

Calculations were carried out for worst-case application scenarios of pyraclostrobin applied to cereals and maize. Conservative crop interception values were chosen as recommended by the FOCUS groundwater scenarios workgroup [*FOCUS (2012): Generic guidance for Tier 1 FOCUS Ground Water Assessments, v2.1, 64 pp.*]. The aerobic soil metabolites BF 500-6 and BF 500-7 were additionally considered in the assessment. Anaerobic soil metabolites (BF 500-3, BF 500-4 and BF 500-5) are not considered relevant for the assessment in soil, since soil organisms are not viable under these conditions. In addition, the anaerobic soil metabolites are immediately further degraded when aerobic conditions are re-established.

Table 9.1.3-2 summarizes the worst-case application scenarios of pyraclostrobin applied to cereals and maize. The minimum application interval for the respective crop was considered as conservative scenario.

Table 9.1.3-2: Worst-case application scenarios of pyraclostrobin applied to various crops considered for the PEC_{soil} calculations

Crop	Cereals	Maize
Growth stage at first application [BBCH]	25	30
Application rate [g a.s. ha^{-1}]	250	200
No. of applications [-]	2	1
Interval [d]	21	-
Interception [%]	50 / 70	50
Amount reaching the soil surface [g a.s. ha^{-1}]	125 / 75	100
Total yearly soil load [g a.s. ha^{-1}]	200	100

Environmental fate parameters

Degradation of pyraclostrobin in soil

The aerobic soil degradation of pyraclostrobin under laboratory conditions was investigated in five studies with altogether 10 soils for 120 to 360 days at a temperature of 20°C and a soil moisture of 40 to 53% of maximum water holding capacity (MWHC) (see M-CA 7.1.2.1). The degradation kinetics of these studies were re-evaluated in a separate study [*CA 7.1.2.1.1/3, Eickler B. – BASF DocID 2014/1093424*]. An overview of the non-normalized DT_{50} values is given in Table 7.1.2.1.1-26.

The dissipation behavior of pyraclostrobin was investigated in two different field dissipation studies conducted in Europe between 1997 and 1999 with altogether six trials located in Germany (n=3), Spain (n=2) and Sweden (n=1) (see M-CA 7.1.2.2). The degradation kinetics were evaluated in a separate study [*CA 7.1.2.2.1/1, Eickler B. – BASF DocID 2014/1093423*]. An overview of the DT_{50} values is given in Table 7.1.2.2.1-24.

In addition four terrestrial field dissipation trials were conducted in Europe between 2011 and 2012 [*CA 7.1.2.2.1/2, Bayer H., Marwitz A. - BASF DocID 2013/1348661*]. These trials were located in Denmark, Germany, Italy and France, and the plots were covered with sand to exclude surface processes according to the requirements of the EFSA guidance for evaluating laboratory and field dissipation studies to obtain $DegT_{50}$ (2010) [*EFSA (2010): Guidance for evaluating laboratory and field dissipation studies to obtain $DegT_{50}$ values of plant protection products in soil. EFSA Journal 2010;8(12):1936, 67 pp.*]. Due to the specific design of the studies, the obtained degradation half-lives in the soil matrix are not appropriate for derivation of trigger endpoints and were therefore not considered for PEC_{soil} calculation.

For the calculations of PEC_{soil} the worst-case DT_{50} from the field studies of 55.8 days (SFO) was used.

Formation and degradation of BF 500-6 and BF 500-7 in soil

Two metabolites of pyraclostrobin, BF 500-6 and BF 500-7, were found in laboratory aerobic soil metabolism and degradation studies with maximum occurrences of 12 to 31% and of 1 to 14% of the applied radioactivity (AR), respectively.

In the older pyraclostrobin field dissipation trials [*old EU Dossier, A II M 7.1.1.2.2/1, Kellner O., Zangmeister W. – BASF DocID 1999/11301; old EU Dossier, A II M 7.1.1.2.2/2, Kellner O., Zangmeister W. – BASF DocID 1999/11292*] BF 500-6 was found only rarely at a single trial site, and BF 500-7 was not detected (limit of quantification 0.01 mg kg^{-1}). In the new field dissipation study [*CA 7.1.2.2.1/2, Bayer H., Marwitz A. – BASF DocID 2013/1348661*], the metabolites BF 500-6 and BF 500-7 were detected at maximum occurrences of 28 and 19% of applied parent amount, respectively.

For PEC_{soil} calculations, the maximum occurrences of 31% observed in the laboratory and 19% observed in the field study were used for BF 500-6 and BF 500-7, respectively.

The $DegT_{50}$ values of the metabolites calculated from laboratory studies with the parent or with the metabolites ranged from 95.9 to 971.2 days and from 81.5 to >1000 days for BF 500-6 and BF 500-7, respectively. As the $DegT_{50}$ values of BF 500-6 and BF 500-7 were close to the worst-case default value of 1000 days this default value was used for PEC_{soil} calculations.

Calculation methods

Maximum, actual and time-weighted average concentrations in soil ($PEC_{soil,max}$, $PEC_{soil,act}$, $PEC_{soil,twa}$) were calculated for the parent substance and its soil metabolites. The calculations were carried out based on the approach given in the guidance of the FOCUS workgroup on degradation kinetics [*FOCUS (2006): "Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration" Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference Sanco/10058/2005 version 1.0 of November 2011, 436 pp.*]. In addition, for the metabolites the potential of accumulation in soil after multi-year use was addressed.

Calculation of maximum concentrations in soil ($PEC_{soil,max}$)

The metabolites BF 500-6 and BF 500-7 are formed by a dimeric reaction, i.e. one metabolite molecule is formed out of two parent molecules. Hence, for the calculation of the respective f_{mol} the molar mass of the parent has to be considered twice (i.e. $f_{mol} = M_{met} / (2 \cdot M_{par})$). The resulting f_{mol} are 0.788 and 0.768 for the metabolites BF 500-6 and BF 500-7, respectively.

The maximum PEC values in soil ($PEC_{soil,max}$) were calculated considering the respective application rate, a soil bulk density of 1.5 g cm^{-3} and a thickness of the soil layer of 5 cm (Equation 9.1.3-1).

Equation 9.1.3-1 Calculation of the maximum PEC_{soil}

$$PEC_{soil,max,n} = \sum_{i=1}^{n} \left[\left(\frac{A_i \cdot (1 - f_{int,i})}{100 \cdot d \cdot bd_{soil}} \cdot f_{max,soil} \cdot f_{mol} \right) \cdot e^{-k \cdot (t_n - t_i)} \right]$$

with:			
	$PEC_{soil,max}$	maximum concentration in soil after n applications	[mg kg^{-1}]
	n	number of applications	[-]
	A_i	application rate at i-th application	[g a.s. ha^{-1}]
	$f_{int,i}$	fraction intercepted by plant cover at i-th application	[-]
	d	depth of soil layer (5 cm)	[cm]
	bd_{soil}	soil bulk density (1.5 g cm^{-3})	[g cm^{-3}]
	k	degradation rate (= ln (2) / DT_{50})	[d^{-1}]
	t_i	time of i-th application	[d]
	t_n	time of n-th (last) application	[d]
	$f_{max,soil}$	maximum observed formation in soil	[-]
	f_{mol}	correction factor for molar mass difference	[-]

Actual and time-weighted average concentrations ($PEC_{soil,act}$ and $PEC_{soil,twa}$)

The actual concentration in soil ($PEC_{soil,act}$) was calculated for different time points t = 1, 2, 4, 7, 14, 21, 28, 50 and 100 days after the occurrence of the maximum concentration according to Equation 9.1.3-2. First order kinetics (SFO) is assumed, since this type of kinetics was observed in laboratory studies and field trials.

Equation 9.1.3-2 Calculation of the actual PEC_{soil}

$$PEC_{soil,act} = PEC_{soil,max} \cdot e^{-k \cdot t}$$

with:			
	$PEC_{soil,act}$	actual concentration in soil	[mg kg^{-1}]
	$PEC_{soil,max}$	maximum concentration in soil	[mg kg^{-1}]
	k	degradation rate (= ln (2) / DT_{50})	[d^{-1}]
	t	time after last application	[d]

The maximum time-weighted average concentrations ($PEC_{soil,twa}$) for exposure periods of 1, 2, 4, 7, 14, 21, 28, 50 and 100 days were derived from the time series of PEC values ranging from day of the first application up to 200 DAT (days after first treatment) using a moving time-frame Excel spreadsheet. For a given exposure period t, the spreadsheet calculates the respective set of time-weighted average concentrations from the time series first (moving time-frame) and scans for the highest value in the set afterwards, see Equation 9.1.3-3.

Equation 9.1.3-3 Calculation of the time-weighted average PEC_{soil}

$$PEC_{soil,twa}(\Delta t) = \max\left[\frac{1}{m}\sum_{t=t_j}^{t_j+\Delta t} PEC_{soil}(t)\right] \qquad \text{for } j = 0,...,200$$

with:			
	$PEC_{soil,twa}$	worst-case time-weighted average concentration in soil for time interval Δt	[mg kg^{-1}]
	PEC_{soil}	concentration in soil at time t	[mg kg^{-1}]
	t	time	[d]
	t_j	start time point for integration	[d]
	Δt	time interval	[d]
	j	running variable for time step	[-]
	m	number of time steps in time interval t	[-]

<u>Maximum PEC_{soil} due to multi-year application ($PEC_{soil,accu}$)</u>

The potential of accumulation in soil was assessed for metabolites BF 500-6 and BF 500-7. For this purpose, the plateau concentration in soil at steady state ($PEC_{soil,plateau}$) and the overall accumulation PEC in soil ($PEC_{soil,accu}$) after application of pyraclostrobin over many years were determined following Equation 9.1.3-4 and Equation 9.1.3-5. The ploughing depth was set to 20 cm to represent the depth of soil cultivation in arable crops.

Equation 9.1.3-4 Calculation of the plateau PEC_{soil}

$$PEC_{soil,plateau} = \frac{PEC_{soil,max,20}}{1-e^{-kt}} \cdot e^{-k\cdot(t-i)}$$

with:			
	$PEC_{soil,plateau}$	plateau concentration at steady state	[mg kg^{-1}]
	$PEC_{soil,max,20}$	maximum soil concentration following last application considering a mixing depth of 20 cm	[mg kg^{-1}]
	t	interval between application seasons (365 days)	[d]
	i	interval between first application and last application in the cropping season	[d]
	k	degradation rate (= ln(2) / DT_{50})	[d^{-1}]

The overall accumulation PEC in soil ($PEC_{soil,accu}$) represents the highest potential soil concentration considering the multi-year accumulation load as background concentration ($PEC_{soil,plateau}$) plus the peak concentration ($PEC_{soil,max}$) after application in the top soil layer. For this purpose, the $PEC_{soil,plateau}$ and the $PEC_{soil,max}$ in the top soil layer of 5 cm were added (see Equation 9.1.3-5).

Equation 9.1.3-5 Calculation of the overall accumulation PEC_{soil}

$$PEC_{soil,accu} = PEC_{soil,plateau} + PEC_{soil,max}$$

with:			
	$PEC_{soil,accu}$	maximum concentration in soil for the accumulation risk assessment	[mg kg^{-1}]
	$PEC_{soil,plateau}$	concentration at steady state (plateau concentration) related to the plough layer depth of 20 cm	[mg kg^{-1}]
	$PEC_{soil,max}$	maximum concentration that gives respect to the soil load after one application period related to a soil layer depth of 5 cm	[mg kg^{-1}]

II. RESULTS AND DISCUSSION

The maximum, actual and time weighted average PEC_{soil} values of pyraclostrobin and its metabolites for a soil layer depth of 5 cm are shown in Table 9.1.3-3.

Table 9.1.3-3: PEC_{soil} of pyraclostrobin, BF 500-6 and BF 500-7 after application to cereals and maize

III. CONCLUSION

Maximum, short-term and long-term actual and time-weighted average PEC_{soil} were calculated for worst-case application scenarios of pyraclostrobin in the formulated product BAS 500 06 F, i.e. twofold application of 250 g a.s. ha^{-1} to cereals and single application of 100 g a.s. ha^{-1} to maize. The aerobic soil metabolites BF 500-6 and BF 500-7 were also considered. Further, their potential of accumulation in soil was assessed.

The predicted concentrations in soil are appropriate to be used for the subsequent risk assessment for soil organisms.

CP 9.2 Fate and behaviour in water and sediment

CP 9.2.1 Aerobic mineralisation in surface water

No studies were performed with BAS 500 06 F. The aerobic mineralisation in surface water is sufficiently addressed by information given in M-CA 7.2.2.2.

CP 9.2.2 Water/sediment study

No water/sediment studies were performed with BAS 500 06 F. Data for the active substance and its metabolites are covered by information given in M-CA 7.2.2.3.

CP 9.2.3 Irradiated water/sediment study

No irradiated water/sediment studies were performed with BAS 500 06 F. Data for the active substance and its metabolites are covered by information given in M-CA 7.2.2.4.

Executive Summary

Predicted environmental concentrations in groundwater (PEC_{gw}) of pyraclostrobin and its aerobic soil metabolites BF 500-6 and BF 500-7, as well as its anaerobic soil metabolites BF 500-3, BF 500-4 and BF 500-5 following application of BAS 500 06 F to cereals and maize were calculated in accordance with the guidance of the FOCUS groundwater scenarios work group (2000, 2009, 2012). Although these anaerobic soil metabolites are degraded quickly under aerobic conditions, they were considered (according to Regulation 1107/2009) for the assessment in groundwater.

Tier 1 PEC_{gw} of pyraclostrobin and its soil metabolites were calculated with the models FOCUS-PEARL 4.4.4 and FOCUS-PELMO 5.5.3 for all available FOCUS scenarios of cereals (twofold application of 250 g a.s. ha^{-1}, BBCH 25, 21 day interval, 50 / 70% interception) and maize (single application of 200 g a.s. ha^{-1}, BBCH 30, 50% interception) with an annual application pattern (continuous cropping over a period of 26 years).

The maximum PEC_{gw} for pyraclostrobin and its soil metabolites were < 0.001 µg L^{-1} and thus clearly below the 0.1 µg L^{-1} threshold value.

I. MATERIAL AND METHODS

The leaching assessment for pyraclostrobin and its metabolites was conducted at Tier 1 of the tiered assessment scheme proposed by the FOCUS groundwater higher tier working group. The aerobic soil metabolites BF 500-6 and BF 500-7 were considered in the assessment. In addition the anaerobic soil metabolites BF 500-3, BF 500-4 and BF 500-5 were considered even though they are degraded quickly under aerobic conditions.

The simulations were carried out using FOCUS-PEARL 4.4.4 and FOCUS-PELMO 5.5.3 in combination with the FOCUS standard scenarios.

Applied procedures, methods and scenarios follow the recommendations of the following guidelines:

- *FOCUS (2009): Assessing Potential for Movement of Active Substances and their Metabolites to Groundwater in the EU Final Report of the Groundwater Workgroup of FOCUS, amending FOCUS (2000), EC Document Reference Sanco/13144/2010, 604 pp.*
- *FOCUS (2000): "FOCUS groundwater scenarios in the EU plant protection product review process" Report of the FOCUS Groundwater Scenarios Workgroup, EC Document Reference Sanco/321/2000, 197 pp.*
- *FOCUS (2012): Generic guidance for Tier 1 FOCUS Ground Water Assessments, v2.1, 64 pp.*

Application scenarios

PEC_{gw} values of pyraclostrobin were calculated for the same worst-case application scenarios as for the PEC_{soil} assessment (see M-CP 9.1.3). PEC_{gw} calculations were performed for all FOCUS groundwater scenarios that are parameterized for winter and spring cereals as well as maize.

Application dates were selected following FOCUS recommendations. The worst-case application scenarios and application dates for all relevant FOCUS scenarios are shown in Table 9.2.4.1-1 and Table 9.2.4.1-2 for cereals and maize, respectively.

Table 9.2.4.1-1 Worst-case application scenarios for PEC_{gw} calculations of pyraclostrobin applied to cereals

Crop	**Cereals**	
Growth stage at first application [BBCH]	25	
No. of applications [-]	2	
Interval [days]	21	
Application rate [g a.s. ha^{-1}]	250

Sevilla	21st March
Thiva	4th May

Environmental fate parameters

Degradation parameters of the parent

A total of 18 degradation endpoints for environmental fate modeling from different laboratory and field trials were reported (see M-CP 9.1.3) in four studies [*CA 7.1.2.1.1/3, Eickler B. – BASF DocID 2014/1093424; CA 7.1.2.1.1/1, Hassink J., Kuhnke G. – BASF DocID 2013/1337273; CA 7.1.2.2.1/1, Eickler B. – BASF DocID 2014/1093423; CA 7.1.2.2.1/4, Pape L. – BASF DocID 2014/1105764*]. As the endpoint in *Hassink J., Kuhnke G.* [*BASF DocID 2013/1337273*] was calculated for actual study conditions, it was further normalized to reference conditions (20°C, pF2). In all other studies normalized degradation endpoints were reported. In study *CA 7.1.2.2.1/1* [*Eickler B. – BASF DocID 2014/1093423*] the two Spanish field trials (ALO/01/98 and ALO/02/98) were considered to be not appropriate for derivation of modeling endpoints as the extreme climatic conditions during the trials were not representative for the EU.

An overview of individual DT_{50} values considered to select endpoints for PEC_{gw} calculations is given in Table 7.1.2.1.1-26 and/or Table 7.1.2.1.1-27 (laboratory studies) and in Table 7.1.2.2.1-24 (field studies).

For derivation of an appropriate degradation endpoint for PEC_{gw} modeling the EFSA endpoint selector was used [*EFSA $DegT_{50}$ and Sorption Endpoint Selector. Download from: http://www.efsa.europa.eu/en/130725a/docs/130725aax1.xls, date of access: 15.04.2014*]. Accordingly, the bias-corrected geometric mean $DegT_{50}$ value of 28.3 days based on the results of the field studies was used as modeling input.

Sorption of pyraclostrobin to soil

The sorption behavior of pyraclostrobin was investigated in six soils by batch-equilibrium experiments [*old EU Dossier, A II M 7.1.2/1, Ziegler G. - BASF DocID 1998/10650*]. An overview of individual $K_{f,oc}$ and 1/n values considered to select endpoints for PEC_{gw} calculations is given in M-CA 7.1.3.1.1. For the PEC_{gw} calculations of pyraclostrobin, an arithmetic mean $K_{f,oc}$ of 9304 mL g^{-1} (equivalent to a $K_{f,om}$ value of 5397 mL g^{-1}) and an arithmetic mean 1/n of 0.95 were used.

Formation and degradation of the metabolites in soil

BF 500-3
In laboratory experiments under aerobic conditions and in field dissipation trials with pyraclostrobin, the metabolite BF 500-3 was either not detected or formed in amounts far below 5% of the amount of applied parent (see M-CA 7.1.1). Under anaerobic conditions it was formed in high amounts by a very fast de-methoxylation of pyraclostrobin (see M-CA 7.1.1). This reaction is the first step also in the aerobic soil degradation process. However, further reaction to successive metabolites and bound residues is too fast to detect this short-lived transient intermediate.

To account for the rapid formation and degradation of BF 500-3 under aerobic conditions, a conservative default DT_{50} of 1 day and a formation fraction of 1 from pyraclostrobin were considered for PEC_{gw} calculations.

BF 500-4
The metabolite BF 500-4 was never found in soil under aerobic conditions. Under anaerobic conditions it was observed with up to 11.1% TAR [*old EU Dossier, A II M 7.1.1.2.1/5, Kellner O. - BASF DocID 1999/10079; old EU Dossier, A II M 7.1.1.2.1/6, Kellner O. - BASF DocID 1999/11103*]. The aerobic degradation of BF 500-4 under laboratory conditions was investigated in three soils [*CA 7.1.2.1.2/3, Ebert D., Dalkmann P. – BASF DocID 2013/1294779*]. The corresponding DT_{50} values were normalized to reference conditions (20°C, pF2), see Table 7.1.2.1.2-24 at the end of study *CA 7.1.2.1.2/3*. The geometric mean of the normalized DT_{50} values of 2.82 days was used as input parameter for BF 500-4 for PEC_{gw} calculations.

In the kinetic re-evaluation of the anaerobic soil degradation studies of pyraclostrobin formation fractions of BF 500-4 from BF 500-3 of 1 and 0.692 were reported [*CA 7.1.2.1.3/1, Pape L. – BASF DocID 2014/1000701*]. Therefore, a formation fraction of 1 was used as worst-case assumption for PEC_{gw} calculations.

BF 500-5
Under aerobic conditions, the metabolite BF 500-5 occurred only in one soil with 2.8% TAR. Under anaerobic conditions it was found with up to 7.7% TAR [*Kellner O. - BASF DocID 1999/11103*]. The aerobic degradation of BF 500-5 under laboratory conditions was investigated in three soils [*CA 7.1.2.1.2/4, Schoof S., Possienke M. – BASF DocID 2013/1294780*]. The corresponding DT_{50} were normalized to reference conditions (20°C, pF2), see Table 7.1.2.1.2-34 at the end of study *CA 7.1.2.1.2/4*. As all DT_{50} values were below 1 day a default DT_{50} value of 1 day was used for PEC_{gw} calculations as worst-case assumption.

In the kinetic re-evaluation of the anaerobic soil degradation studies of pyraclostrobin a formation fraction of BF 500-5 from BF 500-4 of 0.409 was reported and was considered for PEC_{gw} calculations [*CA 7.1.2.1.3/1*, *Pape L. – BASF DocID 2014/1000701*].

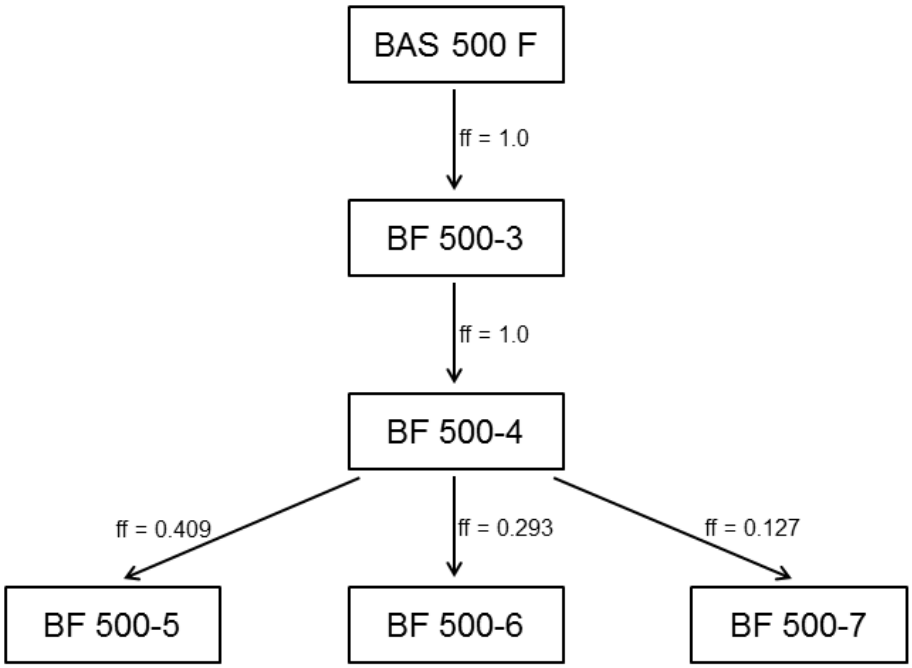
BF 500-6 and BF 500-7
The metabolites BF 500-6 and BF 500-7 were found in aerobic soil degradation studies as well as in field dissipation studies with pyraclostrobin. Degradation endpoints for modeling are available from kinetic evaluations of aerobic laboratory degradation studies with pyraclostrobin and aerobic laboratory degradation studies with the metabolites (see table at the end of study *CA 7.1.2.1.2/4*) as well as with the new field dissipation study with pyraclostrobin (see table at the end of study *CA 7.1.2.2.1/4*) [*Hassink J., Kuhnke G. – BASF DocID 2013/1337273; Eickler B. – BASF DocID 2014/1093424; Pape L. – BASF DocID 2014/1105764; CA 7.1.2.1.2/1, Tornisielo A., Sacchi R.R. – BASF DocID 2011/1142307; CA 7.1.2.1.2/2, Tornisielo A., Sacchi R.R. – BASF DocID 2011/1142308*].

Where necessary, the reported DT_{50} values were normalized to reference conditions (20°C, pF2), see tables at the end of study *CA 7.1.2.1.2/1* (BF 500-6) and at the end of study *CA 7.1.2.1.2/2* (BF 500-7). For derivation of appropriate degradation endpoints for PEC_{gw} modeling the EFSA endpoint selector was used. Accordingly, the bias-corrected geometric mean of pooled laboratory and field DT_{50} values of 321.0 days for BF 500-6 and 312.0 days for BF 500-7 was used for the PEC_{gw} calculations.

Formation fractions of BF 500-6 and BF 500-7 were reported in the kinetic evaluations of laboratory and field studies with pyraclostrobin either directly from the parent or from BF 500-3 (see table at the end of study *CA 7.1.2.1.2/4* and table at the end of study *CA 7.1.2.2.1/4*).

In the aerobic degradation study with BF 500-4, the two metabolites occurred as reaction products of BF 500-4 [*CA 7.1.2.1.2/3, Ebert D., Dalkmann P. – BASF DocID 2013/1294779*]. Consequently, this pathway was also assumed for PEC_{gw} calculations. For the metabolites BF 500-3 and BF 500-4, formation fractions of 1 were considered, respectively (see above). Thus, for BF 500-6 and BF 500-7 the reported formation fractions from pyraclostrobin or from BF 500-3 can be directly considered. As such the arithmetic mean values derived from pooled field and laboratory data (following the EFSA approach for degradation rates) of 0.293 (BF 500-6) and 0.127 (BF 500-7) were used.

The complete transformation scheme considered for the PEC_{gw} calculations is shown in Figure 9.2.4.1-1.



ff formation fraction

Figure 9.2.4.1-1: Transformation scheme of pyraclostrobin in soil used for PEC_{gw} simulations

Sorption of the metabolites to soil

An overview of individual K_{oc} values for the metabolites of pyraclostrobin considered to select endpoints for PEC_{gw} calculations is given in M-CA 7.1.3.1.2 and summarized in the tables below. For BF 500-3 and BF 500-4 arithmetic mean K_{oc} of 9315 mL g^{-1} (n = 6) and 9819 mL g^{-1} (n = 5) as well as a worst-case default 1/n of 1 were used for PEC_{gw} calculations, respectively. For BF 500-5, an arithmetic mean $K_{f,oc}$ of 705 mL g^{-1} (n = 5) and the corresponding arithmetic mean 1/n of 0.85 were considered, while for BF 500-6 and BF 500-7, the median of 11 K_{oc} values of 107301 mL g^{-1} and 149900 mL g^{-1} and a default 1/n of 1 were used.

Input parameters for pyraclostrobin and its metabolites

A summary of the substance parameters used for the Tier 1 PEC_{gw} calculations is given in Table 9.2.4.1-3 to Table 9.2.4.1-8.

II. RESULTS AND DISCUSSION

The 80th percentiles of the predicted annual leachate concentrations in groundwater after application to winter and spring cereals as well as maize were below 0.001 µg L^{-1} for pyraclostrobin and its metabolites BF 500-3, BF 500-4, BF 500-5, BF 500-6 and BF 500-7 for all scenarios. Consequently, the leaching of unacceptable amounts of pyraclostrobin after application to cereals and maize is highly unlikely.

III. CONCLUSION

A tiered approach was considered to address the risk for groundwater following the guidelines of FOCUS groundwater. No risk was identified for the parent compound, nor for its soil metabolites at Tier 1 (PEC_{gw} < 0.001 µg L^{-1}).

CP 9.2.4.2 Additional field tests

No additional field tests were performed with BAS 500 06 F. Data for the active substance and its metabolites are covered by information given in M-CA 7.

CP 9.2.5 Estimation of concentrations in surface water and sediment

Predicted environmental concentrations in surface water (PEC_{SW}) and sediment (PEC_{SED})

Report: CP 9.2.5/1

Extended Summary and Recommendations SANCO/10422/2005 v2.0. 169 pp.

GLP: no

Executive Summary

Predicted environmental concentrations in surface water (PEC_{sw}) and sediment (PEC_{sed}) were calculated for pyraclostrobin after single and twofold spray application of 250 g a.s. ha^{-1} to cereals and single spray application of 200 g a.s. ha^{-1} to maize considering the entry pathways spray drift, drainage and runoff.

The metabolites of pyraclostrobin which were observed in major amounts in water (BF 500-5, BF 500-11, BF 500-13, BF 500-14) and in sediment (BF 500-3, BF 500-6, BF 500-7) were also considered for the assessment in the respective environmental compartments, taking into account their formation after entry of the parent substance.

Additionally, for the metabolites BF 500-6 and BF 500-7 occurring in major amounts in soil under aerobic conditions the entry pathways runoff and drainage of the metabolites into surface water were taken into account. Since both metabolites have very low water solubilities (2 - 3 µg L^{-1}) and extremely high sorption values (K_{oc}>10^5 mL g^{-1}), they will reach surface water bodies via runoff or drainage in a soil particle-bound form. They then sink to the sediment surface, i.e. they are extremely unlikely to occur freely dissolved in molecular form in the water phase. Consequently BF 500-6 and BF 500-7 were only considered for PEC calculations in the sediment compartment.

For the metabolites BF 500-3 and BF 500-5 runoff and drainage of the metabolites are not relevant as entry pathways into surface water as the metabolites did not occur in relevant amounts in soil under aerobic conditions. The metabolite BF 500-4 was not found either in water/sediment studies or in soil under aerobic conditions and was therefore not considered in the assessment.

The calculations were performed according to the FOCUS surface water guidance documents [*FOCUS (2001, 2012)*].

Calculations for pyraclostrobin were carried out at Step 1 to Step 4. A tiered approach was considered for the parent substance, with endpoints derived from a dark water/sediment study being used at Tier 1 and endpoints from an irradiated water/sediment study being used at Tier 2. PEC values for the metabolites were calculated for FOCUS Step 1 and 2 level. Input parameters for the metabolites were derived from the study in which they occurred, i.e. in dark or irradiated water/sediment systems.

The software packages STEPS1-2 in FOCUS version 2.1, FOCUS-PRZM version 1.5.6, FOCUS-MACRO version 4.4.2 and FOCUS-TOXSWA version 3.3.1 for Step 3 were used for the calculations. In addition, the pre- and post-processing software tool PEC Robot v1.4 was used to prepare Step 4 simulations. At Step 2 of the assessment, the regions ‘North Europe’ and ‘South Europe’ were taken into account. At Step 3 and 4, all FOCUS scenarios available for winter and spring cereals as well as maize were considered.

A summary of the maximum PEC_{sw} of pyraclostrobin and its metabolites calculated for each step of the assessment is given in the tables below.

Pyraclostrobin

Tier 1 (parameters from dark water/sediment study)

I. MATERIAL AND METHODS

Predicted environmental concentrations in surface water (PEC_{sw}) and sediment (PEC_{sed}) were calculated for pyraclostrobin after single and twofold spray application of 250 g a.s. ha^{-1} to cereals and single spray application of 200 g a.s. ha^{-1} to maize considering the entry pathways spray drift, drainage and runoff.

The metabolites of pyraclostrobin, which were observed in major amounts in water (BF 500-5, BF 500-11, BF 500-13, BF 500-14) and in sediment (BF 500-3, BF 500-6, BF 500-7), were also considered for the assessment in the respective environmental compartments, taking into account their formation after entry of the parent substance. Additionally, for the metabolites occurring in major amounts in soil under aerobic conditions (BF 500-6, BF 500-7) the entry pathways runoff and drainage of the metabolites into surface water were taken into account.

Since both metabolites have very low water solubilities (2 - 3 µg L^{-1}) and extremely high sorption values (K_{oc}>10^5 mL g^{-1}), they will reach surface water bodies via runoff or drainage in a soil particle-bound form. They then sink to the sediment surface, i.e. they are extremely unlikely to occur freely dissolved in molecular form in the water phase. Consequently BF 500-6 and BF 500-7 were only considered for PEC calculations in the sediment compartment.

For the metabolites BF 500-3 and BF 500-5 runoff and drainage of the metabolites are not relevant as entry pathways into surface water as the metabolites did not occur in relevant amounts in soil under aerobic conditions. Metabolite BF 500-4 was neither found in water/sediment studies nor in soil under aerobic conditions and was therefore not considered in the assessment.

The calculations were performed according to the FOCUS surface water guidance documents [*FOCUS (2001): FOCUS Surface Water Scenarios in the EU Evaluation Process under 91/414/EEC Report of the FOCUS Working Group on Surface Water Scenarios. EC Document Reference SANCO/4802/2001-rev.2. final. 238 pp); FOCUS (2012): "FOCUS Surface Water Scenarios in the EU Evaluation Process under 91/414/EEC" Report of the FOCUS Working Group on Surface Water Scenarios. EC Document Reference SANCO/4802/2001 version 1.2. 357 pp.*].

Application scenarios

The worst-case application scenarios of pyraclostrobin considered for PEC_{sw} and PEC_{sed} calculations are given in Table 9.2.5-11.

Table 9.2.5-11: Application scenarios of pyraclostrobin applied to various crops considered for PEC_{sw} and PEC_{sed} calculations

$FOCUS_{sw}$ crop	Winter cereals	Spring cereals	Maize
Growth stage [BBCH]	25-69		30-65
Application rate [g a.s. ha^{-1}]	250		200
Max. no. of applications [-]	1 / 2		1
Interval [d]	- / 21		-
Total yearly application rate [g a.s. ha^{-1}]	250 / 500		200

Environmental fate parameters

Fate and behavior in soil

Degradation and sorption of pyraclostrobin

The degradation behavior of pyraclostrobin in soil has been investigated under both laboratory and field conditions. An overview of individual DT_{50} considered to select endpoints for PEC calculations is given in the tables at the end of study *CA 7.1.2.1.1/3* and study *CA 7.1.2.2.1/4*. The sorption behavior of pyraclostrobin is described in M-CP 9.2.4 (chapter on PEC_{gw}).

The normalized bias-corrected geometric mean half-life of 28.3 days (at 20°C and pF2) from the eight relevant field trials, an arithmetic mean $K_{f,oc}$ of 9304 mL g^{-1} and the corresponding 1/n of 0.95 were used for the PEC_{sw} calculations.

Degradation and sorption of the metabolites of pyraclostrobin

The degradation behavior of the metabolites of pyraclostrobin in soil has been investigated under laboratory (BF 500-3, BF 500-5, BF 500-6, BF 500-7) and field conditions (BF 500-6, BF 500-7). An overview of individual DT_{50} considered to select endpoints for PEC calculations is given in the tables at the end of study *CA 7.1.2.1.2/4* and study *CA 7.1.2.2.1/4*. The sorption behavior of the metabolites of pyraclostrobin is described in M-CP 9.2.4 (section on PEC_{gw}).

As the metabolites BF 500-3 and BF 500-5 did not occur in relevant amounts in soil under aerobic conditions, a maximum occurrence in soil of 0.01% and a DT_{50} of 1 day were assumed as worst-case default input parameters. The arithmetic mean K_{oc} values of 9315 mL g^{-1} and 705 mL g^{-1} for BF 500-3 and BF 500-5, respectively, were considered for the calculations.

For the metabolite BF 500-6 a maximum occurrence in soil of 31% TAR observed in the laboratory, a bias-corrected geometric mean DT_{50} of 321.0 days and a median K_{oc} value of 107301 mL g^{-1} were used as modeling input.

For the metabolite BF 500-7 a maximum occurrence in soil of 19% TAR observed in field degradation studies, a bias-corrected geometric mean DT_{50} of 312.0 days and a median K_{oc} value of 149900 mL g^{-1} were used as modeling input.

The metabolites BF 500-11, BF 500-13 and BF 500-14 occur only in water. As there are no data on soil degradation and sorption available, a maximum occurrence in soil of 0.01%, a DT_{50} of 1 day and a K_{oc} of 1 x 10^{-10} mL g^{-1} were assumed as worst-case default input parameters.

Fate and behavior in aquatic systems

Pyraclostrobin

Degradation and partitioning of pyraclostrobin in aquatic systems have been investigated in a range of studies with different test designs and an increasing level of environmental relevance: dark and irradiated water/sediment systems and outdoor mesocosm [*old EU Dossier, A II M 7.2.1.3.2/1, Staudenmaier H. - BASF DocID 1999/11241*; *old EU Dossier, A II M 7.2.1.3.2/2, Ebert D. - BASF DocID 1999/11791*; *CA 7.2.2.4/2, Ebert D. – BASF DocID 2011/1101715; old EU Dossier, A III M 10.2.2/1, Dohmen G. P. - BASF DocID 2000/1000011*]. In order to reflect the different test designs in the model calculations a tiered approach was considered.

At **Tier 1** the assessment was based on the results of the water/sediment study conducted under dark laboratory conditions [*Staudenmaier H. - BASF DocID 1999/11241*]. The degradation kinetics were re-evaluated in a separate study [*CA 7.2.2.3/1, Wiedemann G. – BASF DocID 2012/1165029*]. At Level P-I, for System A whole system DT_{50} values of 23.3 and 26.8 days were reported for chlorophenyl- and tolyl-labeled pyraclostrobin, respectively, while for System B no reliable endpoints could be derived. The kinetic evaluation at Level P-II did not result in reliable endpoints. According to FOCUS kinetics a case-by-case decision should be made if reliable endpoints (P-I, System B) cannot be derived with the recommended standard procedures. For System B a $DegT_{90}$ in the whole system of approximately 30 days can be estimated visually, which is considerably shorter than the endpoint calculated for System A. Hence, the results of the kinetic evaluation of System A represent the worst-case of the two w/s systems investigated. Consequently, only the results of the kinetic evaluation of System A are to be considered as worst-case for further usage. In accordance with FOCUS degradation kinetics [*FOCUS (2006)*] the geometric mean DT_{50} in the total system of 25.0 days was considered for the total system at Step 1. Due to the high sorption tendency of pyraclostrobin the total system DT_{50} value of 25.0 days was used at Step 2 and 3 for the sediment phase, while the conservative default value of 1000 days was used for the water phase.

At **Tier 2** the assessment was based on the results of the water/sediment-studies conducted under irradiated laboratory conditions [*Ebert D. - BASF DocID 1999/11791*; *Ebert D. – BASF DocID 2011/1101715*]. While in *Ebert D.* [*BASF DocID 2011/1101715*] degradation endpoints could be derived only at Level P-I, the kinetic re-evaluation of *Ebert D.* [*BASF DocID 1999/11791*] resulted in appropriate degradation endpoints at Level P-I and Level P-II [*CA 7.2.2.4/1, Miles B. - BASF DocID 2012/1021122*]. The reported endpoints (dissipation half-life in water of 4.47 days) are considered as a realistic worst-case scenario compared to the outdoor mesocosm study, where a dissipation half-life in water of 3.5 days was reported. Consequently, the respective Level P-II degradation half-lives of 7.50 days in water and 6.48 days in sediment were used as input for modeling at Step 2 and 3 while for Step 1 calculations a $DegT_{50}$ in the total system calculated at Level P-I of 7.2 days was considered in accordance with FOCUS kinetics [*FOCUS (2006)*].

Metabolites of pyraclostrobin

In the dark water/sediment study the metabolites BF 500-3, BF 500-6 and BF 500-7 occurred as major metabolites [*Staudenmaier H. - BASF DocID 1999/11241*]. Additionally, BF 500-3, BF 500-11, BF 500-13 and BF 500-14 occurred in relevant amounts in the irradiated water/sediment study [*Ebert D. - BASF DocID 1999/11791*], and BF 500-5 was detected as major metabolite in the study on aerobic mineralization in surface water [*CA 7.2.2.2/1, Ebert D., Possienke M. – BASF DocID 2013/1002741*]. An overview of the DT_{50} values for the metabolites of pyraclostrobin in water/sediment systems is shown at the end of M-CA 7.2.2.

BF 500-3 was observed at amounts >5% TAR in the sediment compartment of the water/sediment studies under dark as well as under irradiated conditions, whereas in the water compartment no residues above 5% TAR were detected [*Staudenmaier H. - BASF DocID 1999/11241; Ebert D. - BASF DocID 1999/11791; Ebert D. – BASF DocID 2011/1101715*]. Therefore, PEC_{sed} calculations were conducted considering the results from the dark and the irradiated studies separately. Regarding the calculations representing the dark conditions, the maximum occurrence in the total system (mean of two labels) of 67.7% TAR [*Staudenmaier H. - BASF DocID 1999/11241*] and a conservative default DT_{50} of 1000 days were used, while for irradiated conditions the maximum occurrence in the total system of 21.9% TAR and a DT_{50} in the total system of 92.5 days from the kinetic re-evaluation were considered [*Ebert D. - BASF DocID 1999/11791; CA 7.2.2.4/1, Miles B. - BASF DocID 2012/1021122*].

BF 500-5 was observed as major metabolite in the water phase of the study on aerobic mineralization in surface water, whereas it did not occur in relevant amounts in the sediment phase [*CA 7.2.2.2/1, Ebert D., Possienke M. – BASF DocID 2013/1002741*]. Therefore, PEC_{sw} calculations were conducted considering the maximum occurrence of 10.9% TAR observed in the pelagic test and a conservative default DT_{50} of 1000 days.

BF 500-6 and BF 500-7 were observed at amounts >5% TAR in the sediment compartment of the water/sediment study under dark conditions, whereas in the water compartment no residues above 5% TAR were detected [*Staudenmaier H. - BASF DocID 1999/11241*]. Therefore, PEC_{sed} calculations were conducted considering the maximum occurrences of 6.5% TAR and 6.3% TAR (mean of two labels) for BF 500-6 and BF 500-7, respectively, and a conservative default DT_{50} of 1000 days.

BF 500-11, BF 500-13 and BF 500-14 were observed as major metabolites under irradiated conditions in the water compartment, whereas they did not occur in relevant amounts in the sediment compartment [*Ebert D. - BASF DocID 1999/11791*]. Therefore, PEC_{sw} calculations were conducted considering the sum of the maximum occurrences in water and sediment of 12.0% TAR, 17.8% TAR and 12.1% TAR for BF 500-11, BF 500-13 and BF 500-14, respectively. For BF 500-11 and BF 500-14 the DT_{50} values in the total system of 22.6 days and 17.3 days from the kinetic re-evaluation were considered, respectively [*CA 7.2.2.4/1, Miles B. - BASF DocID 2012/1021122*]. For BF 500-13 a reliable half-life could not be estimated from the data of the irradiated water/sediment study, because the maximum occurrence of the metabolite was at the last sampling date [*Ebert D. - BASF DocID 1999/11791*]. However, results of the aqueous photolysis study show a significant degradation of BF 500-13 in water with a calculated half-life of 30.7 days (rounded value) under continuous irradiation [*old EU Dossier, A II M 7.2.1.2/2, Scharf J. - BASF DocID 1999/11286*]. In order to represent a realistic radiation scenario (12 h radiation followed by 12 h darkness) the reported half-life was multiplied with a factor of 2 resulting in a DT_{50} of 61.3 days, which was used as input parameter for PEC_{sed} calculations.

Surface water assessment according to FOCUS

The calculations were performed in a stepwise approach according to the recommendations of the FOCUS working group on surface water scenarios (2001, 2012).

For all calculations, the following model versions were used: STEPS1-2 in FOCUS version 2.1, FOCUS-PRZM version 1.5.6, FOCUS-MACRO version 4.4.2 and FOCUS-TOXSWA version 3.3.1. The modeling runs were set up with SWASH version 3.1 and PEC Robot v1.4.

Setup of FOCUS surface water runs

Pyraclostrobin

FOCUS Step 1 to Step 4 calculations were carried out for PEC_{sw} and PEC_{sed} for pyraclostrobin considering the entry routes spray drift, drainage and runoff for spray application to winter and spring cereals as well as maize.

STEP 1 and Step 2 scenario settings

At Step 1 and 2, appropriate application periods and parameters for crop interception according to the actual GAP for cereals and maize were considered as shown in Table 9.2.5-12. The regions 'North Europe' and 'South Europe' as implemented in FOCUS STEPS1-2 were considered.

Table 9.2.5-12: Steps 1-2 FOCUS scenarios for the selected FOCUS crops

$FOCUS_{sw}$ crop	Interception class	Application period	Region
Winter cereals	Average crop cover	Mar – May	North and South Europe
Spring cereals			
Maize			

Step 3 scenario settings

At Step 3, all FOCUS scenarios parameterized for winter cereals (D1 - D6, R1, R3, R4), spring cereals (D1, D3 - D5, R4) and maize (D3 - D6, R1 - R4) were selected for the simulations. In the SWASH shell the application method was set to 'ground spray'. The chemical application method (CAM) was set to option '2' (application to foliage). The length of the application window, that is required for the Pesticide Application Tool (PAT) to determine actual application dates, was chosen to cover the whole application window as specified in the GAP. For single application (as for maize) a minimum application window of 30 days is required. For multiple application to cereals, considering the minimum application interval of 21 days, a minimum length of the application window of 51 days is required. The actual dates for field application differ according to the crop development in the different European regions and from year to year.

For winter cereals appropriate dates for the first treatment indicating growth stage 25 were selected for Northern Europe (15th April), Middle Europe (15th March) and Southern Europe (15th February) and were assigned to the ten FOCUS scenarios. The start date of the application window for application to spring cereals was assumed 28 days after application. For both, winter and spring cereals, the last application was assumed 35 days prior to harvest (derived from the pre-harvest interval (PHI) provided in the GAP).

For application to maize, the first application was scheduled at BBCH stage 30, which was assumed to take place 14 days after emergence. The time interval between BBCH growth stages 30 and 65 (first and last application, respectively) was set to 110 days.

The detailed application timing used for the simulations is shown in Table 9.2.5-13 to Table 9.2.5-15.

Table 9.2.5-13: Application timing for pyraclostrobin in winter cereals in the relevant scenarios (Step 3 and 4)

Scenario	Water body	Application window[a]	Application dates according to PAT[b]
Winter cereals			
D1 - Lanna	ditch	15th April - 22nd July	25th April / 16th May

R4 - Roujan	stream	24th April - 12th August	4th May

Mitigation measures at Step 4

At Step 4, drift mitigation of pyraclostrobin due to no-spray buffer zones was taken into account for all FOCUS scenarios parameterized in Step 3. Buffer zones of 5 m up to 20 m for winter and spring cereals and 5 m to 10 m for maize were selected directly from the spray drift mitigation page of PEC Robot. For all crops, drift reduction of 50%, 75% and 90% due to drift reducing nozzles was additionally taken into account. Furthermore, mitigation of the runoff/erosion entry into the surface water bodies by a 10 m or 20 m vegetated filter strip was considered.

The runoff/erosion reduction factors recommended by the FOCUS working group on landscape and mitigation factors in ecological risk assessments [*FOCUS (2007): "Landscape And Mitigation Factors In Aquatic Risk Assessment. Volume 1. Extended Summary and Recommendations". Report of the FOCUS Working Group on Landscape and Mitigation Factors in Ecological Risk Assessment, EC Document Reference SANCO/10422/2005 v2.0. 169 pp., FOCUS (2007a): "Landscape And Mitigation Factors In Aquatic Risk Assessment. Volume 2. Detailed Technical Reviews". Report of the FOCUS Working Group on Landscape and Mitigation Factors in Ecological Risk Assessment, EC Document Reference SANCO/10422/2005 v2.0. 436 pp.*] were considered. Table 9.2.5-16 gives an overview on the runoff/erosion reduction factors used in the assessment.

Table 9.2.5-16: Filtration capacity (factor for the reduction of runoff volume, sediment mass and corresponding pesticide loadings) by vegetated filter strips of 10 m and 20 m for Step 4 calculations

Width of planted buffer strips [m]	Reduction in runoff flux and volume [%]	Reduction in erosion flux and sediment mass [%]	Reference
10	60	85	*FOCUS (2007)*
20	80	95	

Metabolites of pyraclostrobin

For the metabolites of pyraclostrobin, PEC values were calculated at FOCUS Step 1 and 2. The results of the calculations are reported for those compartments where the respective metabolites had been detected as major metabolites. The simulations were carried out according to the approach and application scenarios for the parent compound.

Overview of the FOCUS levels used for the simulations

Table 9.2.5-17 gives an overview of the FOCUS levels, at which the PEC values of the respective compounds were simulated.

Table 9.2.5-17: Summary of the selection of the FOCUS levels for each compound

Compound	PEC_{sw} calculations conducted with FOCUS Step	PEC_{sed} calculations conducted with FOCUS Step	Reported PEC_{sw}	Reported PEC_{sed}
Pyraclostrobin	1, 2, 3, 4	1, 2, 3	max, act, twa	max
BF 500-3	-[1]	1, 2	-[1]	max
BF 500-5	1, 2	-[2]	max	-[2]
BF 500-6	-[3]	1, 2	-[3]	max
BF 500-7	-[3]	1, 2	-[3]	max
BF 500-11	1, 2	-[4]	max	-[4]
BF 500-13	1, 2	-[4]	max	-[4]
BF 500-14	1, 2	-[4]	max	-[4]

[1] BF 500-3 did not occur in soil or water phase in significant amounts
[2] BF 500-5 did not occur in soil or sediment phase in significant amounts
[3] BF 500-6 and BF 500-7 will not occur free in water phase due to low water solubility and high sorption values
[4] BF 500-11, BF 500-13 and BF 500-14 did not occur in soil or sediment phase in significant amounts

Pyraclostrobin

For a summary of the environmental fate parameters of pyraclostrobin used for modeling at Step 1 to Step 4 of the assessment see Table 9.2.5-18. The input parameters for the metabolites are summarized in Table 9.2.5-19 to Table 9.2.5-25. Some default assumptions were made as the measured data could not cover all required model input, e.g. solubility in water, maximum occurrence in soil, DT_{50} in soil and K_{oc} of the aquatic metabolites BF 500-11, BF 500-13 and BF 500-14.

Sum of max. observed occurrence in water/sediment [%]	12.1	Irradiated water/sediment study

II. RESULTS AND DISCUSSION

All calculated PEC_{sw} and PEC_{sed} values are available in the study report. For the sake of compactness, only the maximum concentrations of pyraclostrobin and its metabolites in surface water (PEC_{sw}) and in sediment (PEC_{sed}) are reported below. Actual and time-weighted average concentrations of pyraclostrobin in surface water are presented exemplarily for application to winter cereals at Tier 1 as it provides the worst-case PECs.

SURFACE WATER

Global maximum concentrations – pyraclostrobin

Step 1 and 2

Tier 1 (parameters from dark water/sediment study)

Table 9.2.5-26: Steps 1-2: $PEC_{sw,max}$ of pyraclostrobin following application to various crops (Tier 1)

$FOCUS_{sw}$ crop	Pyraclostrobin $PEC_{sw,max}$ [µg L^{-1}]					
	Step 1		Step 2			
			North Europe		South Europe	
	Single	Multiple	Single	Multiple	Single	Multiple
Cereals	8.516	17.031	2.299	2.168	2.299	2.168
Maize	6.813	-[a]	1.839	-[a]	1.839	-[a]

[a] Only single application calculated for maize

Tier 2 (parameters from irradiated water/sediment study)

Table 9.2.5-27: Steps 1-2: $PEC_{sw,max}$ of pyraclostrobin following application to various crops (Tier 2)

$FOCUS_{sw}$ crop	Pyraclostrobin $PEC_{sw,max}$ [µg L^{-1}]					
	Step 1		Step 2			
			North Europe		South Europe	
	Single	Multiple	Single	Multiple	Single	Multiple
Cereals	8.516	17.031	2.299	2.056	2.299	2.056
Maize	6.813	-[a]	1.839	-[a]	1.839	-[a]

[a] Only single application calculated for maize

Step 3 and 4

Tier 1 (parameters from dark water/sediment study)

Table 9.2.5-28: Step 3 and 4: $PEC_{sw,max}$ of pyraclostrobin following single application of 250 g a.s. ha^{-1} to winter cereals, considering drift and runoff mitigation at Step 4 (Tier 1)

Tier 2 (parameters from irradiated water/sediment study)

For the single application pattern, $PEC_{sw,max}$ at Tier 2 are identical to the $PEC_{sw,max}$ at Tier 1. Consequently, at Tier 2 only $PEC_{sw,max}$ following multiple application to winter and spring cereals are reported here.
$PEC_{sw,max}$ for multiple application as well as $PEC_{sw,twa}$ are very similar for Tier 1 and Tier 2. Although degradation rates in the water compartment between Tier 1 and Tier 2 differ largely, this behavior can be explained by the predominance of the strong sorption behavior of pyraclostrobin to sediment particles against the degradation within the water compartment.

Table 9.2.5-33: Step 3 and 4: $PEC_{sw,max}$ of pyraclostrobin following twofold application of 250 g a.s. ha^{-1} to winter cereals, considering drift and runoff mitigation at Step 4 (Tier 2)

III. CONCLUSION

Predicted environmental concentrations (PEC) were calculated for pyraclostrobin and its metabolites in surface water (BF 500-5, BF 500-11, BF 500-13, BF 500-14) and in sediment (BF 500-3, BF 500-6, BF 500-7) following application of the formulated product BAS 500 06 F to cereals and maize under European conditions.

For the parent compound a tiered approach using endpoints from dark (Tier 1) and irradiated (Tier 2) water/sediment studies was considered for the calculations. While this had almost no effect on maximum PEC_{sw}, the maximum PEC_{sed} in Tier 2 decreased slightly (with approximately 9% for winter cereals, twofold application, R4 –stream). Time weighted average (TWA) values did not differ significantly between the two tiers. Despite the large discrepancy between the degradation rates in the water compartment between the two tiers, the results show that sorption from the water phase to sediment is the dominating process. This is in agreement with the behavior observed in aqueous metabolism studies. Although the selection of endpoints has no major effect on the PEC_{sw} values, it considerably affects the behavior in sediment. Since pyraclostrobin breakdown under irradiated conditions is a relevant pathway and degradation occurs rapidly these Tier 2 endpoints should appropriately be considered for further usage.

The predicted concentrations in surface water are appropriate to be used for the subsequent risk assessment for aquatic organisms.

CP 9.3 Fate and behaviour in air

CP 9.3.1 Route and rate of degradation in air and transport via air

No studies were performed with BAS 500 06 F. The route and rate of degradation in air as well as transport via air is sufficiently addressed by information given in M-CA 7.3.

Predicted environmental concentrations from airborne transport

No risk assessment needs to be performed due to the very low volatilisation potential of pyraclostrobin and its short DT_{50} in air. Consequently no PECs have been calculated.

CP 9.4 Estimation of concentrations for other routes of exposure

No other routes of exposure are relevant for the use of BAS 500 06 F in cereals and maize.

Table of Contents

CP 10 ECOTOXICOLOGICAL STUDIES ON PLANT PROTECTION PRODUCT

BAS 500 06 F is a new representative formulation, which has not been evaluated during the previous Annex I inclusion process.

This document reviews the ecotoxicological studies for BAS 500 06 F, an EC solo formulation containing 200 g/L pyraclostrobin. In addition, risk assessments are provided, which show that BAS 500 06 F is safe for aquatic and terrestrial non-target organisms.

CP 10.1 Effects on birds and other terrestrial vertebrates

The risk assessment on birds and mammals considers the principles given in the latest guidance document by EFSA (*Anonymous 2009: Guidance Document on risk assessment for Birds & Mammals on request from EFSA. EFSA Journal 2009; 7(12):1438. European Food Safety Authority*), hereafter cited as EFSA/2009/1438. EU agreed endpoints and endpoints from new studies are used for the risk assessments on birds and mammals together with data from new additional studies.

In addition, the potential risk to amphibians and reptiles will be addressed following the new requirement under Regulation 1107/2009.

Studies conducted for avian and mammalian risk assessments

An overview on data from new studies relevant for the avian or mammalian risk assessment is shown in Table 10.1-1, full summaries of the studies and documents afterwards. Note that most of the study summaries are included in M-CP 10.1 (irrespective of their use for either the avian or the mammalian risk assessment), because the formal document structure of M-CP 10.1.1 and M-CP 10.1.2 does not include a dedicated chapter for such studies.

Besides the generic studies listed in Table 10.1-1, the higher tier mammalian risk assessments will also rely on results from further higher tier studies and associated evaluations. However, these studies and reports are active substance specific and are hence summarized in Document M-CA at the beginning of chapter 8.1.

Guidelines:	EC 1107/2009 (14 June 2011)
GLP:	yes (certified by Landesamt fuer Umwelt, Messungen und Naturschutz Baden Wuerttemberg, Karlsruhe, Germany)

Executive Summary

The selection of focal species for the refined risk assessment is based on results of a generic monitoring study of hare and rabbits (BASF DocID 2011/1112612) conducted in cereal fields in Germany at two different locations (Lower Saxony and Schleswig-Holstein). The selected areas represented typical cereal fields in arable landscape with regard to size and structure of the surroundings. Monitoring of hares and rabbits was conducted via spotlight scanning by car at night.

The above study was carried out with the specific purpose of deriving generic data to conduct risk assessments for mammals following recommendations given by EFSA/2009/1438. The aim of the study was to assess the frequency of occurrence and abundance of brown hares (*Lepus europaeus*) and European rabbits (*Oryctolagus cuniculus*) in cereal fields (BBCH <30) and consequently their potential of being exposed to plant protection products applied.

In summary, both hares and rabbits use cereal fields at BBCH <30 as night time refuge. While hares were often found in the cereal fields, the number of rabbits was low. Density measures exhibit the same pattern with the hare being frequently abundant in cereal crops

I. MATERIAL AND METHODS

In order to assess the potential exposure risk of hares and rabbits to plant production products in cereal fields, a total number of 90 fields were monitored in two regions of Northern Germany. Monitoring of hares and rabbits was conducted via spotlight scanning at night. For this purpose, alongside of each study field, a transect was defined. Two persons drove slowly (mean speed 12.4 km/h) along these transects in a car and thereby the study field or a part of the study field was surveyed by means of a hand-held spotlight. In this illuminated area (approximate depth of 150 m) all observed hares and rabbits were recorded. Spotlight scanning was carried out at four different sets of study fields, which were monitored on two consecutive nights each, resulting in a total of eight night surveys. Spotlight scanning started approximately 1.5 hours after sun set and was finished before dawn. The abundance of hares and rabbits per 100 hectare surveyed area was calculated as well as the abundance per hectare. Additionally, the frequency of occurrence (FO) was determined based on the total number of study fields (field approach; FO_{field} n=90) and on the total number of surveys (survey approach; FO_{survey} n=180).

Study Sites

Two study sites each containing two sets of individual study fields were selected in Germany (Lower Saxony (Set 1/2) and Schleswig-Holstein (Set 3/4)). The presence of hares and rabbits in these regions was confirmed through recordings in previous years (e.g. information gathered from local game keepers). In total 90 study fields were chosen, in which the BBCH development stage of winter cereals was less than 30, thus providing appropriate conditions for spotting lagomorphs in the crops. Every set of study fields comprised between 20 and 26 cereal fields, on which hares and rabbits were counted during two consecutive nights.

Data recording and analysis

All data were collated and analysed using standard spread sheet applications. The surveyed area for each study field was calculated by multiplying the transect length with the range of the hand-held spotlight (=150 m) and thus quadratic dimensions were assumed. If the latter was not true marginal subareas were identified by the means of Google Earth Pro and either subtracted or added to the calculated surveyed area. In addition, if the study field itself or parts of the study field were less than 150 m deep, exact measures were taken and used for calculating the illuminated area instead.

II. RESULTS AND DISCUSSION

Hares were found in 61 out of 90 of the cereal fields surveyed (FO_{field} = 67.78%). Hares were present in 86 out of 180 of the field field surveys (FO_{survey} = 47.78%). The mean abundance of hares in the cereal fields was 22.22 hares per 100 ha with 0.22 hares per ha.
Rabbits were counted in 8 out of 90 of the cereal fields surveyed (FO_{field} = 8.89%). Rabbits were observed in 12 out of 180 of the fields surveyed (FO_{survey} = 6.67%). The mean abundance of rabbits in the cereal fields was 2.27 rabbits per 100 ha with less than 0.1 rabbits per hectare.

Frequency of occurrence and abundance of rabbits and hare in cereal fields in Germany

Observation period	**10 April - 21 April 2011**				
BBCH growth stage	**23-29**				
Number of cereal fields	**90**				
Number of surveys	**180**				
	Number of cereal fields with record	**FO_{field} [%]**	**FO_{survey} [%]**	**Abundance [number of animals / 100 ha surveyed area] ± SD**	**Abundance [number of animals / ha surveyed area]**
Rabbit	8	8.89	6.67	2.27 ± 1.51	< 0.1
Hare	61	67.78	47.78	22.22 ± 9.44	0.22

III. CONCLUSION

Both hares and rabbits use cereal fields at BBCH growth stages below 30 as a night time refuge e.g. for foraging and probably reproduction (in hares). Hares were often found in the cereal fields investigated whereas the number of rabbits found was low. Density measures exhibit the same pattern with the hare being frequently abundant in cereal crops.

Please note that the following study CP 10.1/3 was erroneously not included in the Application submitted in January 2014 for the renewal of approval of pyraclostrobin.

Report: CP 10.1/3
Pedall I., Riffel M., 2004b
Population dynamics of common voles in winter cereal fields - Field monitoring in South Western Germany
2004/1025715
Guidelines: EEC 91/414, EEC 96/68
GLP: no

Executive Summary

This generic field study was performed to evaluate the population dynamics of common voles in winter cereal fields. Because wood mice were caught in sufficient numbers as well, this species was also included in the evaluation. The particular objective of the study was to identify the point of time (month and BBCH code) when rodents immigrate into winter cereal fields after emergence of the cereal plants.

Considering the detailed results, the common vole (*Microtus arvalis*) is not seen relevant for the risk assessment for cereals, because cereal fields would be only potential secondary refuges during summer and no stable populations can be established in these crops. The wood mouse (*Apodemus sylvaticus*), however, proved to make more regular use of cereal fields over a longer period, which makes this species relevant for the risk assessment for cereals.

I. MATERIAL AND METHODS

Three winter cereal fields bordering grassland plots in the vicinity of Bruchsal (8°35′23′′; 49°7′26′′, Baden-Württemberg, Germany) were chosen as study sites. This area is typical for the cultivation of cereals in Germany. The size of the study plots ranged between 0.3 and 0.315 ha, each including a grassland subplot as well as a cereal field subplot. The rodents were monitored using live traps on both subplots. To assess the recapture rate the specimens were marked with tattoo dye. In each subplot, six capture periods of about 4 days were carried out from January to July 2003. The endpoints of the study included a quantification of vole population numbers in both subplots for each sample site and the determination of immigration time of voles and wood mice into winter cereal fields. Additionally, a list of species trapped in grassland subplots and adjacent cereal fields was prepared.

II. RESULTS AND DISCUSSION

Findings for the common vole: The common vole was the predominant small mammal species observed in the grassland. The numbers of vole individuals in the cereal fields was lower by a factor of 6 compared to the grassland plots. The results of the study are presented in the three following tables below.

Point of immigration time of common voles into cereal fields

	BBCH crop stage
Tolerance value for immigration	39 / 41
Cereal growth stage for a constant population	65

Average population density of common voles in three study sites from January to July 2003 [Individuals/ha]

	Sampling 1	**Sampling 2**	**Sampling 3**	**Sampling 4**	**Sampling 5**	**Sampling 6**
Month	Jan/Feb	Feb/March	March/April	April/May	May/June	June/July
Grassland	23.8	38.1	42.9	71.4	9.5	2.4
Cereals	0	0	0	9.8	13.7	0

Recapture rate of common voles in the field and grassland (for all study sites)

	Field [%]	**Grassland [%]**
Common vole	25	63

Findings for the wood mouse: In contrast to the common vole the wood mouse was occasionally caught in the grassland subplots, but was more common in the cereal field plots and outnumbered the common vole by a factor of 3 there. Based on the low recapture rates, the wood mouse population was considered unstable and it is assumed that it consisted of wandering individuals mostly. The results of the study are depicted in the two following tables below.

Point of immigration time of wood mice into cereal fields

	BBCH crop stage
Tolerance value for immigration	20
Cereal growth stage for regular occurrence of cereal fields	39 / 41

Recapture rate of wood mice in the field and grassland

	Field [%]	Grassland [%]
Wood mouse	40	25

Discussion

Common voles were observed in the grassland and field subplots of every sample site. The grassland subplots were continuously inhabited with much higher population densities compared to the cereal fields. Furthermore, the grassland population was noticeably more constant. The period of colonization of cereal fields proved to be very short and did not exceed the period of two months. It commenced at cereal growth stage of BBCH 39 / 41 (May) with single catches, whereas a more regular use of cereal fields by common voles could be proven for June (growth stage BBCH 65) based on recapture data. The colonization ceased at time of harvest when vole numbers dropped to almost zero. The populations inhabiting both grassland subplots and cereal subplots were also significantly affected by mowing of grassland plots. The population maximum was observed before the harvest of cereal fields and mowing of grassland subplots. The number of voles in the grassland subplots exceeded the number in the cereal subplots by a factor of six.
Generic literature data corroborates that agricultural operations prove detrimental to populations of common voles as was shown in various studies throughout Europe. During harvest the vegetation cover is removed exposing the voles to natural predators. Mechanical operations such as harrowing or ploughing destroy existing vole burrows (Spitz 1977). Hence the voles are able to colonize arable land for a restricted period of the year only. In a field study in Germany vole population inhabiting pasture and arable land were compared in regard to various parameters within the course of several years. Due to ploughing no voles were found on arable land during winter (Jacob 2000). This underlines again that cereal fields would be only potential secondary refuges for the common vole during summer, and that due to harvesting and ploughing no stable populations could be established in these crops.
Wood mice were only sporadically observed in the grassland subplots, but their numbers were consistently higher in the cereal fields and outnumbered the common vole by a factor of 3. The period of colonization of cereal fields proved to be longer than for common voles. Wood mice were first recorded in cereal fields at growth stage BBCH 20 (February / March) and a regular use of fields was recorded up from BBCH 39 / 41 (May). The wood mice numbers reached a maximum in May and declined towards the harvest. Harvesting had a noticeable impact on the wood mouse population and lead to the end of colonization of cereal fields.

III. Conclusion

Considering the detailed data presented above, the common vole (*Microtus arvalis*) is not seen relevant for the risk assessment for cereals, because cereal fields would be only potential secondary refuges during summer and no stable populations can be established in these crops. The wood mouse (*Apodemus sylvaticus*), however, proved to make more regular use of cereal fields over a longer period, which makes this species relevant for the risk assessment for cereals.

CP 10.1.1 Effects on birds

Data of the representative formulation BAS 500 06 F and of the active substance pyraclostrobin are evaluated and the respective risk assessments are presented based on the already registered use of BAS 500 06 F in cereals and maize.

Table 10.1.1-1: Endpoints for birds

Test system	Test species	Study endpoints	Endpoints used in present risk assessment [4]
Acute toxicity	*Colinus virginianus*	LD_{50} > 2000 mg a.s./kg b.w.[1]	LD_{50} (geometric mean) = 1701 mg a.s./kg b.w.[5]
	Serinus canaria	LD_{50} > 1446 mg a.s./kg b.w.[2]	
Reproductive toxicity (long-term)	*Colinus virginianus*	NOEL = 105 mg a.s./kg b.w./d[1)3)]	NOEC = 1000 mg a.s./kg diet NOEL = 105 mg a.s./kg b.w./d[2]

1) Endpoints confirmed in the ecotoxicology section of the Review Report for the active substance pyraclostrobin (SANCO/1420/2001-Final. 8. September 2004).
2) Based on data from a new study and therefore not evaluated during the previous Annex I inclusion process. For the detailed study summary please refer to CA 8.1.1.1/1.
3) Daily Dose [mg/kg b.w./d] calculated based on study data for food consumption and body weight
4) Endpoints according to EFSA/2009/1438
5) For calculation of LD_{50} (geometric mean) please refer to Table 10.1.1-3.

RISK ASSESSMENT

Summary of avian toxicity testing

The avian toxicity studies with pyraclostrobin relevant for the dietary risk assessment for birds are summarized in Table 10.1.1-2. The listed studies have been already evaluated during the previous Annex I listing process except for the acute toxicity study in the canary (BASF DocID 2013/1400375). The two available and already evaluated short term toxicity studies in bobwhite quail and mallard duck are not listed below, because they are no longer part of the core data package according to EFSA/2009/1438.

Table 10.1.1-2: Summary of avian studies on the acute and reproductive toxicity of pyraclostrobin

Test system	Test species	Results	Reference (BASF DocID)
Acute oral toxicity	*Colinus virginianus*	LD_{50} > 2000 mg a.s./kg b.w.[1)]	1997/11136
	Serinus canaria	LD_{50} > 1446 mg a.s./kg b.w.	2013/1400375
Sub-chronic toxicity and reproduction	*Colinus virginianus*	NOEC = 1000 mg a.s./kg diet NOEL = 105 mg a.s./kg b.w./d [1) 2)]	1999/11207
	Anas platyrhynchos	NOEC = 1000 mg a.s./kg diet NOEL = 128 mg a.s./kg b.w./d[2)]	1999/11206

1) Endpoints confirmed in the ecotoxicology section of the Review Report for the active substance pyraclostrobin (SANCO/1420/2001-Final. 8. September 2004).
2) Daily Dose [mg/kg b.w./d] calculated based on study data for food consumption and body weight.

Calculated avian toxicity endpoint for use in the acute tier 1 risk assessment

For pyraclostrobin acute oral studies in the bobwhite quail and the canary are available (Table 10.1.1-2). No mortality occurred in any of the two acute oral toxicity bird studies at the highest dose tested. However, in the study with the bobwhite quail treatment related effects were observed at the two highest dose groups (i.e. dose groups of 1000 and 2000 mg a.s./kg b.w.) and therefore no extrapolation of the LD_{50} >2000 mg a.s./kg b.w.for the bobwhite quail is possible according to EFSA/2009/1438 (2.1.2, p.16). In the study with the canary no clear signs of toxicity were seen up to the highest dose tested of 1446 mg a.s./kg b.w. It would be thus permissible to extrapolate an LD_{50} value upwards. However, for a conservative evaluation an extrapolation of the LD_{50} >1446 mg a.s./kg b.w. for the canary is not conducted.

According to EFSA/2009/1438, a geometric mean of the endpoints can be used in the acute dietary risk assessment as two different species were tested and the endpoint of the most sensitive species (i.e. the canary) is not by a factor of 10 below the overall geometric mean. The most sensitive endpoint with an LD_{50} > 1446 mg a.s./kg b.w./d in the canary is clearly higher than the 'assessment factor LD_{50}' of 170.1 mg a.s./kg b.w./d (Table 10.1.1-3). Hence, the geometric mean of both acute toxicity endpoints will be used.

The overall geometric mean LD_{50} value, i.e. the **LD_{50}** (geometric mean) **= 1701 mg a.s./kg b.w.** is the relevant endpoint to be used for the acute avian risk assessment.

Table 10.1.1-3: Calculation of the relevant avian toxicity endpoint for the acute risk assessment of pyraclostrobin

Characteristic	*Colinus virginianus*	*Serinus canaria*
Experimentally obtained LD_{50} [mg a.s./kg b.w.]	> 2000[1)]	> 1446[2)]
Birds tested/group [no.]	10	10
Mortality at highest dose level [%]	0	0
Extrapolation factor[3)]	--	--
LD_{50} (extrapolated)[4)] [mg a.s./kg b.w.]	--	--
LD_{50} (overall geometric mean)[5)] [mg a.s./kg b.w.]	1701	
Assessment factor LD_{50}[6)]: LD_{50} (overall geometric mean) / 10 [mg a.s./kg b.w.]	170.1	

1) BASF DocID 1997/11136
2) BASF DocID 2013/1400375
3) Extrapolation factor can be applied to an LD_{50} value in case 10 birds were tested and no mortalities occurred at the highest dose tested (EFSA GD 2009, 2.1.2, p.16). For a conservative evaluation an extrapolation of the endpoints derived is not conducted.
4) LD_{50} multiplied by the extrapolation factor
5) Determination of the geometric mean out of the LD_{50} values of >2000 and >1446 mg a.s./kg b.w. of the acute oral toxicity studies (EFSA/2009/1438, 2.4.2)
6) 'Assessment factor LD_{50}' of all the tested species, geometric mean divided by a factor of 10 (EFSA/2009/1438, 2.4.2)

Calculated avian toxicity endpoint for use in the <u>reproductive</u> tier 1 risk assessment

In order to obtain the relevant toxicity endpoint to be used in the screening and tier 1 reproductive risk assessment, the lowest NOEL from available bird reproduction studies and the 'assessment factor LD_{50}' [LD_{50} (overall geometric mean) / 10] from acute toxicity studies (EFSA/2009/1438, p. 33 and 35) have to be considered.

The lowest toxicity value from the avian reproduction study for pyraclostrobin is NOEL = 105 mg a.s./kg b.w./d derived from the study with bobwhite quail (BASF DocID 1999/11207). The acute toxicity endpoint was calculated to be LD_{50} = 1701 mg a.s./kg b.w. (Table 10.1.1-3).

Following EFSA/2009/1438 (p. 33 and 35), either the overall lowest NOEL or the 'assessment factor LD_{50} 'is to be selected as relevant reproductive toxicity endpoint. Since the lowest of both is the NOEL, the value of **NOEL = 105 mg a.s./kg b.w./d** will be used in the screening step and the tier 1 reproductive risk assessment for pyraclostrobin.

Results from available toxicity testing with the formulation

The avian toxicity study with BAS 500 06 F (BASF DocID 2008/1078602) relevant for the risk assessment for birds is summarized in Table 10.1.1-4. Please note that the study was erroneously included in the Application submitted in January 2014 in chapter M-CP 10.1.1.1 and is now given in chapter M-CP 10.1.1.2.

Table 10.1.1-4: Summary of avian study on the acute toxicity of BAS 500 06 F

Test system	Test species	Results	Reference (BASF DocID)
Acute oral toxicity	*Colinus virginianus*	LD_{50} > 2000 mg/kg b.w.	2008/1078602

This study was not evaluated during the previous Annex I listing process. Therefore, the study is submitted within this dossier together with a detailed study summary provided in chapter 10.1.1.2. In addition, an acute risk assessment for BAS 500 06 F considering the **LD_{50} > 2000 mg/kg b.w. for BAS 500 06 F** is provided below.

Metabolites of pyraclostrobin

The metabolism of pyraclostrobin in potential food items of wild living birds or mammals (i.e. green plant matter, fruits, or seeds) was investigated in plant metabolism studies in grapes (BASF DocIDs 1998/10988 and 2000/1000201), potatoes (BASF DocIDs 1999/11419 and 2000/1000048) and wheat (BASF DocID 1999/11137). Most metabolites occurred only at trace amounts far below 10% TRR in the potential food items. The only metabolite that occurred at higher levels in potential food items was the desmethyl metabolite (BF 500-3, synonym: 500M07). It was found at levels of up to 15.3% TRR in grapes, 21.4% TRR in green matter of potatoes, 13.1% TRR in wheat forage, and 10.5% TRR in wheat grain. However, this desmethyl metabolite was also detectable in rats (BASF DocID 1999/11781), goats (BASF DocID 2000/1000004) and hens (BASF DocID 1999/11480). Hence, it can be concluded that the mammalian toxicity studies with pyraclostrobin cover this metabolite, and that the dietary risk assessment for pyraclostrobin provided for birds and mammals covers the potential risk from this metabolite.

Water metabolites are of minor importance for the risk assessment for wild living birds and mammals, considering the predominant route of exposure being via food items like plants, seeds, or arthropods. Water uptake itself or exposure via the aquatic compartment, however, can play a role in the drinking water and the secondary poisoning risk assessment for fish-eaters. Hence in the following the risk from relevant surface water metabolites to birds and mammals is considered. The metabolites BF 500-5, BF 500-11, BF 500-13, BF 500-14 were found at levels slightly above 10% TAR in surface water (for details see M-CA 7.2). However, the risk from these metabolites to birds and mammals is considered to be covered by the presented risk assessments for the parent compound pyraclostrobin due to the following reasons:

i) PEC values of the metabolites are by a factor of ~30-66 below the one of the parent (highest global PECsw, max [µg/L] following FOCUS Step1 are for the metabolites BF 500-5 = 0.256 µg/L, BF 500-11 = 0.407 µg/L, BF 500-13 = 0.533 µg/L, BF 500-14 = 0.573 µg/L, and for the parent BAS 500 F = 17.031 µg/L; for details see M-CP 9.2).

ii) There are no specific toxicity studies with the metabolites BF 500-5, BF 500-11, BF 500-13, BF 500-14 available in birds or mammals. However, the low toxicity of the metabolites was confirmed in standard acute fish toxicity studies with *O. mykiss* (for details see M-CP 10.2).

Summary of relevant avian toxicity endpoints to be used in the screening and tier 1 risk assessments

The avian toxicity endpoints relevant for the screening and tier 1 risk assessments are given in Table 10.1.1-5.

Table 10.1.1-5 Avian toxicity endpoints for screening and tier 1 risk assessments of pyraclostrobin and BAS 500 06 F

Test substance	Test system	Relevant toxicity endpoint
Pyraclostrobin	Acute oral toxicity	LD_{50} (geometric mean) = 1701 mg a.s./kg b.w.
	Sub-chronic toxicity and reproduction	NOEL = 105 mg a.s./kg b.w./d
BAS 500 06 F	Acute oral toxicity	LD_{50} > 2000 mg a.s./kg b.w.

Relevant exposure scenarios

The relevant scenarios for the intended representative use patterns of the formulation BAS 500 06 F (Table 10.1.1-6) are given for cereals in Table 10.1.1-7 and for maize in Table 10.1.1-8.

Table 10.1.1-6: Critical use pattern for BAS 500 06 F

Crop	EFSA/2009/1438 crop group	Application time (BBCH growth stage)	No. of applications	Interval [d]	Maximum application rate per treatment	
					Pyraclostrobin [kg/ha]	BAS 500 06 F [L/ha]
Cereals	Cereals	25 - 69	2	21	0.25	1.25
Maize	Maize	30 - 65	1	--	0.20	1.0

Table 10.1.1-7: Summary of exposure scenarios to be considered for risk assessments for spray applications of BAS 500 06 F in cereals at BBCH 25 – 69

Scenario	Generic focal species
Cereals Early (shoots) autumn-winter BBCH 10-29	Large herbivorous bird "goose"
Cereals BBCH 10 - 29	Small omnivorous bird “lark”
Cereals BBCH 30 -39	Small omnivorous bird “lark”
Cereals BBCH ≥ 40	Small omnivorous bird “lark”

Table 10.1.1-8: Summary of exposure scenarios to be considered for risk assessments for spray applications of BAS 500 06 F in maize at BBCH 30 – 65

Scenario	Generic focal species
Maize BBCH ≥ 20	Small insectivorous bird “wagtail”
Maize BBCH 30 - 39	Medium granivorous bird "gamebird"
Maize BBCH 30 - 39	Medium herbivorous/granivorous bird "pigeon"
Maize BBCH 30 - 39	Small omnivorous bird “lark”
Maize BBCH ≥ 40	Medium granivorous bird "gamebird"
Maize BBCH ≥ 40	Medium herbivorous/granivorous bird "pigeon"
Maize BBCH ≥ 40	Small omnivorous bird “lark”

CP 10.1.1.1 Acute oral toxicity

In this section, the dietary TER acute values for the screening step and tier 1 assessment obtained by means of the EFSA calculator tool (version of 9 July 2010, http://www.efsa.europa.eu/de/efsajournal/pub/1438.htm) are presented for cereals in Table 10.1.1.1-1 and for maize in Table 10.1.1.1-2.

Cereals

Table 10.1.1.1-1: Pyraclostrobin: Acute dietary risk assessment for birds in cereals - results from EFSA calculator tool

Data from Data_Entry worksheet	**Crop**	**Application rate (kg a.s./ha)**	**Number of applications**	**Application Interval**	**DT_{50}**	**LD_{50}**	
	Cereals	0.25	2	21	10.0	1701.0	
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF_{90}**	**Daily Dietary Dose (multiple)**	**TER**	**No refinement step required**
	Small omnivorous bird	158.8	39.70	1.1	43.67	39.0	

First Tier Risk Assessment:					
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**	**Shortcut value**	**TER**	**No refinement required**
	Cereals Early (shoots) autumn-winter BBCH 10-29	Large herbivorous bird "goose" Grass + cereals 100% cereal shoots	30.5	202.8	
	Cereals BBCH 10 - 29	Small omnivorous bird “lark” Combination (invertebrates with interception) 25% crop leaves 25% weed seeds 50% ground arthropods	24.0	257.7	
	Cereals BBCH 30 - 39	Small omnivorous bird “lark” Combination (invertebrates with interception) 25% crop leaves 25% weed seeds 50% ground arthropods	12.0	515.5	
	Cereals BBCH ≥ 40	Small omnivorous bird “lark” Combination (invertebrates with interception) 25% crop leaves 25% weed seeds 50% ground arthropods	7.2	859.1	

Maize

Table 10.1.1.1-2: Pyraclostrobin: Acute dietary risk assessment for birds in maize - results from EFSA calculator tool

Data from Data_Entry worksheet	Crop	Application rate (kg a.s./ha)	Number of applications	Application Interval	DT_{50}	LD_{50}	
	Maize	0.2	1	365	10.0	1701.0	
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF_{90}**	**Daily Dietary Dose (multiple)**	**TER**	**No refinement step required**
	Small omnivorous bird	158.8	31.76	1.0	31.76	53.6	

First Tier Risk Assessment:					
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**	**Shortcut value**	**TER**	**No refinement required**
	Maize BBCH ≥ 20	Small insectivorous bird “wagtail” ground invertebrates with interception 50% ground arthropods, 50% foliar arthropods	12.6	675.0	
	Maize BBCH 30 - 39	Medium granivorous bird "gamebird" Small seeds 100% seed	3.3	2577.3	
	Maize BBCH 30 - 39	medium herbivorous/granivorous bird "pigeon" Non-grass herbs 100% leaves	27.8	305.9	
	Maize BBCH 30 - 39	Small omnivorous bird “lark” Combination (invertebrates without interception) 25% crop leaves 25% weed seeds 50% ground arthropods	12.0	708.8	
	Maize BBCH ≥ 40	Medium granivorous bird "gamebird" Small seeds 100% seed	1.6	5315.6	
	Maize BBCH ≥ 40	medium herbivorous/granivorous bird "pigeon" Non-grass herbs 100% leaves	13.9	611.9	
	Maize BBCH ≥ 40	Small omnivorous bird “lark” Combination (invertebrates without interception) 25% crop leaves 25% weed seeds 50% ground arthropods	6.0	1417.5	

In conclusion, even under the conservative assumptions of the screening and tier 1 acute dietary risk assessments all TER_A values for pyraclostrobin exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low acute risk for birds from the use of BAS 500 06 F in cereals and maize according to the recommended use pattern.

CP 10.1.1.2 Higher tier data on birds

Please note that this section, albeit suggested by its header, does not only include higher tier data on birds. The calculations presented for cereals in Table 10.1.1.2-1 and for maize in Table 10.1.1.2-2 are the dietary TER reproductive values of the screening step and tier 1 assessment obtained by means of the EFSA calculator tool (version of 9 July 2010, http://www.efsa.europa.eu/de/efsajournal/pub/1438.htm).

Cereals

Table 10.1.1.2-1: Pyraclostrobin: Reproductive risk assessment for birds in cereals - results from EFSA calculator tool

Data from Data_Entry worksheet	**Crop**	**Application rate (kg a.s./ha)**	**Number of applications**	**Application Interval**	**DT_{50}**	**Repro End Point (mg/kg b.w./d)**	**Time-weighted average (twa)**
	Cereals	0.25	2	21	10	105.0	0.53
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF_{90}**	**Daily Dietary Dose (multiple)**	**TER**	**No refinement step required**
	Small omnivorous bird	64.8	16.20	1.2	10.30	10.2	
First Tier Risk Assessment:							
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**			**Shortcut value**	**TER**	**No refinement required**
	Cereals Early (shoots) autumn-winter BBCH 10-29	Large herbivorous bird "goose" Grass + cereals 100% cereal shoots			16.2	40.8	
	Cereals BBCH 10 - 29	Small omnivorous bird “lark” Combination (invertebrates with interception) 25% crop leaves 25% weed seeds 50% ground arthropods			10.9	60.6	
	Cereals BBCH 30 -39	Small omnivorous bird “lark” Combination (invertebrates with interception) 25% crop leaves 25% weed seeds 50% ground arthropods			5.4	122.3	
	Cereals BBCH ≥ 40	Small omnivorous bird “lark” Combination (invertebrates with interception) 25% crop leaves 25% weed seeds 50% ground arthropods			3.3	200.1	

Maize

Table 10.1.1.2-2: Pyraclostrobin: Reproductive risk assessment for birds in maize - results from EFSA calculator tool

Data from Data_Entry worksheet	Crop	Application rate (kg a.s./ha)	Number of applications	Application Interval	DT_{50}	Repro End Point (mg/kg b.w./d)	Time-weighted average (twa)
	Maize	0.2	1	365	10	105.0	0.53
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF_{90}**	**Daily Dietary Dose (multiple)**	**TER**	**No refinement step required**
	Small omnivorous bird	64.8	12.96	1.0	6.87	15.3	
First Tier Risk Assessment:							
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**			**Shortcut value**	**TER**	**No refinement required**
	Maize BBCH ≥ 20	Small insectivorous bird “wagtail” ground invertebrates with interception 50% ground arthropods, 50% foliar arthropods			4.8	206.4	
	Maize BBCH 30 - 39	Medium granivorous bird "gamebird" Small seeds 100% seed			1.5	660.4	
	Maize BBCH 30 - 39	medium herbivorous/granivorous bird "pigeon" Non-grass herbs 100% leaves			11.4	86.9	
	Maize BBCH 30 - 39	Small omnivorous bird “lark” Combination (invertebrates without interception) 25% crop leaves 25% weed seeds 50% ground arthropods			5.4	183.4	
	Maize BBCH ≥ 40	Medium granivorous bird "gamebird" Small seeds 100% seed			0.8	1238.2	
	Maize BBCH ≥ 40	medium herbivorous/granivorous bird "pigeon" Non-grass herbs 100% leaves			5.7	173.8	
	Maize BBCH ≥ 40	Small omnivorous bird “lark” Combination (invertebrates without interception) 25% crop leaves 25% weed seeds 50% ground arthropods			2.7	366.9	

In conclusion, even under the conservative assumptions of the screening and tier 1 reproductive dietary risk assessments all TER_{LT} values for pyraclostrobin exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low reproductive risk for birds from the use of BAS 500 06 F in cereals and maize according to the recommended use pattern.

Acute toxicity of the formulation

An acute oral study with the formulation BAS 500 06 F on the bobwhite quail is available and summarized below. Please note that the study was erroneously included in the Application submitted in January 2014 in chapter M-CP 10.1.1.1.

The results of the study show no increased formulation toxicity as the formulation is practically acutely non-toxic to birds (LD_{50} > 2000 mg BAS 500 06 F/kg b.w.).

A detailed study summary is presented in the following. An acute risk assessment for BAS 500 06 F considering the LD_{50} from formulation toxicity testing is provided further below.

Report:	CP 10.1.1.2/1 [redacted]., 2008b BAS 500 06 F - Acute toxicity in the bobwhite quail (Colinus virginianus) after single oral administration (LD50) 2008/1078602
Guidelines:	EPA 540/9-82-024, EPA 71-1, EPA 540/9-85-007, EPA 850.2100, EPA 712-C-96-139
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

An acute oral avian toxicity test with BAS 500 06 F was conducted. The test item was administered via a single-dose of 500, 1000 or 2000 mg BAS 500 06 F/kg body weight to 6-month old northern bobwhite quails. Ten birds (5 males and 5 females) were used in each group. The doses were emulsified in drinking water and administered by gavage into the crop. Feed was removed for 21-22 hours prior to dosing.
All groups were observed for mortality, signs of clinical toxicity, impact on food consumption and body weight for 14 consecutive days post dosing. All groups received food and water *ad libitum* throughout the test. The test was terminated after 14 days.

In males, no mortality and no toxic signs were observed in the control and any of the test item treatments up to the highest tested concentration of 2000 mg BAS 500 06 F/kg bw. One female of the 2000 mg/kg bw group died on the day after dosing, but it was concluded that the mortality cannot be clearly attributed to the test item. Diarrhea, which was observed in the first time after dosing, is a consequence of the fasting period and is usually observed in all dose groups as well as in the control group and is not considered to be a toxic effect. In the 2000 mg/kg bw group the feed uptake during the 1st week after dosing was reduced to 70% in males and to 65% of the control group in females. In the 2nd week after dosing the feed uptake returned to normal. The body weights were not statistically significantly different from the control after 7 and 14 days in any of the dose groups. However, in the 2000 mg/kg bw group a slight tendency towards a decreased body weight was observed 7 days after dosing. No treatment-related macroscopic abnormalities were detected in the gross post-mortem examination.

In an acute toxicity test with the bobwhite quail the LD_{50} of BAS 500 06 F was > 2000 mg/kg body weight. The NOEL was 1000 mg/kg body weight.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F; batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 202.7 g/L (nominal 200 g/L).

Test species: Bobwhite quail (*Colinus virginianus*); indistinguishable from wild birds; age: approx. 6 months; source: H. & E. Küberich, Geesdorf/Wiesenheid, Germany.

B. STUDY DESIGN

Test design: Birds were administered different doses of the test item BAS 500 06 F in drinking water in a total amount of 10 g per kg body weight by gavage into the crop; 5 males and 5 females per dose group were used; observation period of 14 days; assessment of mortality and signs of clinical toxicity was carried out three times on day of dosing, daily thereafter; assessment of body weight was carried out on day 7 and 14. Gross pathological examinations of all birds at termination of the test.

Endpoints: LD_{50}, mortality, clinical signs, feed consumption, body weight (bw), gross pathological examinations were conducted on all birds sacrificed at the termination of the test.

Test concentrations: 0 (Control), 500, 1000 and 2000 mg BAS 500 06 F/kg body weight.

Test conditions: Birds fasted for about 21 - 22 h before administration of the test item; temperature 20.0°C to 24.4°C, deviation for 2 days, 21 h and 45 min from the temperature range of 19°C - 23°C; relative humidity: 38% - 75%, deviation of 10 h and 15 minutes above the limit of 45% - 70%; deviation of 2 h and 30 minutes below the limit of 45% - 70%; photoperiod: 8 hours light : 16 hours dark.

Statistics: Descriptive statistics, Dunnett-test for body weight data ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements:
The results of the analytical verification of the test item concentration in the diet were within a range of 101% to 102% of the nominal concentrations during the test. The biological results are therefore based on the nominal values.

Biological results:
In males, no mortality and no toxic signs were observed in the control and any of the test item treatments up to the highest tested concentration of 2000 mg BAS 500 06 F/kg bw. One female of the 2000 mg/kg bw group died on the day after dosing. According to the test guideline 10% mortality is acceptable for the control group. Thus it was concluded that the mortality cannot be clearly attributed to the test item. Diarrhea in the first time after dosing is a consequence of the fasting period and is usually observed in all dose groups as well as in the control group and is not considered to be a toxic effect. In the 2000 mg/kg b.w. group the feed uptake during the 1st week after dosing was reduced to 70% in males and to 65% of the control group in females. In the 2nd week after dosing the feed uptake returned to normal. The body weights were not statistically significantly different from the control after 7 and 14 days in any of the dose groups. However, in the 2000 mg/kg b.w. group a slight tendency towards a decreased body weight was observed 7 days after dosing. No treatment-related macroscopic abnormalities were detected in the gross post-mortem examination. The relevant endpoints are summarized in the table below.

Acute toxicity of BAS 500 06 F to the bobwhite quail (Colinus virginianus)

Mortality	Dose [mg BAS 500 06 F/kg b.w.]
Highest dose causing no treatment-related mortality	males: 2000 females: 1000[1)]
LD_{50} (14 d)	> 2000
NOEL	1000

b.w . = body weight
1) It was concluded in the study report that the mortality cannot be clearly attributed to the test item.

III. CONCLUSION

In an acute toxicity test with the bobwhite quail, the LD_{50} of BAS 500 06 F was > 2000 mg/kg body weight. The NOEL was 1000 mg/kg body weight.

Acute risk assessment considering the LD_{50} from toxicity testing with BAS 500 06 F

Please note that the use of the endpoint from the acute toxicity study (BASF DocID 2008/1078602) of BAS 500 06 F on bobwhite quails (i.e. setting LD_{50} to 2000 mg/kg b.w. in the tier 1 calculations with EFSA calculator tool) will lead to an over conservative approach as no clear substance-related mortality occurred throughout the study period, and it can thus be expected that the true LD_{50}, which would be actually relevant, is clearly higher.

Nevertheless, a tier 1 acute dietary exposure assessment and TER calculation with the LD_{50} > 2000 mg BAS 500 06 F /kg b.w. from the acute oral bobwhite quail study with the formulation will be carried out (see below).

Exposure

BAS 500 06 F is intended to be used in cereals and maize with a maximum single application rate of 1.25 L BAS 500 06 F/ha in cereals and 1.0 L BAS 500 06 F/ha in maize (see Table 10.1.1-6 for the critical use pattern). Taking into account the density of the formulation of 1.04 g/cm^3, this will result in an application rate of 1.3 kg BAS 500 06 F/ha and 1.04 kg BAS 500 06 F/ha for the critical use patterns in cereals and maize, respectively. The relevant scenarios for the proposed use pattern are given in Table 10.1.1-7 (cereals) and in Table 10.1.1-8 (maize).

Calculation of the screening and tier 1 risk assessment for BAS 500 06 F according to EFSA/2009/1438

The screening and tier 1 TER values for the acute dietary risk assessment for birds as obtained by means of the EFSA calculator tool (version of 9 July 2010, http://www.efsa.europa.eu/de/efsajournal/pub/1438.htm) are presented for cereals in Table 10.1.1.2-3 and in Table 10.1.1.2-4 for maize.

Table 10.1.1.2-3: BAS 500 06 F: Acute risk assessment for birds in cereals - results from EFSA calculator tool

Data from Data_Entry worksheet	**Crop**	**Application rate (kg formulation/ ha)**	**Number of applications**	**Application Interval**	**DT_{50}**	**LD_{50}**	
	Cereals	1.3	2	21	10.0	>2000.0	
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF_{90}**	**Daily Dietary Dose (multiple)**	**TER**	**Please perform first tier risk assessment (see below)**
	Small omnivorous bird	158.8	206.44	1.1	227.08	>8.8	
First Tier Risk Assessment:							
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**			**Shortcut value**	**TER**	**No refinement required**
	Cereals Early (shoots) autumn-winter BBCH 10-29	Large herbivorous bird "goose" Grass + cereals 100% cereal shoots			30.5	>45.9	
	Cereals BBCH 10 - 29	Small omnivorous bird “lark” Combination (invertebrates with interception) 25% crop leaves 25% weed seeds 50% ground arthropods			24.0	>58.3	
	Cereals BBCH 30 -39	Small omnivorous bird “lark” Combination (invertebrates with interception) 25% crop leaves 25% weed seeds 50% ground arthropods			12.0	>116.6	
	Cereals BBCH ≥ 40	Small omnivorous bird “lark” Combination (invertebrates with interception) 25% crop leaves 25% weed seeds 50% ground arthropods			7.2	>194.3	

Table 10.1.1.2-4: BAS 500 06 F: Acute risk assessment for birds in maize - results from EFSA calculator tool

Data from Data_Entry worksheet	**Crop**	**Application rate (kg formulation/ ha)**	**Number of applications**	**Application Interval**	**DT_{50}**	**LD_{50}**	
	Maize	1.04	1	365	10.0	>2000.0	
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF_{90}**	**Daily Dietary Dose (multiple)**	**TER**	**No refinement step required**
	Small omnivorous bird	158.8	165.15	1.0	165.15	>12.1	
First Tier Risk Assessment:							
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**		**Shortcut value**	**TER**	**No refinement required**	
	Maize BBCH ≥ 20	Small insectivorous bird “wagtail” ground invertebrates with interception 50% ground arthropods, 50% foliar arthropods		12.6	>152.6		
	Maize BBCH 30 - 39	Medium granivorous bird "gamebird" Small seeds 100% seed		3.3	>582.8		
	Maize BBCH 30 - 39	medium herbivorous/granivorous bird "pigeon" Non-grass herbs 100% leaves		27.8	>69.2		
	Maize BBCH 30 - 39	Small omnivorous bird “lark” Combination (invertebrates without interception) 25% crop leaves 25% weed seeds 50% ground arthropods		12.0	>160.3		
	Maize BBCH ≥ 40	Medium granivorous bird "gamebird" Small seeds 100% seed		1.6	>1201.9		
	Maize BBCH ≥ 40	medium herbivorous/granivorous bird "pigeon" Non-grass herbs 100% leaves		13.9	>138.4		
	Maize BBCH ≥ 40	Small omnivorous bird “lark” Combination (invertebrates without interception) 25% crop leaves 25% weed seeds 50% ground arthropods		6.0	>320.5		

In conclusion, even under the conservative assumptions of the tier 1 acute dietary risk assessments for the formulation BAS 500 06 F all TER_A values exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low acute risk for birds from the use of BAS 500 06 F in cereals and maize according to the recommended use pattern.

Effects of secondary poisoning

The log P_{ow} of the active substance pyraclostrobin is 3.99 (SANCO/1420/2001-final), which triggers an assessment for the potential risk through secondary poisoning according to EFSA/2009/1438.

Risk assessment for earthworm-eating birds

The risk assessment for earthworm-eating birds will be based on the worst-case PEC_{soil} (twa, 21 days) derived from M-CP 9.1. The calculations and the resulting TER_{LT} values are summarized in Table 10.1.1.2-5.

Table 10.1.1.2-5: Risk assessment for pyraclostrobin concerning earthworm-eating birds (tier 1) – dry soil approach

Parameter	Pyraclostrobin	Reference
PEC_{soil} (twa, 21 days)[1] [mg/kg soil]	0.201	M-CP 9.1
K_{ow}	9772	SANCO/1420/2001-final
K_{oc} (arithmetic mean)	9304	SANCO/1420/2001-final
f_{oc} (default)	0.02	EFSA/2009/1438
BCF[2]	0.635	--
PEC_{worm} [mg/kg][3]	0.128	--
Daily dose [mg/kg b.w./d][4]	0.134	EFSA/2009/1438
NO(A)EL [mg/kg b.w./d]	105.0	Table 10.1.1-1
TER_{LT}[5]	**783.86**	**--**

1) The PEC_{soil} (twa, 21 days) value calculated for applications of BAS 500 06 F in cereals was the highest PEC_{soil} (twa, 21 days) for all crop scenarios. For details see chapter 9.1.
2) Bioconcentration factor (BCF) = $(0.84 + 0.012 \times K_{ow}) / f_{oc} \times K_{oc}$
3) $PEC_{worm} = PEC_{soil} \times BCF$
4) Daily dose = $1.05 \times PEC_{worm}$
5) TER_{LT} = NO(A)EL / Daily dose

Risk assessment for fish-eating birds

The risk assessment for fish-eating birds will be based on the worst-case PEC_{sw} (twa, 21 days) derived from M-CP 9.2. The calculations and the resulting TER_{LT} values are summarized in Table 10.1.1.2-6.

Table 10.1.1.2-6: Risk assessment for pyraclostrobin concerning fish-eating birds (tier 1)

Parameter	Pyraclostrobin	Reference
$PEC_{sw,}$ (twa, 21 days) [mg/L][1)]	$1.552 * 10^{-3}$	M-CP 9.2
BCF fish (max. worst case)	736	SANCO/1420/2001-final
PEC_{fish} [mg/kg][2)]	1.142	--
Daily dose [mg/kg b.w./d][3)]	0.182	EFSA/2009/1438
NO(A)EL [mg/kg b.w./d]	105.0	Table 10.1.1-1
TER_{LT}[4)]	**578.13**	--

1) Highest PEC_{sw} (twa, 21 days) from FOCUS Step 2 (South Europe) calculation for a multiple application scenario of BAS 500 06 F in cereals with parameters from dark water/sediment study as worst-case. For details see chapter M-CP 9.2.
2) $PEC_{fish} = PEC_{sw,}$ (twa, 21 days) x BCF
3) Daily dose = 0.159 * PEC_{fish}
4) TER_{LT} = NO(A)EL / Daily dose

In the above risk assessments for earthworm- and fish-eating birds, the TER values exceed the trigger of 5 set by Commission regulation (EU) 546/2011 for acceptability of effects. It can therefore be concluded that the application of BAS 500 06 F in cereals and maize does not provide reason for concern regarding a potential accumulation of the active substance pyraclostrobin in the food chain or for concern of secondary poisoning.

Biomagnification in terrestrial food chains

No evidence was found for potential of accumulation of pyraclostrobin in animal tissue (Review Report for the active substance pyraclostrobin. Appendix II, endpoints and related information. 1. Toxicology and metabolism. September 2004).

Based on this it can be concluded that the potential for bioaccumulation in animal tissue for pyraclostrobin is low and thus no further assessment on biomagnification is required.

Risk for birds through drinking water

EFSA/2009/1438 proposes an assessment methodology for the risk to birds from active substances in drinking water using small granivorous birds as indicator species in tier 1. Out of the two scenarios, i.e. the leaf and the puddle scenario, the leaf scenario is not relevant for use in cereals and maize, respectively. Consequently, in a drinking water risk assessment for birds only the 'puddle scenario' would need to be considered for the application of BAS 500 06 F in cereals and maize.

According to EFSA/2009/1438 no specific calculations of exposure and TER values are necessary when the ratio of effective application rate (in g/ha) to relevant endpoint (in mg/kg b.w./d) does not exceed 50 in the case of less sorptive substances (Koc < 500 L/kg) or 3000 in the case of more sorptive substances (Koc ≥ 500 L/kg). The ratio calculations for effective application rate to relevant endpoint are detailed in a screening step in Table 10.1.1.2-7. The ratio for acute and reproductive endpoints for pyraclostrobin (0.2 and 3.5, respectively) do not exceed the threshold value of 3000 as given by EFSA/2009/1438 for more sorptive substances (Koc > 500 L/kg), thus no specific calculations of exposure for birds through drinking water for the puddle scenario are necessary (Table 10.1.1.2-7).

In conclusion, the risk through drinking water from the use of BAS 500 06 F in cereals and maize is acceptable.

Table 10.1.1.2-7: Screening step for drinking water risk assessment - ratio of effective application rate to relevant endpoint for birds

Parameter	Pyraclostrobin	Reference
K_{oc} [L/kg]	9304	SANCO/1420/2001-final
DT_{50} (soil) [d]	18	M-CP 9.2
Number of applications	2	Table 10.1.1-6
Interval [d]	21	Table 10.1.1-6
MAF_{mean} [1)]	1.45	--
Max use rate [g/ha]	250 [6)]	Table 10.1.1-6
AR_{eff} [g/ha] [2)]	362.5	--
LD_{50} [mg/kg b.w.]	1701	Table 10.1.1-1
Ratio (acute) [3)]	0.2	--
Reproductive endpoint [mg/kg b.w./d]	105	Table 10.1.1-1
Ratio (repro) [3)]	3.5	--
Trigger [4)]	3000	--
Drinking water assessment required [Yes/No] [5)]	No	--

1) $MAF_{mean} = (1-e^{-nki}) / (1-e^{-ki})$ with $k = ln(2)/DT_{50}$ (rate constant), n = number of applications and i = application interval [d]. Worst-case from application scenario in cereals
2) AR_{eff} = Application rate (g/ha) x MAF_{mean}
3) Ratio of AR_{eff} and relevant toxicity endpoint
4) Trigger according to EFSA/2009/1438
5) Drinking water risk assessment is not necessary when trigger value is not exceeded.
6) Highest application rate for pyraclostrobin in cereals

A quantitative drinking water risk assessment is not triggered for the recommended use pattern of BAS 500 06 F in cereals and maize according to EFSA/2009/1438 criteria. Therefore, the risk to birds via drinking water is acceptable.

CP 10.1.2 Effects on terrestrial vertebrates other than birds

M-CP 10.1.2 was updated with a quantitative higher tier risk assessment of the small herbivorous "vole" mammal scenario taking into account literature data on the composition of vole diet and data on foliar residue decline. Further, data from a new field effect study on common voles were included, showing that there are no adverse effects of BAS 500 06 F on common vole populations (BASF DocID 2015/1126803).

In this chapter, data on BAS 500 06 F are evaluated and the risk assessments are presented for the active substance pyraclostrobin and for effects of the formulation based on the already registered use pattern.

Table 10.1.2-1: Endpoints for mammals

Test system	Test species	EU agreed endpoints	Endpoints used in present risk assessment
Acute toxicity	Rat	LD_{50} > 5000 mg a.s./kg b.w.[1)]	LD_{50} > 5000 mg a.s./kg b.w.
Reproductive toxicity (long-term)	Rat	--	Tier1: NOEL = 3 mg a.s./kg b.w./d[2)]
			Higher tier: NOAEL = 8.2 mg a.s./kg b.w./d[2)]

1) Endpoints confirmed in the Ecotoxicology section of the Review report for the active substance pyraclostrobin, September 2004
2) Daily Dose [mg/kg b.w./d] calculated based on study data for food consumption and body weight

RISK ASSESSMENT

Summary of mammalian toxicity testing

The mammalian toxicity studies with pyraclostrobin relevant for a tier 1 dietary risk assessment for wild mammals are summarized in Table 10.1.2-2.

Table 10.1.2-2: Summary of studies relevant for the mammalian risk assessment for pyraclostrobin

Test system	Test species	Results	Reference (BASF DocID)
Acute oral toxicity	Rat	LD_{50} > 5000 mg a.s./kg b.w.[1)]	1998/10965
Reproductive toxicity	Rat	$NOEL_{Reproduction}$ = 32.6 mg a.s./kg b.w./d[2)] $NOEL_{Offspring}$ = 8.2 mg a.s./kg b.w./d[2)] $NOEL_{Parents}$ = 8.2 mg a.s./kg b.w./d[2)]	1999/11869
Developmental toxicity	Rat	$NOEL_{Rel\ Maternal}$ = 10 mg a.s./kg b.w./d[2)] $NOEL_{Rel\ Developmental}$ = 50 mg a.s./kg b.w./d[2)]	1999/11511
	Rabbit	$NOEL_{Rel\ Maternal}$ = 3 mg a.s./kg b.w./d[2)] $NOEL_{Rel\ Developmental}$ = 5 mg a.s./kg b.w./d[2)]	2001/1003803 and 1999/11512

1) Endpoints confirmed in the Ecotoxicology section of the Review report for the active substance pyraclostrobin, September 2004
2) Daily Dose [mg/kg b.w./d] calculated based on study data for food consumption and body weight

Mammalian toxicity endpoint for use in the acute tier 1 risk assessment

There is one acute oral toxicity test with pyraclostrobin available in rats (BASF DocID 1998/10965). This study resulted in an **LD_{50} > 5000 mg a.s./kg b.w.**, which is the relevant endpoint to be used in the acute risk assessment.

Mammalian toxicity endpoint for use in the reproductive tier 1 risk assessment

In order to obtain the relevant toxicity endpoint for the tier 1 reproductive risk assessment, the lowest NOAEL from the two-generation rat study and the lowest relevant endpoint from the developmental studies have to be considered.

For pyraclostrobin, the lowest toxicity endpoint from these studies (Table 10.1.2-2) is the **NOEL = 3 mg a.s./kg b.w./d** derived from the developmental rabbit study. This value is the endpoint used for the screening and tier 1 reproductive risk assessment. For the higher tier risk assessment the relevant endpoint is the NOEL from the 2-generation rat study, i.e. NOEL = 8.2 mg a.s./kg b.w./d. A full rationale supporting the use of this endpoint in the higher tier risk assessment is given in a separate document (BASF DocID 2014/1010736).

Results from available toxicity testing with the formulation

The mammalian toxicity study with BAS 500 06 F relevant for the risk assessment for mammals is summarized in Table 10.1.2-3.

Table 10.1.2-3: Summary of mammalian study on the acute toxicity of BAS 500 06 F

Test system	Test species	Results	Reference (BASF DocID)
Acute oral toxicity	Rat	LD_{50} ~ 500 mg/kg b.w.	2007/1053390[1)]

1) For detailed study summary please refer to M-CP 7.1.1.

A full summary of this study is given in M-CP 7.1.1. An acute risk assessment for BAS 500 06 F considering the **LD_{50} of 500 mg/kg b.w. for BAS 500 06 F** is provided further below.

Metabolites of pyraclostrobin

A full assessment of the relevance of pyraclostrobin metabolites for the birds and mammals risk assessment is given in M-CP 10.1.1. Please refer to M-CP 10.1.1 for details.

Summary of relevant mammalian toxicity endpoints to be used in the screening and tier 1 risk assessments

The mammalian endpoints relevant for the screening step and for the tier 1 risk assessments are given in Table 10.1.2-4.

Table 10.1.2-4: Mammalian toxicity endpoints for screening and tier 1 risk assessments of pyraclostrobin and BAS 500 06 F

Test substance	Test system	Relevant toxicity endpoint
Pyraclostrobin	Acute oral toxicity	LD_{50} > 5 000 mg a.s./kg b.w.
	Sub-chronic toxicity and reproduction	NOEL = 3 mg a.s./kg b.w./d
BAS 500 06 F	Acute oral toxicity	LD_{50} ~ 500 mg/kg b.w.

Relevant exposure scenarios

The relevant scenarios for the already registered use pattern (Table 10.1.2-5) are given for cereals in Table 10.1.2-6 and for maize in Table 10.1.2-7.

Table 10.1.2-5: Critical use pattern for BAS 500 06 F

Crop	EFSA/2009/1438 crop group	Application time (BBCH growth stage)	No. of applications	Interval [d]	Application rate per treatment	
					Pyraclostrobin [kg/ha]	BAS 500 06 F [L/ha]
Cereals	Cereals	25 - 69	2	21	0.25	1.25
Maize	Maize	30 - 65	1	--	0.20	1.0

Table 10.1.2-6: Summary of exposure scenarios to be considered for risk assessments for spray applications of BAS 500 06 F in cereals at BBCH 25 – 69

Scenario	Generic focal species
Cereals Early (shoots)	Large herbivorous mammal “lagomorph”
Cereals BBCH 10-29	Small omnivorous mammal “mouse”
Cereals BBCH ≥ 20	Small insectivorous mammal "shrew"
Cereals BBCH 30 - 39	Small omnivorous mammal “mouse”
Cereals BBCH ≥ 40	Small herbivorous mammal "vole"
Cereals BBCH ≥ 40	Small omnivorous mammal “mouse”

Table 10.1.2-7: Summary of exposure scenarios to be considered for risk assessments for spray applications of BAS 500 06 F in maize at BBCH 30 – 65

Scenario	Generic focal species
Maize BBCH ≥ 20	Small insectivorous mammal “shrew”
Maize BBCH 30 - 39	Small herbivorous mammal "vole"
Maize BBCH 30 - 39	Small omnivorous mammal “mouse”
Maize BBCH ≥ 40	Small herbivorous mammal "vole"
Maize BBCH ≥ 40	Small omnivorous mammal “mouse”

CP 10.1.2.1 Acute oral toxicity to mammals

In this section, the dietary TER acute values for the screening step and tier 1 assessment obtained by means of the EFSA calculator tool (version of 9 July 2010, http://www.efsa.europa.eu/de/efsajournal/pub/1438.htm) are presented for cereals in Table 10.1.2.1-1 and for maize in Table 10.1.2.1-2.

Cereals

Table 10.1.2.1-1: Pyraclostrobin: Acute dietary risk assessment for mammals in cereals - results from EFSA calculator tool

Data from Data_Entry worksheet	**Crop**	**Application rate (kg a.s./ha)**	**Number of applications**	**Appli-cation Interval**	**DT_{50}**	**LD_{50}**	
	Cereals	0.25	2	21	10.0	>5000.0	
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF_{90}**	**Daily Dietary Dose (multiple)**	**TER**	**No refinement step required**
	Small herbivorous mammal	118.4	29.60	1.1	32.56	>153.6	
First Tier Risk Assessment:							
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**			**Shortcut value**	**TER**	**No refinement required**
	Cereals Early (shoots)	Large herbivorous mammal “lagomorph” Grass + cereals 100% cereal shoots			42.1	>431.9	
	Cereals BBCH 10-29	Small omnivorous mammal “mouse” Combination (invertebrates with interception) 25% weeds 50% weed seeds 25% ground arthropods			17.2	>1057.1	
	Cereals BBCH ≥ 20	Small insectivorous mammal "shrew" ground dwelling invertebrates with interception 100% ground arthropods			5.4	>3367.0	
	Cereals BBCH 30 - 39	Small omnivorous mammal “mouse” Combination (invertebrates with interception) 25% weeds 50% weed seeds 25% ground arthropods			8.6	>2114.2	
	Cereals BBCH ≥ 40	Small herbivorous mammal "vole Grass + cereals 100% grass			40.9	>444.5	
	Cereals BBCH ≥ 40	Small omnivorous mammal “mouse” Combination (invertebrates with interception) 25% weeds 50% weed seeds 25% ground arthropods			5.2	>3496.5	

Maize

Table 10.1.2.1-2: Pyraclostrobin: Acute dietary risk assessment for mammals in maize - results from EFSA calculator tool

Data from Data_Entry worksheet	Crop	Application rate (kg a.s./ha)	Number of applications	Appli-cation Interval	DT_{50}	LD_{50}	
	Maize	0.2	1	365	10.0	>5000.0	
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF_{90}**	**Daily Dietary Dose (multiple)**	**TER**	**No refinement step required**
	Small herbivorous mammal	136.4	27.28	1.0	27.28	>183.3	
First Tier Risk Assessment:							
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**		**Shortcut value**	**TER**	**No refinement required**	
	Maize BBCH ≥ 20	Small insectivorous mammal “shrew” ground dwelling invertebrates with interception 100% ground arthropods		5.4	>4629.6		
	Maize BBCH 30 - 39	Small herbivorous mammal "vole Grass + cereals All maize shoots + later grass		68.2	>366.6		
	Maize BBCH 30 - 39	Small omnivorous mammal “mouse” Combination (invertebrates with interception) 25% weeds 50% weed seeds 25% ground arthropods		8.6	>2907.0		
	Maize BBCH ≥ 40	Small herbivorous mammal "vole Grass + cereals All maize shoots + later grass		34.1	>733.1		
	Maize BBCH ≥ 40	Small omnivorous mammal “mouse” Combination (invertebrates with interception) 25% weeds 50% weed seeds 25% ground arthropods		4.3	>5814.0		

In conclusion, even under the conservative assumptions of the screening step and the tier 1 acute dietary risk assessment all TER_A values for pyraclostrobin exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects.

CP 10.1.2.2 Higher tier data on mammals

Please note that this section, albeit suggested by its header, does not only include higher tier data on mammals. The calculations presented for cereals in Table 10.1.2.2-1 and for maize in Table 10.1.2.2-2 are the dietary TER reproductive values for the screening step and tier 1 assessment obtained by means of the EFSA calculator tool (version of 9 July 2010, http://www.efsa.europa.eu/de/efsajournal/pub/1438.htm).

Cereals

	Maize BBCH ≥ 40	Small herbivorous mammal "vole Grass + cereals All maize shoots + later grass			18.1	1.6	**Higher tier risk assessment required**
	Maize BBCH ≥ 40	Small omnivorous mammal "mouse" Combination (invertebrates with interception) 25% weeds 50% weed seeds 25% ground arthropods			1.9	14.9	**No refinement required**

In conclusion the tier 1 TER_{LT} values for pyraclostrobin are below the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects for four scenarios in cereals and two scenarios in maize. The scenarios failing the trigger values require refinement of the assessments in a higher tier step. The higher tier risk assessments are presented in the following.

Refined reproductive risk assessments for mammals

The following scenarios failed the trigger of 5 in the tier 1 reproductive risk assessment and will be refined:

Applications to cereals:

Large herbivorous mammal “lagomorph” at early stages
Small omnivorous mammal “mouse” at BBCH 10-29
Small omnivorous mammal “mouse” at BBCH 30-39
Small herbivorous mammal "vole" at BBCH ≥ 40

Applications to maize:

Small herbivorous mammal "vole" at BBCH 30-39
Small herbivorous mammal "vole" at BBCH ≥ 40

A. Small herbivorous mammal "vole" scenarios in cereals and maize

According to EFSA/2009/1438 (Appendix A) the representative (default) species to be used for refinement of the small herbivorous mammal scenario “vole” at BBCH 30-39 (in maize) and BBCH ≥ 40 (in cereals and maize) is the common vole, *Microtus arvalis*.
However, there are also reasons to not consider the common vole a relevant focal species in cereals and maize, because arable crops in general do not constitute the common vole’s primary habitat (for more details, see BASF DocID 2011/1248329 and BASF DocID 2004/1025715; please note that both documents were erroneously not included in the Application submitted in January 2014). Furthermore, common vole populations naturally display cyclical changes and a strong ability to recover from decimation, contributing to its pest status in European countries. This notion that the common vole is not considered a relevant focal species in arable crops is supported by a recent literature review (Jacob et al., 2013), in which population dynamics, habitat and food preferences, pest potential and the use of the common vole in risk assessments are presented and discussed in detail. Therefore, BASF still believes that the small herbivorous mammal scenario is covered by another rodent, the omnivorous wood mouse (*Apodemus sylvaticus* L.). As shown in Table 10.1.2.2-1 for cereals and in Table 10.1.2.2-2 for maize, the related TER_{LT} values of the wood mouse are above the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects indicating an acceptable risk for the intended use of BAS 500 06 F in cereals and maize.

However, the relevance of the “vole” scenario has been controversially discussed by the European Member States and a harmonized approach is currently lacking. Therefore, the quantitative higher tier risk assessments for the vole in cereals (Table 10.1.2.2-11) and maize (Table 10.1.2.2-12) are presented below (in addition to the quantitative higher tier risk assessment for the wood mouse in cereals).

B. Large herbivorous mammal "lagomorph", small omnivorous mammal “mouse”, and small herbivorous mammal “vole” scenarios in cereals and maize

The refined dietary reproductive risk assessment for mammals is based on the following refinement points:

Refinement point 1:	Ecologically relevant reproductive toxicity endpoint for pyraclostrobin
Refinement point 2:	Residue decline of pyraclostrobin in plants for refinement of MAF x twa
Refinement point 3:	Identification of representative mammal species including ecological data (PT and PD values and FIR)
Refinement point 4:	Interception by cereal and maize plants

Refinement point 1: Ecologically relevant reproductive toxicity endpoint for pyraclostrobin

According to the latest regulatory Guidance (EFSA/2009/1438) both the multi-generation study and the prenatal toxicity studies need to be taken into account for defining a relevant toxicity value for the long-term risk assessment to mammals. Hence, BASF evaluates in detail the database of mammalian laboratory toxicology studies with pyraclostrobin relevant for the long-term risk assessment for wild mammals, and proposes an ecologically relevant NOAEL for the refined evaluation of the reproductive risk to wild mammals.

The available database comprises one multi-generation study conducted with rats, one prenatal toxicity study conducted with rats, and two prenatal toxicity studies conducted with rabbits. According to the proposal of EFSA 2009/1438 for the first tier risk assessment the lowest toxicity value of these studies, i.e. the NOAEL = 3 mg/kg b.w./d derived from the prenatal toxicity studies conducted with rabbits, is used for TER calculations. For higher tier risk assessment EFSA/2009/1438 recommends a re-examination of the study data to derive an endpoint of biological and/or ecological relevance. Full details of this evaluation are given along with the present dossier in a separate position paper [Anonymous 2014 a, BASF DocID 2014/1010736]. A short summary of the evaluation is given in the following:

In brief, a three-step approach was followed to derive an overall higher tier toxicity endpoint of ecological and population relevance, including:

i) A detailed analysis of the results from the prenatal toxicity studies with rabbits, as the lowest endpoint from these studies was used for the first tier risk assessment of pyraclostrobin.
ii) A discussion of the general relevance of the available types of toxicity studies (multi-generation, prenatal toxicity) for the route and conditions of exposure to wild mammals in the field.
iii) A comparison of the ecologically relevant NOAELs from the different studies to define and propose an overall ecologically relevant endpoint for higher tier risk assessment.

The **detailed analysis the prenatal toxicity studies with rabbits** provided the following main results and arguments:

- A transient decrease in maternal food consumption during treatment days 1-5 in the rabbit developmental studies was followed by a clear recovery of maternal food consumption till the end of the treatment period. The transient variations in food consumption observed during the first days of treatment did not translate into effects on body weight for animals dosed with up to and including 10 mg/kg bw/d pyraclostrobin.

- In respect of overall reproductive outcome up to and including doses of 10 mg/kg bw/d, the number of live, male and female fetuses was not affected. The % of live fetuses per implant was not altered, and no effects were seen on the sex ratio of fetuses. Furthermore, no dead fetuses were reported at any dose rate.

- In respect of parameters for dams, there was no statistically significant difference in the number of corpora lutea, the number of implantation sites, the rate of pre-implantation loss, and the number of late resorptions between all dose groups, the concurrent controls, and the set of historical control data.

- A slight increase in early resorptions and consequently a higher rate of post-implantation loss was observed at the high doses. However, up to and including doses of 10 mg/kg bw/d slight differences in early resorptions and post-implantation loss were not of any significance and did not translate into effects on the overall number of live fetuses and the % of live fetuses per implant.

- Minor changes on the fetal body weights at doses of 10 mg/kg bw/d and above were not of statistical significance as compared to the concurrent controls at any dose rate.

➢ In conclusion, no effect was seen on the overall reproductive success, population relevant parameters, and potential fitness of the offspring, and hence no impact on size and stability of wild mammal populations is to be expected. Consequently, the ecotoxicologically relevant endpoint from the rabbit prenatal toxicity studies is the NOAEL = 10 mg/kg bw/d.

Further, **the different types of toxicity studies (multi-generation, prenatal toxicity) were compared regarding their general relevance for the route and conditions of exposure** to wild mammals in the field. The multi-generation study was found to reflect best the route of exposure (dietary), duration (several generations continuously exposed to treated food) and endpoints (development, survival and, most important for the reproduction risk, reproductive endpoints) relevant for small mammals in the wild. The lowest endpoint from the multi-generation study with rats is the NOEL = 8.2. mg/kg b.w./d.

Finally, in **order to propose an overall ecologically relevant endpoint for higher tier risk assessment, the specific endpoints from the available studies were compared:** The relevant endpoint from the multi-generation study with rats is the NOEL = 8.2 mg/kg b.w./d, and hence well in range with the endpoint from the prenatal toxicity study with rat (NOEL = 10 mg/kg b.w./d). The presented analysis supports furthermore for the prenatal toxicity study in rabbit a NOAEL = 10 mg/kg bw/d as ecotoxicological relevant endpoint.

Overall conclusion: Based on the detailed analysis of the prenatal toxicity studies with rabbits, considerations on the most relevant study type, and the comparison of the ecotoxicologically relevant endpoints from the different available studies, BASF proposes to use as conservative value for the refined wild mammal risk assessment for pyraclostrobin the NOAEL=8.2 mg/kg b.w./d from the multi-generation study with rats.

Refinement point 2: Residue decline of pyraclostrobin in plants for refinement of MAF x twa

According to EFSA/2009/1438 in the Tier 1 risk assessment a default foliar half-life (DT_{50}) of 10 days is considered for calculation of the multiple application factor (MAF) and the time-weighted average factor (f_{twa}). However, data from substance-specific field residue trials with pyraclostrobin indicate a much faster dissipation of pyraclostrobin in foliar plant tissue. BASF conducted thirty-two GLP field residue trials in wheat and peas to obtain foliar residue decline data that are fully applicable for Northern Europe and Southern Europe (BASF DocID 2013/1045207 and BASF DocID 2013/1044539).

The field trials were specifically designed to obtain a solid refinement data package for higher tier risk assessments on birds and mammals. Herbivorous / omnivorous birds and mammals might feed on the leaves of the crop plants themselves, but preferably consume young nutritious weed plants growing within the treated field. Hence, the test item was applied onto wheat and pea plants at early growth stages, i.e. BBCH 12/13 for both peas and wheat, to obtain results being fully relevant for monocotyledonous and dicotyledonous weeds at early growth stages. Under this premise wheat and peas are considered acceptable as surrogate plants for monocotyledonous and dicotyledonous weeds.

Samples were collected on DAT 0, 1, 2, 3, 4, 5, 7, 10, 12, 14. During the sampling period (DAT 0 to DAT 14) the large majority of the test fields were not irrigated. Only trials L120077 and L120078 were irrigated once at late time points of the sampling period (DAT 6 or DAT 7). Considering the observed rapid decline of pyraclostrobin, a bias of the trial results by wash-off can be excluded.

The measured residue data in the plants were used to derive dissipation times of pyraclostrobin in the plants. Following FOCUS guidance (2006) kinetic evaluations of all 32 residue data sets were carried out. For two trials no acceptable kinetic fit could be calculated and therefore no reliable DT_{50} could be estimated (see Table 10.1.2.2-3). Therefore, the dissipation data of these two trials were excluded for further analysis. The evaluation of the remaining 30 residue data sets showed a high goodness-of-fit of the applied kinetic models to estimate DT_{50} values based on the following three criteria:

1) The visual inspections of the fitted models indicated that the calculated curves matched the observed residue behavior very well supported by very low $\chi 2$ minimum error values (mean = 9.1 %, n = 30).

2) The results of the t-test statistics (each p value < 0.001) proved clearly that the derived constant rates (SFO models) were statistically different from zero.

3) The residuals were generally small and randomly scattered around the zero line.

The calculated DT_{50} values are presented below in Table 10.1.2.2-3. For calculation details to obtain DT_{50} values please refer to the reports (BASF DocID 2013/1078114 and BASF DocID 2013/1291161.) Please note that both reports were erroneously not listed in the Application submitted in January 2014. The summaries of the dissipation calculations and the field residue trials are found at the beginning M-CA 8.1.

In these two residue studies with pea and wheat plants, two data sets were generated at each location. Since the two treated plots (plot 2 & 3) were situated very close to each other, the agricultural practice was virtually identical. Therefore, the two treated plots may be considered as pseudo-replicates and not as fully independent replicates. Consequently, for the statistical analysis carried out (see below), a single DT_{50} value was calculated for each location by calculating the mean of the values for the two plots.

Table 10.1.2.2-3: Foliar residue decline trials with pyraclostrobin in Europe: DT_{50} in wheat and peas (BASF DocIDs 2013/1078114 and 2013/1291161)

Geometric mean (n = 8) – Southern Europe DT_{50} [d]					**3.03**	
Geometric mean (n = 16) – Southern and Northern Europe DT_{50} [d]					**2.35**	
~~**Geometric mean (n=30) DT_{50} [d]**~~				~~**2.34**~~	**—**	

1) Arithmetic mean of the two DT_{50} values per each location, with exception of trials L120079 and L120080, for which only a single value per location is available. Arithmetic mean values were used for statistical analyses.

2) Plot discarded, since no acceptable fit could be achieved.

A statistical evaluation of the DT_{50} data set was done to identify which trial data could be merged for the calculation of a geometric DT_{50} value being adequate for the refined risk assessment. This approach follows the peer-review evaluation in the recent EU renewal process of pendimethalin, where the experts agreed to use the geometric mean DT_{50} value based on results of a statistical evaluation of half-life data (EFSA Conclusion for Pendimethalin, EFSA Journal 2016;14(3):4420).

The statisticial analysis of the pyraclostrobin data was based on the following samples sizes: wheat/north (n = 4); wheat/south (n = 4); peas/north (n = 4); peas/south (n = 4). Results are shown below:

Table 10.1.2.2-4: Results of statistical analyses of residue data sets for factors residue zone and plant species

Data sets comparison	p value*
Wheat vs. Peas	**0.59**
North vs. South	0.009
Peas/South vs. Wheat/South	**0.12**
Peas/North vs. Wheat/North	**0.41**
Peas/North vs. Wheat/South	0.025
Peas/South vs. Wheat/North	**0.14**
Wheat/North vs. Wheat/South	0.002
Peas/North vs. Peas/South	**0.50**

* Derived by non-parametric Kruskal-Wallis tests with post-hoc analysis of variance (Dunn test). Note that a t-test is not applicable to the dataset as required assumptions for the t-test could not be fulfilled (i.e. data are not normally distributed), even not with log-transformation of data.

The statistical results showed that there is no significant difference between wheat and pea data (p = 0.59), albeit data sets splitted by region differ significantly (p = 0.009). Taking additionally the results of comparing data subsets into account, it is acceptable to merge the data set "peas/south" with "wheat/south" (p = 0.12) and on the other hand "peas/north" with "wheat/north" (p = 0.41) as the DT_{50} values are consistent across trials in each of the two residue zones irrespective of the plant species. This results finally in two geometric mean DT_{50} values, the first (DT_{50} = 1.83 days, n = 8) covering the Northern zone and a second one (DT_{50} = 3.03 days, n = 8) applicable to the Southern zone.

The lack of a statistical difference between wheat and pea data per zone indicated that extrapolation between plant/crop types is justified, so that the provided residue data of pyraclostrobin are suitable surrogates of food items for small herbivorous mammals such as young grass and weed plant material.

In 2016 BASF conducted three additional foliar residue decline trials in wheat in the Northern residue zone in order to complete the picture on foliar residue decline of pyraclostrobin. In these three trials the application was carried out at a later growth stage (BBCH 25-29) to address uncertainties on the foliar residue dissipation pattern associated with dilution of residues by plant growth. The estimated DT_{50} values (based on a high goodness-of-fit according to FOCUS GD, 2006) are for all three trials < 3 days and therefore well in line with the values based on the already submitted wheat studies. This finding supports that the plant growth stage at the time point of application does not play a major role in the foliar dissipation pattern of pyraclostrobin.

The final study reports are expected to be available in the second quarter of 2017 and can be therefore provided upon request after the commenting period of the dRAR.

Based on the evaluation and statistical analysis of the submitted monocot (wheat) and dicot (pea) data, the calculated geomeans were DT_{50} = 1.83 days for the Northern residue zone and DT_{50} = 3.03 days for the Southern zone. Following a worst-case approach for this EU-wide evaluation, the highest of these two values (DT_{50} = 3.03 days) is used for the refinement of the risk assessments of the mammal scenarios. Therefore, the higher tier calculations and the resulting TER values of the large herbivorous mammal "lagomorph" and small omnivorous mammal “mouse” scenarios in cereals changed slightly and were updated accoordingly.

MAF x twa moving time window approach

The calculation of MAF and twa factor is conducted in accordance with the recommendations from EFSA/2009/1438 (Appendix H). An EXCEL spreadsheet was developed that describes the actual concentration in feed items from the day after first treatment (1 DAFT) up to 200 DAFT. Dissipation between the application events according to single first order kinetics (SFO) was introduced in the EXCEL spreadsheet as well as the build-up of residues through multiple applications. The geometric mean DT_{50} value of 3.03 d for pyraclostrobin is used for the twa calculation.

The calculations follow the basic formula assuming single first order dissipation kinetic:

$$C_{act}(t) = C_0 * e^{-k * t}$$

$C_{act(t)}$	actual concentration at time t
C_0	initial concentration
K	degradation rate constant (= ln(2) / DT_{50})
T	time t

Furthermore, the established spreadsheet calculates - one after the other in a resolution of 0.1 d time steps - the average concentration factors for a 21 d time period, starting from the time of the first treatment (0 DAFT) up to 200 DAFT and scans for the maximum of the resulting twa values (moving time window approach (EFSA 2009/1438, Appendix H)). The high resolution of 0.1 d time steps leads to precise results even under consideration of short DT_{50} values. The calculation of the twa, 21 d is described in the equation below.

Calculation of the twa over 21 d using a "moving time window" approach:

$$twa, 21\ d = max\left[\frac{1}{21 * 10}\sum_{t=t_j\ ,step\ 0.1}^{t_{j+20.9}} C_{act}\ (t)\right]\ for\ j = 0.05,\quad (200 - 21 - 0.05)$$

twa, 21 d	maximum average concentration in feed item for a 21 d interval
$C_{act\ (t)}$	actual concentration at time t
t	time
t_j	start time point for integration
j	time step running variable

For the use of BAS 500 06 F in cereals (2 applications, 21-day interval), the calculation results in a maximum 21-d twa factor of 0.2081 and for the use in maize (1 application), the calculation results in a maximum 21-d twa factor of 0.2064. Please note that the MAF is set to 1 as this factor is already included in the calculation of the maximum 21-d twa factor.

Refinement point 3: Identification of representative mammal species including ecological data (PT and PD values and FIR)

Representative and focal species

Hare

For the large herbivorous mammal scenario at early stages in cereals EFSA/2009/1438 suggests the rabbit (*Oryctolagus cuniculus*) as representative species.

However, data from a recent field study (BASF DocID 2011/1112612, for a detailed study summary please refer to the beginning of chapter M-CP 10.1) suggests that the hare and not the rabbit is the representative focal species at early growth stages of cereals.

In spring 2011, spotlight counts were conducted at two different study sites in central Europe (Germany). In total, 90 cereal fields were monitored and all observed hares and rabbit were recorded. The number of hare per 100 ha surveyed area was ten-fold higher compared to that of rabbits and the frequency of occurrence of the hare (*Lepus europaeus*) was more than seven-fold higher compared to that of rabbits at early growth stages in cereal fields.

The results from this field survey are in agreement with the fact that the habitat requirements of the hare and the rabbit are different (see e.g. Gurney et al. 1998). Whereas the rabbit (*Oryctolagus cuniculus*) prefers areas of short grass like naturally occurring dry heaths or closely grazed agricultural pasture and secure refuge nearby, i.e. diversely structured landscape, the hare (*Lepus europaeus*) prefers arable land predominated by cereals where it feeds (among other items) on cereals at early growth stages (Gurney et al. 1998). Thus, arable land including cereal fields at early growth stages are an important habitat type for the hare (and not so much for the rabbit) in spring.

Wood mouse
According to EFSA/2009/1438 the wood mouse (*Apodemus sylvaticus*) is the representative species for the small omnivorous mammal scenario at BBCH 10-29 and BBCH 30-39.

Common vole
According to EFSA/2009/1438 the common vole (*Microtus arvalis*) is the representative species for the small herbivorous mammal scenario at BBCH 30-39 and BBCH ≥ 40 in maize and BBCH ≥ 40 in cereals.

In conclusion, the refined risk assessment for pyraclostrobin applied as BAS 500 06 F in cereals will be carried out for three species representative of large herbivorous (hare, *Lepus europaeus*), omnivorous (wood mouse, *Apodemus sylvaticus*) and small herbivorous (common vole, *Mircotus arvalis*) mammals using cereal fields as foraging grounds.

Ecological data

Hare (*Lepus europaeus*)

Proportion of diet obtained from the treated area (PT)

It has been shown that hares have large home ranges. Home ranges can vary in size from approximately 20 ha up to >100 ha (for a review, see e.g. Olesen & Asferg, 2006). The occurrence of such large home ranges strongly suggests that it is appropriate to refine the default PT value of 1.

Prosser (2010) presents PT data for the hare, from FERA's (formerly CSL's) previous projects in a single document for easy reference. Prosser (2010) included only animals for which a quantity of data likely to give robust estimates of PT is available. The modelled PT distributions have been fitted by the author to these data, to give a more accurately calculated 90th percentile value of the PT distributions. The 90th percentile value of PT=0.87 from all tracked hares (n=19) for cereals in spring (Prosser, 2010, Table 12) will be used in the refined TER calculations for the hare.

Wood mouse (*Apodemus sylvaticus)*

Fraction of food type in the diet (PD)

The wood mouse is known to be an opportunistic feeder adapted to utilise and exploit various food resources. The default diet (25% weeds, 50% weed seeds, 25% ground arthropods) according to EFSA/2009/1438 used in the tier 1 calculations above, can be refined by data from scientific literature. Most suitable data to conclude on the diet composition of the wood mouse in arable land, especially cereal fields, are found in Green (1979) and Pelz (1989). The data also allow to quantify proportions of the different feed items (PD) for the period when the product BAS 500 06 F is intended to be applied in cereals. For details of this evaluation please refer to Appendix 1 at the end of chapter M-CP 10.1.

The following PD values for the wood mouse in cereals are derived from the evaluation:

- Green plant matter PD = 0.107
- Weed seeds PD = 0.551
- Arthropods PD = 0.187
- Earthworms PD = 0.154

These PD values will be used for the calculation of the Food Intake Rate as summarized in Table 10.1.2.2-6.

Common vole (*Microtus arvalis*)

Fraction of food type in the diet (PD)

For the higher tier risk assessment of the common vole, the fraction of food type in the diet (PD) will be refined.

Rinke (1991) investigated common vole (*Microtus arvalis)* feeding preferences via stomach content analysis in a study area with a high availability of monocotyledonous plants (i.e. meadows) in central Germany. In total, the stomach contents of 363 individuals (186 females and 177 males) caught on five plots of permanent meadow (about 0.5 ha each) during 1984-1987 were analysed. Animals were captured with baited snap traps in spring (April-May), summer (August-September) and autumn (October-December). They were sexed and three age groups based on body weights were established: juveniles (≤ 10g), subadults (10-15g), and adults (> 15g). Stomach contents were analysed microscopically and plant species were determined to the species level. Estimation of volume percentages of mono- and dicotyledonous plants were made based on the area occupied on the slide. The stomach contents of the common voles were classified in five groups as follows: stomach containing (1) 0-20%, (2) 21-40%, (3) 41-60%, (4) 61-80% and (5) 81-100% dicotyledonous plants.

It was shown that the common vole feeds on a broad variety of plant species and exhibits a pronounced selective food intake. Despite the fact that more monocots were available on the study plots (about 70%), the animals showed a clear preference for dicots, even when a larger percentage of monocots were available. Irrespective of season, sex and age, the majority of voles showed >80% dicotyledonous material in their stomach contents. Interestingly, age, sex or season did not strongly impact the common voles' food preference.

The data from Rinke (1991) suggests that the actual diet of the common vole comprises at least >50% dicotyledonous plants. It even consisted of approximately 25% monocots and 75% dicots in spring and summer (see Table 10.1.2.2-5, adapted from Rinke, 1991).

Table 10.1.2.2-5: Diet of common voles (percent volume) in meadows in Germany (adapted from Rinke, 1991) in spring, summer and autumn

	Monocotyledons (percent volume)	Dicotyledons (percent volume)	Number of animals
Spring	24	76	23
Summer	25	75	152
Autum	48	52	188

In conclusion, the 100% monocotyledonous diet as assumed by EFSA (2009) is an unrealistic worst-case estimate, because it has been shown that voles consume both, monocots and dicots. Thus, it is justified to conservatively assume that in spring and summer, the diet of the vole in cereals and maize consists of approximately 25% monocotyledonous plants (grasses) and 75% dicotyledonous plants (non-grass herbs), resulting in PD values of

Grasses	PD = 0.25	
Non-grass herbs	PD = 0.75	PD sum = 1.0

These PD values are used for the refined chronic risk assessment and the calculation of the Food Intake Rate (FIR / b.w.) values (see Table 10.1.2.2-6 below).

Calculation of Food Intake Rate (FIR/b.w.) for the focal species

The FIR/b.w. values for the focal species are calculated following EFSA/2009/1438 (Appendix G - Calculating exposure for the dietary intake approach).

First, based on $PD_{i,fresh}$ (the diet composition in fresh weight) and considering energy content, moisture content and assimilation efficiency, the $FE_{total,\ fresh}$ can be calculated according to the following formula:

$$FE_{total,fresh} = \sum_i \left[PD_{i,fresh} \times FE_i \times \left(1 - \frac{MC_i}{100} \right) \times \frac{AE_i}{100} \right]$$

In which:

$FE_{total,\ fresh}$ = Food energy of total mixed diet [kJ/g fresh weight]
$PD_{i,\ fresh}$ = Fraction of food item [i] in mixed diet [related to fresh weight]
FE_i = Food energy of food item [i] in mixed diet [kJ/g dry weight]
MC_i = Moisture content of food item [i] in mixed diet [%]
AE_i = Assimilation efficiency of food item [i] in mixed diet [%]

Second, using the calculated specific energy content of the mixed fresh diet ($FE_{total,\ fresh}$) the required amount of the mixed diet ($FIR_{total,\ fresh}$) to reach the DEE (daily energy expenditure) of the indicator species can be determined.

$$FIR_{total,fresh} = \frac{DEE}{FE_{total,fresh}}$$

Third, the FIR/b.w. value is calculated as the quotient of $FIR_{total,\ fresh}$ and the species' body weight.

$$FIR/b.w. = FIR_{total,\ fresh} / b.w.$$

The FIR/b.w. value for the hare, the wood mouse, and the common vole are shown below in Table 10.1.2.2-6.

Table 10.1.2.2-6: FIR/b.w. for the hare, the wood mouse and the common vole

Food	$PD_{i,\ fresh}$	FE_i [kJ/g dry weight]	AE_i / 100	MC_i	$FE_{total,\ fresh}$ [kJ/ g fresh weight]	DEE [kJ]	$FIR_{total,\ fresh}$ [g]	Body weight [g]	FIR/ b.w.

[1)] Bodyweight data according to EFSA/2009/1438

Refinement point 4: Interception by cereal and maize plants

Food items like weed seeds, non-grass herbs and grasses on the ground of cereal and maize fields will not receive the total amount of spray solution of a fungicide application. This is due to the fact that significant parts of the spray volume (and hence of the active substance) are intercepted by the crop foliage before reaching the ground.

Regarding interception EFSA/2009/1438 indicates that in a context of a higher tier risk assessment the deposition values given in FOCUS$_{GW}$ (Anonymous 2000/2002) may be used. Indeed, for cereals and maize the interception factors from FOCUS groundwater can more specifically be attributed to the growth stages in cereals and maize at BBCH ≥30, compared to the growth stages as used in the FOCUS surface water document (FOCUS 2001) for Step 2 calculations. However, for the product BAS 500 06 F the earliest application is intended at BBCH 25 in cereals and BBCH 30 in maize (Table 10.1.2.2-7 and Table 10.1.2.2-8) where the FOCUS$_{GW}$ (Anonymous 2000/2002) and the FOCUS surface water document (FOCUS 2001) present the same interception values.
The FOCUS$_{GW}$ document assumes the following successive decrease of soil deposition rates for cereals during the main growing season.

Table 10.1.2.2-7: Deposition rates in cereals according to $FOCUS_{GW}$ (Anonymous 2000/2002)

Growth stage in spring and winter cereals according to $FOCUS_{GW}$ (Anonymous 2000/2002)[1)]		Interception [%]	Deposition factor
Leaf development	10-19[2)]	25[2)]	0.75
Stem elongation (tillering)	20-29[2)]	50[2)]	0.5
Stem elongation (elongation)	30-39	70	0.3
Flowering	40-89	90	0.1

1) From $FOCUS_{GW}$ guidance document (p. 23)
2) Identical values when compared to FOCUS surface water document (FOCUS 2001)

Table 10.1.2.2-8: Deposition rates in maize according to $FOCUS_{GW}$ (Anonymous 2000/2002)

Growth stage in maize according to $FOCUS_{GW}$ (Anonymous 2000/2002)[1)]		Interception [%]	Deposition factor
Leaf development	10-19[2)]	25[2)]	0.75
Stem elongation (elongation)	20-39[2)]	50[2)]	0.5
Flowering	40-89	75	0.25

1) From $FOCUS_{GW}$ guidance document (p. 23)
2) Identical values when compared to FOCUS surface water document (FOCUS 2001)

For the product BAS 500 06 F the earliest application is intended at growth stage BBCH 25 in cereals and BBCH 30 in maize (Table 10.1.2-5). Hence, the deposition factor of DF = 0.5 for the food items weed seeds in cereals will be used in the refined risk assessments for the small omnivorous mammal “mouse” at BBCH 10-29 and BBCH 30-39. The deposition factor of DF = 0.1 for the food items non-grass herbs and grasses in cereals will be used in the refined risk assessments for the small herbivorous mammal "vole" at BBCH ≥ 40 in cereals. The deposition factor of DF = 0.5 for the food items non-grass herbs and grasses in maize will be used in the refined risk assessment for the small herbivorous mammal "vole" at BBCH 30-39, which covers the scenario for the small herbivorous mammal "vole" at BBCH ≥ 40.

Refined reproductive risk assessment for pyraclostrobin: TER calculations

The refined reproductive risk assessments for large herbivorous mammal and small omnivorous mammal scenarios are shown in Table 10.1.2.2-9 for the hare and in Table 10.1.2.2-10 for the wood mouse for cereals. For small herbivorous mammals refined risk assessments are shown in in Table 10.1.2.2-11 for the vole in cereals and in Table 10.1.2.2-12 for the vole in maize.

Table 10.1.2.2-9: Hare: Refined reproductive risk assessment for cereals

Food type[1)]	FIR/ b.w.	$PD_{i,\ fresh}$	PT	RUD [mg a.s./kg]	MAF	Maximum 21-d twa factor	DF	Use rate [kg a.s./ha]	DDD [mg a.s./kg b.w./d]
Grass/cereal shoots	0.319[1)]	1.0[1)]	0.87	54.2[1)]	1[2)]	0.2081[2)]	1	0.25	0.782

Additional qualitative evidence that pyraclostrobin (applied as BAS 500 06 F) has no adverse effects on free-living wood mouse and common vole populations

The low risk to wood mice from applications of BAS 500 06 F in cereals as presented in the quantitative reproductive risk assessment for the wood mouse above was also confirmed by results from a field effect study on the acute and long-term effects of BAS 500 06 F in cereals on populations of small mammals (BASF DocID 2014/1000041). A detailed summary of the study can be found at the beginning of M-CA 8.1. In brief, live trapping (capture-mark-recapture) was carried out from April to October 2013 to compare the abundance and population dynamics of small mammal species in six treated (2 applications of BAS 500 06 F according to the intended use pattern) and six untreated winter cereal fields and adjacent off-crop areas in Germany. Eight different parameters (captures/individuals in- and off-crop, trapping efficiency, minimum number alive, population growth rate, percentage of reproductively active individuals, percentage of juveniles, percentage of females, and adult body weight) were monitored for the whole growth period of winter cereals. Further, although trapping efficiency of common voles was relatively low in this study, no signs of any potential impacts of BAS 500 06 F on voles were observed.

To confirm the initial findings for the common vole, a second field effect study on the acute and long-term effects of BAS 500 06 F on populations of common voles (BASF DocID 2015/1126803) was conducted. The study was performed under realistic worst-case field conditions in meadows, which are – in contrast to e.g. cereal fields - preferred common vole habitats with high abundances of common voles. Meadows were used as a surrogate for other crop types to ensure sufficient numbers of common voles being exposed to the test item BAS 500 06 F. A detailed summary of the study can be found at the beginning of M-CA 8.1. In brief, live trapping (capture-mark-recapture) was carried out in ten trapping sessions from May to October 2015. The abundance and population dynamics of common voles was compared in five treated (2 applications of BAS 500 06 F according to the critical use pattern) and five untreated study fields in Germany. Seven different parameters (trapping success, minimum number alive (MNA), recapture rate, sex ratio, proportion of reproductively active animals, age structure and body weight development) were monitored for the whole study period, which covered the majority of the reproductive season of common voles. Overall, trapping success of common voles was high: 9161 captures of common voles were made, including a total of 2495 individually marked animals. No adverse acute and long-term effects of the fungicide BAS 500 06 F on common vole populations in meadows were detected in any of the parameters investigated.

In conclusion, the studies showed no impacts of the fungicide BAS 500 06 F under field conditions on the common vole (*Microtus arvalis*) and wood mouse (*Apodemus sylvaticus*).

In addition, all relevant TER_{LT} values for pyraclostrobin exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low and acceptable reproductive risk for wild mammals from the use of BAS 500 06 F in cereals and maize.

Acute oral toxicity of the preparation

A study on the acute oral toxicity of BAS 500 06 F on rats was conducted (BASF DocID 2007/1053390) and resulted in an **LD_{50} of around 500 mg BAS 500 06 F/kg b.w.**). The full study summary is included in M-CP 7.1.1.

Please note, an acute risk assessment for BAS 500 06 F with LD_{50} from formulation toxicity testing is provided further below.

Acute risk assessment considering the LD_{50} from toxicity testing with BAS 500 06 F

Toxicity endpoint of the formulation for mammals

Acute oral toxicity studies of formulations are not specifically designed for use in wild mammal risk assessments, but are conducted for the purpose of classification and labelling and include testing of rates with single doses of the intact formulation administered by oral gavage. The type and pattern of exposure of wild mammals following a foliar spray in the field is very different than the exposure pattern tested in acute oral gavage tests.

Hence, the results of such acute oral toxicity tests are of limited relevance for the acute wild mammal risk assessment. Nevertheless, for a conservative estimate, the endpoint of the acute oral toxicity study with BAS 500 06 F on rats, namely LD_{50} = 500 mg/kg b.w., will be used for a tier 1 acute risk assessment of the formulation. The results of the tier 1 acute dietary exposure assessment and TER calculation will be presented below.

Exposure

BAS 500 06 F is intended to be used in cereals and maize with a maximum single application rate of 1.25 L BAS 500 06 F/ha in cereals and 1.0 L BAS 500 06 F/ha in maize (see Table 10.1.2-5 for the critical use pattern). Taking into account the density of the formulation of 1.04 g/cm^3, this will result in an application rate of 1.3 kg BAS 500 06 F/ha and 1.04 kg BAS 500 06 F/ha for the critical use patterns in cereals and maize, respectively. The relevant scenarios for the critical use pattern are given in Table 10.1.2-6 (cereals) and in Table 10.1.2-7 (maize).

Calculation of the screening and tier 1 risk assessment for BAS 500 06 F according to EFSA/2009/1438

The screening and tier 1 TER values for the acute dietary risk assessment for mammals as obtained by means of the EFSA calculator tool (version of 9 July 2010, http://www.efsa.europa.eu/de/efsajournal/pub/1438.htm) are presented for cereals in Table 10.1.2.2-13 and in Table 10.1.2.2-14 for maize.

In conclusion the tier 1 TER_A values for the formulation BAS 500 06 F are below the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects for two scenarios in cereals and one scenario in maize. The scenarios failing the trigger values require refinement of the assessments in a higher tier step. The refined acute risk assessments are presented in the following.

Refined acute dietary risk assessments for the formulation

The following scenarios failed the trigger of 10 in the tier 1 acute risk assessment and will be refined:

Applications to cereals:
Large herbivorous mammal “lagomorph” at early stages
Small herbivorous mammal "vole" at BBCH ≥ 40

Applications to maize:
Small herbivorous mammal "vole" at BBCH 30-39

Refined acute risk assessment for BAS 500 06 F

The refined dietary reproductive risk assessment for mammals is based on the following refinement points:

Refinement point 1: Residue decline of pyraclostrobin in plants for refinement of MAF_{90}

Refinement point 2: Identification of representative mammal species including ecological data (PD values and FIR)

Refinement point 1: Residue decline of pyraclostrobin in plants for refinement of MAF_{90}

Dissipation times of residues

Based on the evaluation and statistical analysis of the submitted monocot (wheat) and dicot (peas) data (BASF DocIDs 2013/1045207, and 2013/1044539), the calculated geomeans were DT_{50} = 1.83 days for the Northern residue zone and DT_{50} = 3.03 days for the Southern zone. Following a worst-case approach for this EU-wide evaluation, the highest of these two values (DT_{50} = 3.03 days) is used for the refinement of the risk assessments of the mammal scenarios. Therefore, the higher tier calculation and the resulting TER value of the large herbivorous mammal "lagomorph" scenario in cereals changed slightly and was also updated. The study details were already introduced in the refined reproductive risk assessment of the active substance. The summaries of the dissipation calculations as well as of the field residue trials are found at the beginning of M-CA 8.1.

The refined MAF_{90} value together with the respective DT_{50} value is presented in Table 10.1.2.2-15.

Table 10.1.2.2-15: Refined multiple application factor (MAF_{90}) for green plant matter based on residue decline data for pyraclostrobin in wheat (monocot.) and pea (dicot.) plants

Plant matrix from field trials	Relevant food item according to EFSA/2009/1438	Interval	No. of applications	Geomean DT_{50} [days]	MAF_{90} [2)]	f_{twa}
Cereal scenario						
Wheat + peas	Green plant material (grasses, cereal shoots)	21	2	3.03 [1)]	1.00	1 [3)]

1) See refinement point 1 for acute risk assessment

2) Relevant Multiple application factor (MAF) for use in acute exposure calculations according to EFSA/2009/1438 is the MAF_{90}

3) Please note, in the acute scenario the time-weighted average factor (f_{twa}) is set to 1 according to EFSA/2009/1438.

Refinement point 2: Identification of representative mammal species including ecological data (PD values and FIR)

For the large herbivorous mammals "lagomorph" scenario the hare (*Lepus europaeus*) is the relevant species for cereals at early growth stages. Please refer to the detailed discussion for the selection of this focal species and relevant ecological data under refinement point 3 for the refined reproductive risk assessment of the active substance.

For the small herbivorous mammals "vole" scenario the common vole (*Microtus arvalis*) is the relevant species for cereals and maize. Please refer to the detailed discussion of the relevant ecological data for the common vole under refinement point 3 for the refined reproductive risk assessment of the active substance.

Refined acute risk assessment for large herbivorous mammal "lagomorph" scenario in cereals

The refined acute risk assessments for large herbivorous mammal scenarios are shown in Table 10.1.2.2-16 for the hare.

Table 10.1.2.2-16: Hare: Refined acute risk assessment for the formulation for applications in cereals

Food type[1)]	FIR/ b.w.	$PD_{i,\ fresh}$	PT	RUD [mg a.s./kg]	MAF_{90}	f_{twa}	DF	Use rate [kg a.s./ha]	DDD [mg a.s./kg b.w./d]
Grass/cereal shoots	0.319[1)]	1.0[1)]	1	102.3[1)]	1.00[2)]	1[3)]	1	1.3	42.37
Toxicity endpoint[mg a.s./kg b.w./d]									500
TER_A									11.80

1) According to EFSA/2009/1438
2) Multiple application factor (MAF_{90}) recalculated based on pyraclostrobin-specific DT_{50} = 3.03 days and an application interval of 21 days for two applications. See refinement point 1 for acute risk assessment for details.
3) Please note, the time-weighted average factor (f_{twa}) is set to 1 in the acute scenario according to EFSA/2009/1438.

In conclusion, the refined TER_A values for BAS 500 06 F exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low and acceptable acute risk for lagomorph mammals from the use of BAS 500 06 F in cereals.

Refined acute risk assessment for small herbivorous mammal "vole" scenarios in cereals and maize

The refined acute risk assessments for the formulation BAS 500 06 F for the small herbivorous mammal scenario “vole” is shown in Table 10.1.2.2-17 for cereals and in Table 10.1.2.2-18 for maize.

Table 10.1.2.2-17: Cereals: Refined acute risk assessment for the formulation for the small herbivorous mammal scenario at BBCH ≥40

1) According to EFSA/2009/1438
2) Please note, the time-weighted average factor (f_{twa}) is set to 1 in the acute scenario according to EFSA/2009/1438.
3) DF = 0.5 for BBCH 30-39 in maize according to Guidance for FOCUS Groundwater Scenarios

In conclusion, the refined TER_A value for BAS 500 06 F for the small herbivorous "vole" scenario in cereals exceeds the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low and acceptable acute risk for voles from the use of BAS 500 06 F in cereals. The refined TER_A value for BAS 500 06 F for the small herbivorous "vole" scenario in maize do not exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. Further higher tier assessment is necessary and will be presented below.

Further higher tier acute risk assessment for small herbivorous mammals in ~~cereals and~~ maize:

To address the potential acute risk and to further support the risk assessments from exposure of wild mammals to the formulation beyond standard risk assessments, the following additional lines of evidence are presented:

i) A full rationale evaluating the acute risk of the formulation to wild mammals under realistic exposure conditions, taking into account data from acute dietary toxicity testing with BAS 500 06 F in rat and wood mouse

ii) A body burden model assessing the acute dietary risk posed by formulated pyraclostrobin (BAS 500 06 F) to the common vole

iii) A field effect study on the acute and long-term effects of BAS 500 06 F on populations of small mammals

iv) A field effect study on the acute and long-term effects of BAS 500 06 F on populations of common voles

The low acute risk of the formulation BAS 500 06 F to small mammals is supported by a detailed rationale evaluating the acute dietary risk of the formulation to wild mammals under realistic exposure conditions, taking into account additional data from dietary toxicity testing with BAS 500 06 F in rat and wood mouse (see BASF DocID 2014/1010735; for summaries of the studies BASF DocIDs 2011/1146588 and 2012/1129348 please refer to M-CA 8.1). In brief, both an exploratory non-GLP laboratory rat study (BASF DocID 2011/1146588) and a GLP laboratory wood mouse study (BASF DocID 2012/1129348) investigated the acute dietary toxicity of the formulated product BAS 500 06 F to mammals under more realistic exposure conditions. To better simulate realistic worst-case field conditions, the study protocols included a restricted daily diet regime ensuring high feeding rates of the test animals and testing of field relevant concentrations of pyraclostrobin. That is, tested concentrations cover the maximum dietary concentrations of pyraclostrobin potentially found in feed items of wild mammals in cereals and maize fields, including also an additional safety factor of 10 and beyond to account for interspecies variation.

The study set-up consequently well covers a possible situation in the field where wild mammals are starved and under pressure to eat quickly, and the results hence are of direct relevance for an estimation of the acute dietary risk under more realistic field conditions. The studies show no apparent significant adverse effects either clinical or behavioral from dietary exposure to environmentally relevant concentrations of BAS 500 06 F. No treatment-related mortalities, symptoms of poisoning, or abnormal behavior were observed in any test group. Further, the results of the studies clearly indicated avoidance of the treated food by the test animals. The observed reduction in food consumption prevented the test animals to ingest lethal doses, possibly using food avoidance as a mechanism to reduce exposure and hence reducing risk. A direct comparison of the toxicity of formulated pyraclostrobin administered via acute oral gavage and via the dietary route further shows no mortality in the dietary studies at dose levels that caused mortality in the acute gavage tests, clearly indicating a lower toxicity of formulated pyraclostrobin when taken up over the diet in comparison to single oral gavage exposure.

A **body burden model** is a mechanistic model that describes the internal content of a chemical in the body over time based on the knowledge about the toxicokinetic properties of that chemical and the foraging behavior of the species of interest. Body-burden models are proposed in EFSA/2009/1438 as potential refinement step for risk assessments at higher tier. Here, a body burden model is presented for the common vole as a representative species of the guild of small herbivorous mammals and the active substance pyraclostrobin applied as a formulated product BAS 500 06 F in arable crops (e.g. cereals or maize) to support in a weight of evidence the low acute risk posed by the intended use of BAS 500 06 F to small mammals. Detailed results are given in the full model report (BASF DocID 2014/1001603). For an executive summary please refer to M-CA 8.1.

In brief, the results of the modeling show that the selected toxicological threshold was not exceeded by any individual in any of the 2000 model runs. For a conservative estimate, the applied toxicological threshold was derived from the acute oral rat laboratory study with the product BAS 500 06 F (BASF DocID 2007/1053390) by dividing the respective LD50 by a safety factor of 10. The latter safety factor was applied in order to cover the uncertainty associated with the interspecies extrapolation. This result suggests that the common voles feeding on grass and cereal shoots in a cereal field during 48 hours after treatment with 1.25 L/ha of BAS 500 06 F (corresponding to the rate of 250 g pyraclostrobin per ha) are highly unlikely to experience acute effects. Due to the high level of realism implemented in the foraging submodel, as well as the direct incorporation of uncertainties about input model parameters into the calculations, the presented risk estimate can be characterized as robust.

Finally, it should also be noted that the low acute risk of the formulation BAS 500 06 F to small mammals is supported by the **two available field-effect studies** (BASF DocID 2014/1000041 and BASF DocID 2015/1126803), which did not show any adverse acute or chronic effects of BAS 500 06 F on free-living wood mouse and common vole populations (for more details see the part ‘refined reproductive risk assessment’ above, and the full summaries in M-CA 8.1).

In conclusion, the low acute risk from the formulation to wild mammals, as predicted from the body burden modelling approach and also indicated from laboratory studies under realistic exposure conditions, are confirmed by results from two long-term field-effect studies, in which no adverse effects on wood mice and common voles occurred. Therefore, considering the outcome of these three independent lines of evidence, it is reasonably concluded that the intended uses of BAS 500 06 F in cereals and maize do not pose any unacceptable acute risk to small mammals.

Effects of secondary poisoning

The log P_{ow} of the active substance pyraclostrobin was determined to be 3.99 (SANCO/1420/2001-final) which triggers an assessment for the potential risk through secondary poisoning according to EFSA/2009/1438.

Risk assessment for earthworm-eating mammals

The risk assessment for earthworm-eating mammals will be based on the worst-case PEC_{soil} (twa, 21 days) derived from M-CP 9.1. The calculations and the resulting TER_{LT} values are summarized in Table 10.1.2.2-19.

Table 10.1.2.2-19: Risk assessment for pyraclostrobin concerning earthworm-eating mammals – dry soil approach

Parameter	Pyraclostrobin	Reference
PEC_{soil} (twa, 21 days)[1] [mg/kg soil]	0.201	M-CP 9.1
K_{ow}	9772	SANCO/1420/2001-final
K_{oc} (arithmetic mean)	9304	SANCO/1420/2001-final
f_{oc} (default)	0.02	EFSA/2009/1438
BCF[2]	0.635	--
PEC_{worm} [mg/kg][3]	0.128	--
Daily dose [mg/kg b.w./d][4]	0.163	EFSA/2009/1438
NO(A)EL [mg/kg b.w./d]	3	Table 10.1.2-1
TER_{LT}[5]	18.37	--

1) The PEC_{soil} (twa, 21 days) value calculated for applications of BAS 500 06 F in cereals was the highest PEC_{soil} (twa, 21 days) for all crop scenarios. For details see M-CP 9.1
2) Bioconcentration factor (BCF) = $(0.84 + 0.012 \times K_{ow}) / f_{oc} \times K_{oc}$
3) $PEC_{worm} = PEC_{soil} \times BCF$
4) Daily dose = $1.28 \times PEC_{worm}$
5) TER_{LT} = NO(A)EL / Daily dose.

The risk assessment for fish-eating mammals will be based on the worst-case PEC_{sw} (twa, 21 days) derived from M-CP 9.2. The calculations and the resulting TER_{LT} values are summarized in Table 10.1.2.2-20.

Table 10.1.2.2-20: Risk assessment for pyraclostrobin concerning fish-eating mammals (tier 1)

Parameter	Pyraclostrobin	Reference
$PEC_{sw,}$ (twa, 21 days) [mg/L][1)]	$1.552 * 10^{-3}$	M-CP 9.2
BCF fish (max. worst case)	736	SANCO/1420/2001-final
PEC_{fish} [mg/kg][2)]	1.142	--
Daily dose [mg/kg b.w./d][3)]	0.162	EFSA/2009/1438
NO(A)EL [mg/kg b.w./d]	3.0	Table 10.1.2-1
TER_{LT}[4)]	18.50	--

1) Highest PEC_{sw} (twa, 21 days) from FOCUS Step 2 (South Europe) calculation for a multiple application scenario of BAS 500 06 F in cereals with parameters from dark water/sediment study as worst-case. For details see M-CP 9.2.
2) $PEC_{fish} = PEC_{sw}$ x BCF
3) Daily dose = 0.142 x PEC_{fish}
4) TER_{LT} = NO(A)EL / Daily dose

In the above risk assessments for earthworm- and fish-eating mammals, the TER values exceed the trigger of 5 set by Commission regulation (EU) 546/2011 for acceptability of effects. It can therefore be concluded that the application of BAS 500 06 F in cereal and maize does not provide reason for concern regarding a potential accumulation of the active substance pyraclostrobin in the food chain or for concern of secondary poisoning.

Biomagnification in terrestrial food chains

No evidence was found for potential of accumulation of pyraclostrobin in animal tissue (Review report for the active substance pyraclostrobin. Appendix II, endpoints and related information. September, 2004).

Based on this it can be concluded that the potential for bioaccumulation in animal tissue for pyraclostrobin is low and thus no further assessment on biomagnification is required.

Risk for mammals through drinking water

EFSA/2009/1438 proposes an approach for assessing the risk to mammals from active substances in drinking water using small granivorous mammals as indicator species in tier 1. Out of the two scenarios, i.e. the leaf and the puddle scenario, the leaf scenario is not relevant for small mammals. Consequently, only the risk from the 'puddle scenario' will be considered.

According to EFSA/2009/1438 no specific calculations of exposure and TER values are necessary when the ratio of effective application rate (in g/ha) to relevant endpoint (in mg/kg b.w./d) does not exceed 50 in the case of less sorptive substances (Koc < 500 L/kg) or 3000 in the case of more sorptive substances (Koc ≥ 500 L/kg). The ratio calculations for effective application rate to relevant endpoint are detailed in a screening step in Table 10.1.2.2-21. The ratio for acute and reproductive endpoints for pyraclostrobin (<0.1 and 120.8, respectively) do not exceed the threshold value of 3000 as given by EFSA/2009/1438 for more sorptive substances (Koc > 500 L/kg), thus no specific calculations of exposure for mammals through drinking water for the puddle scenario are necessary.

In conclusion, the risk through drinking water from the use of BAS 500 06 F in cereals and maize is acceptable.

Table 10.1.2.2-21: Screening step for drinking water risk assessment - ratio of effective application rate to relevant endpoint for mammals

Parameter	Pyraclostrobin	Reference
K_{oc} [L/kg]	9304	SANCO/1420/2001-final
DT_{50} (soil) [d]	18	M-CP 9.2
Number of applications	2	Table 10.1.2-5
Interval [d]	21	Table 10.1.2-5
MAF_{mean} [1)]	1.45	--
Max use rate [g/ha]	250 [6)]	Table 10.1.2-5
AR_{eff} [g/ha] [2)]	362.5	--
LD_{50} [mg/kg b.w.]	> 5 000	Table 10.1.2-1
Ratio (acute) [3)]	<0.1	--
Reproductive endpoint [mg/kg b.w./d]	3	Table 10.1.2-1
Ratio (repro) [3)]	120.8	--
Trigger [4)]	3 000	--
Drinking water assessment required [Yes/No] [5)]	No	--

1) $MAF_{mean} = (1-e^{-nki}) / (1-e^{-ki})$ with $k = ln(2)/DT_{50}$ (rate constant), n = number of applications and i = application interval [d]. Worst-case from application scenario in cereals
2) AR_{eff} = Application rate (g/ha) x MAF_{mean}
3) Ratio of AR_{eff} and relevant toxicity endpoint
4) Trigger according to EFSA/2009/1438
5) Drinking water risk assessment is not necessary when trigger value is not exceeded.
6) Highest application rate for use in cereals

Appendix to chapter M-CP 10.1.2.2

Appendix 1: Diet composition (PD) of the wood mouse (*Apodemus sylvaticus*)

The formulation BAS 500 06 F is intended for use in cereals between growth stages BBCH 25 to 69 corresponding to the calendar months April to June. For the refined risk assessment, the diet composition of the wood mouse typical for this time period is considered.

Data are available from a study on wood mouse ecology on arable farmland in the UK (Green 1979) detailing the diet composition of 15 wood mice (determined by stomach content analysis) caught on winter wheat fields between April and June (Table 10.1.2.2-22 to Table 10.1.2.2-24). It is noteworthy that seeds of *Poa annua* and *Stellaria media* formed the bulk of the diet in the wood mouse stomachs examined for the time period April to June.

Further information can be derived from a comprehensive multi-annual study conducted on farmland in Germany (Pelz 1989) (Table 10.1.2.2-22 to Table 10.1.2.2-24). The diet composition of wood mice in the study area, consisting mainly of sugar beet, winter wheat and winter barley fields, over a time period of several years was evaluated by stomach content analysis (n = 136 for the time period April to June). The results were estimated from Figure 3.3 in Pelz (1989) for the purpose of this refined risk assessment.

Compared to other authors who also examined the diet composition of the wood mouse (Watts 1968, Rogers & Gorman 1995 and Gorman & Zubaid 1993), the data published by Green (1979) and Pelz (1989) are considered to be most appropriate due to the clear relation of the diet composition to arable land or even cereal fields.

Mean values for the proportion of a certain food type in the overall diet were calculated on a monthly basis, thus weighing both relevant studies equally. Individual analysis of the studies with subsequent averaging would have therefore yielded identical results. The percentage of **green plant matter** recorded in the diet of wood mice is shown in Table 10.1.2.2-22.

Table 10.1.2.2-22: Percentage of green plant matter in the diet of the wood mouse

Month	Habitat	Feed item	% of diet	Reference
April	Arable farms Rhineland, Germany	Vegetative plant tissue	24	Pelz 1989
May			16	
June			9	
April - June	Winter wheat Suffolk, UK	Leaf and other plant tissue	1	Green 1979
April - June	Ploughed land, previously cereal Suffolk, UK		No data	
Mean proportion of green plant matter for April – June, corresponding to BBCH growth stages 25-69 in cereals[1)]			**8.7**	Pelz 1989 Green 1979

1) From existing mean values for a period of months (e.g. April - June), values for individual months were derived by employing the mean value of the period for each single month.

The percentage of **weed seeds** recorded in the diet of wood mice is shown in Table 10.1.2.2-23.

Table 10.1.2.2-23: Percentage of weed seeds in the diet of the wood mouse

Month	Habitat	Feed item	% of diet	Reference
April	Arable land	Dicot. seeds	0	Pelz 1989
May			4	
June			25	
April - June	Winter wheat	Seeds other than cereals	80	Green 1979
April - June	Ploughed land, previously cereal	Seeds other than cereals	No data	
April - June	Ploughed land, previously sugar beet	Seeds other than cereals	No data	
Mean proportion of weed seeds for April – June, corresponding to BBCH growth stages 25-69 in cereals[1)]			**44.8**	Pelz 1989 Green 1979

1) From existing mean values for a period of months (e.g. April - June), values for individual months were derived by employing the mean value of the period for each single month.

The percentage of **arthropods and earthworms** recorded in the diet of wood mice is shown in Table 10.1.2.2-24.

Table 10.1.2.2-24: Percentage of arthropods and earthworms in the diet of the wood mouse

Month	Habitat	Feed item	% of diet	Reference
April	Arable farms Rhineland, Germany	Insects	45	Pelz 1989
May			10	
June			25	
April	Arable farms Rhineland, Germany	Earthworms	26	Pelz 1989
May			40	
June			9	
April - June	Winter wheat Suffolk, UK	Arthropods	12	Green 1979
April - June	Ploughed land, previously cereal Suffolk, UK		No data	
April - June	Ploughed land, previously sugar beet UK		No data	
April - June	Winter wheat Suffolk, UK	Earthworms	0	
April - June	Ploughed land, previously cereal Suffolk, UK		No data	
April - June	Ploughed land, previously sugar beet UK		No data	
Arable crops mean (insects) for April - June, corresponding to BBCH growth stages 25-69 in cereals [1)]			**15.3**	Pelz 1989 Green 1979
Arable crops mean (earthworms) for April - June, corresponding to BBCH growth stages 25-69 in cereals[1)]			**12.5**	

1) From existing mean values for a period of months (e.g. April - June), values for individual months were derived by employing the mean value of the period for each single month.

The potential exposure of wood mice to the active substance is estimated by employing the mean consumption values for green plant matter, weed seeds, arthropods and earthworms as given in Table 10.1.2.2-22 to Table 10.1.2.2-24. Thus, for the refined exposure assessment the proportions of the different feed items in the diet (PD) would be as follows:

Green plant matter	PD = 0.087	
Weed seeds	PD = 0.448	
Arthropods	PD = 0.153	
Earthworms	PD = 0.125	Sum of individual PD values = 0.813

Individual PD values for food items should sum up to 1 when all possible food types are taken into account. Since food items obviously not being found in cereal fields at BBCH 25 - 69, e.g. cereal grain, were excluded from the above evaluation, the individual PD values needed to be normalised via multiplication with a factor of 1.23 (1.23 = 1 / 0.813). Thus, the proportions of the different feed items in the diet (PD) to be finally used in the refined exposure assessment are as follows:

Green plant matter	**PD = 0.107**	
Weed seeds	**PD = 0.551**	
Arthropods	**PD = 0.187**	
Earthworms	**PD = 0.154**	Sum of individual PD values = 1.0

CP 10.1.3 Effects on other terrestrial vertebrate wildlife (reptiles and amphibians)

In a literature review a few references on amphibian studies with pyraclostrobin, respectively pyraclostrobin-containing formulations were identified. Summaries of these publications are provided in M-CA.8.1.4. Please refer to this part of the dossier for details. There are no specific investigations or findings indicating impacts on reptiles.

The following amphibian studies with the European common frog (*Rana temporaria)* and the Common toad (*Bufo bufo*) had been conducted due to the new data requirements to address potential adverse effects on amphibians as indicated in publications. These reports have not been evaluated previously on EU level.

Report: CP 10.1.3/1
[redacted] 2014a
Effects of BAS 500 06 F to juvenile Rana temporaria under worst case laboratory conditions
2013/1375098
Guidelines: none
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The effect of BAS 500 06 F on survival of juvenile European common frog (*Rana temporaria)* was investigated over a period of 7 days under worst-case laboratory conditions. The animals were exposed to BAS 500 06 F on a bare soil surface *via* direct overspray at nominal rates of 197.6, 312.5 and 494.1 mL product/ha corresponding to 39.5, 62.5 and 98.8 g a.s./ha (equivalent to 15.8%, 25% and 39.5% of the maximum label rate of BAS 500 06 F) in 10 replicates per treatment containing one metamorph each. In addition, a water control and a blank formulation control was set up. An “up-and-down” testing approach was applied to minimize the use of animals. Animals were maintained on the soil and observed for mortality and sub-lethal effects approx. 1, 2 and 4 hours after application and twice per day from 1 day after treatment (DAT) to DAT 6 and at test termination on DAT 7. Body weight and body length of test organisms were assessed at the start and the end of experiment.

Several individual metamorphs managed to escape from the test containers. Escape was not related to treatment and did not influence the results. No mortalities, abnormal behavior or other sub-lethal effects occurred in the control groups and in the treatment group of 197.6 mL BAS 500 06 F/ha.
In the treatment group of 312.5 mL BAS 500 06 F/ha some transient sub-lethal effects, but no mortalities occurred. Sub-lethal effects were observed shortly after treatment and subsequent recovery of animals occurred within 24 h. No further impact of the test substance was observed afterwards.

In the treatment group of 494.1 mL BAS 500 06 F/ha 70% mortality occurred within one day after treatment. Two further animals were sub-lethally affected; however, both animals had recovered at the first observation on DAT 1 and DAT 2, respectively. Body weight and body length development was not influenced by the test item in all treatments.

The LR_{50} (7 d) in a worst-case laboratory study on *Rana temporaria* was determined to be 470 mL BAS 500 06 F/ha (94 g pyraclostrobin/ha). The LR_0 (7 d) was determined to be 313 mL BAS 500 06 F/ha (63 g a.s./ha).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 0005018890, EC formulated product, content of a.s.: pyraclostrobin: 203.8 g/L (nominal: 200 g/L); density: 1.037 g/cm³.

B. STUDY DESIGN

Test species: European common frog (*Rana temporaria*) metamorphs approx. 2 - 4 weeks old (age after metamorphosis), obtained from in-house culture (non-GLP); mean body weights: 0.35 - 0.48 g; mean body lengths: 16 - 17 mm; egg clutches were collected from a pond in Kaltenbrunnertal, Germany.

Test design: The test organisms were exposed to the test item on a bare soil surface in the laboratory *via* direct overspray using a laboratory sprayer. The test duration was 7 days with a step-wise testing ("up-and-down") procedure of different rates of BAS 500 06 F, plus a water control and a blank formulation control with 10 individuals per treatment (one animal per container): at the first day of treatment (t_0) a water control, a blank formulation control and test item rate of 312.5 mL/ha were tested; at the second day of treatment (t_1) a water control and test item rates of 197.6 and 494.1 mL/ha were tested. To maintain soil moisture during the study, 40 mL of water were added in all test containers on DAT 4 (via injection into a cotton wool underlayment of the soil layer). Mortalities and sub-lethal effects were assessed 1, 2 and 4 hours after application and twice daily from DAT 1 - DAT 6 and once on DAT 7. Body weight and body length of test organisms were measured at the start and end of the experiment.

Endpoints: LR_0, LR_{50}, NOER, mortality, sub-lethal effects (behavior, body length and body weight).

Test rates:	Water control (tap water), blank formulation control (nominal rate of 1250 mL/ha), 197.6, 312.5 and 494.1 mL BAS 500 06 F/ha (P2-t_1), corresponding to 39.5, 62.5 and 98.8 g a.s./ha (*i.e.* 15.8%, 25% and 39.5% of the maximum label rate of BAS 500 06 F (1250 mL/ha)).
Test conditions:	Test containers: Makrolon Type II (22.5 x 16.7 cm x 14 cm; floor area: 375 cm^2), containing a 5 g cotton wool underlayment soaked with 50 mL water and covered by a bare soil layer (LUFA soil 2.3; soil moisture at test start: approx. 60% of the max. water holding capacity); containers were covered with a meshed metal lid for ventilation and to avoid escape of animals; mean temperature: 18.2°C - 21.9°C ; mean relative humidity: 64.1% - 90.7%; mean light intensity: 1282 - 1568 lux, moisture content of the soil: 42% - 70% of maximum water holding capacity; feeding: flightless *Drosophila*, aphids and crickets from DAT 1 to DAT 7 ad libitum.
Analytics:	Analytical verification of test item concentrations in all spray solutions was conducted using an HPLC-method with MS-detection.
Statistics:	Descriptive statistics; Fisher`s exact binomial test with Bonferroni correction (α = 0.05) for determination of NOER; probit analysis using linear maximum likelihood regression for determination of the LR_{50}.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations in the spray solutions. Mean measured concentrations of pyraclostrobin were between 83.4% and 103.9% of nominal confirming the correct application of the intended rates. No (or only negligible amount of) test item was detected in the spray liquid of the controls.

Biological results: A few individual metamorphs managed to escape from the containers. Escape was not related to treatment and did not influence the results. All observed effects and also recovery of animals occurred within the first 24 h and no further impact of the test substance was observed afterwards. For evaluation of the data set, it was assumed that escaped animals were vital / unaffected (only vital animals could manage to climb the vessel walls and squeeze underneath the container lid). No mortalities or sub-lethal effects occurred in the water control, blank formulation control group and in the lowest treatment group of 197.6 mL BAS 500 06 F/ha.
In the treatment group of 312.5 mL BAS 500 06 F/ha no mortalities occurred. Transient sub-lethal effects were observed within the first 4 hours after application. Affected animals were lethargic and in two cases lying immobile on the soil surface. All affected animals had completely recovered on DAT 1 showing no visual damage, abnormal behavior or impact on biomass development until the end of the exposure phase.
In the treatment group of 494.1 mL BAS 500 06 F/ha, 70% mortality occurred within one day after treatment. Two further animals were transiently sub-lethally affected (*i.e.* lethargy, animals lying flat / immobile on the soil). Both animals had completely recovered at the first observation on DAT 1 and DAT 2, respectively.

Body weight and body length development was not influenced by the test item in all treatments after seven days. The results are summarized in Table 10.1.3-1.

Table 10.1.3-1: Effects of BAS 500 06 F on European common frog (*Rana temporaria*) in a worst-case laboratory trial

Test item rate [mL BAS 500 06 F/ha] (% of max. label rate)	Water control (t_0)	Water control (t_1)	Blank formulation control	197.6 (15.8%)	312.5 (25.0%)	494.1 (39.5%)
Test item rate [g a.s./ha]	--	--	--	39.5	62.5	98.8
Mortality [%] (7 d) [1)]	0	0	0	0	0	70 [4)] *
Mean weight gain [2)] (over 7 d) [g]	0.06	0.00	0.07	0.00	0.06	0.09
Mean length gain [2)] (over 7 d) [mm]	2	0	1	1	1	1
Sub-lethal effects [3)]	none	none	none	none	L, G, I, SL [#], *	P, L, G, I, SL [##], *

Endpoints		
	[mL BAS 500 06 F/ha]	[g a.s./ha]
LR_{50} (7 d) [5)]	470	94
LR_0 (7 d)	313	63
$NOER_{overall}$ (7 d)	198	40

1) Statistical evaluation was done for results after 7 days, assuming survival of the escaped test organisms.
2) Escaped and dead animals were excluded for calculation of mean values.
3) Sublethal effects: G = animal lying flat on the ground; L = lethargy; I = animal immobile on the ground; P = animal in a slightly ducked position; SL = slight lethargy.
4) All of the seven animals died on DAT 1.
5) 95% confidence limits could not be calculated.
* Statistically significant difference compared to the control (Fisher`s Exact Binomial Test with Bonferroni Correction, $\alpha = 0.05$).
\# Sub-lethal effects were only observed on DAT 0.
\## Sub-lethal effects were only observed on DAT 0 and DAT 1.

III. CONCLUSION

The LR_{50} (7 d) in a worst-case laboratory study on *Rana temporaria* was determined to be 470 mL BAS 500 06 F/ha (94 g pyraclostrobin/ha). The LR_0 (7 d) was determined to be 313 mL BAS 500 06 F/ha (63 g a.s./ha).

Report:	CP 10.1.3/2 [redacted] 2015 a Effects of residues of BAS 500 06 F on soil to juvenile *Bufo bufo* under laboratory conditions 2014/1221859
Guidelines:	<none>
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The effects of soil residues of BAS 500 06 F on survival of juvenile common toad (*Bufo bufo*) were investigated over 7 days under laboratory conditions in 10 replicates per treatment group containing one toad each. The test units (containers with a bare soil layer) were sprayed at nominal rates of 625, 884 and 1250 mL BAS 500 06 F/ha, equivalent to 50%, 70.7% and 100% of the max. label rate. Measured application rates were 775, 1096 and 1550 mL BAS 500 06 F (mean recovery 124% of nominal) corresponding to 155, 219 and 310 g pyraclostrobin/ha. A water control was tested in parallel.
The toads were introduced into the test units immediately after drying of the spray film (approx. 15 min after spraying) and at 1550 mL/ha in addition 1 and 4 hours after application. Mortalities and sub-lethal effects were assessed 1, 2 and 4 hours after introduction of animals, one day after treatment (DAT 1) and daily from DAT 2 - DAT 7. Body weight was measured at test initiation and termination.

The biological results are based on measured application rates. No mortalities or sub-lethal effects occurred in the control groups and at 775 mL BAS 500 06 F/ha. No mortality occurred at 1096 mL BAS 500 06 F/ha, however, transient sub-lethal effects (slight lethargy and immobility) were observed in two toads on DAT 0 with recovery within one day.
At the treatment rate of 1550 mL BAS 500 06 F/ha and exposure of animals shortly after application, 6 toads showed sub-lethal effects on DAT 0, four of them recovered until DAT 1, two died. Two of the toads introduced 1 h after application died at 1550 mL/ha. No treatment related mortality or sub-lethal effects occurred at 1550 mL/ha with animals introduced 4 hours after application. Body weight development was not influenced by the test item.

The LR_{50} (7 d) was determined to be > 1550 mL BAS 500 06 F/ha (> 310 g pyraclostrobin/ha) based on measured application rates for test organisms introduced shortly after as well as 4 hours after application.

The NOEL (7 d) was 775 mL BAS 500 06 F/ha (155 g pyraclostrobin/ha) for test organisms introduced shortly after application and ≥ 1550 mL BAS 500 06 F/ha (> 310 g pyraclostrobin/ha) for test organisms introduced 4 hours after application.

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 500 06 F, batch no. 0005018890, content of a.s.: pyraclostrobin: 203.8 g/L (nominal: 200 g/L); density: 1.037 g/cm³

B. STUDY DESIGN

Test species:	Common toad (*Bufo bufo*), metamorphs approx. 3 - 5 weeks old (age after metamorphosis), obtained from in-house culture (non-GLP), body weights: 0.77 - 0.93 g, body lengths: 21 - 23 mm, strings of eggs were collected from two ponds in Kaltenbrunnertal and Gommersheim, Germany.
Test design:	The test container with a bare soil layer were sprayed with the test item in a step-wise (up-to-down) approach to minimize the use of animals. At all test rates, one group of animals was introduced into the test containers 15 min after application. In the 1250 mL BAS 500 06 F/ha treatment two additional groups of animals were introduced 1 and 4 hours after application to take into account a more thorough desiccation of the test item. The test duration was 7 days with different rates of BAS 500 06 F, plus a water control with 10 individuals per treatment (one animal per container). The test trials started on two different days (t_0 and t_1). To maintain soil moisture during the study, 40 mL of water were added in all test containers on DAT 3 and DAT 5 via injection into a cotton wool underlayment of the soil layer. Mortalities and sub-lethal effects were assessed 1, 2 and 4 hours after introduction of animals. Observations were done twice on DAT 1 and daily from DAT 2 - DAT 7. Body weight and body length (snout to vent) of test organisms were measured at the start and end of the experiment.
Endpoints:	LR_{50}, NOEL, mortality, sub-lethal effects (behavior, body length and body weight)
Test rates:	Water control (tap water) as well as 625, 884 and 1250 mL BAS 500 06 F/ha, equivalent to 50%, 70.7% and 100% of the maximum label rate; based on measured concentrations actual rates of 775, 1096 and 1550 mL BAS 500 06 F were applied (mean recovery 124% of nominal) corresponding to 155, 219 and 310 g pyraclostrobin/ha, respectively.

Test conditions:	Test containers: Makrolon Type II (22.5 cm x 16.7 cm x 14 cm; floor area: 375 cm^2), containing a 5 g cotton wool underlayment soaked with 50 mL water and covered with a standard filter paper before introduction of the bare soil layer (LUFA soil 2.3; soil moisture at test start: approx. 45% of the max. water holding capacity); containers were covered with a meshed metal lid for ventilation and to avoid escape of animals; temperature: 18.8°C - 24.3°C; relative humidity: 57.0% - 79.0%;; light intensity: 3.0 - 5.9 klux; light-dark cycle of 16:8 h; moisture content of soil: 35 - 62% of maximum water holding capacity; feeding: flightless *Drosophila* from DAT 1 to DAT 6 ad libitum.
Analytics:	Analytical verification of test item concentrations was conducted in all spray solutions using an HPLC-method with MS-detection. The actual applied amount of test item was measured taking samples during spraying.
Statistics:	Descriptive statistics; Fisher`s exact binomial test with Bonferroni correction ($\alpha = 0.05$) for determination of NOEL; one-way ANOVA for statistical evaluation of body weight data

II. RESULTS AND DISCUSSION

Analytical measurements: Spray solution samples for analytical verification of test item concentrations were taken on each day of treatment. Mean recovery values were between 101 - 105% of nominal. Mean measured concentrations of the applied amount of pyraclostrobin (samples taken during spraying) were between 121 and 125% of nominal. The biological results are based on measured application rates.

Biological results: No mortalities, abnormal behavior or other sub-lethal effects occurred in the control groups and in the 775 mL BAS 500 06 F/ha treatment. After 7 days of exposure 0% mortality occurred in the 1096 mL BAS 500 06 F/ha treatment. Transient sub-lethal effects (slight lethargy and immobility) were observed in two toads at the treatment rate of 1096 mL BAS 500 06 F/ha on DAT 0. On the next day both animals were appearing normal. At 1550 mL BAS 500 06 F/ha and exposure of animals 15 min after application, 6 toads showed sub-lethal effects on DAT 0, four of them recovered until DAT 1, two died. If toads were exposed to 1550 mL BAS 500 06 F/ha 60 min after application, sub-lethal effects were observed at 4 individuals on DAT 0, whereas 2 animals recovered on the next day, the other two died. No treatment related mortality and no sub-lethal effects occurred in the 1550 mL/ha treatment group with animals introduced 4 hours after application. Two mortalities occurred, which are not considered treatment related. One animal was observed to be in a poor condition, lying on the ground with reduced reaction to stimulus on DAT 4 and the animal was found dead on DAT 5. One further animal died due to accidental desiccation of the soil.
Body weight development was not influenced by the test item. The biological results are summarized in the table below.

Table 10.1.3-2: Effects of residues of BAS 500 06 F on common toad (*Bufo bufo*) introduced on pre-sprayed bare soil in a laboratory study

NOEL (7 d)	4 h	≥ 1550	≥ 310

[#] Time of treatment of the step-wise testing approach (t_0 = first day of treatment; t_1 = second day of treatment)
[1)] Mortality considered not to be test item related.
[2)] Dead animals were excluded for calculation of mean values.
[3)] Sub-lethal effects: I = animal immobile on the ground; L = lethargy
[4)] Sub-lethal effects were observed on DAT 0.
[5)] Sub-lethal effects were observed on DAT 0 and DAT 1.

III. CONCLUSION

The LR_{50} (7 d) was determined to be > 1550 mL BAS 500 06 F/ha (> 310 g pyraclostrobin/ha) based on measured application rates for test organisms introduced shortly after as well as 4 hours after application.

The NOEL (7 d) was 775 mL BAS 500 06 F/ha (155 g pyraclostrobin/ha) for test organisms introduced shortly after application and ≥ 1550 mL BAS 500 06 F/ha (> 310 g pyraclostrobin/ha) for test organisms introduced 4 hours after application.

Report: CP 10.1.3/3
[redacted] 2014b
Effects of BAS 500 06 F to juvenile Rana temporaria in winter wheat (semi-field trial)
2013/1375099
Guidelines: none
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The effect of BAS 500 06 F on survival of juvenile European common frog (*Rana temporaria)* was investigated over a period of 7 days under realistic conditions in a semi-field trial. The animals were exposed in fenced enclosures in a winter cereal field at growth stage BBCH 25 for 7 days. BAS 500 06 F was applied *via* spray application at nominal rates of 0 (water control), 937.5, 1250.0 and 1562.5 mL product/ha corresponding to 187.5, 250.0 and 312.5 g a.s./ha (equivalent to 75, 100 and 125% of the maximum label rate of BAS 500 06 F). For each test item rate and the water control, 4 replicates with 4 individuals per replicate were used. Animals were observed for mortality and sublethal effects 2 and 4 hours after application, 1 day after treatment (DAT) and on DAT 2, DAT 5 and DAT 7. Body weight and body length of test organisms were assessed at the start (DAT -1) and the end of the experiment (DAT 7).

No mortalities occurred in the control and in all test item treatment groups. No abnormal behavior or sub-lethal effects were observed in the control replicates and the BAS 500 06 F treatment rates of 937.5 mL/ha (75% field rate) and 1250.0 mL/ha (max. field rate). In the treatment group of 1562.5 mL BAS 500 06 F/ha (125% field rate) a single animal was observed showing uncoordinated movement and lethargy during the observations 2 and 4 hours after application on DAT 0. The animal had recovered on DAT 1 showing no visual damage or abnormal behavior until the end of the exposure phase. No other treatment related impact was observed. Mean body weight and mean length development were not influenced by the test item.

The NOER (7 d) for BAS 500 06 F obtained in the study on *Rana temporaria* under semi-field conditions was determined to be ≥ 1563 mL BAS 500 06 F/ha (≥ 312.5 g a.s./ha; 125% of the max. label rate of BAS 500 06 F).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 0005018890, EC formulated product, content of a.s.: pyraclostrobin: 203.8 g/L (nominal: 200 g/L); density: 1.037 g/cm³.

B. STUDY DESIGN

Test species: European common frog (*Rana temporaria*), juveniles approx. 4 months old (*i.e.* after metamorphosis) at test start, obtained from in-house culture (non-GLP); mean body weights: 2.3 - 2.6 g and mean body lengths: 29 - 30 mm at DAT -1; egg clutches were collected from a pond in Kaltenbrunnertal, Germany.

Test design: The test organisms were exposed in fenced enclosures in a winter cereal field (BBCH 25) at BASF Agrarzentrum Limburgerhof, Germany for 7 days. For each rate of BAS 500 06 F and the water control, 4 replicate enclosures with 4 individuals per replicate were used. The animals were introduced into the enclosures one day prior to spray application. Mortalities and sub-lethal effects were assessed 2 and 4 hours after application and on DAT 1, 2, 5 and DAT 7 (observations were done only visually on DAT 0 and DAT 5, detailed observations by means of short removal of animals from enclosures on DAT 1, DAT 2 and DAT 7). Body weight and body length of test organisms were assessed at the start (DAT -1) and end of the experiment (DAT 7).

Endpoints: NOER, mortality, sub-lethal effects (the behavior, body length and body weight).

Test concentrations: Water control (tap water), 937.5, 1250.0 and 1562.5 mL BAS 500 06 F/ha with a water volume of 200 L/ha; corresponding to 187.5, 250.0 and 312.5 g a.s./ha (*i.e.* 75%, 100% and 125% of the maximum label rate of BAS 500 06 F).

Test conditions: Fenced enclosures: height: 0.5 m above ground, buried into the ground at approx. 0.1 m depth, covered with a fine-meshed lid; study plots: approx. 1.2 m x 0.84 m covering about 6 cereal rows (standard sowing distance between rows of approx. 14 cm); temperature: 5.7 - 23.1°C (mean daily temperature: 11.1 - 16.6°C); precipitation: 8.1 mm on DAT -1, < 1 mm on DAT 0 and DAT 3, 7.9 mm on DAT 4 and 2.9 mm on DAT 7; relative humidity 69.4% and wind speed ≤ 2.5 m/s at time of application; animals were provided with additional feed (*Drosophila* and mealworms) on DAT 2.

Analytics: Analytical verification of test item concentrations in all spray solutions was conducted using an HPLC-method with MS-detection. The applied amount of test item in the field was analytically verified using petri dishes, which were placed at the targeted height of the application and on the ground between the cereal rows.

Statistics: Descriptive statistics; Fisher`s exact binomial test with Bonferroni correction ($\alpha = 0.05$) for determination of the NOER.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations in spray solutions was conducted in all spray solutions. Mean measured concentrations of pyraclostrobin in the spray solutions of the test item treatments were between 104.7% and 105.5% of nominal confirming the correct application of the intended rates. No test item was detected in the spray liquid of the control. In the petri dishes placed on the target height in the field, mean recovery values of 89% - 101% were measured and therewith confirming the intended application rates. In the petri dishes placed on the ground, mean recovery ranged from 24% (based on nominal values) respectively 27% (based on target height recovery values) to 32%, indicating approximately 70% interception by the crop.

Biological results: No mortalities occurred in the control and in all test item treatment groups. No abnormal behavior or sub-lethal effects were observed in the control replicates and the BAS 500 06 F treatment rates of 937.5 mL/ha (75% field rate) and 1250.0 mL/ha (max. field rate). In the treatment group of 1562.5 mL BAS 500 06 F/ha (125% field rate) a single animal was observed showing uncoordinated movement and lethargy during the observations 2 and 4 hours after application on DAT 0. The animal had recovered on DAT 1 showing no visual damage or abnormal behavior until the end of the exposure phase. No other treatment-related impact was observed. Mean body weight and mean length development were not influenced by the test item. The results are summarized in Table 10.1.3-2.

Table 10.1.3-3: Effects of BAS 500 06 F on European common frog (*Rana temporaria*) in a semi-field study

Test item rate [mL BAS 500 06 F/ha] (% of max. label rate)	**Water control**	**937.5 (75%)**	**1250.0 (100%)**	**1562.5 (125%)**
Test item rate [g a.s./ha]	**--**	**187.5**	**250.0**	**312.5**
Mortality [%]	0	0	0	0
Mean weight gain (DAT 7 - DAT -1) [g]	0.3	0.4	0.3	0.3
Sub-lethal effects				U, L [#]
	Endpoint			
	[mL BAS 500 06 F/ha]		**[g a.s./ha]**	
NOER (7 days)	≥ 1562.5		≥ 312.5	

[#] Sublethal effects (U = uncoordinated movements; L = lethargy) were only observed for a single animal during the observations 2 and 4 hours after application on DAT 0; the animal had recovered on DAT 1 showing no visual damage or abnormal behavior until the end of the exposure phase.

III. CONCLUSION

The NOER (7 d) for BAS 500 06 F obtained in the study on *Rana temporaria* under semi-field conditions was determined to be ≥ 1563 mL BAS 500 06 F/ha (≥ 312.5 g a.s./ha; 125% of the max. label rate of BAS 500 06 F).

Report:	CP 10.1.3/4 [redacted] 2016 a Effects of BAS 500 06 F to juvenile *Bufo bufo* in winter wheat (semi-field trial) 2015/1240163
Guidelines:	<none>
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The effect of BAS 500 06 F on survival of juvenile common toad (*Bufo bufo*) was investigated over 7 days in a semi-field trial. The animals were exposed in enclosures in a winter wheat field at growth stage BBCH 30. BAS 500 06 F was sprayed at nominal rates of 0 (water control), 1250, 1875 and 12500 mL BAS 500 06 F/ha, corresponding to 250 (max. label rate), 375 and 2500 g pyraclostrobin/ha (10x label rate), respectively. The control and the two lower treatments consisted of 4 replicates with 4 individuals each. For the 12500 mL/ha treatment one replicate with 4 organisms was used to minimize animal sacrifices. The test organisms were observed for mortality and sub-lethal effects 2 hours after application and on DAT (days after treatment) 1, 3 and 7. Body weight and body length were assessed at the test initiation and termination.

The biological results are based on nominal application rates. No mortalities and no sub-lethal effects occurred in the control and in the treatment groups up to and including 1875 mL BAS 500 06 F/ha. At the highest treatment rate of 12500 mL BAS 500 06 F/ha 50% mortality was observed during the exposure period. One additional animal was sub-lethally affected at the end of the experimental phase and therefore euthanized. Mean body weight development was not affected up to 1875 mL BAS 500 06 F/ha.

The NOEL (7 d) for BAS 500 06 F in the semi-field study on juvenile common toads (*Bufo bufo*) was determined to be 1875 mL/ha, corresponding to 375 g pyraclostrobin/ha (150% of the max. label rate of BAS 500 06 F).

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 500 06 F, batch no. FD-150202-0013, content of a.s.: pyraclostrobin: 200.3 g/L (nominal: 200 g/L); density: 1.033 g/cm³

B. STUDY DESIGN

Test species:	Common toad (*Bufo bufo*), juveniles approx. 3 - 4 months old (*i.e.* after metamorphosis), obtained from in-house culture (non-GLP), body weights: 2.0 - 2.4 g, body lengths: 28 - 30 mm at DAT -1, egg strings were collected from a pond in Kaltenbrunnertal, Germany.
Test design:	The test organisms were exposed in fenced enclosures in a winter wheat field (BBCH 30) located in Limburgerhof, Germany for 7 days. The control and the treatments of 1250 and 1875 mL BAS 500 06 F/ha consisted of 4 replicates with 4 individuals each. For the 12500 mL BAS 500 06 F/ha treatment only one replicate with 4 organisms was used in order to minimize animal sacrifices. Testing was done "step-wise" with application on two different days (t_0 and t_1). The water control group was maintained in parallel to the second treatment and therewith observed for overall 9 days. Toads were introduced into each enclosure one day prior to application. Due to dry weather conditions, plots were watered by hand with an amount corresponding to about 10 mm of rainfall. The test organisms were observed for mortality and sub-lethal effects 2 hours after application and on day after treatment (DAT) 1, 3 and 7. The toads exposed to a treatment rate of 12500 mL BAS 500 06 F/ha were observed additionally on DAT 5. Body weight and body length were assessed at start (DAT -1) and at test termination (DAT 7).
Endpoints:	NOEL based on mortality and sub-lethal effects
Test concentrations:	0 (water control), 1250, 1875 and 12500 mL BAS 500 06 F/ha, corresponding to 250 (max. label rate), 375 and 2500 g a.s./ha, respectively.
Test conditions:	Fenced enclosures: height: 0.5 m above ground, buried into the ground at approx. 0.1 m depth, covered with a fine-meshed lid; study plots: approx. 1.2 m x 0.84 m covering about 6 cereal rows (standard sowing distance between rows of approx. 14 cm); for application a standard sprayer representing commercial application of the test item according to Good Agricultural Practice was used ("Spritzrad"); mean daily temperature: 11.2 - 16.5°C (min.: 4.1°C, max.: 22.7°C); relative humidity 38.7 - 42.4% at time of application, wind speed 0.2 - 3.5 m/s at time of application; animals were provided with additional feed (*Drosophila* and mealworms) on DAT 3.
Analytics:	Analytical verification of test item concentrations was conducted in all spray solutions using an HPLC-method with MS-detection. The applied amount of test item in the field was analytically verified using 'Speedisks' (Octadecyl, C18; CAS no.: 71889-02-6) for sampling, which were placed at the targeted height of the application (i.e. at about plant height) and on the ground underneath the plant canopy.

Statistics: Descriptive statistics; one-way ANOVA for statistical evaluation of body weight data

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical recovery values of the spray solutions were between 99 - 107% of nominal. No test item was detected in the spray liquid of the water control. Mean recovery values of 92 - 150% of nominal were measured in the field on the targeted height roughly confirming the intended application rates. On the ground, individual recovery values ranged from 13 - 43% (based on nominal application rates), indicating high variation of the amount of test item reaching the ground and corresponding to approximately 60 - 90% interception by the crop. The biological results are based on nominal application rates.

Biological results: No mortalities and sub-lethal effects occurred in the control and in the treatment groups up to and including 1875 mL BAS 500 06 F/ha. At the highest treatment rate 50% mortality was observed during the exposure period. One additional animal was sub-lethally affected at the end of the experimental phase and therefore euthanized. Mean body weight development was not affected. The results are summarized in the table below.

Table 10.1.3-4 Effects of BAS 500 06 F on common toad (*Bufo bufo*) in a semi-field study

Test item rate [mL BAS 500 06 F/ha] (% of max. label rate)	**Water control**	**1250 (100%)**	**1875 (150%)**	**12500 (1000%)**
Test item rate [g a.s./ha]	--	250	375	2500
Mortality [%]	0	0	0	50[1)]
Mean weight gain (over 7 d) [g]	0.34	0.31	0.32	--[2)]
Sub-lethal effects	none	none	none	U[3)]
Endpoints (based on nominal application rates)				
	[mL BAS 500 06 F/ha]		**[g a.s./ha]**	
NOEL (7 days)	1875		375	

1) One additional animal was sub-lethally affected at the end of the exposure phase and therefore euthanized.
2) Mean weight gain cannot be calculated due to mortalities
3) Sub-lethal effects: U = uncoordinated movements, observed on DAT 7

III. CONCLUSION

The NOEL (7 d) for BAS 500 06 F in the semi-field study on juvenile common toads (*Bufo bufo*) was determined to be 1875 mL/ha, corresponding to 375 g pyraclostrobin/ha (150% of the max. label rate of BAS 500 06 F), based on nominal application rates.

Risk assessment - other terrestrial vertebrate wildlife: reptiles and amphibians

The laboratory studies conducted under worst-case conditions, using sensitive life stages (metamorphs) and maximizing exposure via direct overspray over animals and bare soil (Belden et al., 2010; Bruehl et al., 2013; BASF DocID 2013/1375098), indicate inherent toxicity of pyraclostrobin, respectively pyraclostrobin containing formulations to amphibians. The results from the two investigations by Belden et al. (2010) and Bruehl et al. (2013) (non-GLP studies, for more details see M-CA 8.1.4) on *Rana temporaria* and *Bufo cognatus* show no impact of the test substance at 22 g a.s./ha, whereas 220 g a.s./ha (reflecting the field rate) caused high mortality (100 and 70% at 220 g a.s./ha for *Rana temporaria* and Bufo cognatus, respectively). The BASF laboratory study with *Rana temporaria* provides comparable results while narrowing down the toxicity range. Results are shown in Table 10.1.3-5.
The above-mentioned laboratory studies show that young, juvenile frogs and toads can be sensitive if oversprayed directly with EC formulated pyraclostrobin (containing organic solvents). BASF conducted additionally a study (BASF DocID 2014/1221859) investigating the impact of the same product when not overspraying the toads directly, but exposing them to bare soil that has been oversprayed before. The toxicity to animals exposed to the soil residues shortly after spraying was significantly reduced as compared to direct overspray, and following a time interval of about four hours between spraying and animals moving onto the contaminated soil, no effects on the toads were observed even at elevated rates of 310 g a.s./ha.

The studies with the EC-formulation (emulsifiable concentrate) indicate toxicity at the field rate while the study with a CS-formulation (capsule suspension) shows no relevant toxicity even at an elevated rate. The EC-formulation containing significant amounts of organic solvents maximizes full and rapid bioavailability of the active substance while the alternative formulation with significantly less organic solvents leads to a slow release of the active substance.

Table 10.1.3-5: List of endpoints obtained in studies with amphibians

Study	Test species	Test substance	Formulation type	Appl. rate [g a.s./ha]	Effect (% mortality)
Belden et al. (2010)	*Bufo cognatus*	BAS 500 00 F (Headline®)	EC (emulsifiable concentrate)	22	0
				220	70
				2200	100
Bruehl et al. (2013)	*Rana temporaria*	BAS 500 00 F (Headline®)	EC	22	0
				220	100
		BAS 500 18 F	CS (capsule suspension)	2200	no significant effect
BASF DocID 2013/1375098	*Rana temporaria*	BAS 500 06 F	EC	40	0
				63	0 sublethal symptoms
				99	70
BASF DocID 2014/1375098	*Bufo bufo*	BAS 500 06 F	EC	155 / 15 min 219 / 15 min 310 / 15 min 310 / 60 min 310 / 4 h[1)]	0 0 (20% sublethal) 20 (60% sublethal) 20 (40% sublethal) (20)[2)] (0% sublethal)

[1)] Animals were exposed to the respective rates either shortly (within 15 minutes) or 1 h or 4 h after spraying.
[2)] The observed toxicity is in this case not considered treatment-related.

In previous chapters it has been demonstrated that there is a low risk of pyraclostrobin to bird and mammal species. Yet, pyraclostrobin and certain pyraclostrobin containing formulations can be toxic to amphibians. The particular sensitivity of amphibians is most likely due to their specific skin morphological and physiological differences (dermal toxicity). The amphibian skin not only constitutes a much lesser barrier as compared to the skin of mammals and birds (Quaranta et al., 2009), however, it is itself a sensitive organ relevant for respiration and uptake of water and regulation of minerals in amphibians (see Wells, 2007 for a review). It seems likely that pyraclostrobin, in case sufficiently large surfaces of the skin are exposed, impacts mitochondrial respiration in the skin and thus disturbs a vital process for respiration and function of the skin. However, if the vital function is not sufficiently (largely) disturbed, the substance being rapidly metabolized and excreted (compare M-CA 5.1 and M-CA 6.2) will not cause any further sub-lethal or chronic latency effects. This is in agreement with the observed finding: effects are observed rather rapidly and if there are no rapid effects or once recovery from initial effects occurs, then there is no delayed or long-term toxicity.

The laboratory studies indicate the potential intrinsic toxicity of pyraclostrobin. However, conditions as simulated in these worst-case laboratory studies bear little relevance to field situations.

In general, amphibians need both terrestrial and aquatic habitats. In Europe, most amphibian species depend on aquatic breeding sites and use the terrestrial habitat within 300 - 1000 m of the surrounding area (e.g. Semlitsch and Bodie 2003, Schabetsberger et al. 2004, Sinsch et al. 2012, Berger et al. 2011). Agricultural landscapes, too, may constitute habitats used by amphibians, if these are in the range of the aquatic breeding sites (summary in Berger et al. 2011).
However, agricultural landscapes are generally perceived as low quality environments for most amphibian species for several reasons, posing high resistance to movement for aquatic breeding amphibians, which is corroborated by studies showing lower abundance and association of amphibians with arable land (Pagetti et al. 2006, e.g. *Bufo bufo*: Kyek et al. 1997, Piha et al. 2007; *Epidalea calamita*: Miaud and Sanuy 2005; *Triturus carnifex, T. marmoratus*: Jehle and Arntzen 2000). In particular, agricultural fields with no or low plant cover are avoided since amphibians have to face high water losses in anthropogenically disturbed areas without sufficient plant cover (Rothermel and Semlitsch 2002, Mazerolle and Desrochers 2005, Cosentino et al. 2011). The risk of desiccation and the lack of cover against predators are likely the major factors leading to avoidance of amphibians of such areas. Mazerolle and Vos (2006) observed that *Rana esculenta* opted to take migration routes with higher cover rather than taking shortcuts through bare field. Similar behaviour was reported by Berger et al. (2011) during telemetry and mark-and recapture studies with *Bufo bufo, Triturus cristatus* and *Pelobates fuscus* in agricultural fields in Germany: individuals migrated either fast through the field taking the shortest route, and subsequently stayed in off-crop habitats, which offer more plant cover and structure; or they returned into cover offered by the pond's surrounding. Individuals of *B. bufo* continued to stay in the arable field when favourable conditions, i.e. burrows, stubble field with clods and sufficient plant material, were found (see also Kneitz 1998). Thus, habitat use and behaviour of amphibians in agricultural landscapes highly depend on availability of cover in the respective area (Berger et al. 2011).

The dependence on a moist and the preference for a structured environment with high plant cover is especially crucial for juvenile amphibians. Due to their smaller size and volume to surface ratio, juvenile amphibians are more sensitive to environmental influences, especially desiccation, than adult life stages (Rittenhouse et al. 2008). Accordingly, Vos et al. (2007) found an even more pronounced preference for meadows in contrast to arable land in *Rana temporaria* juveniles than in adults (individuals found in meadows: arable land; 9.6:1 (juveniles), 4.3:1 (adults)). Crop fields might therefore be used by these sensitive stages only if they offer sufficient plant cover and therefore a favourable microclimate and protection against predators.

Habitat use, of course, depends on biology and ecology of the respective species. A few amphibian species, which are physiologically and behaviourally adapted to arid conditions, may also use agricultural fields with low plant cover as habitats (e.g. *P. fuscus, Epidalea calamita*). However, also for these species availability of shelter and cover are of crucial importance (Seebacher and Alford 2002). By their fossorial behaviour and staying in moist shelters (e.g. stone embankments, burrows) during the day, postponing search for food to the night and using short rainy events for rehydration (Nöllert and Nöllert 1992, Miaud et al. 2000, Eggert 2002) they avoid dehydration and extreme temperatures (Seebacher and Alford 2002).

This predominantly nocturnal activity (and hiding behaviour during the day) can be found in many European amphibian species (e.g. *Rana temporaria*, *B. bufo, Lissotriton vulgaris*, see Günther 1996). Furthermore, nocturnal activity, the use of shelter and plant cover also limits visual encounter by predators, a strong selective force shaping behaviour in organisms (Lima and Dill 1990). At the same time this behaviour reduces significantly potential exposure to pesticide applications generally.

The life-cycle of pond-breeding amphibians is characterized by yearly migrations between terrestrial habitats and breeding sites. From early to mid-spring, adults leave their overwintering habitat and migrate to the breeding ponds. After oviposition, adults leave the breeding ponds and migrate to their summer habitats. Depending on weather conditions, early migrations of amphibian species in central Europe start in February / March (e.g. *B. bufo*, *R. temporaria*), while migration periods of other species continue till approximately May (for details see Berger et al. 2011). During these migrations of adult amphibians, agricultural fields can be crossed early in the season and - when there is no alternative - using fields with low plant coverage, too.
Activity and migratory behaviour of amphibians is highly dependent on climatic variables such as temperature and precipitation (e.g. Beebee 1995, Baldwin et al. 2006, Timm et al. 2007). This is especially true for juveniles, emigrating at high temperatures in summer entering terrestrial habitats (Mazerolle 2001). However, literature data on development of amphibian larvae indicate, that migration of metamorphs concur with late growth stages or the time of harvest of field crops in Germany, e.g. earliest *R. temporaria* and *B. bufo* metamorphs mainly occur beginning or mid of June to mid of July (Blab 1982, Günther 1996), see also summary in Berger et al. (2011). This was also exemplarily shown by Berger et al. (2013) in a study assessing the co-occurrence of juvenile stages of *Rana arvalis*, *T. cristatus, P. fuscus* and *Bombina bombina* with agricultural measures in crop fields in Germany. At this time, common field crops (e.g. winter cereals BBCH > 50) already comprise late growth stages and therefore high plant cover with high interception (interception 90%, BBCH 40-89 for winter cereals, Anonymous 2002).

Fungicide treatments in cereals are mainly performed from beginning of May until the end of June. The earlier treatments could coincide with the return of adult anurans from their breeding ponds and the latest applications could coincide with dispersal of metamorphs. In both cases there will be a dense plant cover (BBCH > 30 for the early applications and BBCH > 39 for the later applications) providing 70-90% crop interception. The earliest application of BAS 500 06 F according to label would be BBCH 25 (> 50% interception); however, this early stage would be relevant only for adult specimen and not for the more vulnerable metamorphs. Furthermore, the semi-field study (see below) performed in cereals at BBCH 25 demonstrated low risk to young frogs, too.

In summary, a number of aspects will significantly reduce potential exposure and thus the risk to pesticides under realistic field conditions:

- avoidance of agricultural sites, particularly those with low plant cover
- behavioral aspects: burrowing, hiding, nocturnal activity
- more sensitive juveniles will migrate into or through agricultural fields later in the year, when there is either dense plant cover and/or no pesticide use.

The risk assessment has to consider the likely exposure next to the toxicity data. In order to do this appropriately it is essential to consider behavioral aspects in addition to simple interception calculations.
Therefore, a semi-field study was designed and conducted. This study covers realistic (worst-case) exposure and behavior; the semi-field study in addition covers all routes of exposure: direct spraying, contact to treated surfaces and uptake of contaminated feed.

First experiments performed in midsummer during high temperatures in cereal fields at late growth stages confirmed that juvenile frogs are dependent on suitable conditions, i.e. sufficient moist soil and moist hiding places. In these first experiments most juvenile frogs had disappeared (either desiccated or escaped) from the plots despite some watering of the plots before the trials.

The final experiment was conducted after the hot summer period at more suitable weather conditions with medium temperatures and some rain before and during the study. Accordingly, all animals survived and could be recovered healthy from the trials. Early seeded winter cereal plots were used for the study at a BBCH of 25; cereal plants were grown otherwise according to standard agricultural practice, providing a good and sufficient plant cover.

The plot size was approx. 1.2 m long and 0.84 m (covering six rows of cereals). This plot size is quite sufficient to allow for ‘normal’ movement of the frogs and thus potential uptake of the pesticide from contaminated surfaces. The laboratory studies demonstrated anyway that the initial contamination is decisive; all effects were observed only in the first few hours after test substance application. Animals not impacted within the first 24 hours did not show any symptoms later during the trial; in actual fact even animals impacted sublethally recovered shortly after application. This indicates that later movement over contaminated soil (once the pesticide film has dried up) does not contribute further to the test substance toxicity.

The semi-field study demonstrated that applications of BAS 500 06 F under realistic conditions will be of low risk to amphibians. Even an elevated rate corresponding to over 300 g a.s./ha did not cause any mortality. At this rate only a single individual had shown a transient behavioral impact, which is considered to be of marginal biological relevance.

A second semi-field study was performed in order to verify the results of the first one. Furthermore, higher application rates were used and the study was conducted with the Common toad, an amphibian species more likely to be encountered on agricultural sites than the European common frog. This study very well confirmed the results of the first semi-field study: no effects were observed in the field at application rates up to 375 g a.s/ha in winter cereals at BBCH 30. 50% mortality (75% when including an animal that was euthanized after showing sub-lethal effects) was observed under extreme conditions at the tenfold application rate of 12.5 L BAS 500 06 F/ha (corresponding to 2500 g a.s./ha).

In conclusion, while BAS 500 06 F may harm amphibians under worst-case conditions in the laboratory, there is a low risk to amphibians from BAS 500 06 F applications under realistic field conditions.

In the case of reptiles there is even less information available than for amphibians (see the revision by Fryday and Thompson, 2009). The risk from dietary exposure can be assumed to be lower for reptiles than for birds and mammals (Fryday and Thompson 2009). This is because reptiles are poikilotherm (i.e., do not maintain a constant body temperature) and as a result feeding activity will peak at warm days and will be zero during hibernation or at cold days. In contrast, birds and mammals will have to maintain a constant body temperature and, hence, will need to feed every day (Fryday and Thompson 2009). Uncertainties remain on the contribution of dermal exposure to the overall exposure to reptiles. However, in contrast to amphibians the skin of reptiles is much less permeable; it functions in general as protection and barrier and it is not an organ used for respiration or water/mineral exchange with the environment. Thus, reptiles are considered less vulnerable to dermal exposure as compared to amphibians. Nevertheless, some uncertainty with respect to the risk to reptiles, i.e. whether they are sufficiently covered by other (more standard) ecotoxicological data will remain and further research is needed.

However, pyraclostrobin containing products have been used for many years in many countries worldwide. So far, there are no publications indicating a potential risk of this compound to reptiles and despite the long term use worldwide the applicant is not aware of findings or (incidence) reports that amphibians or reptiles were harmfully affected by correct applications of pyraclostrobin containing fungicides.

CP 10.2 Effects on aquatic organisms

The EU agreed endpoints for the active substance pyraclostrobin (BAS 500 F) and its major metabolites plus endpoints from new studies and revised endpoints from EU agreed studies, respectively, are used for the risk assessment on aquatic organisms (see Table 10.2-1). The new representative formulation BAS 500 06 F was not evaluated within the previous Annex I inclusion process. The respective data are presented within this chapter. A comprehensive risk assessment for the active substance, its metabolites and the formulation based on the already registered use pattern is provided below. The risk assessment is based on the "Guidance on tiered risk assessment for plant protection products for aquatic organisms in edge-of-field surface waters", EFSA Journal 2013; 11(7):3290.

Different code numbers of different numbering systems are assigned to the metabolites of pyraclostrobin. In this chapter all metabolites are identified by the BF-code and synonym metabolite codes are given in brackets only where deemed to be helpful.

Table 10.2-1: EU agreed and new /revised endpoints for aquatic species

Test substance	Test species	EU agreed endpoints	Endpoints used in standard and refined risk assessment
Acute toxicity to fish			
Pyraclostrobin	*Oncorhynchus mykiss*	96 h LC_{50} = 0.00616 mg/L	96 h LC_{50} = 0.00616 mg/L
Pyraclostrobin	*O. mykiss* [1)]	--	96 h LC_{50} = 0.00620 mg/L
Pyraclostrobin	*Cyprinodon variegatus* [1), 2)]	--	96 h LC_{50} = 0.0769 mg/L
Pyraclostrobin	*Cyprinus carpio*	96 h LC_{50} = 0.0177 mg/L	96 h LC_{50} = 0.0177 mg/L
Pyraclostrobin	*Danio rerio* [4)]	96 h LC_{50} = 0.0619 mg/L	96 h LC_{50} = 0.0619 mg/L
Pyraclostrobin	*Lepomis macrochirus*	96 h LC_{50} = 0.0254 mg/L	96 h LC_{50} = 0.0254 mg/L
Pyraclostrobin	*L. macrochirus* [3)]	--	96 h LC_{50} = 0.0114 mg/L
Pyraclostrobin	*Leuciscus idus melanotus* [3)]	96 h LC_{50} = 0.0191 mg/L	96 h LC_{50} = 0.0191 mg/L
Pyraclostrobin	*Oryzias latipes* [3)]	96 h LC_{50} = 0.0533 mg/L	96 h LC_{50} = 0.0533 mg/L
Pyraclostrobin	*Pimephales promelas* [3)]	96 h LC_{50} = 0.0161 mg/L	96 h LC_{50} = 0.0161 mg/L
BF 500-3	*O. mykiss* [1)]	--	96 h LC_{50} > 0.0948 mg/L
BF 500-5	*O. mykiss* [1)]	--	96 h LC_{50} =11.3 mg/L
BF 500-11	*O. mykiss*	96 h LC_{50} > 100 mg/L	96 h LC_{50} > 100 mg/L
BF 500-13	*O. mykiss*	96 h LC_{50} > 50 < 100 mg/L	96 h LC_{50} > 50 < 100 mg/L
BF 500-14	*O. mykiss*	96 h LC_{50} > 39.4 < 82.6 mg/L	96 h LC_{50} > 39.4 < 82.6 mg/L
BAS 500 06 F	*O. mykiss* [1)]	--	96 h LC_{50} = 0.0360 mg/L

Test substance	Test species	EU agreed endpoints	Endpoints used in standard and refined risk assessment
Chronic toxicity to fish			
Pyraclostrobin	*O. mykiss* (ELS study)	98 d NOEC = 0.002 mg/L	98 d NOEC = 0.00235 mg/L
Pyraclostrobin	*C. variegatus* [1), 2)] (ELS study)	--	36 d NOEC = 0.0108
Pyraclostrobin	*P. promelas* [1)] (ELS study)	--	36 d NOEC = 0.00414
Acute toxicity to aquatic invertebrates			
Pyraclostrobin	*Daphnia magna*	48 h EC_{50} = 0.0157 mg/L	48 h EC_{50} = 0.0157 mg/L
BF 500-3	*D. magna* [1)]	--	48 h EC_{50} > 0.100 mg/L
BF 500-5	*D. magna* [1)]	--	48 h EC_{50} > 10.0 mg/L
BF 500-11	*D. magna*	48 h EC_{50} > 100 mg/L	48 h EC_{50} > 100 mg/L
BF 500-13	*D. magna*	48 h EC_{50} > 100 mg/L	48 h EC_{50} > 100 mg/L
BF 500-14	*D. magna*	48 h EC_{50} > 60.9 mg/L	48 h EC_{50} > 60.9 mg/L
BAS 500 06 F	*D. magna* [1)]	--	48 h EC_{50} = 0.065 mg/L
Chronic toxicity to aquatic invertebrates			
Pyraclostrobin	*D. magna*	21 d NOEC = 0.004 mg/L	21 d NOEC = 0.004 mg/L
Acute toxicity to sediment dwelling aquatic invertebrates			
Pyraclostrobin	*Leptocheirus plumulosus* [1), 2)] (spiked sediment)	--	10 d LC_{50} = 4.41 mg/kg dry sediment
Chronic toxicity to sediment dwelling aquatic invertebrates			
Pyraclostrobin	*Chironomus riparius* (spiked water)	28 d NOEC = 0.040 mg/L	28 d NOEC = 0.040 mg/L
Pyraclostrobin	*C. riparius* [1)] (spiked sediment)	--	28 d NOEC = 1.37 mg/kg dry sediment
BF 500-3	*C. riparius* [1)] (spiked sediment)	--	28 d NOEC ≥ 16.0 mg/kg dry sediment
BF 500-6	*C. riparius* [1)] (spiked sediment)	--	28 d NOEC 1.2 mg/kg dry sediment
BF 500-7	*C. riparius* [1)] (spiked sediment)	--	28 d NOEC ≥ 123.5 mg/kg dry sediment

[1] Study not submitted during the previous Annex I inclusion process of pyraclostrobin.

[2] Marine / saltwater species

[3] Study was performed with the previous representative solo-formulation BAS 500 00 F; however, results are given in mg a.s./L

[4] In accordance to recent guidelines (EFSA, 2013; OECD, 2011), the 72 h endpoints of the EU agreed study on the green alga have been (re-)calculated from original data. The re-calculated values are presented here and are used in the aquatic risk assessment; for details on these calculations please refer to the respective supplement. A summary of this study and the re-calculations is provided in M-CA 8.2.

[5] In accordance to recent guidelines (EFSA, 2013; OECD, 2011), the 72 h endpoints obtained in the 96 h / 120 h alga studies are considered as relevant endpoint and are presented here.

[6] Endpoint obtained in the 96 hour TTE study after exposure over respective duration, i.e. the value in brackets (0.5, 2 or 8 h exposure time).

Risk assessment for aquatic organisms

Toxicity

An overview on all available toxicity data for all aquatic organisms is provided in Table 10.2-2 for the active substance and the formulated product and in Table 10.2-3 for the metabolites of pyraclostrobin.

Studies with the formulated product BAS 500 06 F are summarized in this chapter, while summaries of the new studies with the active substance and its major metabolites are provided in M-CA 8.2. For completeness this includes some older studies not been submitted during the previous Annex I inclusion process (e.g. because there was no respective data requirement in the EU) and also EU agreed studies that have been amended in the meantime (e.g. due to recalculations of endpoints or a new evaluation according to current guidelines). Further information on the EU agreed studies, which have been already evaluated within the previous Annex I inclusion process of pyraclostrobin, can be found in the Monograph (Vol. 3, Annex B.9, August 2001) and the EU Review Report (SANCO/1420/2001-final, September 2004). Furthermore, the reports of these studies will be provided to RMS, co-RMS and EFSA and are available upon request for other member states.

Active substance and formulated product

Table 10.2-2: List of studies and endpoints for aquatic organisms with the active substance pyraclostrobin (BAS 500 F) and the formulated product BAS 500 06 F

Bold endpoints: Where several endpoints are available for the same group or where several endpoints are available for one study based on different effect parameters, the respective endpoint printed bold is used in the standard TER calculations.
ELS = early life stage; NO(E)AEC = No observed (ecologically) adverse effect concentration; LC = life cycle; TTE = Time-To-Effect/Event; SSD = Species Sensitivity Distribution; HC_5 = 5% hazardous concentration

[#] At tier I level, only the endpoints for the standard aquatic test species are considered even though studies on additional invertebrate/alga species are available partly resulting in lower endpoints. This is justified considering the information from higher tier studies such as a mesocosm study covering the risk to a great number of different aquatic invertebrate and alga species (for detailed justifications see below).

[+] Spearman-Karber estimate of LC_{50} with confidence limits

[*] Geometric mean with corresponding LC_0 (>) and LC_{100} (<) values.

[1)] Study has not been submitted during the previous Annex I inclusion process of pyraclostrobin (summaries for the studies with pyraclostrobin and its metabolites are provided in M-CA 8.2; summaries for the studies with the formulation are provided below).

[2)] Marine / saltwater species

[3)] Study was performed with the solo-formulation BAS 500 00 F (same formulation type as the new representative formulation)

[4)] The 48-h LC_{50} obtained in the 96 h study is used in the risk assessment according to EU Regulation 283/2013 (European Commission, 2013) on the data requirements for active substances and the EFSA Aquatic Guidance Document (EFSA, 2013).

[5)] In accordance with the recent aquatic guidance document (EFSA, 2013; OECD, 2011), the 72 h endpoints of the EU agreed study on the green alga have been (re-)calculated from original data. The re-calculated values are presented here and are used in the aquatic risk assessment; for details on these calculations please refer to the supplement. A summary of this study and the re-calculations is provided within this chapter together with the summaries of the new studies.

[6)] In accordance with recent guidelines (EFSA, 2013; OECD, 2011), the 72 h endpoints obtained in the 96 h / 120 h alga studies are considered as relevant endpoint and are presented here

[7)] In this study the 24, 48, and 72 hour effective concentrations were not calculated because sufficient growth had not yet occurred in any of the test groups to allow for these calculations; thus the 96 h endpoints obtained in the 120 h alga studies are presented here.

[8)] Due to the reasoning given above, the study on this alga species is considered to be not valid.

[9)] Based on frond numbers

[10)] Based on dry weight

[11)] Endpoint obtained in the TTE study after peak exposure over respective duration, i.e. the value in brackets (0.5, 2 or 8 h exposure time).

[12)] For details on SSD / geometric mean calculations and derivation of respective RAC values please refer to the refined risk assessment presented below.

[13)] During the peer review this study had been considered to be not valid; however, this was done apparently based on a misunderstanding of the data; more explanation in the respective text on the fish RA.

[14)] A statistically significant impact based on a small reduction in male weight was given at 0.676 µg/L; however, a biologically relevant impact (based on female weight reduction and a corresponding reduced reproduction level) was observed at the highest test concentration only (but which had no impact on the F1 generation) Accordingly, the NOEC is 1.28 µg/L.

Metabolites of pyraclostrobin (BAS 500 F)

The results from toxicity tests on representative freshwater species with the major aquatic metabolites are summarized in Table 10.2-3.

In the dark water/sediment study the metabolites BF 500-3, BF 500-6 and BF 500-7 occurred as major metabolites (see M-CP 9.1 - 9.2). Additionally, BF 500-3, BF 500-11, BF 500-13 and BF 500-14 occurred in relevant amounts in the irradiated water/sediment study and BF 500-5 was detected as a major metabolite in the study on aerobic mineralization in surface water.

The pyraclostrobin metabolite BF 500-3 was not observed in standard aerobic soil metabolism studies, but only in soil under anaerobic conditions (see M-CP 9.1 - 9.2), however, aerobic conditions are predominant in soil. The sorption behavior of BF 500-3 was investigated in the context of the EU review of pyraclostrobin showing a mean K_{oc} of 9315 mL/g (see M-CP 9.2). Due to its non-occurrence under more relevant aerobic conditions and its high K_{oc}, this metabolite will not be relevant for drainage or runoff entry into surface water. BF 500-3 was observed in sediment with a maximum occurrence of 16.9% TAR in an irradiated water/sediment study. The highest amount of BF 500-3 in the water phase never exceeded 5.0% TAR and thus, this metabolite is only relevant in the sediment phase. Nevertheless, toxicity studies were performed for BF 500-3 on fish, daphnids and algae (on the request of Canadian authorities) that were not included in the previous pyraclostrobin EU review; summaries for these studies are provided in M-CA 8.2. These studies (see Table 10.2-3) showed no toxicity up to the solubility level of this metabolite. The evaluation above shows that both theoretical considerations and also the evidence from toxicity studies demonstrate a very low risk to aquatic organisms resulting from water exposure to metabolite BF 500-3. Therefore, the results from these studies are not considered further in the risk assessment. However, as a major sediment metabolite it has also been tested in a 28 d spiked sediment study with *Chironomus riparius* and the results are used in the respective TER calculations (see below).

The aerobic soil metabolites BF 500-6 and BF 500-7 show very high sorption indicating that they are non-mobile in soil (BF 500-6: median K_{oc} of 107301 mL/g; BF 500-7: median K_{oc} of 149900 mL/g; see M-CP 9.2). Considering the high sorption, the low mobility in soil and the very low water solubility, it can be concluded that BF 500-6 and BF 500-7 will not enter surface water in any ecotoxicologically relevant amount. Furthermore, studies with these metabolites and soil organisms indicate very low toxicity and overall low ecotoxicological potential. To assess the risk to sediment dwelling organisms, 28 d spiked sediment studies on *C. riparius* have been conducted with both metabolites. Study summaries are provided in M-CA 8.2 and the results are considered for the risk assessment below.

The metabolite BF 500-5 was found in relevant amounts in the OECD 309 study (dark) in water and was not detected in the sediment phase of the suspended solid test. This metabolite was therefore considered not to be relevant for the sediment.

The metabolites BF 500-11, BF 500-13 and BF 500-14 were observed in the water phase of irradiated water/sediment systems. The highest amount of the metabolites BF 500-11, BF 500-13 and BF 500-14 in the sediment phase of water/sediment systems never exceeded 0.6, 2.1 and 0.7% TAR, respectively; these metabolites were therefore considered not to be relevant for the sediment.

Further information on the metabolites of pyraclostrobin can be found in document N3.

Table 10.2-3: Summary of toxicity values for aquatic organisms of the major metabolites of pyraclostrobin

	72 h E_bC_{50}	46.6	

1) Study has not been submitted during the Annex I inclusion process of pyraclostrobin (study summaries are provided in M-CA 8.2).
2) In accordance with recent guidelines (EFSA, 2013; OECD, 2011), the 72 h endpoints obtained in the 96 h alga study are considered as relevant endpoints and are presented here.
3) The pyraclostrobin metabolites BF 500-6 and BF 500-7 do not occur to any significant extent in water; they are thus considered to be only of relevance in sediment.

Exposure

The critical use pattern of BAS 500 06 F considered in the risk assessment below is presented in Table 10.2-4.

Table 10.2-4: Critical use pattern

Crop	Application time (BBCH growth stage)	Number of applications	Minimum interval [days]	Application rate per treatment	
				pyraclostrobin [kg a.s./ha]	BAS 500 06 F [L/ha]
cereals	25 - 69	2	21	0.25	1.25
maize	30 - 65	1	--	0.20	1.00

Aquatic organisms may be exposed to BAS 500 06 F through spray drift and to the active substance pyraclostrobin and its metabolites through spray drift, run-off and drainage from the application site into adjacent water bodies. Exposure of aquatic organisms from these routes was estimated by calculating Predicted Environmental Concentrations in surface water (PEC_{sw}) and sediment (PEC_{sed}) for the active substance and its major metabolites using the FOCUS surface water models. The PEC values were calculated for single and twofold application of BAS 500 06 F in cereals at a use rate of 1.25 L/ha (equivalent to 250 g pyraclostrobin/ha) and for single application in maize at 1.0 L/ha (equivalent to 200 g a.s./ha). A stepwise approach has been followed starting with simple worst-case assumptions in the first two steps and proceeding to more realistic worst-case conditions in the third step and adding spray drift mitigation (i.e. no-spray buffer zones, drift reducing nozzles) and runoff mitigation measures (i.e. vegetated filter strips) in the fourth step of the exposure assessment.
PEC values were calculated with endpoints derived from a dark water/sediment study (Tier 1) and additionally with parameters derived from an irradiated water/sediment study (Tier 2). However, only tier 1 PEC values were considered for the following aquatic risk assessment, except for the metabolites BF 500-11, BF 500-13 und BF 500-14 that were mainly observed in irradiated water/sediment studies. Accordingly, only PEC values derived from irradiated water/sediment studies are reported for these metabolites.

The resulting worst-case PEC_{sw} and PEC_{sed} values for pyraclostrobin and its major metabolites are presented in Table 10.2.3-1 to Table 10.2.3-6. For cereals, only the worst-case PEC values are presented, either resulting from calculations for single or multiple applications. The pyraclostrobin metabolites BF 500-3, BF 500-6 and BF 500-7 do not occur to any significant extent in water. They are thus considered to be of relevance only in sediment and only PEC_{sed} values have been calculated for these metabolites. The highest amount of the metabolites BF 500-11, BF 500-13 and BF 500-14 in the sediment phase of water/sediment systems never exceeded 0.6, 2.1 and 0.7% TAR, respectively; the metabolite BF 500-5 was not detected in the sediment phase of the suspended solid test. These metabolites were therefore considered to be not relevant for the sediment and no PEC_{sed} values were calculated.

A summary of the FOCUS $PEC_{sw, max}$ values for pyraclostrobin and its major metabolites used for the aquatic risk assessment are provided in the Appendix at the end of this chapter. For full details of the assumptions used in the exposure calculations, please see M-CP 9.2.5.

Toxicity exposure ratios

The following TER calculations were conducted based on application of BAS 500 06 F according to the already registered uses in cereals and maize. The initial risk assessments were carried out by comparing the $PEC_{sw, max}$ and $PEC_{sed, max}$ values with the acute and long-term toxicity endpoints.

The toxicity data obtained in the studies with the formulation (re-calculated to the active substance) are similar to the respective data from the studies with pyraclostrobin and therefore indicate no significantly higher (or unexpected) toxicity of the formulation than predicted based on the results of the active substance. For example, the measured toxicity to trout as the most sensitive species of the product BAS 500 06 F - 0.036 mg/L - provides a slightly higher endpoint (i.e. slightly lower toxicity) than predicted from the data on the active substance - 0.032 mg/L (see Table 10.2-5). Accordingly, no synergisms or additional toxicity occurs due to the co-formulants. The acute and chronic risk resulting from BAS 500 06 F is thus sufficiently addressed by the risk assessment for the active substance and no additional TER calculations were performed for the formulated product. This is also in agreement with the proposals of the EFSA Aquatic Guidance Document (EFSA, 2013), because dividing the re-calculated mixture toxicity ($LC_{50}/EC_{50mix\text{-}CA}$) by the measured mixture toxicity (LC_{50}/EC_{50PPP}) would result in model deviation ratios (MDR) between 0.33 and 1.24 (see Table 10.2-5).

Table 10.2-5: Comparison of the toxicity of the formulated product BAS 500 06 F and the active substance pyraclostrobin

Test species	Endpoint & Test system	Measured toxicity of BAS 500 06 F [mg product/L]	Calculated toxicity of BAS 500 06 F based on a.s. content and toxicity § [mg product/L]	Measured toxicity of the a.s. pyraclostrobin [mg a.s./L]	Ratio (MDR) (calculated / measured)
O. mykiss	LC_{50}, acute, 96 h	0.036	0.032	0.00616	0.89
D. magna	EC_{50}, acute, 48 h	0.065	0.0809	0.0157	1.24
P. subcapitata #	E_rC_{50}, static, 72 h	14.2	--	> 0.843	--
	E_yC_{50}, static, 72 h	2.4	0.783	0.152	0.33

MDR = model deviation ratio

§ The mixture toxicity of the formulation was re-calculated based on the measured toxicity data of pyraclostrobin, the analyzed content of pyraclostrobin (i.e. 202.7 g/L) within the formulation and the formulation density (i.e. 1.044 g/cm^3).

As no clear growth rate endpoint was obtained in the study with pyraclostrobin on green algae (i.e. E_rC_{50} > 0.843 mg/L), the endpoint yield was used for comparison of the toxicity data.

TER_A for fish

Two acute toxicity endpoints for *O. mykiss* are available for the active substance; a study performed under static conditions and an additional study performed for the US under flow-through conditions. Both studies provide nearly identical endpoints based on mean measured concentrations, i.e. of 6.16 and 6.2 µg/L, respectively. In the following risk assessment of pyraclostrobin the rounded value of 6.2 µg/L is used. The TER_A values were calculated using worst-case FOCUS Step 1 and 2 $PEC_{sw, max}$ values. The results are presented in Table 10.2-6. The acute risk to fish from the product BAS 500 06 F is addressed by the risk assessment for the active substance (see reasoning above).

Table 10.2-6: Fish acute TER values for pyraclostrobin and its major metabolites using worst-case FOCUS Step 1 and 2 $PEC_{sw, max}$ values

Test organism	Test substance	96 h LC_{50} [µg/L]	FOCUS Step	$PEC_{sw, max}$ [µg/L]	TER_A	Trigger value
cereals						
O. mykiss	Pyraclostrobin	6.2	2	2.299	**2.7**	100
O. mykiss	BF 500-5	11300	1	0.256	44141	100
O. mykiss	BF 500-11	> 100000	1	0.407	> 245700	100
O. mykiss	BF 500-13	> 50000 < 100000	1	0.533	> 93809 < 187617	100
O. mykiss	BF 500-14	> 39400 < 82600	1	0.573	> 68761 < 144154	100
maize						
O. mykiss	Pyraclostrobin	6.2	2	1.839	**3.4**	100
O. mykiss	BF 500-5	11300	1	0.102	110784	100
O. mykiss	BF 500-11	> 100000	1	0.163	> 613497	100
O. mykiss	BF 500-13	> 50000 < 100000	1	0.213	> 234742 < 469484	100
O. mykiss	BF 500-14	> 39400 < 82600	1	0.229	> 172052 < 360699	100

TERs shown in **bold** fall below the relevant trigger.

The calculated TER_A values for pyraclostrobin are below the trigger value of 100 based on FOCUS Step 2 calculations following application of BAS 500 06 F in cereals and maize. Therefore, additional TER calculations considering Step 3 and 4 $PEC_{sw, max}$ values are presented in Table 10.2-7.

The TER_A values for the metabolites BF 500-5, BF 500-11, BF 500-13 and BF 500-14 by far exceed the trigger value of 100 based on worst-case FOCUS Step 1 calculations, indicating low ecotoxicological relevance of the metabolites.

Table 10.2-7: Fish acute TER values for pyraclostrobin using worst-case FOCUS Step 3 and 4 $PEC_{sw, max}$ values

FOCUS Scenarios		96 h LC_{50} [µg/L]	FOCUS Step 3		FOCUS Step 4

TERs shown in **bold** fall below the relevant trigger.
D = Drift mitigation using no-spray buffer zones, N = drift mitigation due to drift reducing nozzle techniques,
R = runoff mitigation by vegetated filter strips.

Based on FOCUS Step 3 and 4 calculations the TER_A values for pyraclostrobin are below the standard trigger of 100 for the majority of scenarios following application of BAS 500 06 F in cereals and maize.

Therefore, additional studies and a refined risk assessment have been conducted. Besides the standard fish species *O. mykiss,* seven further fish species were tested in acute 96 h laboratory studies with pyraclostrobin (see Table 10.2-2). To ease test item application, some of the additional tests were conducted using pyraclostrobin in the form of the previous representative solo-formulation BAS 500 00 F (due to the low water solubility of pyraclostrobin) the addition of solvents is appropriate anyway). A comparison of acute toxicity data with trout tested with the solo-formulation and the active substance provided a slightly lower endpoint for the formulation (4 µg/L compared to 6.2 µg/L for the a.s.). These data were considered in the previous Annex I inclusion process. Therefore, the use of data from tests with this formulation is considered a conservative surrogate for active substance testing.
Pyraclostrobin shows a very steep concentration response relationship. Therefore, in several cases no effect was observed at the first concentration whereas 100% mortality was found at the next higher concentration. In other studies, only one mortality measurement could be made between 0 and 100% mortality. To obtain relevant figures for the following calculations, in the first case the LC_{50} was determined as geometric mean between the two concentrations, while in the latter case a Spearman-Karber estimate of the LC_{50} was calculated using the original mortality and analytical data for the relevant concentrations from the study reports. Thereby the results may deviate slightly from those given in some of the reports, where no statistical analysis of the LC_{50} had been performed. The respective results were corrected for analytically determined concentrations. These studies and the respective endpoint re-calculations have already been evaluated during the previous Annex I inclusion process.

Additional species testing reduces uncertainty in the risk assessment by addressing better capturing of inter-species variations in sensitivity. According to the proposals of the EFSA Panel on Plant Protection Products and their Residues (PPR) given in the Aquatic Guidance Document (EFSA, 2013), it is recommended to preferably apply a species sensitivity distribution (SSD) approach for refined risk assessment if data on a sufficient number of species is available for the respective group of aquatic organisms. For fish, the SSD approach should be applied if toxicity data is available for at least 5 different species (for pyraclostrobin data on 8 species are available). The PPR Panel further recommends to use acute NOEC/LC_{10} values to construct the SSD for fish, since a higher protection level is desired for vertebrates than for invertebrates and plants.

Therefore, an SSD analysis based on the 96 h NOEC values for 8 fish species was conducted and the results of these calculations are presented below. The data used for SSD calculations are summarized in Table 10.2-8. For fish species where more than one study was performed (i.e. *O. mykiss* and *L. macrochirus*), the arithmetic mean of the endpoints of these studies was considered for SSD calculations.

Table 10.2-8: Pyraclostrobin endpoints selected for calculation of the Hazardous Concentrations based on Species Sensitivity Distribution (SSD) Analysis

Test species	LC_{50} [µg a.s./L]	NOEC / LC_{10} [µg a.s./L]	Ratio (LC_{50}/NOEC)	Reference (BASF DocID)

Bold values were used for SSD calculations.
* Arithmetic mean value of two studies conducted with the same species.
\# Spearman-Karber estimate of LC_{50} (for confidence limits see endpoint tables above, Table 10.2-2).
\+ Geometric mean (for corresponding LC_0 (>) and LC_{100} (<) values see endpoint tables above).

The SSD calculations have been performed using the software tool ETX 2.0 (RIVM, 2004). The results (graphs and statistical results) are shown below. In the first step, the toxicity data (NOEC) were subjected to three different goodness of fit tests (Anderson-Darling, Kolmogorov-Smirnov and the Cramer von Mises), where the normality was checked at different significance levels. The respective analysis of the NOEC values confirms normal distribution of the data (see below).

Analysis of normality

Parameters of the normal distribution

Name	Value	Description
mean	1.114	mean of the log toxicity values
s.d.	0.341	sample standard deviation
n	8	sample size

Goodness of fit tests

Figure 10.2-1: SSD Histogram (based on 96 h NOEC values for 8 fish species)

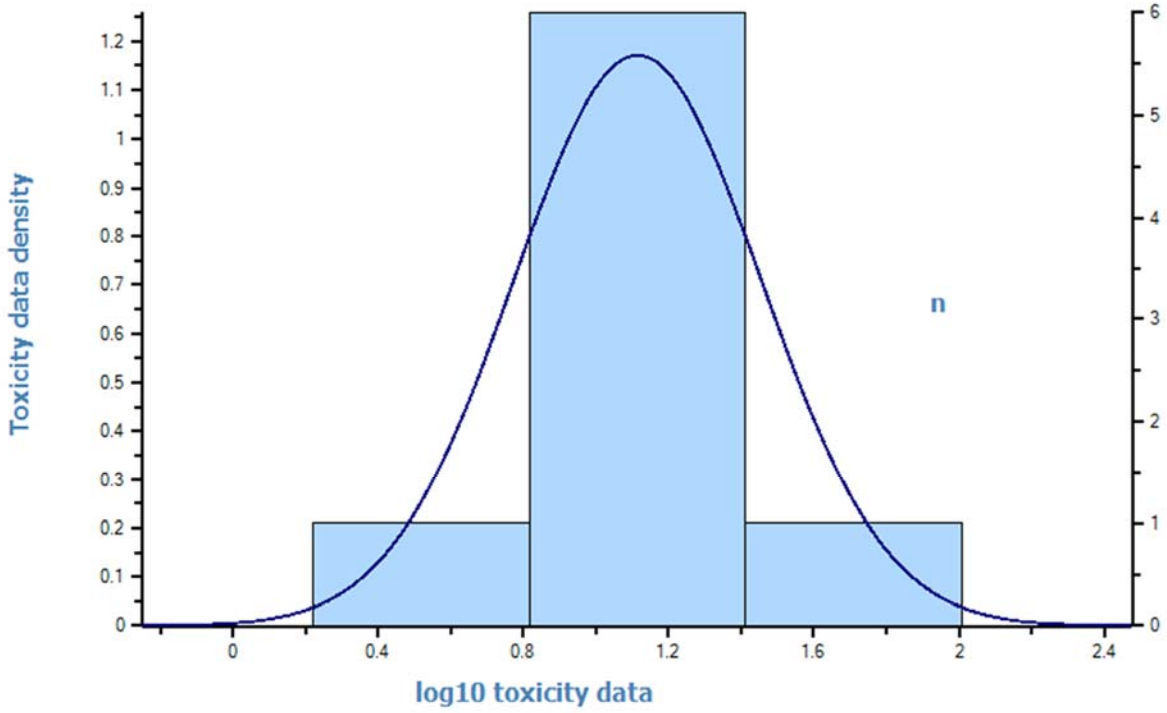

Figure 10.2-2: Species sensitivity distribution (based on 96 h NOEC values for 8 fish species)

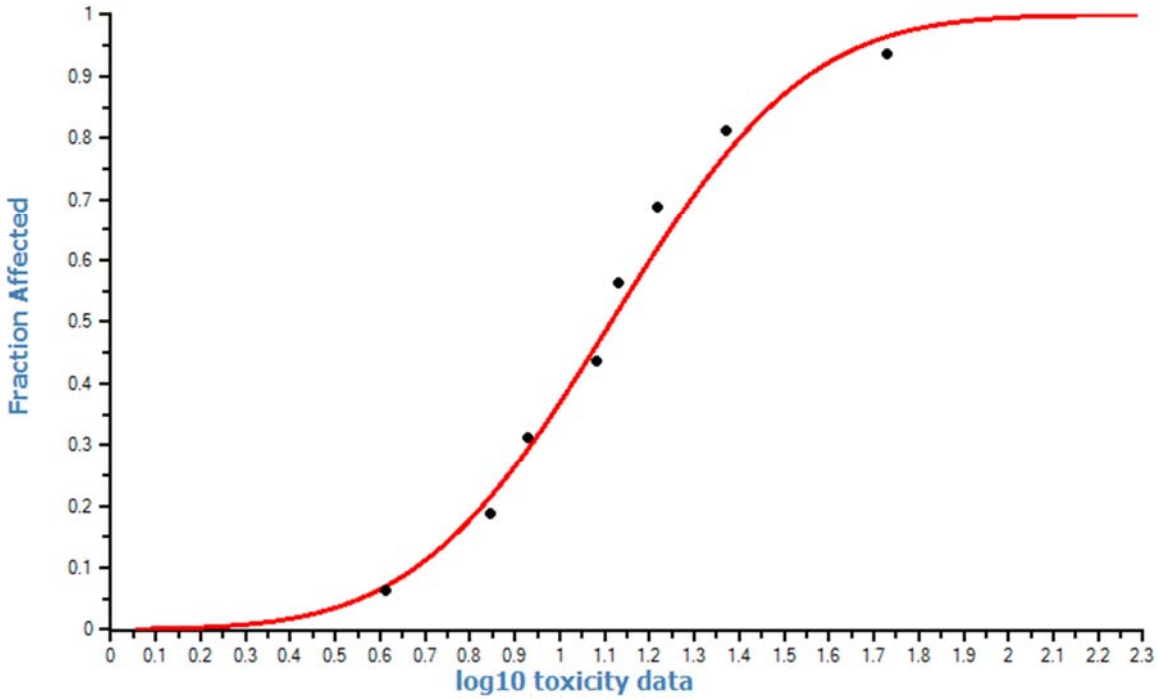

The median HC_5 (hazardous concentration to 5% of the tested species that is predicted with 50% certainty) and also the lower limit HC_5 values ($LLHC_5$; hazardous concentration to 5% of the tested species that is predicted with 95% certainty) can be derived from the SSD curves (see table below).

HC_5 results based on acute (96 h) NOEC data for 8 fish species

Name	Value	log10(value)	Description
LL HC_5	1.069	0.029	lower estimate of the HC_5
HC_5	**3.381**	0.529	median estimate of the HC_5
UL HC_5	6.139	0.788	upper estimate of the HC_5
sprHC_5	5.745	0.759	spread of the HC_5 estimate

The **median limit HC_5** for fish can thus be determined to be **3.381 µg a.s./**L.

According to the recommendation given in the EFSA Aquatic GD (2013), an **assessment factor of 3** should be applied on the median HC_5 from an SSD constructed with acute NOEC values for fish for derivation of an SSD-RAC (Regulatory Acceptable Concentration) when latency of effects is not to be expected, which is clearly the case for pyraclostrobin (compare chronic risk assessment for fish below). In this case, the use of an AF of 3 is considered warranted also taking into account the various aspects mentioned in the aquatic GD:

- The quality of the acute toxicity data used to construct the SSD is high. All data are based on endpoints from GLP studies meeting all the listed criteria and including analytical support. A wide taxonomical range has been covered with eight species from five different fish families.
- The lower limit value of the HC_5 is about one third of the median HC_5, the fit of the curve is good and the relevant statistical parameters are met well.
- The SSD-RAC is not higher than the tier 3 RAC derived from effect class 1 of the mesocosm study. In fact, it is about three times lower (might indicate the appropriateness of a lower assessment factor).
- The position of the toxicity data in the lower tail of the SSD are either on the SSD curve or are positioned on the right side of the SSD curve (might indicate the appropriateness of a lower assessment factor).
- The steepness of the SSD curve is less than a factor of 100 between the lowest and the highest NOEC, however, it has to be considered that this is an SSD approach for fish only, where in general the difference between species sensitivities is much less than for the taxonomically more diverse group of invertebrates. In fact, a wide range of sensitivities has been covered in this investigation.
- Since sufficient information is available for the substance, read-across information for compounds with a similar mode of action is not needed.
- The acute to chronic ratio is significantly smaller than 10 (might indicate the appropriateness of a lower assessment factor).

Accordingly, an assessment factor of three is well justified and still conservative.

The endpoint obtained with the marine fish species (*Cyprinodon variegatus)* is twice higher than the next least sensitive species. It might be considered to omit this endpoint from the freshwater fish risk assessment as it may not be representative for freshwater species. However, omitting this higher NOEC value, the resulting median and lower limit HC_5 and the lower limit of this value would be slightly higher (3.89 µg/L, respectively 1.48 µg/L as compared to 3.38 and 1.07 µg/L). As a conservative assumption the lower HC_5 value (i.e. including the higher toxicity endpoint) will be used.

Following this approach and applying the recommended assessment factor an **$SSD\text{-}RAC_{acute}$ of 1.13 µg a.s./L** can be derived. This concentration is considered unlikely to cause unacceptable toxicity to fish, the most sensitive group of aquatic organisms.

TER_A calculations based on the HC_5 value and worst-case FOCUS Step 3 and 4 $PEC_{sw, max}$ values are shown in Table 10.2-9.

Table 10.2-9: Fish acute TER values for pyraclostrobin based on the median HC_5 and worst-case FOCUS Step 3 and 4 $PEC_{sw, max}$ values

TERs shown in **bold** fall below the trigger of 3.
* A TER trigger of 3 is considered appropriate for comparison to the median HC_5 (for justification see above).
D = Drift mitigation using no-spray buffer zones, N = drift mitigation due to drift reducing nozzle techniques

Based on the SSD approach the TER_A values for pyraclostrobin indicate that a no-sprayed buffer zone of 5 m or the use of 50% drift reducing nozzles will be sufficient to avoid pyraclostrobin toxicity to fish following application of BAS 500 06 F in winter and spring cereals. For application in maize safe uses could be shown with no need for any additional mitigation measures.

In addition, a time-to-effect study has been performed with pyraclostrobin on rainbow trout as the most sensitive fish species (see M-CA 8.2.1, BASF DocID 2000/1014919). The study was conducted to assess the impact of short exposure pulses typical for moving water bodies such as streams by employing different exposure durations (i.e. 0.5, 2 and 8 hours). The results of this study demonstrate that short term exposure, which might be encountered in plumes of moving water bodies, will be tolerated at much higher levels. For short exposure times (i.e. 0.5 h), simulating average flow velocities in moving water bodies such as creeks and streams, LC_{50} values of > 27 µg/L were found. In a slower moving stream, generating exposure times of about 2 hours, concentrations of up to 18 µg/L are tolerated by the most sensitive species, and even more long-term pulses (8 hours) resulted in 2 - 3 times lower toxicity as compared to the standard 96 hour exposure period. This shows that - different from the values in Table 10.2-9 - there will be low risk to fish for winter and spring cereal application in moving water bodies such as streams without the need of an additional buffer zone.

We propose to base the overall RAC for edge of field surface waters on the hazardous concentrations (HC_5) derived from species sensitivity distributions with fish as recommended in Table 6 of the Aquatic Guidance Document (EFSA, 2013) considering that:

- There is a large dataset from acute and chronic fish studies
- Toxicity is driven by the acute toxicity
- There are no sub-lethal effects at concentrations without mortality even in long-term chronic studies
- Latency of effects is clearly not given
- Pyraclostrobin dissipates quite rapidly from water (short exposure periods only)

Nevertheless, for completeness the chronic risk will be addressed below and TER_{LT} will be provided as well.

TER_{LT} for fish

The long-term risk assessment to fish is based on a number of chronic fish studies. Next to a 28 day juvenile growth test, there is a standard ELS study on trout as well as a higher tier ELS study on trout with variable exposure pattern covering numerous peaks. Furthermore, there are two ELS studies with two additional fish species, fathead minnow and sheepshead minnow.

The higher tier ELS study (BASF DocID 1999/11537) had been considered to be not valid in the ECCO peer review based on “low survival in the control” (ECCO Peer Review Program, Full Report on Pyraclostrobin, 2002). However, this evaluation is assumed to be due to a misunderstanding. Within the report it is stated: “…the survival in the viability control (= fertilization success) after 14 days was only 28%”. This describes the fertilization rate and not the survival of the controls, which in fact was high and well within the standard validation criteria. The fertilization rate was rather low, because eggs and sperm were derived from fish out of the usual breading season. Therefore, a higher number of eggs was fertilized and only fertilized eggs were used further in the test, which then showed a sufficiently high survival (well above the validity criteria). Accordingly, this study is considered valid for the assessment of chronic toxicity to fish from a realistic worst-case, multiple peak exposure scenario covering different life stages and all relevant chronic endpoints.

In addition to the ELS study on *O. mykiss,* ELS studies on two other fish species have been performed (i.e. *C. variegatus* and *P. promelas;* see Table 10.2-2). The results for the three tested fish species can be used to calculate the **geometric mean of 4.72 µg a.s./L.** Considering the standard chronic assessment factor of 10 this results in a **Geomean-RAC$_{chronic}$ of 0.472 µg a.s./L**.

This approach is in line with the EFSA Aquatic GD (2013), which states that the geometric mean-AF approach may be applied for refined risk assessment, when toxicity data for a limited number of additional test species are available. All preconditions for using this approach that were set out in the EFSA Aquatic GD (chapter 8.3.2 and 8.3.3) are fulfilled:

- *similar endpoints:*
  NOEC values are all derived from ELS fish studies and are based on the same effect parameter (i.e. mortality)
- *species of the same taxonomic group:*
  aquatic vertebrates (fish)
- *available data exceed the first tier data requirements:*
  additional studies on *C. variegatus* and *P. promelas*
- *most sensitive species should not be more than a factor of 10 (for chronic tests) below the geometric mean:*
  O. mykiss NOEC= 2.35 µg/L, geomean = 4.72 µg/L, factor = 2
- *< 5 species tested:*
  3 different species
- *if the lowest toxicity value is higher than the Geomean-RAC value, it is acceptable to use the Geometric mean approach:*
  O. mykiss NOEC= 2.35 µg/L > Geomean-RAC value = 0.472 µg/L

Alternatively, the endpoint from the higher tier trout ELS study can be used for the long-term risk assessment for fish. This study employed a slightly more realistic but still worst-case exposure and resulted in a NOEC of 5 µg/L. Applying the standard assessment factor of 10 would derive a RAC of 0.5 µg/L. In the following we use the more conservative lower endpoint based on the Geomean of the three fish ELS studies (4.72 µg/L).

The TER$_{LT}$ values for pyraclostrobin and fish based on worst-case FOCUS Step 2 PEC$_{sw}$ values are shown in Table 10.2-10 to Table 10.2-12.

Table 10.2-10: Fish long-term TER values for pyraclostrobin based on the geomean of three fish ELS studies and worst-case FOCUS Step 3 and 4 $PEC_{sw,\ max,\ ini}$ values for BAS 500 06 F applications in winter cereals

D = Drift mitigation using no-spray buffer zones, N = drift mitigation due to drift reducing nozzle techniques,
R = runoff mitigation by vegetated filter strips.

Based on FOCUS Step 3 and 4 calculations using initial $PEC_{sw, max\ ini}$ values and considering the standard assessment factor of 10, low chronic risk to fish can be demonstrated if certain mitigation measures are considered for the proposed uses of BAS 500 06 F, the level of which depends on the GAP and FOCUS scenario.
However, considering the very narrow acute to chronic ratio and the clear lack of any latency of effects and the relatively short half-life of pyraclostrobin in water it is proposed to derive the overall RAC for edge-of-field surface waters based on hazardous concentrations derived from species sensitivity distribution with fish (= 1.13 µg a.s./L).

In conclusion, taking into account all relevant data and the results of different refinement approaches there is overall weight-of-evidence that no-spray buffer zones of 5 m or the use of drift reducing nozzles (50% drift reduction) for winter and spring cereals and no additional mitigation measure for maize will be sufficient to avoid unacceptable long-term risk to fish following the proposed uses of BAS 500 06 F.

Amphibian tadpoles

There is some limited information from literature on amphibian tadpoles, another aquatic vertebrate group. Hooser et al. (2012) (see CA 8.2.8/6) observed tadpole toxicity to the active substance pyraclostrobin (LC_{50} = 10 µg/L), which is in the range of fish data. The spacing of concentrations was rather rough (factor of three). Therefore, a more precise derivation of the LC_{50} is difficult. They observed higher toxicity for a pyraclostrobin formulated product (LC_{50} = 3.7 µg/L) with apparently slight mortality at 1.7 µg/L already. In another study of the same research group (Hartman et al. 2014, see CA 8.1.4/3) tadpoles of the same species were used again and exposed over a long term period at 1.7 µg/L. In this study they did not find any mortality at all; in contrast they found that tadpoles within this treatment group performed actually better than the control showing a shorter development time, without negative impact at all on biomass development. The slightly positive impact of the fungicide treatment is difficult to evaluate as the overall and particularly the control performance of the tadpoles (i.e. the development time) was rather poor.

Several literature evaluations compare the aquatic toxicity of amphibians to other aquatic organisms and fish in particular (Aldrich, 2009; Fryday and Thompson, 2012). The most comprehensive one was published recently (Weltje et al., 2013). A common conclusion of these data evaluations is that other aquatic endpoints (generally available for pesticides) cover the potential toxicity to amphibians in water.
The literature data shown above is not fully conclusive, however, seems to confirm in general the same trend. Accordingly, we consider that the risk assessment performed for fish as the most sensitive group of aquatic organisms should also cover the risk to amphibians.
It has to be borne in mind though that amphibian tadpoles may inhabit shallower water bodies than fish. If such sensitive water bodies are close to treated fields and if tadpoles inhabit such systems during time of application, there might be a higher risk to this group of organisms. The exact level would need to be determined by a proper and robust test on tadpoles. If for example we assume a twice lower water level, but if toxicity to tadpoles would also be twice lower as compared to the most sensitive fish species (which is roughly the case here considering the a.s. data for tadpoles (Hooser E.A. et al., 2012, see CA 8.2.8/6) and the lowest fish endpoint), then the resulting risk would be the same.

TER_A for *Daphnia magna*

The TER_A values for *Daphnia magna* were calculated for pyraclostrobin and its major metabolites using worst-case FOCUS Step 1 and 2 $PEC_{sw, max}$ values and are given in Table 10.2-13.

Table 10.2-13: Acute TER values for *D. magna* exposed to pyraclostrobin and its major metabolites using worst-case FOCUS Step 1 and 2 $PEC_{sw, max}$ values

Test organism	Test substance	48 h EC_{50} [µg/L]	FOCUS Step	$PEC_{sw, max}$ [µg/L]	TER_A	Trigger value
cereals						
D. magna	pyraclostrobin	15.7	2	2.299	**6.8**	100
D. magna	BF 500-5	> 10000	1	0.256	> 39063	100

TERs shown in **bold** fall below the relevant trigger.
D = Drift mitigation using no-spray buffer zones, N = drift mitigation due to drift reducing nozzle techniques,
R = runoff mitigation by vegetated filter strips.

Based on FOCUS Step 3 and 4 standard calculations using maximum initial PEC_{sw} values, the TER_A values for pyraclostrobin exceed the trigger value of 100, considering vegetated buffer zones of up to 20 m and/or the use of drift reducing nozzles following application of BAS 500 06 F in cereals and maize.

However, a mesocosm study is available indicating low risk to aquatic invertebrates at concentrations of 8 µg a.s./L or less (for more details see also the following chapter on *Daphnia* long term risk assessment).

Comparison of the respective worst-case FOCUS Step 2 $PEC_{sw, max}$ value for the active substance pyraclostrobin (= 2.299 µg a.s./L for cereals and 1.839 µg a.s./L for maize) to the proposed $RAC_{mesocosm}$ demonstrates low risk to aquatic invertebrates following the proposed uses of BAS 500 06 F with no need for additional mitigation measures.

Additional studies have been conducted with the marine invertebrate species *A. bahia* and *C. virginica*, partly resulting in lower endpoints compared to EC_{50} for *D. magna* (see M-CA 8.2). However, the mesocosm study includes a great number of different and more relevant freshwater invertebrate species (for more details see below and chapter M-CA 8.2). Thus, the higher tier assessment based on the mesocosm study is most appropriate to address the risk to aquatic invertebrates.

TER_{LT} for *Daphnia magna*

The TER_{LT} values for *Daphnia magna* were calculated for pyraclostrobin using the FOCUS Step 2 $PEC_{sw, max}$ values and are given in Table 10.2-17.

Table 10.2-17: Long-term TER values for *D. magna* exposed to pyraclostrobin using worst-case FOCUS Step 2 $PEC_{sw, max}$ values

Crop	Test organism	21 d NOEC [µg/L]	FOCUS Step	$PEC_{sw, max}$ [µg/L]	TER_{LT}	Trigger value
cereals	*D. magna*	4.0	2	2.299	**1.7**	10
maize	*D. magna*	4.0	2	1.839	**2.2**	10

TERs shown in **bold** fall below the relevant trigger.

The TER_{LT} values for pyraclostrobin are below the long-term trigger value of 10 based on FOCUS Step 2 calculations for application in cereals and maize. Therefore, additional TER calculations based on FOCUS Step 3 and 4 $PEC_{sw, max}$ values are presented in Table 10.2-18 to Table 10.2-20.

Table 10.2-18: Long-term TER values for *D. magna* exposed to pyraclostrobin using worst-case FOCUS Step 3 and 4 $PEC_{sw, max}$ values following applications of BAS 500 06 F in winter cereals

TERs shown in **bold** fall below the relevant trigger.
D = Drift mitigation using no-spray buffer zones, N = drift mitigation due to drift reducing nozzle techniques,
R = runoff mitigation by vegetated filter strips.

Based on FOCUS Step 3 and 4 standard calculations using maximum initial PEC_{sw} values, the TER_{LT} values for pyraclostrobin exceed the trigger value of 10, considering vegetated filter strips up to 10 m following application of BAS 500 06 F in winter cereals. Regarding application of BAS 500 06 F in spring cereals and maize safe uses can be demonstrated for all FOCUS scenarios if no spray-buffer zones of up to 10 m (and/or equivalent mitigation measures) are considered.

However, a mesocosm study is available (BASF DocID 2000/1000011 + supplement 2012/1357084) and a refined risk assessment has been performed providing more realistic information about the potential risk to aquatic invertebrates.

A mesocosm study provides a complex and compelling impression of the potential effects of a test substance under realistic conditions. Thus, mesocosm data allows for a general conclusion on aquatic ecosystems since major direct effects will be quite comparable within different systems (Leeuwangh, 1994).

The Dutch Platform for Assessment of Higher-Tier Studies has produced a Guidance Document on how micro-/mesocosm data should be presented and evaluated in a uniform and transparent manner (RIVM Guidance Document; de Jong et al., 2008;). The EFSA Aquatic GD (EFSA, 2013) proposes to largely use this document to present and evaluate micro-/mesocosm studies for regulatory purposes when placing plant protection products on the European market. Consequently, the mesocosm study has been evaluated following the RIVM Guidance document; for details please refer to the supplement to this study (BASF DocID 2012/1357084). Executive summaries of the originally submitted study and the evaluation according to RIVM are provided in M-CA 8.2. The mesocosm evaluation according to this new procedure results basically in the same conclusion as previously given during the Annex I listing process, i.e. a high quality study covering a wide range of sensitive species and measurements providing robust endpoints.

The results of the extensive and complex mesocosm study using a worst-case exposure scenario (i.e. 8 applications of the test substance applied as the solo-formulation BAS 500 00 F) showed that pyraclostrobin can have effects on a few species at concentrations of 24 µg a.s./L. For all plankton species the effects were found to be reversible. These transient effects are thus not considered to pose a significant (ecologically unacceptable) risk to planktonic communities in aquatic ecosystems. However, fish and molluscs may also be affected at this concentration. No effects on any species or endpoint were observed at the second highest test concentration of 8 µg a.s./L, constituting the ecosystem NOEC. The multitude of endpoints and species and environmental conditions in this mesocosm study show clearly that at this (and lower) concentration no adverse effects on aquatic communities can be expected even after multiple applications. The ecologically acceptable concentration (NOEAEC) of pyraclostrobin is thus between 8 µg a.s./L and 24 µg a.s./L.

In addition, this study still encompassed unrealistic worst case conditions (8 applications of the test substance). The number of applications will be much less under practical conditions (1-4). It is highly unlikely, that eight times a 95% worst case situation with respect to drift will be encountered.

Considering the multitude of endpoints covered, the inclusion of sensitive and relevant species, the worst-case character of the mesocosm study related to exposure and the realistic worst-case test system applied, it can be concluded that no assessment factor to the **NOEC of 8 µg a.s./L** is warranted (which is also in line with previous recommendations and guidances). However, the new Aquatic Guidance Document (EFSA 2013) recommends using an assessment factor of two in this case for the ETO-RAC derivation. Following this approach, this results in an **$RAC_{mesocosm}$ of 4 µg a.s./L.**

A comparison of the respective worst-case FOCUS Step 2 $PEC_{sw, max}$ value for the active substance pyraclostrobin (= 2.299 µg a.s./L for cereals and 1.839 µg a.s./L for maize) to the proposed $RAC_{mesocosm}$ demonstrates low risk to aquatic invertebrates following the proposed uses of BAS 500 06 F with no need for any additional mitigation measures.

TER_A for aquatic insect

Acute tests were not conducted with an aquatic insect species. Instead, chronic studies were performed with the active substance pyraclostrobin and its soil metabolites BF 500-3, BF 500-6 and BF 500-7 on *Chironomus riparius*, which address the potential long-term risk of the active substance to aquatic insects (see below). Furthermore, a mesocosm study is available for pyraclostrobin covering various aquatic invertebrate species including aquatic insects.

TER_{LT} for aquatic insect

TER_{LT} values for *Chironomus riparius* were calculated for water and sediment exposure.

The resulting TER_{LT} values for pyraclostrobin following water exposure using FOCUS Step 2 PEC_{sw} values are given in Table 10.2-21.

Table 10.2-21: Long-term TER values for *C. riparius* exposed to pyraclostrobin using worst-case FOCUS Step 2 $PEC_{sw, max}$ values (water exposure)

Test organism	28 d NOEC [µg/L]	Crop	FOCUS Step	$PEC_{sw, max}$ [µg/L]	TER_{LT}	Trigger value
C. riparius (spiked water)	40	cereals	2	2.299	17	10
		maize	2	1.839	22	10

The TER_{LT} values for pyraclostrobin exceed the long-term trigger of 10 based on FOCUS Step 2 calculations, indicating low chronic risk to aquatic insects resulting from water exposure following application of BAS 500 06 F in cereals and maize.

In order to assess similarly the risk arising from sediment exposure, TER values were calculated using the 28 d NOECs from chronic spiked-sediment studies with *C. riparius.* The resulting TER_{LT} values for pyraclostrobin and its soil (sediment) metabolites BF 500-3, BF 500-6 and BF 500-7 using FOCUS Step 1 and 2 PEC_{sed} values are given in Table 10.2-22.

Table 10.2-22: Long-term TER values for *C. riparius* exposed to pyraclostrobin and the metabolites BF 500-3, BF 500-6 and BF 500-7 using worst-case FOCUS Step 1 and 2 $PEC_{sed, max}$ values (sediment exposure)

Test substance	Test organism	28 d NOEC [µg/kg dry sediment]	FOCUS Step	$PEC_{sed, max}$ [µg/kg dry sediment]	TER_{LT}	Trigger value
cereals						
pyraclostrobin	*C. riparius* (spiked sediment)	1370	2	187.230	**7.3**	10
BF 500-3	*C. riparius* (spiked sediment)	≥ 16000	1	20.030	≥ 799	10
BF 500-6	*C. riparius* (spiked sediment)	1200	2	60.344	20	10
BF 500-7	*C. riparius* (spiked sediment)	≥ 123500	1	182.976	≥ 675	10
maize						
pyraclostrobin	*C. riparius (spiked sediment)*	1370	2	95.014	14	10
BF 500-3	*C. riparius* (spiked sediment)	≥ 16000	1	8.012	≥ 1997	10
BF 500-6	*C. riparius (spiked sediment)*	1200	2	24.752	48	10
BF 500-7	*C. riparius (spiked sediment)*	≥ 123500	1	73.190	≥ 1687	10

TERs shown in **bold** fall below the relevant trigger.

The TER_{LT} value for pyraclostrobin is just below the trigger of 10 based on FOCUS Step 2 calculation for application in cereals. Therefore, additional TER calculations based on FOCUS Step 3 PEC values for cereals are presented in Table 10.2-23. For application of BAS 500 06 F in maize, the TER_{LT} value for pyraclostrobin exceeds the trigger based on FOCUS Step 2 calculation, indicating low chronic risk to aquatic insects resulting from sediment exposure.

The TER_{Lt} values for the metabolites BF 500-3, BF 500-6 and BF 500-7 exceed the trigger value of 10 based on Step 1 and 2 calculations, indicating low ecotoxicological relevance of the metabolites.

Table 10.2-23: Long-term TER values for *C. riparius* exposed to pyraclostrobin using worst-case FOCUS Step 3 $PEC_{sed,\ max}$ values for application in cereals (sediment exposure)

Based on FOCUS Step 3 calculations, the TER_{LT} values for pyraclostrobin by far exceed the standard trigger of 10, indicating low risk to aquatic (sediment dwelling) insects resulting from sediment exposure following application of BAS 500 06 F in cereals.

Furthermore, a mesocosm study is available for pyraclostrobin covering various aquatic invertebrate species including aquatic insects. Based on the mesocosm results a $RAC_{mesocosm}$ of 4 µg a.s./L could be received (see text above), demonstrating low risk to aquatic organisms (at FOCUS Step 2 level) following the proposed uses of BAS 500 06 F with no need for any additional mitigation measures.

TER_A for aquatic crustacean

An acute spiked sediment study has been conducted with the estuarine amphipod *Leptocheirus plumulosus.* The sensitivity of this marine crustacean species seems to be within the range of freshwater species (NOEC = 2.74 mg/kg as compared to 1.37 mg/kg for *Chironomus* in the chronic test). Although this study is not required for registration in the EU, TER calculations based on the resulting 10-day LC_{50} value and worst-case FOCUS Step 2 $PEC_{sed, max}$ are presented in Table 10.2-24.

Table 10.2-24: Acute TER values for *L. plumulosus* exposed to pyraclostrobin using worst-case FOCUS Step 2 $PEC_{sed, max}$ values (sediment exposure)

Test organism	10 d LC_{50} [µg/kg dry sediment]	Crop	FOCUS Step	$PEC_{sed, max}$ [µg/kg dry sediment]	TER_A	Trigger value
Leptocheirus plumulosus	4410	cereals	2	187.230	**24**	100
		maize	2	95.014	**46**	100

TERs shown in **bold** fall below the relevant trigger.

The TER_A values for sediment exposure to pyraclostrobin are below the required trigger of 100 based on FOCUS Step 2 calculations for application of BAS 500 06 F in cereals and maize. Therefore, additional TER calculations based on FOCUS Step 3 PEC values are presented in Table 10.2-25.

Table 10.2-25: Acute TER values for *L. plumulosus* exposed to pyraclostrobin using worst-case FOCUS Step 2 $PEC_{sw, max}$ values (sediment exposure)

Based on FOCUS Step 3 calculations, the TER_A values for pyraclostrobin exceed the standard trigger of 100, indicating low acute risk.

Furthermore, a mesocosm study is available for pyraclostrobin covering various aquatic invertebrate species including aquatic crustacean species (see above).

TER_{LT} for aquatic crustacean

TER_{LT} calculations for the freshwater crustacean *Daphnia magna* are presented above.

An additional chronic study has been conducted with the marine species *A. bahia* showing lower endpoints compared to the NOEC *for D. magna*. However, the mesocosm study (see above) includes a great number of different and relevant freshwater invertebrate species providing strong evidence that the mysid data are not representative for freshwater organisms. Thus, the higher tier assessment based on the mesocosm study provides the more relevant and more comprehensive data base for the assessment of the risk to freshwater invertebrates.

TER_A for aquatic gastropod mollusc

TER_A values for aquatic gastropod molluscs are not required since BAS 500 06 F is not foreseen for direct application to surface water.
An additional chronic study has been conducted for the US with the marine species *C. virginica* showing endpoints in the range of *D. magna* endpoints. However, the mesocosm study (see above) includes a great number of different and relevant freshwater invertebrate species including aquatic gastropod molluscs. Thus, the higher tier assessment based on the mesocosm study provides the more relevant and more comprehensive data base for the assessment of the risk to freshwater invertebrates.

TER_{LT} for aquatic gastropod mollusc

TER_{LT} values for aquatic gastropod molluscs are not required since BAS 500 06 F is not foreseen for direct application to surface water. Therefore, no investigations have been performed with aquatic gastropod molluscs. Furthermore, mesocosm data are available for the active substance pyraclostrobin and thus information on gastropod mollusc species.

TER for algae

Besides the study on the standard green alga *P. subcapitata*, studies on three further alga species have been conducted, partly resulting in lower endpoints compared to the endpoints for the green alga. However, following the recommendations and validity criteria defined in the current OECD guideline 201 for alga testing (OECD, 2011) the 120 h studies with the blue-green alga *Anabaena flos-aquae* and marine diatom *Skeletonema costatum* are considered to be not valid because in both studies, at least one validity criterion is not met (for details please refer to chapter M-CA 8.2).
The study with the freshwater diatom *Navicula pelliculosa* showed some shortcomings, too, i.e. no clear dose-response relationship could be shown, because effects at the four highest tested concentrations were in a similar range (i.e. growth rate after 120 h at the four highest tested concentrations is between 68 and 72% of control). Moreover, a mesocosm study is available including a great number of different algae species (including *Navicula* species). Thus, the higher tier assessment based on the mesocosm study provided above also covers the risk to algae. At tier 1 level, TER calculations are thus only performed based on the re-calculated 72 hour growth rate endpoint from the 96 hour study with the standard green alga *P. subcapitata.*
The resulting TER values for pyraclostrobin and its major metabolites using FOCUS Step 1 $PEC_{sw, max}$ values are given in Table 10.2-26.

Table 10.2-26: TER values for algae exposed to pyraclostrobin and its major metabolites using worst-case FOCUS Step 1 $PEC_{sw, max}$ values

Test organism	Test substance	72 h E_rC_{50} [µg/L]	FOCUS Step	$PEC_{sw, max}$ [µg/L]	TER	Trigger value
cereals						
P. subcapitata	pyraclostrobin	> 843	1	17.031	> 49	10
P. subcapitata	BF 500-5	5330	1	0.256	20820	10
S. subspicatus	BF 500-11	> 100000	1	0.407	> 245700	10
S. subspicatus	BF 500-13	> 100000	1	0.533	> 187617	10
S. subspicatus	BF 500-14	> 100000	1	0.573	> 174520	10
maize						
P. subcapitata	pyraclostrobin	> 843	1	6.813	> 124	10
P. subcapitata	BF 500-5	5330	1	0.102	52255	10
S. subspicatus	BF 500-11	> 100000	1	0.163	> 613497	10
S. subspicatus	BF 500-13	> 100000	1	0.213	> 469484	10
S. subspicatus	BF 500-14	> 100000	1	0.229	> 436681	10

The TER values for pyraclostrobin and its metabolites BF 500-5, BF 500-11, BF 500-13 and BF 500-14 exceed the trigger of 10 based on worst-case FOCUS Step 1 calculations, indicating low risk to algae following application of BAS 500 06 F in cereals and maize with no need for additional mitigation measures.

TER_{LT} for aquatic plants

Additional aquatic plant testing would not be required for this fungicide, however, for registration purposes in the USA a Lemna study is available. The respective TER_{LT} values for aquatic plants (given in Table 10.2-27) were calculated for pyraclostrobin using the growth rate endpoint of the 14 day study with *Lemna gibba* and FOCUS Step 1 $PEC_{sw, max}$ values.

Table 10.2-27: TER_{LT} values for *Lemna gibba* exposed to pyraclostrobin using FOCUS worst-case Step 1 $PEC_{sw, max}$ values

Test organism	14 d E_rC_{50} [µg/L]	Crops	FOCUS Step	$PEC_{sw, max}$ [µg/L]	TER_{LT}	Trigger value
L. gibba	1720	cereals	1	17.031	101	10
		maize	1	6.813	252	10

The TER_{LT} values for pyraclostrobin exceed the trigger of 10 based on worst-case FOCUS Step 1 calculations, indicating low risk to aquatic plants following application of BAS 500 06 F in cereals and maize with no need for additional mitigation measures.

Summary of the Refined Risk Assessment

Pyraclostrobin is toxic to aquatic organisms. Based on standard precautionary assumptions, a risk to aquatic organisms is indicated following applications of a product containing this active substance. In order to refine the risk a number of additional and higher tier studies were performed. These include additional species testing, tests using more realistic exposure scenarios, a time-to-effect study and a mesocosm investigation.

The mesocosm study, which covers a wide range of relevant and sensitive aquatic organisms (but only one fish species), results in a clear NOEC of 8 µg/L, even though it simulates a worst case exposure situation. Accordingly, an ETO-RAC of 4 µg/L can be derived.
In order to further refine the risk assessment for fish besides the standard fish species *O. mykiss,* seven additional fish species were tested in acute 96 h laboratory studies with pyraclostrobin. In line with the recommendations of the Aquatic Guidance document (EFSA, 2013) an SSD analysis was conducted based on the 96 h NOEC values. The median HC_5 for fish was determined to be 3.381 µg a.s./L. An assessment factor of 3 was shown to be warranted to be applied on the median HC_5. Following this approach an overall **RAC** for edge-of-field surface waters **of 1.13 µg a.s./L** can be derived.

Overall Conclusion

The fungicidal product BAS 500 06 F and the active substance pyraclostrobin, respectively, show toxicity to aquatic organisms and contamination of aquatic ecosystems must be avoided. However, the refined risk assessment provided for pyraclostrobin and the standard assessment for its major metabolites demonstrate that application of BAS 500 06 F in cereals and maize according to good agricultural practice is of low risk to aquatic ecosystems without additional mitigation measures for maize and if no-spray buffer zones of 5 m or 50% drift reducing nozzles are considered for winter and spring cereals.

CP 10.2.1 Acute toxicity to fish, aquatic invertebrates, or effects on aquatic algae and macrophytes

The following fish acute toxicity study performed with the new representative formulation BAS 500 06 F is provided in support of the assessment and has not been previously evaluated on the EU-level.

Report:	CP 10.2.1/1 [redacted] 2008a BAS 500 06 F - Acute toxicity study with the rainbow trout (Oncorhynchus mykiss) 2008/1018046
Guidelines:	OECD 203, EEC 92/69 A V C 1, EPA 72-1, EPA 850.1075, EPA 540/9-82-024, EPA 712-C-96-118
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a static acute toxicity laboratory study, juvenile rainbow trout were exposed to nominal concentrations of 0.005, 0.010, 0.022, 0.050 and 0.10 mg BAS 500 06 F/L (corresponding to mean measured concentrations of 0.0056, 0.0105, 0.0166, 0.0393 and 0.0930 mg/L) and a water control in groups of 10 animals in glass aquaria containing 50 L water. Fish were observed for survival and symptoms of toxicity within 1 hour after start of exposure and 6, 24, 48, 72 and 96 hours after start of exposure.

The biological results are based on mean measured concentrations of the active substance. After 96 hours of exposure no mortality was observed in the control and at mean measured concentrations of up to and including 0.0166 mg BAS 500 06 F/L, whereas 80% and 100% mortality occurred at the two highest tested concentrations of 0.0393 mg/L and 0.0930 mg/L, respectively. After 96 hours of exposure no sublethal effects were observed for surviving fish.

In a static acute toxicity study with rainbow trout, the LC_{50} (96 h) of BAS 500 06 F was 0.036 mg/L based on mean measured concentrations. The NOEC (96 h) was determined to be 0.017 mg/L (mean measured).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304428): 202.7 g/L (nominal: 200 g/L); density: 1.044 g/cm^3.

B. STUDY DESIGN

Test species: Rainbow trout (*Oncorhynchus mykiss*); age: approx. 4 months; mean body length: 5.8 cm (5.2 - 6.3 cm); mean body weight: 1.81 g (1.14 - 2.29 g); supplied by "Forellenzucht Trostadt GbR", Trostadt, Germany.

Test design: Static system (96 hours); 10 fish per aquarium (loading: 0.36 g fish/L) and per concentration, assessments of mortality and symptoms of toxicity within 1 h after start of exposure and 6, 24, 48, 72 and 96 h after start of exposure.

Endpoints: LC_{50}, NOEC, mortality and sub-lethal effects.

Test concentrations: Control, 0.005, 0.010, 0.022, 0.050 and 0.100 mg BAS 500 06 F/L (nominal); corresponding to mean measured concentrations of 0, 0.0056, 0.0105, 0.0166, 0.0393 and 0.0930 mg/L.

Test conditions: Glass aquaria with stainless steel frame (60 x 35 x 40 cm), test volume: 50 L, non-chlorinated, filtered tap water mixed with deionized water; temperature: 13°C; pH 8.0 - 8.2; oxygen content: 8.1 mg/L - 10.3 mg/L; total hardness about 1 mmol/L; conductivity approx. 250 µS/cm; acid capacity about 2.5 mmol/L; photoperiod: 16 h light : 8 h dark; light intensity: approx. 100 lux - 490 lux; no aeration, no feeding.

Analytics: Analytical verification of test item concentrations was conducted using an HPLC-method with MS-detection.

Statistics: Descriptive statistics; probit analysis for calculation of LC_{50}.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each concentration at the beginning and at the end of the test. The initially measured concentrations of pyraclostrobin in the three highest test concentrations were within 10% of the nominal concentrations (i.e. between 93 and 97%). In the two lowest concentrations the initially measured values ranged from 124 to 135% of nominal. At test termination, the analytically determined values for pyraclostrobin decreased to 54 - 93% of nominal. The biological results are based on mean measured concentrations.

Biological results: After 96 hours of exposure no mortality was observed in the control and at mean measured concentrations of up to and including 0.0166 mg BAS 500 06 F/L, whereas 80% and 100% mortality occurred at the two highest tested concentrations of 0.0393 mg/L and 0.0930 mg/L, respectively. After 96 hours of exposure no sublethal effects were observed for surviving fish. The results are summarized in Table 10.2.1-1.

Table 10.2.1-1: Acute toxicity of BAS 500 06 F on rainbow trout (*Oncorhynchus mykiss*)

Concentration [mg/L] (nominal)	**Control**	**0.005**	**0.010**	**0.022**	**0.050**	**0.100**
Concentration [mg/L] (mean measured)	**Control**	**0.0056**	**0.0105**	**0.0166**	**0.0393**	**0.0930**
Mortality (96 h) [%]	0	0	0	0	80	100
Symptoms (96 h)	none	none	none	none	none	n.d.
Endpoints [mg BAS 500 06 F/L] (mean measured)						
LC_{50} (96 h)	0.036					
NOEC (96 h)	0.017					

n.d. = not determined; all animals dead

III. CONCLUSION

In a static acute toxicity study with rainbow trout, the LC_{50} (96 h) of BAS 500 06 F was 0.036 mg/L based on mean measured concentrations. The NOEC (96 h) was determined to be 0.017 mg/L (mean measured).

The following fish acute toxicity study was performed with BAS 500 06 F for the registration in Japan. It has not been previously evaluated on the EU-level. As this study does not provide a lower endpoint (compared to the standard acute toxicity study) and as the correct test item application was confirmed by initial analytical measurements, an additional re-calculation of endpoints considering mean measured concentrations of the a.s. is not needed.

Report:	CP 10.2.1/2 [redacted] 2012a BAS 500 06 F - Acute toxicity study in the common carp (Cyprinus carpio) 2012/1250190
Guidelines:	(EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part C.1, OECD 203 (1992)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a static acute toxicity laboratory study, juvenile common carp were exposed to nominal concentrations of 0.032, 0.056, 0.10, 0.18 and 0.32 mg BAS 500 06 F/L and a water control in groups of 10 animals in glass aquaria containing 50 L water. Fish were observed for survival and symptoms of toxicity within 1 hour after start of exposure and 6, 24, 48, 72 and 96 hours after start of exposure.

The biological results are based on nominal concentrations of the test item. After 96 hours of exposure no mortality was observed in the control and at the lowest tested concentration of 0.032 mg BAS 500 06 F/L, whereas 10 and 40% mortality was observed at 0.056 mg/L and 0.10 mg/L, respectively. 100% mortality was observed at the two highest tested concentrations of 0.18 and 0.32 mg/L. After 96 hours of exposure, sublethal effects (i.e. swimming at the bottom) were observed for some of the surviving fish in the 0.10 mg/L test item treatment.

In a static acute toxicity study with common carp, the LC_{50} (96 h) of BAS 500 06 F was 0.098 mg/L based on nominal concentrations. The NOEC (96 h) was determined to be 0.032 mg/L (nominal).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 0003223026; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304428): 200.7 g/L (nominal: 200 g/L); density: 1.038 g/cm^3.

B. STUDY DESIGN

Test species: Common carp (*Cyprinus carpio*); age: approx. 3 months; mean body length: 6.2 cm (5.6 - 6.9 cm); mean body weight: 2.62 g (1.78 - 3.83 g); supplied by "Fischzucht Rhönforelle GmbH", Gersfeld, Germany.

Test design: Static system (96 hours); 10 fish per aquarium (loading: 0.52 g fish/L) and per concentration, assessments of mortality and symptoms of toxicity within 1 h after start of exposure and 6, 24, 48, 72 and 96 h after start of exposure.

Endpoints: LC_{50}, NOEC, mortality and sub-lethal effects.

Test concentrations: Control, 0.032, 0.056, 0.10, 0.18 and 0.32 mg BAS 500 06 F/L (nominal).

Test conditions: Glass aquaria with stainless steel frame (60 x 35 x 40 cm); test volume: 50 L; non-chlorinated, filtered tap water mixed with deionized water; temperature: 22°C - 23°C; pH 8.1 - 8.5; oxygen content: 6.0 mg/L - 8.7 mg/L; total hardness about 100 mg $CaCO_3$/L; conductivity approx. 250 µS/cm; acid capacity about 2.5 mmol/L; photoperiod: 16 h light : 8 h dark; light intensity: approx. 62 lux - 415 lux; no aeration over the first 48 hours, but slight aeration during the subsequent days of exposure due to decreased oxygen content after 48 hours, no feeding.

Analytics: Analytical verification of test item concentrations was conducted using an HPLC-method with MS-detection.

Statistics: Descriptive statistics; probit analysis for calculation of LC_{50}.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each concentration at the beginning of the test, after 48 hours and, except for the highest concentration, at the end of the test. The measured concentrations of pyraclostrobin ranged from 86.8 to 108.5% of the nominal concentrations at test initiation and from 47.5 to 79.5% of the nominal concentrations at test termination. As the initially measured concentrations confirmed correct application of the test substance, the following biological results are based on nominal concentrations.

Biological results: After 96 hours of exposure no mortality was observed in the control and at the lowest tested concentration of 0.032 mg BAS 500 06 F/L, whereas 10 and 40% mortality was observed at 0.056 mg/L and 0.10 mg/L, respectively. 100% mortality was observed at the two highest tested concentrations of 0.18 and 0.32 mg/L. After 96 hours of exposure, sublethal effects (i.e. swimming at the bottom) were observed for some of the surviving fish in the 0.10 mg/L test item treatment. The results are summarized in Table 10.2.1-2.

Table 10.2.1-2: Acute toxicity of BAS 500 06 F on common carp (*Cyprinus carpio*)

Concentration [mg/L] (nominal)	**Control**	**0.032**	**0.056**	**0.10**	**0.18**	**0.32**
Mortality (96 h) [%]	0	0	10	40	100	100
Symptoms (96 h) [#]	none	none	none	D	n.d.	n.d.
Endpoints [mg BAS 500 06 F/L] (nominal)						
LC_{50} (96 h)	0.098 (95% confidence limits: 0.080 - 0.13)					
NOEC (96 h)	0.032					

[#] Symptoms after 96 hours of exposure: D = swimming at the bottom
n.d. = not determined; all animals dead

III. CONCLUSION

In a static acute toxicity study with common carp, the LC_{50} (96 h) of BAS 500 06 F was 0.098 mg/L based on nominal concentrations. The NOEC (96 h) was determined to be 0.032 mg/L (nominal).

The following acute aquatic invertebrate toxicity study performed with BAS 500 06 F is provided in support of the assessment and has not been previously evaluated on the EU-level.

Report:	CP 10.2.1/3 Funk M., 2004a Effect of BAS 500 06 F on the immobility of Daphnia magna STRAUS in a 48 hours static, acute toxicity test 2004/1004393
Guidelines:	OECD 202, EEC 79/831 A V C 2, EPA 850.1010
GLP:	yes (certified by Landesamt fuer Umweltschutz und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a static acute toxicity laboratory study, water flea neonates were exposed to BAS 500 06 F at nominal concentrations of 0.0056, 0.010, 0.018, 0.032, 0.056 and 0.10 mg/L in 4 replicates per concentration, containing 5 daphnids each. Daphnids were observed for immobility 24 hours and 48 hours after start of exposure.

The biological results are based on nominal concentrations of the test item. After 24 and 48 hours of exposure no immobility of daphnids was observed in the control and at test item concentrations of up to and including 0.032 mg BAS 500 06 F/L. After 48 hours of exposure, 25 and 100% of the daphnids were immobile at the two highest tested concentrations of 0.056 and 0.10 mg/L, respectively.

In a 48-hour static acute toxicity study with *Daphnia magna*, the EC_{50} of BAS 500 06 F was 0.065 mg/L based on nominal concentrations. The NOEC was determined to be 0.032 mg/L (nominal).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304428): 202.7 g/L (nominal: 200 g/L).

B. STUDY DESIGN

Test species: Water flea (*Daphnia magna* STRAUS), neonates collected from in-house culture (originally obtained from Institute National de Recherché Chimique Appliquée, France), less than 24 hours old at test initiation.

Test design: Static system (48 hours), 6 test concentrations plus control, 4 replicates with 5 daphnids each; assessment of immobility after 24 and 48 hours.

Endpoints: NOEC, EC_{50} based on immobility of daphnids.

Test concentrations: Control, 0.0056, 0.010, 0.018, 0.032, 0.056 and 0.10 mg/L (nominal).

Test conditions: Glass vessels; test volume 50 mL; dilution water "M4" (Elendt medium); pH 7.87 - 8.03; oxygen content: 9.11 mg/L - 9.95 mg/L; total hardness: 2.52 mmol/L at test initiation; conductivity: 615 µS/cm at test initiation; temperature 20.0°C - 21.5°C; light intensity: < 1500 lux; photoperiod: 16 h light :8 h dark; no feeding, no aeration.

Analytics: Analytical verification of test item concentrations was conducted using an HPLC-method with UV-detection.

Statistics: Descriptive statistics; log-log and probit analysis for calculation of EC_{50}.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each concentration at the beginning and at the end of the test. The analytically detected concentrations for pyraclostrobin ranged from 83.1 to 100.6% of the nominal concentration at test initiation and from 89.8 to 94.5% of nominal at test termination. As the measured concentrations confirmed correct application of the test substance, the following biological results are based on nominal concentrations.

Biological results: After 24 and 48 hours of exposure no immobility of daphnids was observed in the control and at test item concentrations of up to and including 0.032 mg BAS 500 06 F/L. After 48 hours of exposure, 25 and 100% of the daphnids were immobile at the two highest tested concentrations of 0.056 and 0.10 mg/L, respectively. For results see Table 10.2.1-3.

Table 10.2.1-3: Effect of BAS 500 06 F on *Daphnia magna* immobility

Concentration [mg/L] (nominal)	**Control**	**0.0056**	**0.010**	**0.018**	**0.032**	**0.056**	**0.10**
Immobility (24 h) [%]	0	0	0	0	0	15	70
Immobility (48 h) [%]	0	0	0	0	0	25	100
Endpoints [mg BAS 500 06 F/L] (nominal)							
EC_{50} (48 h)	0.065 (95% confidence limits: 0.057 - 0.075)						
NOEC (48 h)	0.032						

III. CONCLUSION

In a 48-hour static acute toxicity study with *Daphnia magna*, the EC_{50} of BAS 500 06 F was 0.065 mg/L based on nominal concentrations. The NOEC was determined to be 0.032 mg/L (nominal).

The following algae toxicity study performed with BAS 500 06 F is provided in support of the assessment and has not been previously evaluated on the EU-level.

Report:	CP 10.2.1/4 Hoffmann F., 2008a Effect of BAS 500 06 F on the growth of the green alga Pseudokirchneriella subcapitata 2008/1009325
Guidelines:	OECD 201
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a 72-hour static toxicity laboratory study, the effect of BAS 500 06 F on the growth of the green alga *Pseudokirchneriella subcapitata* was investigated. The following nominal concentrations were applied: 0 (control), 0.31, 0.77, 1.92, 4.80, 12.0 and 30.0 mg BAS 500 06 F/L (corresponding to mean measured concentrations of 0, 0.39, 0.84, 2.11, 4.80, 13.0 and 34.0 mg/L). Assessment of growth was conducted 0 h, 24 h, 48 h and 72 h after test initiation.

The biological results are based on mean measured concentrations of the test item. No morphological effects on the algae were observed in the control and at mean measured test item concentrations of up to and including 2.11 mg BAS 500 06 F/L. At 4.8 mg/L about 10%, at 13.0 mg/L about 50% and at 34.0 mg/L nearly all cells got round.

In a 72-hour algae test with *Pseudokirchneriella subcapitata*, the E_rC_{50} of BAS 500 06 F was determined to be 14.2 mg/L and the E_yC_{50} was 2.4 mg/L, based on mean measured concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304428): 202.7 g/L (nominal: 200 g/L).

B. STUDY DESIGN

Test species:	Unicellular fresh water green alga, *Pseudokirchneriella subcapitata* (Reinsch) Korshikov (syn. *Selenastrum capricornutum* Prinz), SAG 61.81; stock obtained from the "Sammlung von Algenkulturen" Göttingen, Germany.
Test design:	Static system; test duration 72 hours; 6 test concentrations, each with 5 replicates per treatment plus a control with 10 replicates; daily assessment of growth.
Endpoints:	EC_{10} and EC_{50} with respect to growth rate and yield after exposure over 72 hours.
Test concentrations:	Control, 0.31, 0.77, 1.92, 4.80, 12.0 and 30.0 mg/L (nominal); corresponding to mean measured concentrations of 0.39, 0.84, 2.11, 4.80, 13.0 and 34.0 mg/L.
Test conditions:	Erlenmeyer dimple flasks; test volume 60 mL; test medium according to OECD 201; initial cell densities: 1×10^4 cells/mL; pH 8.1 at test initiation and pH 7.82 - 8.04 at test end; temperature: 22°C ± 1°C; continuous light at about 8000 lux; continuous shaking.
Analytics:	Analytical verification of test item concentrations was conducted using an HPLC-method with MS-detection.
Statistics:	Descriptive statistics, probit analysis for determination of EC_x values for growth rate and yield.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each concentration at the beginning and at the end of the test. The analytically detected concentrations for pyraclostrobin ranged from 115.9 to 142.0% of the nominal concentration at test initiation and from 82.9 to 108.8% of nominal at test termination. The biological results are based on mean measured concentrations.

Biological results: No morphological effects on the algae were observed in the control and at mean measured test item concentrations of up to and including 2.11 mg BAS 500 06 F/L. At 4.8 mg/L about 10%, at 13.0 mg/L about 50% and at 34.0 mg/L nearly all cells got round. The effects on algal growth are summarized in Table 10.2.1-4.

Table 10.2.1-4: Effect of BAS 500 06 F on the growth of the green alga *Pseudokirchneriella subcapitata*

Concentration [mg/L] (nominal)	**Control**	**0.31**	**0.77**	**1.92**	**4.80**	**12.0**	**30.0**
Concentration [mg/L] (mean measured)	**Control**	**0.39**	**0.84**	**2.11**	**4.80**	**13.0**	**34.0**
Inhibition in 72 h (growth rate) [%]	-	0.8	7.3	14.7	23.7	44.1	72.7
Inhibition in 72 h (yield) [%]	-	3.6	28.8	49.7	67.2	87.8	97.4
	Endpoints [mg BAS 500 06 F/L] (mean measured)						
E_rC_{50} (0-72 h)	**14.2** (95% confidential limits: 13.1 - 15.4)						
E_rC_{10} (0-72 h)	1.6 (95% confidential limits: 1.4 - 1.7)						
E_yC_{50} (0-72 h)	2.4 (95% confidential limits: 2.3 - 2.5)						
E_yC_{10} (0-72 h)	0.42 (95% confidential limits: 0.38 - 0.46)						

III. CONCLUSION

In a 72-hour algae test with *Pseudokirchneriella subcapitata*, the E_rC_{50} of BAS 500 06 F was determined to be 14.2 mg/L based on mean measured concentrations.

CP 10.2.2 Additional long-term and chronic toxicity studies on fish, aquatic invertebrates and sediment dwelling organisms

Chronic toxicity to fish and aquatic invertebrates
The results obtained in the acute study on *O. mykiss* and *D. magna* with the formulated product BAS 500 06 F are in good agreement with the results expected from the data with the active substance (see reasoning given above). This demonstrates that the formulation does not cause significant unexpected (additional) toxicity to fish and daphnids. No synergisms or additional toxicity is thus expected to occur due to co-formulants. Therefore, the studies conducted with the active substance can be used to assess the chronic risk resulting from BAS 500 06 F application. No further testing with the product is indicated.

CP 10.2.3 Further testing on aquatic organisms

Marine or estuarine organisms
Studies on marine or estuarine species are not required according to EU requirements and no studies have been conducted with the formulation BAS 500 06 F on marine or estuarine organisms. The contamination of estuarine and marine environments is considered to be minimal compared to freshwater habitats adjacent to agricultural land according to the use pattern, the potential route of contamination and the dissipation of the active substance. Thus, the risk to those habitats is covered by the risk assessment for freshwater ecosystems.

Microcosm or mesocosm study
No microcosm or mesocosm study has been performed with the formulated product BAS 500 06 F, however, a mesocosm study has been performed with pyraclostrobin (using the previous representative solo formulation BAS 500 00 F, which is of the same formulation type). The mesocosm study has been evaluated following the RIVM Guidance document (de Jong et al., 2008). Executive summaries of the originally submitted study and the evaluation according to RIVM are provided in M-CA 8.2.
The mesocosm study provided a clear NOEC of 8 µg a.s./L. The ecologically acceptable concentration (NOEAEC) of pyraclostrobin was determined to be between 8 µg a.s./L and 24 µg a.s./L. Based on the results of this study a **$RAC_{mesocosm}$ of 4 µg a.s./L** could be derived (by applying an assessment factor of 2 on NOEC), which was considered for a refined risk assessment (as described above).

Residue data in fish
A respective evaluation has been performed during the previous Annex I inclusion process. No new data are provided. The following gives a brief summary of the previous evaluation:
The log P_{ow} of the active substance pyraclostrobin was determined to be 3.99 (EU Review Report, SANCO/1420/2001-final, September 2004). Hence, a bioaccumulation study in fish has been performed with pyraclostrobin, which is (together with a new fish metabolism study, CA 6.2.5/2) discussed in detail in M-CA 6.2.5 (please refer to CA 6.2.5/1). An apparent steady state was reached after 2 - 4 days of exposure. The bioconcentration factors for whole fish were 379 - 507 (two labels). The half-life for elimination was 0.9 days. The time for elimination of 90% of the activity varied between 2.8 and 3.0 days. The nature of radioactivity in fish tissues after 28 days of exposure consisted of the parent substance (39 - 74%) and 4 metabolites (2 - 9%). Due to the limited bioaccumulation and the rapid metabolization and excretion of the active substance (and its metabolites), there is no risk of bioaccumulation. In addition, pyraclostrobin dissipates rapidly in water prohibiting continuous exposure.

Residues of pyraclostrobin in fish are of no concern and no accumulation in the food chain is to be expected.

Accumulation in aquatic non-target organisms
A respective evaluation has been performed during the previous Annex I inclusion process. No new data are provided. Bioaccumulation of the active substance pyraclostrobin under natural conditions is not expected to occur (see "Residue data in fish" above). Additional studies are not required or necessary to determine bioaccumulation in aquatic non-target organisms.

CP 10.3 Effects on arthropods

The new representative formulation BAS 500 06 F was not evaluated within the previous Annex I inclusion process. It is an emulsifiable concentrate (EC) containing 200g/L pyraclostrobin.

CP 10.3.1 Effects on bees

The EU agreed endpoints for the active substance pyraclostrobin as described in the EU Review Report (SANCO/1420/2001-final, September 2004) plus endpoints from new studies with the active substance and the new representative formulation BAS 500 06 F are used for the risk assessment on honeybees (see Table 10.3.1-1).

Table 10.3.1-1: Ecotoxicological endpoints for honeybees and bumblebees

Test substance	EU agreed endpoints	Endpoints used in risk assessment
Studies on adult honeybees		
Pyraclostrobin	oral (48 h) LD_{50} > 73.1 µg a.s./bee contact (48 h) LD_{50} > 100.0 µg a.s./bee	oral (48 h) LD_{50} > 73.1 µg a.s./bee contact (48 h) LD_{50} > 100.0 µg a.s./bee
Pyraclostrobin [1)]	--	oral (48 h) LD_{50} > 110.0 µg a.s./bee contact (48 h) LD_{50} > 100.0 µg a.s./bee
BAS 500 06 F	--	oral (48 h) LD_{50} > 381.84 µg/bee contact (72 h) LD_{50} > 368.20 µg/bee
Studies on adult bumblebees		
Pyraclostrobin	--	Oral (96 h) LD_{50} > 97.2 µg a.s./bumblebee Contact (96 h) LD_{50} > 100 µg a.s./bumblebee
Field studies		
BAS 500 06 F	--	Semi-field tunnel test (*Phacelia tanacetifolia*): no unacceptable lethal or sublethal effects on honeybee colonies exposed to 1.25 L product/ha.
Residue studies		
Pyraclostrobin [2)]	--	Applied rate: 143 g pyraclostrobin/ha Highest residue: 16.6 mg pyraclostrobin/kg (90^{th} percentile, found in sunflower pollen)
Pyraclostrobin [2)]	--	Applied rate: 143 g pyraclostrobin/ha Highest residue: 6.7 mg pyraclostrobin/kg (90^{th} percentile, found in oilseed rape pollen)

[1)] New acute study has been conducted since the results for the reference substance were out of range in the original study; the results of the new study will be used in the risk assessments below.

[2)] Study was carried out with BAS 556 03 F as a surrogate for pyraclostrobin. BAS 556 03 F contains 130 g pyraclostrobin/L and 80 g metconazole/L and is an EC formulation like BAS 500 06 F. The study is presented as additional information.

Overall summary

Data on BAS 500 06 F and its potential effects on honeybees are evaluated and appropriate risk assessments are provided for the active substance and the formulation based on the already registered use pattern in cereals and maize (critical GAP: maximum 2 x 250 g pyraclostrobin per ha).

The endpoints and calculated HQs for acute oral and acute contact exposure of honeybees to pyraclostrobin and BAS 500 06 F (see Table 10.3.1-2) are below the trigger value of 50 demonstrating low acute risk to honeybees.

Table 10.3.1-2: Toxicity data, maximum single application rates and HQ values for honeybees

Test substance	Use pattern	Exposure route	Endpoint [µg/bee]	Maximum single application rate	Hazard quotient (HQ)	HQ assessment trigger
Risk assessment on adult honeybees						
Pyraclostrobin	cereals, maize	acute oral	$LD_{50} > 110$	250 g a.s./ha	< 2.3	50
		acute contact	$LD_{50} > 100$		< 2.5	
BAS 500 06 F		acute oral	$LD_{50} > 381.84$	1305 g/ha *	< 3.4	
		acute contact	$LD_{50} > 368.20$		< 3.5	

* Taking into account the density of BAS 500 06 F of 1.044 g/cm^3.

Two studies were conducted with pyraclostrobin containing products in two different crops, sunflower and oilseed rape (OSR) to determine the residues in the bee relevant matrices pollen and nectar. The highest exposure was found in pollen, i.e. 16.6 mg/kg (sunflower) and 6.7 mg/kg (OSR).

Also for non-*Apis* bees currently no risk assessment scheme exists under Regulation (EC) No 1107/2009. Nevertheless, the potential acute toxicity (oral and contact) of pyraclostrobin to adult bumblebees was addressed in a laboratory study (BASF DocID 2016/1000530), which is described in M-CA 8.3.1.1).

Furthermore, no unacceptable effects were observed in a semi-field tunnel study conducted with BAS 500 06 F on honeybee colonies in flowering *Phacelia tanacetifolia* with focus on bee brood at a rate of 1.25 L/ha. The study was carried out according to EPPO Guideline 170 (4) and the OECD Guidance Document on Honey Bee (*Apis mellifera* L.) "Brood Test under Semi-Field Conditions, Series on Testing and Assessment, No. 75, August 2007".

The test item caused no unacceptable effects on honeybee survival, colony development and colony strength when applied at a rate of 1.25 L BAS 500 06 F per ha under semi-field conditions (tunnel) to *P. tanacetifolia* during active foraging conditions. The brood termination rates, the brood indices as well as the brood compensation indices indicate no test item related effect on the brood development following the labelling of the eggs.

Overall conclusion:

The proposed uses of BAS 500 06 F in cereals and maize present a low risk to honeybees and will not adversely affect honeybees or honeybee colonies.

Toxicity

Table 10.3.1-3 presents the results of honeybee and bumblebee toxicity studies. For pyraclostrobin study summaries please refer to M-CA 8.3. A semi-field tunnel study has been carried out in support of the assessment of pyraclostrobin as contained in BAS 500 06 F. Further details regarding the tests with the formulation are provided in M-CP 10.3.1.1.

Table 10.3.1-3: Summary of endpoints of pyraclostrobin and BAS 500 06 F to honeybees and bumblebees

Substance	Endpoint	LD_{50} [µg/bee]	Reference (BASF DocID)
Studies on adult honeybees			
Pyraclostrobin	48 h oral LD_{50}	> 73.1	1999/11457
	48 h contact LD_{50}	> 100	
Pyraclostrobin [1)]	48 h oral LD_{50}	> 110	2013/1003210
	48 h contact LD_{50}	> 100	
BAS 500 06 F	48 h oral LD_{50}	> 381.84	2004/1015008
	72 h contact LD_{50}	> 368.20	
Studies on adult bumblebees			
Pyraclostrobin	96 h oral LD_{50}	> 97.2 µg a.s./bee	2016/1000530
	96 h contact LD_{50}	> 100 µg a.s./bee	
Field studies			
BAS 500 06 F	Semi-field cage test (*Phacelia tanacetifolia*): no unacceptable lethal or sublethal effects on honeybee colonies exposed to 1.25 mL product/ha.		2011/1112669
Residue studies			
BAS 556 03 F [2)] containing 130 g pyraclostrobin/L	Applied rate: 143 g pyraclostrobin/ha Highest residue: 16.6 mg pyraclostrobin/kg (90th percentile, found in sunflower pollen)		2014/1000204
BAS 556 03 F [2)] containing 130 g pyraclostrobin/L	Applied rate: 143 g pyraclostrobin/ha Highest residue: 6.7 mg pyraclostrobin/kg (90th percentile, found in oilseed rape pollen)		2014/1000182

1) New acute study has been conducted since the results for the reference substance were out of range in the original study; the results of the new study will be used in the risk assessments below.

2) Study was carried out with BAS 556 03 F as a surrogate for pyraclostrobin. BAS 556 03 F contains 130 g pyraclostrobin/L and 80 g metconazole/L and is an EC formulation like BAS 500 06 F. The study is presented as additional information.

Exposure

Applications of pesticides can potentially result in exposure of honeybees either through direct over-spray, or by contact with residues on plants while bees are foraging for food, but cereals and maize are crops of low attractiveness to foraging bees. However, in order to consider a worst-case scenario, the maximum application rate for pyraclostrobin as applied with the maximum recommended rate of 2 x 1.25 L BAS 500 06 F per ha in cereals is used for the risk assessment. The use in cereals is also covering the intended use of 1 x 1.0 L BAS 500 06 F per ha in maize.

Table 10.3.1-4: Critical use pattern of BAS 500 06 F

Crop	Application time (BBCH growth stage)	Number of applications	Interval [d]	Application rate per treatment	
				Pyraclostrobin [g a.s./ha]	BAS 500 06 F [L/ha]
cereals	25 - 69	2	21	250	1.25
maize	30 - 65	1	--	200	1.0

Risk assessment for bees

The acute risk to honeybees from the use of BAS 500 06 F in cereals (and maize) was assessed using the maximum single application rate and the LD_{50} values to calculate hazard quotients [*EPPO/OEPP, 2003: Environmental risk assessment scheme for plant protection products, Chapter 10: Honeybees (PP 3/10(2)). Bulletin OEPP/EPPO Bulletin 33: 141-145*] as follows:

$$\text{Hazard Quotient (HQ)} = \frac{\text{Maximum application rate [g formulation/ha]}}{\text{Acute } LD_{50} \text{ [µg formulation/bee]}}$$

HQs for honeybees were calculated for oral exposure and contact exposure to BAS 500 06 F. An HQ < 50 indicates low risk to honeybees in the field.

Table 10.3.1-5: Risk to honeybees from exposure to pyraclostrobin and BAS 500 06 F considering the worst-case application rate

Test substance	Application rate [g/ha]	Endpoint	LD_{50} [µg/bee]	Hazard quotient HQ	Trigger
Risk assessment on adult honeybees					
Pyraclostrobin[1)]	250	48 h oral	> 110	< 2.3	50
		48 h contact	> 100	< 2.5	
BAS 500 06 F	1305 g/ha *	48 h oral	> 381.84	< 3.4	
		72 h contact	> 368.20	< 3.5	

* Taking into account the density of BAS 500 06 F of 1.044 g/cm^3.

1) New acute study has been conducted since the results for the reference substance were out of range in the original study; the results of the new study will be used in the risk assessments below.

The calculated HQs for acute oral and acute contact exposure of honeybees to pyraclostrobin and BAS 500 06 F are below the trigger value of 50. Therefore, low risk to honeybees is expected from the application of BAS 500 06 F in cereals and maize.

In an acute toxicity study on adult bumblebees with pyraclostrobin, the oral LD_{50} after 96 h was ≥ 97.2 µg a.s./bumblebee, while the contact LD_{50} after 96 h was > 100 µg a.s./bumblebee. As currently no risk assessment scheme exists, these results are presented as additional information.

Risk Assessment Based on Higher Tier Studies

In addition to the laboratory tests, a semi-field study (tunnel test) was conducted with BAS 500 06 F according to EPPO Guideline 170 (4) and the OECD Guidance Document on Honey Bee (*Apis mellifera* L.) "Brood Test under Semi-Field Conditions, Series on Testing and Assessment, No. 75, August 2007". The test was carried out to gain additional information about the potential toxicity of BAS 500 06 F covering effects on bee brood under more realistic conditions. The product was applied at a rate of 1.25 L/ha (equivalent to 1305 g/ha) during active foraging of the honeybees onto flowering *Phacelia tanacetifolia* enclosed within a tunnel. Details of the study are given in chapter M-CP 10.3.1.5.

The test item caused no unacceptable effects on honeybee survival, colony development and colony strength, when applied at a rate of 1.25 L BAS 500 06 F/ha under semi-field conditions (tunnel) to *Phacelia tanacetifolia* during active foraging conditions. The brood termination rates, the brood indices as well as the brood compensation indices indicate no test item related effect on the brood development following the labelling of the eggs.

Thus, the results of the higher tier study confirm the assessment based on the HQs, indicating that the use of BAS 500 06 F according to good agricultural practice presents low risk to honeybees and will not adversely affect honeybee colonies.

CP 10.3.1.1 Acute toxicity to bees

CP 10.3.1.1.1 Acute oral toxicity to bees

Report:	CP 10.3.1.1.1/1 Bocksch S., 2004a Assessment of side effects of BAS 500 06 F to the honey bee, Apis mellifera L. in the laboratory 2004/1015008
Guidelines:	OECD 213, OECD 214
GLP:	yes (certified by Ministerium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Executive Summary

In a dose response test, young adult worker bees (*Apis mellifera carnica*) were exposed orally to BAS 500 06 F. Therefore, nominal concentrations of 12.5, 25.0, 50.0, 100.0 and 150.0 µg a.s./bee were tested, resulting in an actual uptake of 10.61, 22.99, 33.52, 58.98 and 75.25 µg a.s./bee. Additionally, honeybees were treated with Perfekthion as reference item at 0.09 to 0.21 µg/bee (nominal) or with a solution of water and sugar as a control. The test was conducted with 5 replicates per treatment group; each replicate contained 10 bees. Assessment of mortality was done after 4, 24 and 48 hours.

No mortality was observed after 48 hours in the control. In the test item treatments mortality between 0.0 and 50% after 48 hours, but no behavioral abnormalities of the surviving bees were observed.

The oral LD_{50} value (48 h) for BAS 500 06 F was 73.15 µg a.s./bee, equivalent to 381.84 µg BAS 500 06 F per bee.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 200 g/L (202.7 g/L analyzed); density: 1.044 g/cm^3.

Test species: Honeybees *Apis mellifera carnica*; young adult worker bees; derived from a healthy colony which descended from a breeding line of a beekeeper in Rheinland-Pfalz, Germany, collected one day before test start.

B. STUDY DESIGN

Test design: Dose response test for oral toxicity; duration 48 h; 5 replicates per treatment group, each replicate consisting of 10 bees per cage; assessment of mortality after 4, 24 and 48 hours.

Endpoints: Mortality, resulting in an LD_{50} value; behavioral abnormalities.

Reference item: Perfekthion (dimethoate, nominal 400 g/L).

Test concentrations: Control, 12.5, 25.0, 50.0, 100.0 and 150.0 µg a.s./bee (nominally equivalent to 65.3, 130.5, 261.0, 522.0 and 783.0 µg product/bee); resulting in an actual uptake of 10.61, 22.99, 33.52, 58.98 and 75.25 µg a.s./bee (nominally equivalent to 55.4, 120.0, 175.0, 307.9 and 392.8 µg product/bee).

Test conditions: Temperature: 24 – 27°C; relative humidity: 50% - 73%; photoperiod: 24 h darkness.

Statistics: Descriptive statistics, Probit analysis for LD_{50} value.

II. RESULTS AND DISCUSSION

No mortality was observed after 48 hours in the control. In the test item treatments mortality between 0.0 and 50% after 48 hours was observed. The LD_{50} was determined to be 73.15 µg a.s./bee, equivalent to 381.84 µg product/bee. No behavioral abnormalities of the surviving bees could be observed. The results are summarized in Table 10.3.1.1.1-1.

Table 10.3.1.1.1-1: Toxicity of BAS 500 06 F to honeybees (*Apis mellifera*) in an oral toxicity test

Treatment [µg a.s./bee]	Uptake of test item [µg a.s./bee]	Mortality [%]	
		24 h	48 h
Control	--	0.0	0.0
12.5	10.61	0.0	0.0
25.0	22.99	0.0	0.0
50.0	33.52	14.0	14.0
100.0	58.98	34.0	36.0
150.0	75.25	46.0	50.0
Endpoint			
	[µg a.s./bee]	**[µg formulation/bee]**	
LD_{50} (48 h)	73.15 (63.73 - 90.67 [1)])	381.84	

[1)] Upper and lower confidential limits, $\alpha = 0.05$.

The LD_{50} value (24 h) for the reference item in the oral toxicity test was determined to be 0.15 µg a.s./bee.

III. CONCLUSION

The oral LD_{50} value (48 h) for BAS 500 06 F was 73.15 µg a.s./bee, equivalent to 381.84 µg BAS 500 06 F per bee.

CP 10.3.1.1.2 Acute contact toxicity to bees

Report:	CP 10.3.1.1.2/1 Bocksch S., 2004a Assessment of side effects of BAS 500 06 F to the honey bee, Apis mellifera L. in the laboratory 2004/1015008
Guidelines:	OECD 213, OECD 214
GLP:	yes (certified by Ministerium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Executive Summary

In a dose response test, young adult worker bees (*Apis mellifera carnica*) were exposed to BAS 500 06 F. The toxicity of the test product was determined in a contact dose response test at nominal concentrations of 12.5, 25.0, 50.0, 100.0 and 150.0 µg a.s./bee. Additionally, honeybees were treated with Perfekthion as reference item at 0.14 to 0.30 µg/bee or with water as a control. The test was conducted with 5 replicates per treatment group, each replicate contained 10 bees. Assessment of mortality was done after 4, 24, 48 and 72 hours.

No mortality was observed in the control. In the test item treatment mortality between 0.0 and 100.0% was observed after 72 hours. No behavioral abnormalities of the surviving bees could be observed.

The contact LD_{50} value (72 h) for BAS 500 06 F was 70.53 µg a.s./bee, equivalent to 368.2 µg BAS 500 06 F per bee.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 200 g/L (202.7 g/L analyzed); density: 1.044 g/cm^3.

Test species: Honeybees *Apis mellifera carnica*; young adult worker bees; derived from a healthy colony which descended from a breeding line of a beekeeper in Rheinland-Pfalz, Germany, collected one day before test start.

B. STUDY DESIGN

Test design: Dose response test for contact toxicity; duration 72 h; 5 replicates per treatment group, each replicate consisted of 10 bees per cage; assessment of mortality after 4, 24, 48 and 72 hours.

Endpoints: Mortality, resulting in a LD_{50} value; behavioral abnormalities.

Reference item: Perfekthion (dimethoate, nominal 400 g/L).

Test concentrations: Control, 12.5, 25.0, 50.0, 100.0 and 150.0 µg a.s./bee (nominally equivalent to 65.3, 130.5, 261.0, 522.0 and 783.0 µg product/bee).

Test conditions: Temperature: 24 – 27°C; relative humidity: 50% - 73%; photoperiod: 24 h darkness.

Statistics: Descriptive statistics, Probit analysis for LD_{50} value.

II. RESULTS AND DISCUSSION

No mortality was observed in the control. In the test item treatment mortality between 0.0% and 100.0% was observed after 72 hours. The LD_{50} was determined to be 70.53 µg a.s./bee, equivalent to 368.2 µg product/bee. No behavioral abnormalities of the surviving bees could be observed. The results are summarized in Table 10.3.1.1.2-1.

Table 10.3.1.1.2-1: Toxicity of BAS 500 06 F to honeybees (*Apis mellifera*) in a contact toxicity test

Treatment [µg a.s./bee]	Mortality [%]		
	24 h	48 h	72 h
Control	0.0	0.0	0.0
12.5	0.0	0.0	0.0
25.0	0.0	0.0	0.0
50.0	20.0	20.0	20.0

	[µg a.s./bee]		[µg formulation/bee]
LD_{50} (72 h)	70.53 (63.46 - 77.88 [1])		368.2

[1] Upper and lower confidential limits, p = 0.05.

The LD_{50} value (24 h) for the reference item in the contact toxicity test was determined to be 0.17 µg a.s./bee.

III. CONCLUSION

The contact LD_{50} value (72 h) for BAS 500 06 F was 70.53 µg a.s./bee, equivalent to 368.2 µg BAS 500 06 F per bee.

CP 10.3.1.2 Chronic toxicity to bees

According to SANCO/10606/2014 (May 16th, 2014) a study on chronic toxicity on honeybees is not required for AIR 3 substances submitted before January 1st, 2015. In addition, this data point is covered by M-CA 8.3.1.3

CP 10.3.1.3 Effects on honey bee development and other honey bee life stages

As BAS 500 06 F does not pose an unacceptable risk to honeybees, further tests are not necessary.

CP 10.3.1.4 Sub-lethal effects

As BAS 500 06 F does not pose an unacceptable risk to honeybees, further tests are not necessary.

CP 10.3.1.5 Cage and tunnel tests

A tunnel study with flowering *Phacelia* as food source was conducted to address chronic effects and effects on bee brood of the active substance pyraclostrobin. This study was conducted with the representative solo-formulation BAS 500 006 F since the test design requires spray application to flowering plants. The study is considered to also address the data point for the active substance.

Report:	CP 10.3.1.5/1 Barth M., 2012a Effects of BAS 500 06 F on the honeybee Apis mellifera L. under semi-field conditions (tunnel test) with additional assessments on colony and brood development 2011/1112669
Guidelines:	EPPO PP 1/170 (4) (2010), OECD 75 (2007)
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

A tunnel test was carried out to determine the effects of BAS 500 06 F on honeybee colonies under semi-field conditions. For this purpose, BAS 500 06 F was applied at a rate of 1250 mL BAS 500 06 F/ha to flowering *Phacelia tanacetifolia* with foraging honeybees being present in the crop. Additionally, a water treated control and a reference item were included in the study. Each of the three treatment groups was replicated four times, with one honeybee colony per tunnel. Mortality of the honeybees was assessed daily from 2 days before to 28 days after application (DAT), respectively. Foraging activity was assessed from DAT -2 to DAT 28. Sub-lethal effects were recorded daily. Colony conditions were assessed 1 day prior to application and on DAT 4, 10, 17, 22 and 28. Brood status assessments (brood indices and brood compensation indices) were carried out on brood fixing day (BFD) 0, 5, 11, 18 and 23.

No increased mortality in the test item treatment compared to the control was observed at any time during the test; neither directly after application between DAT 0 – DAT 7, nor during post-exposure between DAT 7 – 28, nor at overall comparisons. Exposure of honeybees to the reference item did not increase the number of dead adults.
No increased mortality of honeybee larvae and pupae was observed in the control, test item and reference item treatments on the days before application, indicating comparable, healthy and well adapted colonies. Throughout the test period between DAT 0 – 28, no statistically significant numbers of dead larvae or pupae were found in the control or test item treatment, in contrast to the period between DAT 8 and DAT 22 in the reference item treatment.
Exposure of honeybees to the test item did not result in abnormal behavior or intoxication symptoms.
Colony strength was similar in all three test treatment groups and was not significantly affected by the test item or the reference item in comparison to the control, respectively.
The mean brood termination rate on BFD 23 was 26.2 and 27.0% in the control and in the test item treatment, respectively, and no significant effect of the test item on brood development was detected. The brood indices of the control and the test item treatments showed no statistically significant differences at any assessment day, while the reference item treatment significantly decreased brood indices at BFD 18 and 23, respectively.

Under semi-field conditions (tunnel test), BAS 500 06 F was applied in a single application at a rate of 1250 ml/ha (equivalent to 250 g a.s./ha) to flowering *Phacelia tanacetifolia* during active foraging conditions. No unacceptable effects on mortality, foraging activity, colony development, colony strength or bee brood were observed after application. Overall, based on the results of this study, BAS 500 06 F does not adversely affect honeybee colonies.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 0003223026, content of a.s: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 200.7 g/L (nominal 200.0 g/L), density: 1.038 g/cm^3.

Test species: *Apis mellifera carnica* P. (honeybees); healthy small bee colonies, one body containing 11 combs, including 4 – 9 brood combs with all brood stages present and 8 – 10 combs with food; source: local beekeeper in Leipzig/Rehbach, Germany.

B. STUDY DESIGN

Test plots: The test site was located near Cunnersdorf, Germany; separate tunnels for the different groups and replicates; tunnel size: 18 m × 6 m × 2.5 m (length × width × height); effective crop area: 93.5 m^2; after bee flight of the last day of exposure, the colonies were moved to a monitoring site without flowering crops or intensive agriculture near D-04828 Neualtenbach, Germany, where further assessments were performed.

Test design: Honeybee semi-field test in *Phacelia tanacetifolia*; three treatment groups (control, test item group, reference item); exposure of the bees to control, test item and reference item treatments during flowering of *Phacelia* in separate tunnels; 1 colony/tunnel and 4 tunnels/treatment group; honeybee colonies were introduced to the tunnels 3 days before application; post-application exposure period was 7 days; post-application assessments of mortality on 28 d in dead bee traps and 7 d on gauze sheets; assessment of foraging activity for 7 d on three 1 m^2 plots/tunnel; behavior, colony health, colony strength, general and detailed brood development in marked cells; after the exposure phase, colonies were removed from the tunnels and further brood development was assessed until 28 days after treatment (DAT).

Endpoint: Mortality: daily assessment starting 2 days before to 7 and 28 days after application;
Foraging activity: daily assessment starting 2 days before to 7 and 28 days after application;
Sublethal effects: behavioral changes were monitored daily until test end;
Colony assessments: (food stores, brood status and colony strength): 1 day before and 4, 10, 17, 22 and 28 days after treatment application (DAT) (equal to brood fixing day (BFD) 0, 5, 11, 18, 23 and 29);
Detailed brood status: 1 day before (= BFD 0) and 4 (= BFD 5), 10 (= BFD 11), 17 (= BFD 18) and 22 (= BFD 23) days after the application.

Reference item: Insegar 25 WG (fenoxycarb, 250 g/kg nominal).

Application rates: BAS 500 06 F: 1250 mL/ha; control: tap water (400 L/ha); reference item: 1200 g/ha Insegar 25 WG 8corresponding to 300 g a.s./ha); all substances were applied in 400 L/ha water.

Test conditions: Natural field conditions. Good weather conditions during application; cloud coverage: 20 – 100%; wind: 0 – 0.3 m/s; no precipitation; temperature: 23.7 – 25.1°C; 3.5, 4.0, 2.5 and 7.0 mm precipitation on DAT 1, 4, 5, 6.

Statistics: Descriptive statistics; TUKEY-test ($\alpha = 0.05$) for pre-treatment data evaluation for comparisons between control, test item and reference item treatments.
Post-treatment data evaluation: pair-wise testing for comparisons between treatments (test item or reference item) separately against control, STUDENT-t test (for variance homogeneous data) or WELCH-t test (for variance inhomogeneous data). Mortality and brood termination rate: one-sided greater; brood indices: one-sided smaller. Significance levels of all tests: $\alpha = 0.05$; percentage values of brood termination rate were arcsine-transformed to ensure data homogeneity.

II. RESULTS AND DISCUSSION

The results are summarized in Table 10.3.1.5-1.

Table 10.3.1.5-1: Effects of BAS 500 06 F on honeybee mortality, foraging activity and bee brood under semi-field conditions (tunnel test)

Parameter	Control	BAS 500 06 F [1.25 L/ha]	Reference Item [1.2 kg/ha]
Mean mortality of worker bees / colony / day [n] 1)			
pre-application phase 2)	32.2	33.3	36.1
exposure phase in the tunnels 2)	27.4	29.5	29.0

	3.9	4.1	2.4 *

1) Each with 4 tunnels (replicates).
2) Sum of dead honeybees found in dead bee traps and on gauze strips in the tunnels.
3) Dead honeybees found in dead bee traps, only.
* Statistically significantly different (comparing treatment vs. control, STUDENT-t test or WELCH-t test, $\alpha = 0.05$) at post-application period; mortality: one-sided greater; foraging activity: one-sided smaller; brood termination rate: one-sided greater, brood index and brood compensation index: one-sided smaller.
BFD = brood fixing day

Mortality
Adult honeybees: Pre-application mortality was similarly low in control, test item and reference item treatments, indicating well adapted and comparable colonies. No statistically significant differences between the three treatment groups were observed between DAT -2 and DAT 0, as well as at overall comparisons before application (TUKEY-test, two-sided, $\alpha = 0.05$).
No increased mortality in the test item treatment compared to the control was observed at any time during the test; neither directly after application between DAT 0 – DAT 7, nor during post-exposure between DAT 7 – 28, nor at overall comparisons (STUDENT-t or WELCH-t test, one-sided greater, $\alpha = 0.05$). Statistically significant differences (STUDENT-t test, one sided greater, $\alpha = 0.05$) due to very low variability between and within the treatment groups found on DAT 8 only were considered to be not biologically relevant. Exposure of honeybees to the reference item did not increase the number of dead adults.

No increased mortality of honeybee larvae and pupae was observed in the control, test item and reference item treatments on the days before application, indicating comparable, healthy and well adapted colonies. Throughout the test period between DAT 0 – 28, no statistically significant numbers of dead larvae or pupae were found in the control or test item treatment, respectively. Distinctly increased numbers of dead pupae were found between DAT 8 and DAT 22 in the reference item treatment.

Foraging activity
Overall foraging activity before application was 12.5, 13.1 and 12.3 bees/m^2/day in the control, test item and reference item treatments, indicating that the honeybees were equally adapted to the environmental conditions. Shortly before application, foraging activity was average 12.9, 13.4 and 12.3 bees/m^2 in the control, test item and reference item treatments respectively, indicating sufficient exposure of the bees during application. Foraging activity in the test item group was slightly reduced for 1 hour after application before returning to pre-application and control level. During the remaining course of the test, the overall daily means of foraging activity in the test item and reference item treatments were not statistically significantly different from the control and the reference item (STUDENT-t test, one sided-smaller, $\alpha = 0.05$). Overall mean foraging activity in these groups was 97 and 93% compared to the foraging activity shortly before application. Foraging activity in the reference item group was slightly reduced on DAT 0. During the remaining post-application period from DAT 1 – 28, the overall foraging activity of the reference item treatment group was not statistically significantly different from the control (STUDENT-t test, one sided-smaller, $\alpha = 0.05$).

Bee behavior
Exposure of honeybees to the test item did not result in abnormal behavior or intoxication symptoms. Bees were calm and actively foraging nectar and pollen on the treated *Phacelia tanacetifolia* field.

Colony strength
Colony assessment (estimated number of bees/colony) on DAT -1 was similar in the control, test item and reference item treatment groups, respectively. During the post-application period, the development of colony strength was similar in both, the control and the test item treatment group. In contrast, the colony strength of the reference item treatment group was fluctuating strongly in the course of the study and increased only slightly in comparison to the control. The mean number of bees per colony in the three treatment groups one day before application was similar (5709 to 6300 mean number of bees per colony).

Table 10.3.1.5-2: Estimated average number of honeybees/colony:

Treatment group	DAT -1	DAT 4	DAT 10	DAT 17	DAT 22	DAT 28
Control	5709	4922	6722	7959	7959	8156
BAS 500 06 F	5484	5738	6975	8972	9563	8916
Reference item	6300	6075	8466	7931	7144	7481

General brood assessments – brood area
On DAT -1, honeybee queens were in healthy condition actively laying eggs and brood production was at an equal level in all test colonies.
The total mean brood nest area (sum of comb area occupied by eggs, larvae and capped cells) increased comparable during the course of the study in both the control and test item treatment group. The mean comb area of the test item treatment group contained eggs, larvae or pupae at an equal amount as the control.
The total mean brood nest size of the reference item treatment group was on a lower level and decreasing constantly on assessments performed on DAT 4 and DAT 28 in comparison to the control. The effect of the reference item on brood development demonstrated the sensitivity of the test system to detect possible effects on brood development.

Detailed brood assessments in marked cells
Brood termination rate (%)
The mean brood termination rate on BFD 23 was 26.2 and 27.0% in the control and in the test item treatment, respectively, and no significant effect of the test item on brood development was detected (STUDENT-t test, one-sided greater, $\alpha = 0.05$). An increase on the termination rate of 57.8% in the reference item test group, together with an increased pupal mortality, indicated the suitability of the test system to detect possible effects of the test item on brood development.

Brood index
The brood index is a measure for the normal brood development. It is derived by tracking the development of eggs marked at BFD 0 by assigning a developmental stage specific value to each cell at the BFDs. Therefore, the brood index as an indicator for the bee brood development facilitates a comparison between the different treatments. According to the termination rates, the brood indices of the control and the test item treatments showed no statistically significant differences at any assessment day (STUDENT-t test, one-sided smaller, $\alpha = 0.05$). The reference item treatment statistically significantly decreased brood indices at BFD 18 and 23, respectively (STUDENT-t test, one-sided smaller, $\alpha = 0.05$).

Table 10.3.1.5-3: Mean [1] brood-indices [n]:

Treatment group	BFD 0	BFD 5	BFD 11	BFD 18	BFD 23
Control	1.0	2.1	2.9	3.1	3.7
BAS 500 06 F	1.0	1.9	3.0	3.1	3.7
Reference item	1.0	1.7	2.6	1.7 *	2.1 *

1) Mean of n = 4
* Statistically significant differences compared to the control (STUDENT-t test, one-sided smaller, $\alpha = 0.05$).
BFD = brood fixing day

Brood compensation index
The brood compensation index is a measure for the potential of a colony to compensate for lost brood by refilling cells of terminated brood with new eggs. The brood compensation index shows a continuous brood development in the test item and in the control treatment groups. Despite a great loss of brood stages in the reference item group between BFD 0 and BFD 18, several emptied cells were refilled with eggs, and the brood compensation indices were slightly higher than the corresponding brood indices at these assessment days.

Table 10.3.1.5-4: Mean [1] brood compensation-indices [n]:

Treatment group	BFD 0	BFD 5	BFD 11	BFD 18	BFD 23
Control	1.0	2.1	3.1	3.4	3.9
BAS 500 06 F	1.0	1.9	3.2	3.4	4.1
Reference item	1.0	1.7	2.7	1.8 *	2.4 *

[1] Mean of n = 4
* Statistically significant differences compared to the control (STUDENT-t test, one-sided smaller, α = 0.05).
BFD = brood fixing day

III. CONCLUSION

Under semi-field conditions (tunnel test), BAS 500 06 F was applied in a single application at a rate of 1250 ml/ha (equivalent to 250 g a.s./ha) to flowering *Phacelia tanacetifolia* during active foraging conditions. No unacceptable effects on mortality, foraging activity, colony development, colony strength or bee brood were observed after application. Overall, based on the results of this study, BAS 500 06 F does not adversely affect honeybee colonies.

CP 10.3.1.6 Field tests with honeybees

As BAS 500 06 F does not pose an unacceptable risk to honeybees, further tests are not necessary.

CP 10.3.2 Effects on non-target arthropods other than bees

The new representative formulation was not evaluated within the previous Annex I inclusion process. Consequently, no EU agreed endpoints are available for non-target arthropods. Endpoints from new studies with the new representative formulation BAS 500 06 F are used for the risk assessments (see Table 10.3.2-1).

Table 10.3.2-1: Ecotoxicological endpoints for non-target arthropods

Test substance	Test species	EU agreed endpoints	Endpoints used in risk assessment
Tier I			
BAS 500 06 F	*Typhlodromus pyri*	--	LR_{50} = 0.87 L/ha
BAS 500 06 F	*Aphidius rhopalosiphi*	--	LR_{50} = 0.04 L/ha
Tier II			
BAS 500 06 F	*Typhlodromus pyri* extended laboratory test	--	LR_{50} = 2.45 L/ha No unacceptable effects on reproduction up to 2.5 L/ha
BAS 500 06 F	*Aphidius rhopalosiphi* extended laboratory test	--	LR_{50} > 2.5 L/ha No unacceptable effects on reproduction up to 2.5 L/ha
BAS 500 06 F	*Chrysoperla carnea* extended laboratory test	--	LR_{50} = 0.72 L/ha No unacceptable effects on reproduction up to 0.63 L/ha
BAS 500 06 F	*Chrysoperla carnea* aged residue design	--	No unacceptable effects on survival and reproduction after exposure to fresh dried residues at 1.25 L/ha 0 DAT and after exposure to aged residues at 2.5 L/ha 7 DAT
BAS 500 06 F	*Aleochara bilineata* extended laboratory test	--	No unacceptable effects on reproduction up to 3.75 L/ha

Overall summary

Data on BAS 500 06 F and its potential effects on non-target arthropods are evaluated and appropriate risk assessments are provided based on the already registered use pattern in cereals and maize (critical GAP: maximum 2 x 250 g pyraclostrobin per ha).

The endpoints of non-target arthropods to BAS 500 06 F are shown in Table 10.3.2-2.

Table 10.3.2-2: Effects on other arthropod species

Test substance	Species / Life stage	Test type	Endpoint [L/ha]	PER in-field [L/ha]	PER off-field [L/ha] 1)	HQ in-field	HQ off-field
Tier I							
BAS 500 06 F	*T. pyri* protonymphs	Laboratory test, artificial substrate, 2D	LR_{50} = 0.87	2.125	0.005	**2.4**	0.057
	A. rhopalosiphi adults		LR_{50} = 0.04	2.125	0.005	**53**	0.125
Tier II							
BAS 500 06 F	*T. pyri* protonymphs	Extended laboratory test, natural substrate, 2D	LR_{50} = 2.45 L/ha ER_{50} > 2.5 L/ha	2.125	0.005	Endpoint ≥ PER → acceptable risk	
	A. rhopalosiphi adults	Extended laboratory test, natural substrate, 3D	LR_{50} > 2.5 L/ha ER_{50} > 2.5 L/ha	2.125	0.051	Endpoint ≥ PER → acceptable risk	
	C. carnea larvae	Extended laboratory test, natural substrate, 2D	LR_{50} = 0.72 ER_{50} > 0.63	2.125	0.005	Endpoint < PER 2) → further testing necessary	
	C. carnea larvae	Extended laboratory test, natural substrate, 2D	no unacceptable effects on survival and reproduction after exposure to fresh dried residues at 1.25 L/ha 0 DAT and after exposure to aged residues at 2.5 L/ha 7 DAT	2.125	0.005	Endpoint ≥ PER → acceptable risk	
	A. bilineata adults	Aged-residue design, natural substrate, 2D	ER_{50} > 3.75	2.125	0.051	Endpoint ≥ PER → acceptable risk	

PER = predicted environmental rate, HQ = Hazard Quotient
HQ values in **bold** are above the trigger.

1) In the Tier 2 off-field risk assessment, the standard 5-fold uncertainty (correction) factor should be included to the calculation to cover the inter-species variability in sensitivity of off-field non-target arthropod species. However, as additional species are tested, the uncertainty is reduced and no additional safety factor was applied.

2) Endpoint < $PER_{in\text{-}field}$, $PER_{off\text{-}field}$ is covered.

The risk assessment was conducted for the critical application rate in cereals (covering also maize). Based on the calculated $HQ_{in\text{-}field}$ of *T. pyri* and *A. rhopalosiphi*, a potential in-field risk to non-target arthropods cannot be excluded (HQ > 2) at this level of testing. Therefore, higher Tier II tests were carried out with *T. pyri* and *A. rhopalosiphi* and additionally with the foliage-dweller *Chrysoperla carnea* and the soil-dweller *Aleochara bilineata*.

For *T. pyri*, *A. rhopalosiphi* and *A. bilineata* no risk was indicated for in- and off-field habitats. Based on the results of an extended laboratory study with *C. carnea*, a potential risk for in-field habitats cannot be excluded. Therefore, an aged residue study with *C. carnea* was carried out under more realistic conditions (field application techniques instead of laboratory sprayer, aging under rain protected outdoor conditions instead of laboratory conditions and application on a 3-dimensional substrate (i.e. whole plants) instead of 2-dimensional substrate), which resulted in no unacceptable effects on survival and reproduction at DAT 0 up to 1.25 L/ha and DAT 7 up to 2.5 L/ha. Based on the results of the aged residue study, no in-field and off-field risk for *C. carnea* is indicated.

Overall conclusion:

Taking all available data into account, it can be concluded that low risk for non-target arthropods is expected from the application of BAS 500 06 F in cereals and maize. No unacceptable effects on non-target arthropods are expected in in-field and off-field habitats.

Toxicity

The toxicity of BAS 500 06 F to non-target arthropods has been investigated. The testing and risk assessment strategy used follow the approach recommended in the ESCORT 2 guidance document [*Candolfi et al. (2000) 'Guidance Document on regulatory testing procedures for plant protection products with non-target arthropods' From the workshop, European Standard Characteristics of Non-target Arthropod Regulatory Testing (ESCORT 2) 21-23 March 2000*], ESCORT 3 [*Alix, et al. (2012) 'Linking non-target arthropod testing and risk assessment with protection goals'*] and the EC Guidance Document on Terrestrial Ecotoxicology (SANCO/10329, 17 October 2002).

The toxicity of BAS 500 06 F to non-target arthropods has been investigated by carrying out Tier I tests on *Aphidius rhopalosiphi* and *Typhlodromus pyri* and Tier II tests on *Aphidius rhopalosiphi, Typhlodromus pyri*, *Chrysoperla carnea* and *Aleochara bilineata.* These species are tested, in accordance with ESCORT 2 and ESCORT 3, as representative non-target arthropods since they have been found to be particularly sensitive species, and therefore can be considered as indicators of potential effects to the most sensitive arthropods in the field. For convenience, the results of these studies are summarized in Table 10.3.2-3. Study summaries are provided below (see M-CP 10.3.2.1).

Table 10.3.2-3: Summary of toxicity data for BAS 500 06 F to non-target arthropods

Exposure

Table 10.3.2-4: Critical use pattern of BAS 500 06 F

Crop	Application time (BBCH growth stage)	Number of applications	Interval [d]	Application rate per treatment	
				Pyraclostrobin [g a.s./ha]	BAS 500 06 F [L/ha]
cereals	25 - 69	2	21	250	1.25
maize	30 - 65	1	--	200	1.0

In-field exposure

Non-target arthropods inhabiting the crop can be exposed to residues of BAS 500 06 F by direct contact, either as a result of overspray or through contact with residues on plants and soil or in food items. BAS 500 06 F is applied at a maximum rate of 2 x 1.25 L/ha in cereals (worst-case scenario). Since the cereal scenario is also covering the maize scenario, no specific risk assessment is presented for maize.

The in-field exposure (predicted environmental rate, PER) is calculated according to ESCORT 2 using the following equation:

$PER_{in\text{-}field}$ = Application rate [L/ha] x MAF

The MAF is a generic multiple application factor, which is used to take into account the potential build-up of applied substances between applications based on the application interval, DT_{50} value and number of applications. Default foliar and soil MAF values following multiple applications are given in the ESCORT 2 Guidance Document. For 2 applications, the default MAF of 1.7 (foliar) and 1.9 (soil) is considered, respectively. However, as a pre-emergence or early post-emergence application is not foreseen according to the proposed use pattern, the PER (soil) will not be used in the following risk assessment.

The maximum predicted environmental rate (PER) occurring within the field after application of BAS 500 06 F at the maximum application rate are presented in Table 10.3.2-5.

Table 10.3.2-5: In-field PER values for application of BAS 500 06 F

Substance	Worst-case application rate	$PER_{in\text{-}field}$ (foliar) [L/ha]
BAS 500 06 F	2 x 1.25 L/ha	2.125

Off-field exposure

Risk assessment of areas immediately surrounding the crop is considered important since these areas represent a natural reservoir for immigration, emigration and reproduction of arthropod populations and provide increased species diversity. Exposure of non-target arthropods to BAS 500 06 F living in off-field areas will mainly be due to spray drift from field applications. Off-field areas are assumed to be densely vegetated and thus spray drift is unlikely to reach bare ground. Therefore, evaluation of exposure via soil residues in off-field areas was not considered. Off-field foliar PER values were calculated from in-field foliar PERs in conjunction with drift values published by the BBA [*90th percentile drift according to BBA (2000): Bundesanzeiger Jg. 52 (Official Gazette), Nr 100, S. 9879-9880 (25.05.2000) Bekanntmachung über die Abtrifteckwerte, die bei der Prüfung und Zulassung von Pflanzenschutzmitteln herangezogen werden*] as shown in the following equation:

$$PER_{off\text{-}field} = \frac{\text{maximum } PER_{in\text{-}field} \times (\%\ \text{drift}/100)}{\text{vegetation distribution factor}}$$

The model used to estimate spray drift was developed for drift onto a two-dimensional water surface and, as such, does not account for interception and dilution by three-dimensional vegetation in off-crop areas. Therefore, a vegetation distribution or dilution factor is incorporated into the equation when calculating PERs to be used in conjunction with toxicity endpoints derived from two-dimensional (glass plate or leaf disc) studies. A dilution factor of 10 is recommended by ESCORT 2. For 3-dimensional studies, *i.e.* where the spray treatment is applied onto whole plants, the dilution factor of 10 is not used, as any dilution over the 3-dimensional vegetation surface is accounted for in the study design. The correction factor from the ESCORT 2 formula for off-field exposure calculation is considered for in the respective risk assessment.

The drift value for two applications at 1 m distance in field crops is 2.38% of the application rate (82^{th} percentile drift). The drift factor (% drift/100) is therefore 2.38/100 = 0.0238. The resulting PER off-field values are shown in Table 10.3.2-6.

Table 10.3.2-6: Off-field Predicted Environmental Rates (PER)

Study type	Maximum $PER_{in\text{-}field}$ [L/ha]	drift factor [% drift/100]	Vegetation distribution factor	$PER_{off\text{-}field}$ [L/ha]
2D exposure scenario	2.125	0.0238	10	0.005
3D exposure scenario	2.125	0.0238	--	0.051

Risk assessment for other non-target arthropods

The risk to non-target arthropods is assessed using the approach recommended in the published ESCORT 2 document [*Candolfi et al. 2001*] and the EC Guidance Document on Terrestrial Ecotoxicology (SANCO/10329, 17 October 2002).

In-field risk assessment (Tier I)

The potential risk of BAS 500 06 F to in-field non-target arthropods was assessed by calculation of the hazard quotient (HQ) using the $PER_{in\text{-}field}$ and the lowest lethal rate (LR_{50}) values according to the following equation:

$$HQ_{in\text{-}field} = \frac{PER_{in\text{-}field}\ [L/ha]}{LR_{50}\ [L/ha]}$$

The HQ trigger for Tier I laboratory studies is 2. The resulting $HQ_{in\text{-}field}$ values are presented, in Table 10.3.2-7.

Table 10.3.2-7: In-field HQs for non-target arthropods

Species	LR_{50} [L/ha]	In-field		Trigger
		PER [L/ha]	HQ	
T. pyri Tier I, 2D exposure scenario	0.87	2.125	**2.4**	2
A. rhopasoliphi Tier I, 2D exposure scenario	0.04	2.125	**53**	

HQ values in **bold** are above the trigger.

Based on the calculated $HQ_{in\text{-}field}$ of *T. pyri* and *A. rhopalosiphi*, a potential in-field risk to non-target arthropods cannot be excluded (HQ > 2) at this level of testing. According to ESCORT 2, a higher tier study with *T. pyri* and *A. rhopalosiphi* on natural substrate is required, as well as testing of one additional species. Besides the higher tier test with *T. pyri* and *A. rhopalosiphi*, extended laboratory studies were carried out with the foliage-dweller *Chrysoperla carnea* and additionally with the soil-dweller *Aleochara bilineata*.

In-field risk assessment (Tier II)

A summary of the Tier II risk assessment is provided in Table 10.3.2-8.

Table 10.3.2-8: In-field Tier II risk assessment for non-target arthropods

Species	Endpoints [L/ha]	$PER_{in\text{-}field}$ [L/ha]	Trigger
T. pyri, 2D exposure scenario, extended laboratory test	LR_{50} = 2.45 ER_{50} > 2.5	2.125	Endpoint ≥ PER → acceptable risk
A. rhopalosiphi, 3D exposure scenario, extended laboratory test	LR_{50} > 2.5 ER_{50} > 2.5	2.125	Endpoint ≥ PER → acceptable risk
C. carnea, 2D exposure scenario, extended laboratory test	LR_{50} = 0.72 ER_{50} > 0.63	2.125	Endpoint < PER → further testing necessary
C. carnea, 3D exposure scenario, aged residue design	No unacceptable effects on survival and reproduction after exposure to fresh dried residues at 1.25 L/ha 0 DAT and after exposure to aged residues at 2.5 L/ha 7 DAT	2.125	Endpoint ≥ PER → acceptable risk
A. bilineata, 2D exposure scenario, extended laboratory test	ER_{50} > 3.75	2.125	Endpoint ≥ PER → acceptable risk

Typhlodromus pyri:
The rate of 2.45 L/ha (no unacceptable effects on survival observed) and the rate of 2.5 L/ha (no unacceptable effects on reproduction observed) exceeded the $PER_{in\text{-}field}$ of 2.125 L/ha. Therefore, no risk or unacceptable effects are expected for *T. pyri* resulting from the intended use of BAS 500 06 F considering in-field habitats.

Aphidius rhopalosiphi:
The rate of 2.5 L/ha, at which no unacceptable effects on survival and reproduction were observed, exceeded $PER_{in\text{-}field}$ of 2.125 L/ha. Therefore, no risk or unacceptable effects are expected for *A. rhopalosiphi* resulting from the intended use of BAS 500 06 F considering in-field habitats.

Chrysoperla carnea:
A potential in-field risk to non-target arthropods cannot be excluded based on the extended laboratory study. The LR_{50} of 0.72 L/ha and the rate of 0.63 L/ha, at which no unacceptable effects on survival and reproduction were observed, did not exceed the in-field foliar predicted environmental rate (PER) of 2.125 L/ha, respectively. Therefore, an aged residue study with *C. carnea* for a higher tier risk assessment was carried out.
The main criterion for the acceptability of effects on arthropods living in-field is defined as the potential for recovery of any affected population, i.e. demonstrating that residual toxicity declines sufficiently rapidly to allow recovery within one year. This is usually done by aged-residue trials exposing the arthropods to residues, which have been aged for increasing time periods. Thus, aged residue trials are used to show the acceptability of the effects by assessing the decline in residual toxicity of a product. In this case, *C. carnea* was used as bio-indicator, because it proved to be the most sensitive species. According to ESCORT 2, the most sensitive test species identified by dose-response studies using natural substrate is selected for aged residue studies. It is anticipated that for less sensitive non-target arthropods the potential re-colonization will be faster.

The aged residue study presents a more realistic exposure scenario, since the application was done on whole bean plants, representing a 3-dimensional structure, whereas the application in the extended laboratory study was done on detached leaves, representing a 2-dimensional structure. Further, application in this study was carried out under more realistic conditions, i.e. using field application techniques instead of laboratory sprayer and aging under rain protected outdoor conditions instead of laboratory conditions.
In this study, two application rates (1.25 and 2.5 L/ha) were tested. No unacceptable effects on survival and reproduction were observed at DAT 0 following the application of 1.25 L/ha BAS 500 06 F, as well as on DAT 7 and DAT 14 following the application of 2.5 L/ha BAS 500 06 F. This application rate is higher than the maximum $PER_{in\text{-}field}$ of 2.125 L/ha. Therefore, no risk or unacceptable effects are expected for *C. carnea* resulting from the intended use of BAS 500 06 F considering in-field habitats.

Aleochara bilineata:
The rate of 3.75 L/ha, at which no unacceptable effects on reproduction were observed, exceeded the foliar $PER_{in\text{-}field}$ of 2.125 L/ha. Therefore, no risk or unacceptable effects are expected for *A. bilineata* resulting from the intended use of BAS 500 06 F considering in-field habitats.

Off-field risk assessment (Tier I)

In order to assess the potential risk of BAS 500 06 F to off-field non-target arthropods, the predicted environmental rate (Table 10.3.2-6) is compared with the toxicity endpoints according to the following formula:

$$HQ_{off\text{-}field} = \frac{PER_{off\text{-}field}\ [L/ha]}{LR_{50}\ [L/ha]} \times \text{Correction factor}$$

The HQ trigger value for Tier I laboratory studies is 2. Furthermore, ESCORT 2 recommends a correction factor of 10 for Tier I data in the off-field risk assessment to account for extrapolation from testing just two representative species to the higher species diversity expected in off-crop areas. The results are presented in Table 10.3.2-9.

Table 10.3.2-9: Off-field HQ values for non-target arthropods

Species	LR_{50} [L/ha]	$PER_{off\text{-}field}$ [L/ha]	Correction factor	$HQ_{off\text{-}field}$	Trigger value
Typhlodromus pyri, Tier I, 2D exposure scenario	0.87	0.005	10	0.06	2
Aphidius rhopalosiphi, Tier I, 2D exposure scenario	0.04	0.005		1.25	

The calculated $HQ_{off\text{-}field}$ values for *T. pyri* and *A. rhopalosiphi* fall below the trigger value, indicating no unacceptable risk to non-target arthropods in off-field areas resulting from exposure to BAS 500 06 F.

Off-field risk assessment (Tier II)

Both $HQ_{off\text{-}field}$ for the standard indicator species *T. pyri* and *A. rhopalosiphi* were below the trigger value of 2. In addition, the lowest endpoint from extended lab testing (no unacceptable effects on survival and reproduction for *Chrysoperla carnea* in aged residue DAT 0 at 1.25 L/ha) provides sufficient margin of safety to the anticipated off-field PER-values. Therefore, no further assessment is considered necessary.

CP 10.3.2.1 Standard laboratory testing for non-target arthropods

Report: CP 10.3.2.1/1
Sipos K., 2007a
Effect of BAS 500 06 F on the predatory mite (Typhlodromus pyri) in a laboratory trial
2007/1035599
Guidelines: Bluemel et al. (2000)
GLP: yes
(certified by National Institute of Pharmacy, Budapest, Hungary)

Executive Summary

In a worst-case laboratory study, *Typhlodromus pyri* (Acarina: Phytoseiidae) was exposed to dried residues of BAS 500 06 F. The test item was applied to glass plates at application rates of 0.046, 0.139, 0.417, 1.25 and 3.75 L BAS 500 06 F/ha. Additional test units were treated with deionized water as control and with Perfekthion as a reference item. Endpoint of the study was the mortality after 7 days of exposure, including determination of the LR_{50}.

After 7 days of exposure, the mortality in the test item treatments was between 18.33 and 95.00% in comparison to 8.00% in the control. Based on this, the corrected mortality for the different test item rates ranged between 11.23 and 94.57%. A statistically significant difference compared to the control was observed at the test rates of 0.417, 1.25 and 3.75 L BAS 500 06 F/ha.

In a worst-case laboratory study with BAS 500 06 F the LR_{50} for the predatory mite *Typhlodromus pyri* was determined to be 0.87 L/ha BAS 500 06 F in 200 L water/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 200 g/L (202.7 g/L analyzed).

Test species: The predatory mite *Typhlodromus pyri*; protonymphs (not older than 24 h); source: in-house originating from PK- Nützlingszuchten, Germany.

B. STUDY DESIGN

Test design:	The mites were exposed to dried residues on glass plates. Seven treatments (5 test item rates, water treated control and reference item) were tested. For the control 5 replicates were set up, for the test item and the reference item 3 replicates were used. Each replicate contained 20 mites. Assessment of mortality was done 1, 3 and 7 days after application.
Endpoints:	Mortality after exposure over 7 days, including determination of a LR_{50}.
Reference item:	Perfekthion (dimethoate: nominal 400 g/L).
Test rates:	Control, 0.046, 0.139, 0.417, 1.25 and 3.75 L BAS 500 06 F/ha. The reference item was applied at an application rate of 0.015 L/ha. All treatment groups were applied in 200 L water/ha. The substances were sprayed onto glass plates with a laboratory spraying equipment and air dried afterwards.
Test conditions:	Temperature: 23.7°C - 26.4°C; relative humidity: 63% - 89%; photoperiod: 16 h light : 8 h dark; light intensity: 911.0 lux; food: pollen of *Pinus* sp..
Statistics:	Descriptive statistics. Probit analysis for calculation of LR_{50} and Bonferroni t-test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

After 7 days of exposure, the mortality in the test item treatments was between 18.33 and 95.00% in comparison to 8.00% in the control. Based on this, the corrected mortality for the different test item rates ranged between 11.23 and 94.57%. A statistically significant difference compared to the control was observed at the test rates of 0.417, 1.25 and 3.75 L BAS 500 06 F/ha.
The LR_{50} was calculated to be 0.87 L/ha BAS 500 06 F in 200 L water/ha (Bonferroni t-test, $\alpha = 0.05$). The results are summarized in Table 10.3.2.1-1.

Table 10.3.2.1-1: Effects of BAS 500 06 F on predatory mites (*Typhlodromus pyri*) mortality under worst-case laboratory conditions

Treatment	Rate [1] [L/ha]	Mortality [2] [%]	Corrected mortality [3] [%]
Control	--	8.00	--
BAS 500 06 F	0.046	18.33	11.23
BAS 500 06 F	0.139	25.00	18.48
BAS 500 06 F	0.417	40.00 *	34.78
BAS 500 06 F	1.25	76.67 *	74.64
BAS 500 06 F	3.75	95.00 *	94.57
Endpoint [L/ha BAS 500 06 F]			
LR_{50} (95% CL [4])	0.87 (0.65 - 1.10)		

1) Application rate in 200 L water/ha.
2) Mortality after 7 day exposure to BAS 500 06 F on treated glass plates.
3) Corrected overall mortality according to Abbott.
4) 95% CL means lower and upper 95% confidence limits.
* = statistically significant differences compared to the control (Bonferroni t-test, $\alpha = 0.05$).

100% mortality was observed in the reference item treatment after 7 days of exposure.

III. CONCLUSION

In a worst-case laboratory study with BAS 500 06 F the LR_{50} for the predatory mite *Typhlodromus pyri* was determined to be 0.87 L/ha BAS 500 06 F in 200 L water/ha.

Report:	CP 10.3.2.1/3 Sipos K., 2007c Amendment to the final report: Effect of BAS 500 06 F on the parasitic wasp (Aphidius rhopalosiphi) in a laboratory trial 2007/1050841
Guidelines:	Mead-Briggs M. et al. (2000)
GLP:	yes (certified by National Institute of Pharmacy, Budapest, Hungary)

Executive Summary

In a worst-case laboratory study, adults of *Aphidius rhopalosiphi* (Hymenoptera: Braconidae) were exposed to dried residues of BAS 500 06 F. The test item was applied to glass plates at application rates of 0.006, 0.019, 0.056, 0.167, 0.25 and 0.5 L BAS 500 06 F/ha. Additional test units were treated with deionized water as control and with Perfekthion as a reference item. Endpoint of the study was the mortality after 48 hours of exposure, including determination of the LR_{50}.

After 48 hours, the mortality in the test item treatments was between 22.50 and 100.00% in comparison to 7.50% in the control. Based on these results the corrected mortality for the different rates ranged between 16.22 and 100.00%. A statistically significant difference compared to the control was observed at the test item rates of 0.056, 0.167, 0.25 and 0.5 L/ha BAS 500 06 F.

In a worst-case laboratory study with BAS 500 06 F, the LR_{50} for the parasitic wasp *Aphidius rhopalosiphi* was determined to be 0.04 L/ha BAS 500 06 F in 200 L water/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 200 g/L (202.7 g/L analyzed).

Test species: The parasitic wasp *Aphidius rhopalosiphi*; adults less than 48 hours old; source: Katz Biotech AG, Welzheim, Germany.

B. STUDY DESIGN

Test design: Exposure of the wasps was reached via air-dried residues on treated glass plates. Eight treatments (6 test item rates, water treated control and a reference item) were set up with 4 replicates each. Each replicate contained 10 wasps. Assessment of mortality was carried out 2, 24 and 48 h after test initiation.

Endpoints: Mortality after exposure over 48 h, including determination of a LR_{50}.

Reference item: Perfekthion (dimethoate: nominal 400 g/L).

Test rates: Control, 0.006, 0.019, 0.056, 0.167, 0.25 and 0.5 L BAS 500 06 F/ha. The reference item was applied at an application rate of 0.3 mL/ha. All treatment groups were applied in 200 L water/ha. The test item was sprayed onto glass plates via laboratory spraying equipment and air dried afterwards.

Test conditions: Temperature: 18.9°C - 21.3°C; relative humidity: 63% - 81%; photoperiod: 16 h light : 8 h dark; light intensity: 925.0 lux; food: 1:3 v/v solution of honey and water.

Statistics: Descriptive statistics. Probit analysis for calculation of LR_{50} and Dunnett`s Test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

After 48 hours, the mortality in the test item treatments was between 22.50 and 100.00% in comparison to 7.50% in the control. Based on these results the corrected mortality for the different rates ranged between 16.22 and 100.00%. A statistically significant difference compared to the control was observed at the test item rates of 0.056, 0.167, 0.25 and 0.5 L/ha BAS 500 06 F (Dunnett`s Test, $\alpha = 0.05$). The LR_{50} was calculated to be 0.04 L/ha BAS 500 06 F in 200 L water/ha. The results are summarized in Table 10.3.2.1-2.

Table 10.3.2.1-2: Effects of BAS 500 06 F on parasitic wasps (*Aphidius rhopalosiphi)* mortality under worst-case laboratory conditions

Treatment	Rate [1] [L/ha]	Mortality [2] [%]	Corrected mortality [3] [%]
Control	--	7.50	--

1) Application rate in 200 L water/ha.
2) Mortality: after 48 hours of exposure to BAS 500 06 F on treated glass plates.
3) Corrected mortality according to Abbott (1925).
4) 95% CL means lower and upper 95% confidence limits.
* = Statistically significant differences compared to the control (Dunnett`s Test, $\alpha = 0.05$).

III. CONCLUSION

In a worst-case laboratory study with BAS 500 06 F, the LR_{50} for the parasitic wasp *Aphidius rhopalosiphi* was determined to be 0.04 L/ha BAS 500 06 F in 200 L water/ha.

CP 10.3.2.2 Extended laboratory testing, aged residue studies with non-target arthropods

Report:	CP 10.3.2.2/1 Vaughan R., 2008a A rate-response extended laboratory test to determine the effects of BAS 500 06 F on the predatory mite, Typhlodromus pyri (Acari: Phytoseiidae) 2008/1010712
Guidelines:	Bluemel et al. (2000)
GLP:	yes (certified by Department of Health of the Government of the United Kingdom, The United Kingdom)

Executive Summary

A rate response extended laboratory study was carried out to determine the toxicity of BAS 500 06 F on protonymphs of the predatory mite *Typhlodromus pyri* (Acari: Phytoseiidae). For determination of mortality the mites were exposed to fresh residues of BAS 500 06 F on leaf disks from bean plants (*Phaseolus vulgaris*). Application rates were 0.3125, 0.625, 1.25, 2.50 and 3.75 L/ha BAS 500 06 F. A water treated control and a reference were applied to additional leaves. Endpoints were mortality in order to determine a LR_{50} and effects on reproduction for those treatments in which ≤ 60% corrected mortality was observed.

After 7 days of exposure the mortality was 14.0% in the control, compared to 25.0 to 71.7% in the test item treatments. This resulted in corrected mortality rates between 12.8 and 67.1%. The results for mortality differed significantly from the control in the four highest test item treatments.
The mean number of eggs per female was 9.9 in the control. The mean number of eggs produced in the test item treatments was 5.8 to 8.7 eggs/female, resulting in an effect on reproduction of 11.7 to 41.3%. There were no statistically significant reductions in egg production compared to the control at treatment rates up to and including 0.625 L/ha.

The LR_{50} of BAS 500 06 F on *Typhlodromus pyri* under extended laboratory conditions was 2.4524 L/ha. No unacceptable effects on reproduction were observed at treatment rates up to and including 2.5 L/ha BAS 500 06 F in 200 L water/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 200 g/L (202.7 g/L analyzed).

Test species: Predatory mite (*Typhlodromus pyri*), protonymphs (less than 24 h old); source: in-house culture.

B. STUDY DESIGN

Test design: Exposure of the mites was reached via air-dried residues on the treated upper (adaxial) side of leaves of dwarf French bean plants (*Phaseolus vulgaris)*. Seven treatment groups (5 test item rates, control and reference item) with 5 replicates for the control and 3 replicates for the test item and reference item were set up, each with 20 mites. Assessment of mortality was carried out 1 and 7 days after application.
For the reproduction assessment mites from the control and the test item treatments displaying a corrected mortality rate ≤ 60% were sexed, left *in situ* and the number of eggs/female was recorded during the second week. Reproduction capacity of the mites was assessed 7 and 14 days after application.

Endpoints: Mortality after 7 days of exposure; reproduction capacity between day 7 and 14 after application.

Reference item: Perfekthion (dimethoate: nominal 400 g/L).

Test rates: Control, 0.3125, 0.625, 1.25, 2.50 and 3.75 L/ha BAS 500 06 F. The reference item was applied at an application rate of 30 mL/ha. All substances were applied in 200 L water/ha. The substances were sprayed onto the upper (adaxial) surfaces of bean leaf disks via a calibrated laboratory track-sprayer and left air dried afterwards.

Test conditions: Exposure period: temperature: 25°C - 27°C, relative humidity: 65% - 80%. Reproduction period: temperature: 25°C - 26°C, relative humidity: 67% - 74%.
Photoperiod: 16 h light : 8 h dark; light intensity: 900 lux - 1600 lux.
Food: 1:1 mixture of almond (*Prunus* sp.) and apple (*Malus* sp.) pollen.

Statistics: Descriptive statistics. Probit analysis for calculation of LR_{50}, Fishers exact test for mortality data and Dunnett-test for reproduction data ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

The LR_{50} value was 2.4524 L/ha BAS 500 06 F.

After 7 days of exposure the mortality was 14.0% in the control, compared to 25.0 to 71.7% in the test item treatments. This resulted in corrected mortality rates between 12.8 and 67.1%. The results for mortality differed significantly from the control in the four highest test item treatments (Fishers exact test, $\alpha = 0.05$).
The mean number of eggs per female was 9.9 in the control. The mean number of eggs produced in the test item treatments was 5.8 to 8.7 eggs/female, resulting in an effect on reproduction of 11.7 to 41.3%. There were no statistically significant reductions in egg production compared to the control at treatment rates up to and including 0.625 L/ha (Dunnett-test, $\alpha = 0.05$). The results are summarized in Table 10.3.2.2-1.

Table 10.3.2.2-1: Effects on predatory mites (*Typhlodromus pyri*), exposed to fresh dried residues of BAS 500 06 F in an extended laboratory trial.

Treatment	Rate [1] [L/ha]	Mortality [2] [%]	Corrected mortality [3] [%]	Reproduction [4] [eggs/female]	Effect on reproduction [%]
Control	--	14.0	--	9.9	--
BAS 500 06 F	0.3125	25.0	12.8	8.7	11.7
BAS 500 06 F	0.625	31.7 *	20.5	7.5	24.6
BAS 500 06 F	1.25	28.3 *	16.7	5.8 *	41.3
BAS 500 06 F	2.50	60.0 *	53.5	6.2 *	36.8
BAS 500 06 F	3.75	71.7 *	67.1	--	--
Endpoint [L/ha BAS 500 06 F]					
LR_{50} (95% CL[5])	2.452 (1.6105 - 5.3037)				
Effects on reproduction	$ER_{50} > 2.5$				

1) Application rate in 200 L water/ha.
2) Mortality after 7 day exposure to BAS 500 06 F on the treated bean leaves.
3) Corrected overall mortality according to Abbott (1925).
4) Reproduction: mean number of eggs per female from day 7 to 14.
5) 95% CL means lower and upper 95% confidence limits.
* = statistically significant effects compared to the control (Fishers exact-test for mortality, Dunnett-test for reproduction, $\alpha = 0.05$).

The reference item produced a corrected mortality of 84.5% of exposed mites after 7 days.

III. CONCLUSION

The LR_{50} of BAS 500 06 F on *Typhlodromus pyri* under extended laboratory conditions was 2.452 L/ha. No unacceptable effects on reproduction were observed at treatment rates up to and including 2.5 L/ha BAS 500 06 F in 200 L water/ha.

Report:	CP 10.3.2.2/2 Stevens J., 2008a A rate-response extended laboratory test to determine the effects of BAS 500 06 F on the parasitic wasp, Aphidius rhopalosiphi (Hymenoptera, Braconidae) 2008/1010713
Guidelines:	Mead-Briggs M. et al. (in preparation) An extended laboratory test for evaluating the effects of plant protection products on the parasitic wasp Aphidius rhopalosiphi (De Stefani-Perez) (Hymenoptera Braconidae)
GLP:	yes (certified by Department of Health of the Government of the United Kingdom, The United Kingdom)

Executive Summary

In an extended laboratory study adults of the parasitic wasp, *Aphidius rhopalosiphi* (Hymenoptera Braconidae) were exposed to dried residues of 0.07, 0.15, 0.30, 0.60, 1.25 and 2.50 L/ha BAS 500 06 F on treated barley seedlings. The mortality of the wasps was assessed 2, 24 and 48 h after treatment. Additionally, for the reproduction assessment 15 females from the control and the 3 highest treatment groups displaying ≤ 60% corrected mortality were transferred individually to pots with untreated, aphid-infested barley plants for 24 h and then removed. The number of parasitized aphid mummies was recorded after 10 days. Additional test units were treated with water as a control and with Perfekthion as reference item.

During the first 3 h of the test 38.7% of the wasps in the control treatment settled on the treated plants compared to 28.7 to 34.0% in the test item treatments. After 24 h and 48 h 43.3% of the wasps in the control treatment settled on the treated plants compared to 35.8 to 41.4% in the test item treatments. A statistically significant difference compared to the control was not observed. After 48 h of exposure no mortality could be detected in the control. Corrected mortalities of 0.0 to 20.0% were observed in the test item treatments. Only the mortality in the 2.50 L/ha treatment rate differed significant from the control. The mean number of mummies per female was 26.1 in the control and ranged from 23.9 to 25.9 in evaluated test item groups. This resulted in effects on reproduction between 0.8 and 8.7%. There were no significant effects on reproduction, relative to the control, at rates up to and including the highest rate of 2.50 L/ha BAS 500 06 F.

The LR_{50} of BAS 500 06 F on *Aphidius rhopalosiphi* under extended laboratory conditions was > 2.5 L/ha. The test item caused no unacceptable effects on reproduction if applied up to and including a rate of 2.5 L/ha BAS 500 06 F in 400 L water/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 200 g/L (202.7 g/L analyzed).

Test species: Parasitic wasp *(Aphidius rhopalosiphi)*, adults, age: less than 48 h; source: in-house culture.

B. STUDY DESIGN

Test design: Exposure of the parasitoids was reached via air-dried residues on treated barley seedlings (*Hordeum vulgare)*. The study included 8 treatment groups (6 test item rates, water treated control, reference item) with 6 replicates per treatment, each containing 5 female wasps. Repellence was assessed after 3, 24 and 48 h. Wasp mortality was assessed 2, 24 and 48 hours after test initiation. At 48 h 15 female wasps from the 3 highest treatment groups displaying ≤ 60% corrected mortality were transferred individually to pots with untreated, aphid-infested barley plants for 24 h and then removed for the reproduction assessment. The number of parasitized aphid mummies was recorded after 10 days. Host: cereal aphids (*Rhopalosiphum padi, Metopolophium dirhodum*).

Endpoints: Mortality after 48 h of exposure; effects on reproduction capacity after additional 24 h.

Reference item: Perfekthion (dimethoate, nominal 400 g/L).

Test rates: Control, 0.07, 0.15, 0.30, 0.60, 1.25 and 2.50 L/ha BAS 500 06 F. The reference item was applied at an application rate of 0.01 L/ha. All treatments were applied in 400 L/ha water. The treatments were sprayed on potted barley seedlings using a calibrated laboratory track sprayer and left air dried afterwards.

Test conditions: Exposure period: temperature: 20°C; relative humidity: 68% - 88%; photoperiod: 16 h light : 8 h dark; light intensity: 2810 lux.
Reproduction period: temperature: 18°C - 22°C; photoperiod: 16 h light : 8 h dark, light intensity: 4590 lux.
Food: fructose-water solution (10%), sprayed onto test plants before application.

Statistics: Descriptive statistics. Fishers exact test for mortality, one-way analysis of variance (ANOVA) for repellence and for reproduction data (α = 0.05).

II. RESULTS AND DISCUSSION

The LR_{50} value was > 2.50 L/ha BAS 500 06 F.

During the first 3 h of the test 38.7% of the wasps in the control treatment settled on the treated plants compared to 28.7 to 34.0% in the test item treatments. After 24 h and 48 h 43.3% of the wasps in the control treatment settled on the treated plants compared to 35.8 to 41.4% in the test item treatments. A statistically significant difference compared to the control was not observed (ANOVA, $\alpha = 0.05$).
After 48 h of exposure no mortality could be detected in the control. Corrected mortalities of 0.0 to 20.0% were observed in the test item treatments. Only the mortality in the 2.50 L/ha treatment rate differed significantly from the control (Fishers exact test, $\alpha = 0.05$).
The mean number of mummies per female was 26.1 in the control and ranged from 23.9 to 25.9 in evaluated test item groups. This resulted in effects on reproduction between 0.8 and 8.7%. There were no significant effects on reproduction, relative to the control, at rates up to and including the highest rate of 2.50 L/ha BAS 500 06 F (ANOVA, $\alpha = 0.05$). The results are summarized in Table 10.3.2.2-2.

Table 10.3.2.2-2: Effects of BAS 500 06 F on parasitoids (*Aphidius rhopalosiphi*) mortality and reproduction under extended laboratory conditions

Treatment	Rate [1)] [L/ha]	Mortality [2)] [%]	Corrected mortality [3)] [%]	Reproduction [4)] [mummies/ female]	Effects on reproduction [%]
Control	--	0.0	0.0	26.1	--
BAS 500 06 F	0.07	0.0	0.0	--	--
BAS 500 06 F	0.15	0.0	0.0	--	--
BAS 500 06 F	0.30	0.0	0.0	--	--
BAS 500 06 F	0.60	0.0	0.0	25.9	0.8
BAS 500 06 F	1.25	10.0	10.0	23.9	8.7
BAS 500 06 F	2.50	20.0 *	20.0	25.9	0.8
Endpoint [L/ha BAS 500 06 F]					
LR_{50}	> 2.5				
Effects on reproduction	ER_{50} > 2.5				

1) Application rate in 400 L water/ha.
2) Mortality: after 48 hours of exposure to BAS 500 06 F on barley seedlings.
3) Corrected mortality according to Abbott (1925).
4) Reproduction: mean number of parasitized aphids/surviving female.
* = Statistically significant differences compared to the control (Fisher's exact test, $\alpha = 0.05$).

The reference item caused 73.3% corrected mortality after 48 h of exposure.

III. CONCLUSION

The LR_{50} of BAS 500 06 F on *Aphidius rhopalosiphi* under extended laboratory conditions was > 2.5 L/ha. The test item caused no unacceptable effects on reproduction if applied up to and including a rate of 2.5 L/ha BAS 500 06 F in 400 L water/ha.

Report:	CP 10.3.2.2/3 Roehlig U., 2008a Effects of BAS 500 06 F on the green lacewing Chrysoperla carnea STEPH. under extended laboratory conditions - Rate-response test 2008/1032666
Guidelines:	Vogt H. et al. (2000) Laboratory method to test effects of plant protection products on larvae of Chrysoperla carnea (Neuroptera Chrysopidae)
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

An extended laboratory study was carried out to determine the effects of the fungicide BAS 500 06 F on the green lacewing *Chrysoperla carnea* (Neuroptera: Chrysopidae). For determination of the mortality larvae were exposed to fresh, dry residues of BAS 500 06 F on bean leaves at rates of 0.31, 0.63, 1.25, 2.5 and 3.75 L/ha with a water volume of 200 L/ha. Additional test units were treated with deionized water as control and with Perfekthion as reference item. Endpoints of the study were the pre-imaginal mortality and additionally effects on reproduction. Assessment of mortality was carried out regularly until hatching of adult lacewings. Effects on reproduction were assessed by number of eggs produced per female and the hatching rate.

In the water treated control 2.0% mortality was observed. Corrected mortalities between 8.2% and 100.0% were observed in the test item treatments. No statistically significant effect on mortality was determined in the 0.31 L/ha treatment group. In all other test item treatment groups a statistically significant effect on mortality was observed.
In the control as well as in the 0.31 and 0.63 L/ha BAS 500 06 F test item treatments the number of eggs per female per day was ≥ 15 and the hatching rate was ≥ 70%.

In an extended laboratory study with BAS 500 06 F the LR_{50} for *Chrysoperla carnea* was determined to be 0.72 L/ha BAS 500 06 F in 200 L water/ha. No unacceptable effects on reproduction of *Chrysoperla carnea* occurred when BAS 500 06 F was applied at rates up to and including 0.63 L/ha BAS 500 06 F.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 200 g/L (202.7 g/L analyzed).

Test species: Green lacewing (*Chrysoperla carnea*); larvae (2-3 days old); source: in-house.

B. STUDY DESIGN

Test design: Exposure of the lacewings was reached via air-dried residues on excised bean leaves. The study encompassed seven treatment groups (5 test item rates, control, reference item), each with 50 replicates (1 larvae/replicate) per treatment. Condition of exposed individuals was assessed until emergence of adult lacewings. Mortality assessment was carried out regularly until hatching of the adult lacewings. In addition, for the control and the test item groups, in which corrected mortality was < 50% the reproduction performance, i.e. egg deposition and hatching rate, was determined (2 assessments/week, 24 h period each).

Endpoints: Pre-imaginal mortality (mortality of exposed larvae and pupae until hatching of adults) including the determination of a LR_{50}. Reproductive capacity: assessment of number of eggs per female per day and hatching rate.

Reference item: Perfekthion (dimethoate, nominal 400 g/L).

Test rates: Control, 0.31, 0.63, 1.25, 2.5 and 3.75 L/ha BAS 500 06 F. The reference item was applied at an application rate of 40 mL/ha. All substances were applied in 200 L/ha water. The substances were sprayed on bean leaves (*Phaseolus vulgaris*) via calibrated laboratory spraying equipment and air dried afterwards.

Test conditions: Temperature: 23°C - 27°C; relative humidity: 68% - 73%; photoperiod: 16 hours light : 8 hours dark; light intensity: 2180 lux.
Food: larvae: *Sitotroga cerealella* eggs (UV-sterilized); adults: artificial diet

Statistics: Descriptive statistics. Fishers Exact Binominal Test for pre-imaginal mortality data ($\alpha = 0.05$), Probit analysis for LR_{50}.

II. RESULTS AND DISCUSSION

The LR_{50} value was determined to be 0.72 L/ha BAS 500 06 F.

In the water treated control 2.0% mortality was observed. Corrected mortalities between 8.2% and 100.0% were observed in the test item treatments. No statistically significant effect on mortality was determined in the 0.31 L/ha treatment group. In all other test item treatment groups a statistically significant effect on mortality was observed (Fisher's Exact Binominal Test, $\alpha = 0.05$).
In the control as well as in the 0.31 and 0.63 L/ha BAS 500 06 F test item treatments the number of eggs per female per day was ≥ 15 and the hatching rate was $\geq 70\%$. The results are summarized in Table 10.3.2.2-3.

Table 10.3.2.2-3: Effects on lacewings (*Chrysoperla carnea*) exposed to BAS 500 06 F in an extended laboratory trial

Treatment	Rate [1] [L/ha]	Mortality[2] [%]	Corrected mortality[3] [%]	Mean number [eggs/female/day]	Hatching rate [%]
Control	--	2.0	--	22.8	79.4
BAS 500 06 F	0.31	10.0	8.2	26.7	78.7
BAS 500 06 F	0.63	46.0 *	44.9	23.0	78.1
BAS 500 06 F	1.25	82.0 *	81.6	n.d.	n.d.
BAS 500 06 F	2.5	94.0 *	93.9	n.d.	n.d.
BAS 500 06 F	3.75	100.0 *	100.0	n.d.	n.d.
Endpoint [L/ha BAS 500 06 F]					
LR_{50} (95% CL[4])	0.72 (0.62 - 0.84)				
Effects on reproduction	$ER_{50} > 0.63$				

1) Application rate in 200 L water/ha.
2) Percentage of individuals, which did not reach maturity.
3) Corrected mortality according to Abbott (1925).
4) 95% CL means lower and upper 95% confidence limits.
* = statistically significant differences compared to the control (Fishers exact binominal test, $\alpha = 0.05$).
n.d. = not determined, corrected mortality > 50% compared to the control.

In the reference treatment 75.5% corrected mortality was observed.

III. CONCLUSION

In an extended laboratory study with BAS 500 06 F the LR_{50} for *Chrysoperla carnea* was determined to be 0.72 L/ha BAS 500 06 F in 200 L water/ha. No unacceptable effects on reproduction of *Chrysoperla carnea* occurred when BAS 500 06 F was applied at rates up to and including 0.63 L/ha BAS 500 06 F.

Report:	CP 10.3.2.2/4 Roehlig U., 2008b Effects of BAS 500 06 F on the green lacewing Chrysoperla carnea STEPH. in an extended laboratory test (under semi-field conditions aged residues on bean plants) 2008/1042190
Guidelines:	Vogt et al. (2000)
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

An aged residue extended laboratory study was carried out to determine the effects of the fungicide BAS 500 06 F on the green lacewing, *Chrysoperla carnea* (Neuroptera: Chrysopidae). Larvae were exposed to both freshly-dried and field aged residues of BAS 500 06 F on bean leaves at rates of 1.25 and 2.50 L/ha with a water volume of 400 L/ha. Additional test units were treated with deionized water as control and with Perfekthion as reference item. Extended laboratory bioassays were initiated within 1 hour after application (DAT 0) and also at 7 and 14 days after treatment (DAT 7, DAT 14). Endpoints of the study were the pre-imaginal mortality and additionally effects on reproduction. Assessment of mortality was carried out regularly until hatching of adult lacewings. Effects on reproduction were assessed by number of eggs produced per female and the hatching rate.

In the bioassay started at DAT 0 corrected mortality rates of 36.2 and 66.0% were observed at treatment rates of 1.25 and 2.5 L/ha, respectively. In the control as well as in the 1.25 L/ha treatment the number of eggs per female per day was > 15 and the hatching rate was > 70%. In the 2.50 L/ha test item treatment group no reproduction test was carried out, because corrected mortality was > 50%.
In the bioassay started on DAT 7 corrected mortality rates of 6.3 and 41.7% were observed. In the control as well as in both BAS 500 06 F treatments the number of eggs per female per day was > 15 and the hatching rate was > 70%.
In the bioassay started on DAT 14 corrected mortality rates of 2.0 and 10.0% were observed. No statistically significant effects on mortality were determined in both test item groups. In the control as well as in both BAS 500 06 F treatments the number of eggs per female per day was > 15 and the hatching rate was > 70%.

In an aged residue extended laboratory study with BAS 500 06 F no unacceptable effects on survival or reproduction were observed after exposure to freshly dried residues (DAT 0) obtained from a rate of 1.25 L/ha in 400 L water/ha. After exposure to aged residues (DAT 7and DAT 14) no unacceptable effects on survival or reproduction were observed at an application rate of 1.25 and 2.5 L BAS 500 06 F/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 200 g/L (202.7 g/L analyzed).

Test species: Green lacewing (*Chrysoperla carnea*); larvae (2-3 days old); source: in-house.

B. STUDY DESIGN

Test design: Exposure of the lacewings was reached via both, freshly-dried and field aged residues on bean leaves. The study encompassed four treatment groups (2 test item rates, control and reference item), each with 50 replicates (1 larvae/replicate) per treatment. Following treatment, the plants were maintained outdoors but under UV light-permeable rain protection. Bioassays were initiated within 1 hour after application (DAT 0) and also at 7, 14 and 21 days after treatment (DAT 7, DAT 14, DAT 21). The results of the DAT 14 bioassay indicated that the test item had no adverse effects and the bioassay started on DAT 21 was terminated and not reported. For each bioassay exposure lasted until pupae were transferred to oviposition boxes for development of adults. Mortality assessment was carried out regularly until hatching of the adult lacewings. In addition, for the control and the test item groups, in which < 50% corrected pre-imaginal mortality was observed, the reproduction performance, i.e. egg deposition and hatching rate, was determined (2 assessments/week, 24 h period each).

Endpoints: Pre-imaginal mortality (mortality of exposed larvae and pupae until hatching of adults). Reproductive capacity: assessment of number of eggs per female per day and hatching rate.

Reference item: Perfekthion (dimethoate, nominal 400 g/L).

Test rates: Control, 1.25 and 2.50 L/ha BAS 500 06 F. The reference item was applied at an application rate of 0.10 L/ha. All substances were applied in 400 L/ha water. The substances were sprayed on bean leaves (*Phaseolus vulgaris*) via plot-sprayer and air dried afterwards.

Test conditions: Temperature: 23°C - 26°C (DAT 0, DAT 7 and DAT 14); relative humidity: 64% - 88% (DAT 0 and DAT 7), 64% - 84% (DAT 14); light intensity: 2070 lux (DAT 0), 2180 lux (DAT 7) and 2190 lux (DAT 14). Photoperiod: 16 hours light : 8 hours dark; food: larvae: *Sitotroga cerealella* eggs (UV-sterilized), adults: artificial diet.

Statistics: Descriptive statistics. Fishers Exact Binominal Test for pre-imaginal mortality data ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

In the bioassay started at DAT 0 corrected mortality rates of 36.2 and 66.0% were observed. Statistically significant effects on mortality were determined in both test item treatments (Fishers Exact Binominal Test, $\alpha = 0.05$). In the control as well as in the 1.25 L/ha treatment the number of eggs per female per day was > 15 and the hatching rate was > 70%. In the 2.50 L/ha test item treatment group no reproduction test was carried out, because corrected mortality was > 50%.
In the bioassay started on DAT 7 corrected mortality rates of 6.3 and 41.7% were observed. Statistically significant effects on mortality were determined only in the 2.5 L/ha treatment. In the control as well as in both BAS 500 06 F treatments the number of eggs per female per day was > 15 and the hatching rate was > 70%.
In the bioassay started on DAT 14 corrected mortality rates of 2.0 and 10.0% were observed. No statistically significant effects on mortality were determined in both test item groups (Fishers Exact Binominal Test, $\alpha = 0.05$). In the control as well as in both BAS 500 06 F treatments the number of eggs per female per day was > 15 and the hatching rate was > 70%. The results are summarized in Table 10.3.2.2-4.

Table 10.3.2.2-4: Effects on lacewings (*Chrysoperla carnea*) exposed to BAS 500 06 F in an aged residue extended laboratory study

Treatment	Rate [1)] [L/ha]	Mortality[2)] [%]	Corrected mortality[3)] [%]	Mean number [eggs/female/day]	Hatching rate [%]
DAT 0 [4)]					
Control	--	6.0	--	25.4	81.0
BAS 500 06 F	1.25	40.0*	36.2	20.8	80.8
BAS 500 06 F	2.50	68.0*	66.0	n.d.	n.d.
DAT 7 [4)]					
Control	--	4.0	--	21.8	78.4
BAS 500 06 F	1.25	10.0	6.3	22.1	79.2
BAS 500 06 F	2.50	44.0*	41.7	20.3	79.5
DAT 14 [4)]					
Control	--	0	--	19.4	79.1
BAS 500 06 F	1.25	2.0	2.0	20.3	79.3
BAS 500 06 F	2.50	10.0	10.0	20.8	78.4

1) Application rate in 400 L water/ha.
2) Percentage of individuals, which did not reach maturity.
3) Corrected mortality according to Abbott (1925).
4) DAT = Days After Treatment (equivalent to days over which residues were aged before bioassay was initiated).
* = statistically significant differences compared to the control (Fishers exact binominal test, $\alpha = 0.05$).
n.d. = no determined, corrected mortality > 50% compared to control.

In the bioassay DAT 0, the reference item caused 85.1% corrected mortality of exposed lacewings.

III. CONCLUSION

In an aged residue extended laboratory study with BAS 500 06 F no unacceptable effects on survival or reproduction were observed after exposure to freshly dried residues (DAT 0) obtained from a rate of 1.25 L/ha in 400 L water/ha. After exposure to aged residues (DAT 7and DAT 14) no unacceptable effects on survival or reproduction were observed at an application rate of 1.25 and 2.5 L BAS 500 06 F/ha.

Report:	CP 10.3.2.2/5 Schmitzer S., 2008a Effects of BAS 500 06 F on the reproduction of rove beetles (Aleochara bilineata) - Extended laboratory study 2008/1010700
Guidelines:	Grimm et al. (2000) A test for evaluating the chronic effects of plant protection products on the rove beetle Aleochara bilineata Gyll. (Coleoptera: Staphylinidae) under laboratory and extended laboratory conditions
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Laendlichen Raum und Verbraucherschutz)

Executive Summary

An extended laboratory study was performed to determine the effects of the fungicide BAS 500 06 F on the staphylinid beetle *Aleochara bilineata*. The test item was applied to the soil (LUFA 2.1) surface at rates of 2.5 and 3.75 L BAS 500 06 /ha. The study covers the complete life cycle of the beetle: parental generation, mating and oviposition of parental generation, hatching of F1 larvae and parasitization period until emergence of the F1 adults. The endpoint of the study was the effect on reproduction represented by the living offspring hatched from the onion fly pupae, which were added to the natural test soil during the first 3 weeks of the study.

The number of hatched beetles was 550 in the control. In the two test item treatments 471 and 492 beetles hatched. This is corresponding to an effect of 14.4 and 10.6%, respectively, relative to the control. No statistically significant difference compared to control was observed.

In an extended laboratory study with BAS 500 06 F, no unacceptable effects on reproduction of *Aleochara bilineata* occurred after exposure to natural soil treated with 2.5 and 3.75 L BAS 500 06 F/ha in 400 L water/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 200 g/L (202.7 g/L analyzed).

Test species: Staphylinid beetle (*Aleochara bilineata*), adults 2 - 4 days old, source: De Groene Vlieg, Nieuwe Tonge, The Netherlands.

B. STUDY DESIGN

Test design: The test item rates, a control and a reference item were sprayed via laboratory spray applicator on the soil surface. Exposure of the beetles was reached via treated natural soil LUFA 2.1. The beetles were introduced to the test units immediately after treatment. Four replicates per treatment group were set up with 10 female and 10 male beetles each. This study included the complete life cycle of the beetles: parental generation, mating and oviposition of parental generation, hatching of F1 larvae and parasitization period until emergence of the F1 adults. On day 7, 14 and 21 approximately 500 pupae of *Delia antiqua* were dug into the soil to be parasitized by larvae of the beetles. On day 28 adults were separated from the soil and the soil with the pupae was allowed to dry for seven days. On day 35 the pupae were sieved out of the natural soil and transferred into an emergence container. The emergence of the F1-generation of beetles was observed from day 38 - 75.

Endpoints: Effect on reproduction (reproduction capacity).

Reference item: Perfekthion EC (dimethoate, nominal 400 g/L).

Test rates: Control, 2.5 and 3.75 L/ha BAS 500 06 F. The reference item was applied at a rate of 4.4 L/ha. All substances were applied in 400 L water/ha directly on soil surface via laboratory spraying equipment.

Test conditions: Temperature: 18°C - 22°C; relative humidity: 68% - 90%; photoperiod: 16 h light : 8 h dark; light intensity: 520 lux - 1250 lux. Food: frozen midge larvae (*Chironomus* sp.).

Statistics: Descriptive statistics. Student t-test, one-sided smaller, for reproduction data ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

The number of hatched beetles was 550 in the control. In the two test item treatments 471 and 492 beetles hatched. This is corresponding to an effect of 14.4 and 10.6%, respectively, relative to the control. No statistically significant difference compared to control was observed (Student t-test, one-sided smaller, $\alpha = 0.05$). The results are summarized in Table 10.3.2.2-5.

Table 10.3.2.2-5: Effects on staphylinid beetles (*Aleochara bilineata*) exposed to BAS 500 06 F in an extended laboratory trial

Treatment	Rate [1)] [L/ha]	Reproduction [mean number of emerged beetles ± standard deviation]	Effects on reproduction [2)] [%]
Control	--	550 ± 71	--
BAS 500 06 F	2.5	471 ± 56	14.4
BAS 500 06 F	3.75	492 ± 91	10.6
Endpoint [L/ha BAS 500 06 F]			
ER_{50}	> 3.75		

1) Application rate in 400 L water/ha.
2) Effects on reproduction calculated based on the exact raw data (calculation: (1-Rt/Rc)*100%).

The reference item resulted in a reduction of reproduction of 99.8% compared to the control.

III. CONCLUSION

In an extended laboratory study with BAS 500 06 F, no unacceptable effects on reproduction of *Aleochara bilineata* occurred after exposure to natural soil treated with 2.5 and 3.75 L BAS 500 06 F/ha in 400 L water/ha.

CP 10.3.2.3 Semi-field studies with non-target arthropods

As BAS 500 06 F does not pose an unacceptable risk to non-target arthropods, further tests are not necessary.

CP 10.3.2.4 Field studies with non-target arthropods

As BAS 500 06 F does not pose an unacceptable risk to non-target arthropods, further tests are not necessary.

CP 10.3.2.5 Other routes of exposure for non-target arthropods

As BAS 500 06 F does not pose an unacceptable risk to non-target arthropods, further tests are not necessary.

CP 10.4 Effects on non-target soil meso- and macrofauna

The new representative formulation BAS 500 06 F was not evaluated within the previous Annex I inclusion process. It is an emulsifiable concentrate (EC) containing 200g/L pyraclostrobin.

Endpoints from new studies with the active substance, its metabolites and the new representative formulation BAS 500 06 F are used for the risk assessment on earthworms and other non-target soil meso- and macrofauna (see Table 10.4-1).

Table 10.4-1: Ecotoxicological endpoints for earthworms and other non-target soil meso- and macrofauna

Test substance	Test species	EU agreed endpoints	Endpoints used in risk assessment
Acute			
Pyraclostrobin	*Eisenia fetida*	LC_{50} = 567 mg a.s./kg dry soil $LC_{50\ CORR:}$ = 283 mg a.s./kg dry soil [1)]	--

BF 500-7 *[2)]		--	NOEC ≥ 800 mg/kg dry soil
BAS 500 06 F [2)]		--	NOEC = 125.0 mg/kg dry soil (corresponding to 23.9 mg pyraclostrobin/kg dry soil) [3)]
BAS 500 06 F [2)]	*Hypoaspis aculeifer*	--	NOEC ≥ 90.0 mg/kg dry soil (corresponding to ≥ 17.3 mg pyraclostrobin/kg dry soil) [3)]
Field studies			
BAS 500 06 F	earthworm field population	--	no unacceptable effects up to and including 6.25 L/ha
BAS 500 06 F	organic matter decomposition	--	no unacceptable effects at 1.25 L/ha equivalent to 0.333 mg a.s./kg dry soil

1) Toxicity endpoint is re-adjusted using a soil factor of 2 to address the organic content of the soil (peat 10%), and the log P_{ow} of the substance is > 2.
2) Test was conducted with only 5% peat in the test substrate.
3) Based on a nominal content of BAS 500 06 F (200.0 g/L pyraclostrobin) and taken into account the density of 1.04 g/cm^3.
* Study summary is presented in M-CA 8.4.

Overall summary

Data on pyraclostrobin, its metabolites and BAS 500 06 F and their potential effects on earthworms and other non-target soil meso- and macrofauna are evaluated and appropriate risk assessments are provided for the formulation and relevant metabolites based on the already registered use pattern in cereals and maize (critical GAP: maximum 2 x 250 g pyraclostrobin per ha).

The endpoints and calculated toxicity/exposure ratios are shown in Table 10.4-2.

Table 10.4-2: Toxicity/exposure ratios for earthworms and other soil non-target macro-organisms

Test substance	Use pattern	Species	Test type	Endpoint [mg/kg dry soil]	PEC [mg/kg dry soil]	TER	TER risk assessment trigger
Pyraclostrobin	2 x 250 g a.s./ha	*Eisenia fetida*	56-d reproduction test	$NOEC_{CORR}$ = 11.6	0.228	51	5
BF 500-6	--	*Eisenia fetida*	56-d reproduction test	$NOEC_{CORR} \geq 160$	0.121	≥ 1322	
BF 500-7	--	*Eisenia fetida*	56-d reproduction test	$NOEC_{CORR} \geq 160$	0.073	≥ 2192	
Pyraclostrobin in BAS 500 06 F	2 x 250 g a.s./ha	*Eisenia fetida*	56-d reproduction test	NOEC = 5.75	0.228	25	
BF 500-6	--	*Folsomia candida*	28-d reproduction test	NOEC ≥ 1000	0.121	≥ 8264	
BF 500-7	--	*Folsomia candida*	28-d reproduction test	NOEC ≥ 800	0.073	≥ 10959	
Pyraclostrobin in BAS 500 06 F	2 x 250 g a.s./ha	*Folsomia candida*	28-d reproduction test	NOEC = 23.9	0.228	105	
Pyraclostrobin in BAS 500 06 F	2 x 250 g a.s./ha	*Hypoaspis aculeifer*	14-d reproduction test	NOEC ≥ 17.3	0.228	≥ 76	

Acute studies on earthworms were performed with pyraclostrobin, the metabolites BF 500-6 and BF 500-7 (see SANCO/1420/2001-final, Monograph 12945/ECCO/BBA/01) and with the formulation BAS 500 06 F. According to Regulation 1107/2009 the tier 1 data requirement for acute toxicity on earthworms has been replaced by a requirement for chronic toxicity (i.e. reproduction) on earthworms. However, from previous submissions according to the former Directive EC 91/414 data on the acute toxicity of BAS 500 06 F to earthworms is available, which is for completeness presented as additional information, although acute endpoints are not used anymore in the current risk assessment (see below for respective chronic studies).

Chronic studies on earthworms were carried out with pyraclostrobin (see M-CA 8.4), the metabolites BF 500-6 and BF 500-7 (see M-CA 8.4), as well as with the formulation BAS 500 06 F.

Furthermore, chronic studies on collembolans were carried out with BF 500-6 and BF 500-7 (see M-CA 8.4) and BAS 500 06 F and a chronic study on soil mites was conducted with BAS 500 06 F. Additionally, a field study with BAS 500 06 F on earthworms has been done (see M-CP 10.4.1.2).

In the risk assessment, all TER values exceeded the trigger value of 5 for chronic exposure.

Moreover, a study with BAS 500 06 F on organic matter breakdown has been carried out, which is presented as additional information in M-CP 10.4.2.2.

Overall conclusion:
It is concluded that the use of BAS 500 06 F in cereals and maize will not pose any unacceptable risks to populations of earthworms or other soil macro-organisms.

CP 10.4.1 Earthworms

Toxicity

Acute and chronic earthworm studies have been carried out with pyraclostrobin, its metabolites BF 500-6 and BF 500-7, as well as with the formulation BAS 500 06 F. Furthermore, an earthworm field study has been carried out with BAS 500 06 F. Further details on the studies with the formulation are given below (M-CP 10.4.1, M-CP 10.4.1.1 and M-CP 10.4.1.2) and on the studies with the active substance and metabolites in M-CA 8.4. The acute endpoints of the study with BAS 500 06 F are presented as additional information. The earthworm endpoints are summarized in Table 10.4.1-1.

For substances with log P_{ow} values > 2 and a high content of organic material in the artificial soil (i.e. 10% peat), the resulting endpoints have to be corrected by a soil factor of 2 (f_{oc}) in the risk assessment in order to address lower contents of organic material in soil. The log P_{ow} for the active substance is > 2 (i.e. 3.99). Therefore, the correction was done for the endpoints obtained from the studies, where the artificial soil contained more than 5% peat.

Table 10.4.1-1: Summary of earthworm endpoints for BAS 500 06 F, pyraclostrobin and metabolites

Test substance	Endpoint	Value [mg/kg dry soil]	Reference (BASF DocID)
Acute toxicity			
Pyraclostrobin	$LC_{50\ CORR}$	283	1999/10708
BF 500-6	$LC_{50\ CORR}$	> 500	1999/11308
BF 500-7	$LC_{50\ CORR}$	> 500	1999/11309
Pyraclostrobin in BAS 500 06	$LC_{50\ CORR}$	37.0 [1)]	2004/1004367
Chronic toxicity			
Pyraclostrobin	$NOEC_{CORR}$	11.6	2014/1000461
BF 500-6	$NOEC_{CORR}$	≥ 160	2013/1003174
BF 500-7	$NOEC_{CORR}$	≥ 160	2013/1224029
Pyraclostrobin in BAS 500 06 F	NOEC	5.75 [1)]	2008/1036409

1) Based on a nominal content of BAS 500 06 F (200.0 g/L pyraclostrobin) and taken into account the density of 1.044 g/cm^3.
2) Test was conducted with only 5% peat in the test substrate.

Exposure

Table 10.4.1-2: Critical use pattern

Crop	Application time (BBCH growth stage)	Number of applications	Interval [d]	Application rate per treatment	
				Pyraclostrobin [g a.s./ha]	BAS 500 06 F [L/ha]
cereals	25 - 69	2	21	250	1.25
maize	30 - 65	1	--	200	1.0

The exposure to soil organisms was estimated by calculating the maximum predicted environmental concentrations in soil (PEC_{soil}). For multiple applications, the worst-case maximum PEC_{soil} will be the one immediately after the final application. The worst-case use pattern of BAS 500 06 F foresees two applications in cereals with a maximum dose rate of 250 g pyraclostrobin/ha (equivalent to 1.25 L BAS 500 06 F/ha).

For details see M-CP 9.1. The resulting maximum PEC_{soil} values are presented in Table 10.4.1-3.

Table 10.4.1-3: PEC_{soil} values for pyraclostrobin and relevant metabolites *

Test substance	$PEC_{soil, max}$ [mg/kg dry soil]	$PEC_{soil, plateau}$ [mg/kg dry soil]	$PEC_{soil, accu}$ [mg/kg dry soil]
Pyraclostrobin	0.228	--	--
BF 500-6	0.065	0.057	0.121
BF 500-7	0.039	0.034	0.073

* Only worst-case scenario is presented.

Risk assessment for earthworms

The potential long-term risk of BAS 500 06 F to earthworms was assessed by calculating long-term TER (TER_{LT}) values by comparing the NOEC values and the maximum instantaneous PEC_{soil} using the following equation:

$$TER_{LT} = \frac{NOEC\ [mg/kg]}{PEC_{soil}\ [mg/kg]}$$

The resulting TER_{LT} values are presented below:

Table 10.4.1-4: Long-term TER values for earthworms

Test substance	NOEC [mg/kg dry soil]	PEC_{soil} [mg/kg dry soil]	TER_{LT}	TER trigger
Pyraclostrobin	11.6	0.228	51	5
BF 500-6	≥ 160	0.121	≥ 1322	
BF 500-7	≥ 160	0.073	≥ 2192	
Pyraclostrobin in BAS 500 06 F	5.75	0.228	25	

The long-term TER values calculated for BAS 500 06 F, pyraclostrobin and the relevant soil metabolites are above the trigger of 5. Therefore, chronic risk for earthworms arising from long-term use of BAS 500 06 F is negligible. However, for additional information, a field study was carried out with BAS 500 06 F.

The test site in this study was a grassland site. At an application scenario of up to 6.25 L BAS 500 06 F/ha (equivalent to 1250 g pyraclostrobin/ha), no unacceptable effects to earthworm populations were observed (for details see M-CP 10.4.1.2). The intended maximum use of BAS 500 06 F, i.e. 2 x 1.25 L/ha (equivalent to 2 x 250 g pyraclostrobin/ha) in cereals is therefore covered by the tested field rate. Thus, it can be concluded that the use of BAS 500 06 F will be of low risk to natural earthworm communities.

Based on the standard risk assessment and on data from the field study, it is concluded that earthworm communities will be at low risk following the use of BAS 500 06 F in cereals and maize according to the recommended use pattern.

Earthworms – acute toxicity

This study was a former requirement under Council Directive 91/414/EEC and SANCO/10329/2002 rev 2. However, under Regulation (EC) 1107/2009 it is not required anymore. Therefore, the study is considered as additional information.

Report:	CP 10.4.1/1 Fleischer G., 2004a Effect of BAS 500 06 F on the mortality of the earthworm Eisena fetida 2004/1004367
Guidelines:	ISO 11268-1 (1993)
GLP:	yes (certified by Landesamt fuer Umweltschutz und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Adult earthworms, of the species *Eisenia fetida*, were exposed to BAS 500 06 F. The test item was mixed into artificial soil at a rate of 197.5, 296.3, 444.4, 666.7 and 1000.0 mg BAS 500 06 F/kg dry soil. For the control treatment, the soil was left untreated. The test soil had an organic content of approximately 10% (as sphagnum peat). The worms were placed on the surface of the soil. Four replicates were prepared for each treatment group and the control, each containing 10 worms. Assessment of mortality was made 7 and 14 days after treatment. Assessment of worm weight was made after 14 days.

After 14 days of exposure no mortality was observed in treatment groups up to 296.3 mg/kg dry soil. High mortality was observed at test concentrations of 444.4 mg/kg dry soil and higher. All treatment groups including the control showed reduction in biomass. Statistically significant differences were determined in the treatment group with the test concentration of 444.4 mg/kg dry soil; surviving worms in this test concentration were shorter and thinner. No other particular behavioral or morphological changes were observed.

In a 14-d toxicity study with BAS 500 06 F on earthworms (*Eisenia fetida)* the LC_{50} was 385.6 mg BAS 500 06 F/kg dry soil. The NOEC related to mortality and biomass was 296.3 mg BAS 500 06 F/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 200 g/L (202.7 g/L analyzed), density: 1.044 g/cm³.
Test species:	Earthworm (*Eisenia fetida*), adult worms (with clitellum and weight 300 - 600 mg), less than 1 year old; source: in-house culture.

B. STUDY DESIGN

Test design:	14-d exposure in treated artificial soil; different concentrations of the test item were mixed homogeneously into the soil which was filled in glass vessels before the earthworms were introduced on top of the soil; 6 treatment groups (5 test item rates, control); 4 replicates/group with 10 worms each. Earthworm mortality effects were assessed after 7 and 14 d, measurement of weight change as sublethal parameter after 14 d.
Endpoints:	Mortality of earthworms after exposure over 14 days, weight change.
Reference item:	2-chloroacetamide. The effects of the toxic reference item were evaluated in a separate study.
Test concentrations:	Control, 197.5, 296.3, 444.4, 666.7 and 1000.0 mg BAS 500 06 F/kg dry soil.
Test conditions:	Artificial soil according to ISO 11268-1:1993(E) with 10% sphagnum peat; pH 6.1; water content: 28.8 g/100 g dry soil at test initiation, 26.4 g/100 g dry soil at test termination; temperature: 20°C ± 2°C; photoperiod: 16 h light : 8 h dark, light intensity: 400 lux - 800 lux.
Statistics:	Descriptive statistics. Spearman-Karber Estimate for determination of LC_{50} and Bonferroni t-Test for biomass development ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

The LC_{50} derived from the results was 385.63 mg BAS 500 06 F/kg dry soil.

After 14 days of exposure no mortality was observed in treatment groups up to 296.3 mg/kg dry soil. High mortality was observed at test concentrations of 444.4 mg/kg dry soil and higher. All treatment groups including the control showed reduction in biomass. Statistically significant differences (Bonferroni t-Test, $\alpha = 0.05$) were determined in the treatment group with the test concentration of 444.4 mg/kg dry soil, surviving worms in this test concentration were shorter and thinner. No other particular behavioral or morphological changes were observed. The results are summarized in Table 10.4.1-5.

Table 10.4.1-5: Effect of BAS 500 06 F on earthworm (*Eisenia fetida)* mortality and biomass (14 d)

BAS 500 06 F [mg/kg dry soil]	Control	197.5	296.3	444.4	666.7	1000
Mortality [%]	0.00	0.00	0.00	85.00	100.00	100.00
Weight change [%]	-12.87	-8.90	-14.82	-34.02 *	--	--
Endpoints [mg/kg dry soil]						
NOEC	296.3					
LC_{50} (95% CL) [1)]	385.63 (368.71 - 403.32)					

[1)] Median effect concentration calculated using Spearman-Karber Estimate (with 95% Confidence Limits).
* = statistically significant differences compared to the control (Bonferroni t-Test; $\alpha = 0.05$).

III. CONCLUSION

In a 14-d toxicity study with BAS 500 06 F on earthworms (*Eisenia fetida)* the LC_{50} was 385.6 mg BAS 500 06 F/kg dry soil. The NOEC related to mortality and biomass was 296.3 mg BAS 500 06 F/kg dry soil.

CP 10.4.1.1 Earthworms – sub-lethal effects

Report:	CP 10.4.1.1/1 Luehrs U., 2008a Effects of BAS 500 06 F on reproduction and growth of earthworms Eisenia fetida in artificial soil with 5% peat 2008/1036409
Guidelines:	OECD 222, ISO 11268-2 (1998)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Laendlichen Raum und Verbraucherschutz)

Executive Summary

The effects of BAS 500 06 F on mortality, biomass development and reproduction of the earthworm *Eisenia fetida* were investigated in a 56-day extended laboratory study. Five application rates (3.8, 7.5, 15.0, 30.0 and 60.0 mg BAS 500 06 F/kg dry soil) were incorporated into the soil (5% peat) with four replicates per treatment (each containing 10 worms). An untreated control with 8 replicates was included. The reference item was tested in a separate study. Assessment of adult worm mortality and biomass development was carried out after 28 days, assessment of reproduction rate (number of juveniles) was carried out after 56 days.

No mortality of parent earthworms was observed in any treatment group. No statistically significant effects on body weight were observed up to the highest test concentration of 60 mg BAS 500 06 F/kg dry soil. The number of juveniles was statistically significantly reduced in the highest test item concentration of 30 mg BAS 500 06 F/kg dry soil. No behavioral abnormalities were observed in any of the treatment groups.

In a 56-day reproduction study with BAS 500 06 F, no statistically significant effects on mortality and growth of earthworms (*Eisenia fetida*) were observed up to a rate of 60 mg BAS 500 06 F/kg dry soil. The NOEC for reproduction was 30 mg BAS 500 06 F/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. no.: 304 428): 200 g/L (202.7 g/L analyzed), density: 1.044 g/cm³.

Test species: Earthworm (*Eisenia fetida*), adult worms (with clitellum and weight of 300 - 600 mg), approximately 10 months old; source: in-house culture.

B. STUDY DESIGN

Test design: 56-day test in treated artificial soil according to OECD 222 (5% peat). Different concentrations of the test item are mixed homogeneously into the soil. 6 treatment groups (5 test item rates, control) were set up with 8 replicates for the control and 4 replicates for the test item group, each with 10 worms. Assessment of worm mortality, behavioral effects and weight change was done after 28 days of exposure, after an additional 28 days (56 days after application) the number of offspring was counted.

Endpoints: Mortality, weight change, behavioral effects, reproduction rate.

Reference item: Brabant Carbendazim Flowable (carbendazim, 500 g/L nominal). The effects of the reference item were investigated in a separate study.

Test rates: Control, 3.8, 7.5, 15.0, 30.0 and 60.0 mg BAS 500 06 F/kg dry soil.

Test conditions: Artificial soil according to OECD 222 (with a reduced content of peat of 5%); pH 5.6 - 5.7 at test initiation, pH 6.1 at test termination; water content at test initiation: 49.7% to 54.1% of maximum water holding capacity (WHC), 52.1% to 57.9% of maximum WHC at test termination; temperature: 19°C - 21°C; photoperiod: 16 hours light : 8 hours dark; light intensity: 410 lux - 700 lux; feeding with cattle manure.

Statistics: Descriptive statistics. Dunnett-test for weight changes and reproduction data ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

No mortality of parent earthworms was observed in any treatment group. No statistically significant effects on body weight were observed up to the highest test concentration of 60 mg BAS 500 06 F/kg dry soil (Dunnett-test, $\alpha = 0.05$). The number of juveniles was statistically significantly reduced in the highest test item concentration of 30 mg BAS 500 06 F/kg dry soil (Dunnett-test, $\alpha = 0.05$). No behavioral abnormalities were observed in any of the treatment groups. The feeding activity in the test item groups was comparable to the control. The results are summarized in Table 10.4.1.1-1.

Table 10.4.1.1-1: Effect of BAS 500 06 F on earthworm (*Eisenia fetida*) in a 56-day reproduction study

BAS 500 06 F [mg/ kg dry soil]	**Control**	**3.8**	**7.5**	**15.0**	**30.0**	**60.0**
Mortality (28 d) [%]	0	0	0	0	0	0
Weight change (28 d) [%]	29.9	35.6	34.0	29.8	27.8	26.7
Number of juveniles (56 d)	234	193	207	224	208	151*
Reproduction (56 d) [% of control]	--	82.6	88.5	95.9	88.7	64.4
	Endpoints [mg BAS 500 06 F/kg dry soil]					
$NOEC_{mortality,\ weight\ change}$ (28 d)	60					
$NOEC_{reproduction}$ (56 d)	30					

* = Statistically significant compared to the control (Dunnett-test, $\alpha = 0.05$).

III. CONCLUSION

In a 56-day reproduction study with BAS 500 06 F, no statistically significant effects on mortality and growth of earthworms (*Eisenia fetida*) were observed up to a rate of 60 mg BAS 500 06 F/kg dry soil. The NOEC for reproduction was 30 mg BAS 500 06 F/kg dry soil.

CP 10.4.1.2 Earthworms – field studies

Report:	CP 10.4.1.2/1 Luehrs U., 2010a Field study to evaluate the effects of BAS 500 06 F on earthworms 2010/1000056
Guidelines:	ISO 11268-3 (1999), Kula et al. (2006) - Technical Recommendations for the Update of the ISO Earthworm Field Test Guideline (ISO 11268-3)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

A grassland site was chosen as a natural habitat of earthworms. The treatments with 1.25 L/ha, 2.5 L/ha and 6.25 L BAS 500 06 F/ha were assigned randomly to the plots within each replicate. Over the experimental period from May 2009 until May 2010 four earthworm samplings were evaluated. Earthworm extraction was achieved using the electrical octet method in combination with hand sorting.
Prior to the treatment, the test site yielded sufficiently high numbers of earthworms of 202.8 individuals per m^2 representing various common earthworm species such as *Aporrectodea caliginosa*, *Octolasion tyrtaeum* and *Lumbricus terrestris*.

No statistically significant differences between BAS 500 06 F treatments and the untreated control could be detected in terms of total earthworm abundance 1.5, 5 and 12 months after application. The total biomass was reduced after 6 weeks with statistically significant differences compared to the control at 1.25 L and 6.25 L BAS 500 06 F/ha. However, total biomass had fully recovered after 5 months of exposure. After one year, exposure biomass was reduced at a rate of 1.25 L BAS 500 06 F/ha, however based on lacking dose-response it was not considered to be treatment related. For the most abundant earthworm species *Lumbricus terrestris* and *Aporrectodea caliginosa* the abundance was slightly lower at 6.25 L BAS 500 06 F/ha after 6 weeks and had recovered after 5 months. At the end of the study (12 month after application) no statistically significant effects were found, i.e. all reductions observed during the study were transient.

Based on the results of this field study, it is concluded that exposure of earthworm populations to rates up to 6.25 L BAS 500 06 F/ha does not cause unacceptable long-term effects.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F): 200 g/L (202.7 g/L analyzed), density: 1.044 g/cm³.

Test species: Naturally occurring population of earthworms comprising all mobile stages (juveniles and adult worms) including epilobous species such as Aporrectodea caliginosa, Aporrectodea limicola, Aporrectodea rosea, Octolasion tyrtaeum and Octolasion cyaneum as well as tanylobous species such as Lumbricus castaneuss and Lumbricus terrestris.

B. STUDY DESIGN

Test site: Grassland site near Klein-Zimmern in municipality Groß-Umstad, Germany. The site had not received chemical applications for the past 5 years and none were applied during the study apart from the test and reference item.

Test design: Randomized block design with 5 treatment groups (control, 3 test item rates and reference item) each with of 4 replicates. A number of 20 plots each 10 m x 10 m, were arranged. The substances in all treatments were applied in a water volume equivalent to 400 L/ha. Application was performed using a plot sprayer with 2.5 m boom width. Natural rainfall within 2 days after application was 23 mm, therefore no additional irrigation.

Endpoints: Total abundance and biomass of earthworms.

Reference item: Luxan Carbendazim-500 FC (carbendazim, 500 g/L).

Test rates: Untreated control; BAS 500 06 F: 1.25 L/ha, 2.5 L/ha, 6.25 L/ha; reference item: 6 kg carbendazim/ha.

Application date: 15.05.2009.

Method of extraction: Earthworm extraction was achieved by using the electrical octet method in combination with hand sorting. 4 samples per plot were taken from the inner area of the plots.

Sampling dates: Pre-sampling: 2 to 3 days before application (12. + 13.05.2009); 1st sampling: approx. 6 weeks after application (24. + 25.06.2009); 2nd sampling: approx. 5 months after application (20. + 21.10.2009); 3rd sampling: approx. 12 months after application (10. + 11.05.2010).

Test conditions:	Natural field conditions; strong clayey silt to strong silty clay (according to DIN 4220), pH 5.9 - 6.2, 2.2 - 2.3% total organic carbon, max. water holding capacity 61.0%.
Air temperature at application day:	13.4°C - 16.6°C, Soil temperature at application day: 14.9°C - 15.6°C.
Analytics:	Analytical verification of pyraclostrobin in 5 soil cores taken from each treated plot using an LC-MC/MS method.
Statistics:	Descriptive statistics; Dunnett's t-test and Bonferroni-Welch t-test for the test item treatment groups, Student t-test for the reference item group ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

No measurable residues of BAS 500 06 F were determined in any of the soil samples of the control plots. In the plots treated with the test item BAS 500 06 F, mean residue values of 58 to 68% (ranging from 44 to 92% of the expected soil concentration) of the application rate were found. All mean recoveries were in the recommended range of 50-150%.

Prior to the treatment, the test site yielded sufficiently high numbers of earthworms of 202.8 individuals per m^2 representing various common earthworm species such as *Aporrectodea caliginosa*, *Octolasion tyrtaeum* and *Lumbricus terrestris*.
Surface monitoring on days 1-3 after application showed that there was no acute primary effect on earthworms by the test item. No alive, moribund and dead earthworms were found on the soil surface in any of the plots treated with BAS 500 06 F and in the control plots.
No statistically significant differences between BAS 500 06 F treatments and the untreated control could be detected in terms of total earthworm abundance 1.5, 5 and 12 months after application. The total biomass was reduced after 6 weeks (maximum 27.7%) with statistically significant differences compared to the control at 1.25 L and 6.25 L BAS 500 06 F/ha (Bonferroni-Welch t-test, $\alpha = 0.05$). However, total biomass had fully recovered after 5 months of exposure. After one year, exposure biomass was reduced at a rate of 1.25 L BAS 500 06 F/ha, which was not considered to be treatment related as no dose relation could be observed. For the most abundant earthworm species *Lumbricus terrestris* and *Aporrectodea caliginosa* the abundance was slightly but not statistically significantly reduced at 6.25 L BAS 500 06 F/ha after 6 weeks and had recovered after 5 months (Dunnett's t-test, $\alpha = 0.05$). The slight but not significant reduction of juvenile earthworms after 6 weeks had recovered after 12 months. Moreover, no statistically significant effects were found at the end of the study. The results are summarized in Table 10.4.1.2-1.

Table 10.4.1.2-1: Summary of total earthworm abundance and biomass in a field study with BAS 500 06 F

Treatment	Pre sampling 12. + 13.05.2009	First sampling 24. + 25.06.2009	Second sampling 20. + 21.10.2009	Third sampling 10. + 11.05.2010
Total earthworm abundance [Ind./m²]				
Control	202.8	261.0	235.0	211.0
1.25 L/ha BAS 500 06 F	195.5	235.5	214.0	185.5
% of control	**96.4**	**90.2**	**91.1**	**87.9**
2.5 L/ha BAS 500 06 F	202.5	218.5	209.0	205.5
% of control	**99.9**	**83.7**	**88.9**	**97.4**
6.25 L/ha BAS 500 06 F	206.8	185.0	188.5	197.0
% of control	**102.0**	**70.9**	**80.2**	**93.4**
Reference item: carbendazim	102.2% of control	38.5% of control *	38.9% of control *	55.0% of control *
Total earthworm biomass [g/m²]				
Control	75.3	80.9	60.9	66.7
1.25 L/ha BAS 500 06 F	65.3	58.9	61.9	46.6
% of control	**86.7**	**72.8 ***	**101.7**	**69.8**
2.5 L/ha BAS 500 06 F	66.4	65.9	60.4	59.3
% of control	**88.2**	**81.5**	**99.2**	**88.9**
6.25 L/ha BAS 500 06 F	78.7	59.0	61.1	56.2
% of control	**104.5**	**73.0 ***	**100.4**	**84.2**
Reference item: carbendazim	101.2% of control	31.6% of control *	47.7% of control *	57.9% of control *

* Statistically significantly different compared to the control (Dunnett's t-test, Bonferroni-Welch t-test or Student t-test, α = 0.05).

The validity criterion for the reference item Luxan Carbendazim-500 FC was fulfilled by reductions > 50% and statistically significant differences in earthworm abundance and biomass at the first and second sampling (Student t-test, α = 0.05).

III. CONCLUSION

Based on the results of this field study, it is concluded that exposure of earthworm populations to rates up to 6.25 L BAS 500 06 F/ha does not cause unacceptable long-term effects.

CP 10.4.2 Effects on non-target soil meso- and macrofauna (other than earthworms)

According to SANCO/10329/2002 rev2 final the test on 'sub-lethal effects on collembola or soil mites' is required if *(a)* the $DT_{90, field}$ is between 100 and 365 days and *(b)* the standard HQ for arthropods (*T. pyri* and *A. rhopalosiphi*) is above 2.

Toxicity and Exposure

Since the worst-case $DT_{90, field}$ values of pyraclostrobin and the metabolites BF 500-6 and BF 500-7 exceed 100 days and the standard HQ values for *T. pyri* and *A. rhopalosiphi* exceed the trigger value of 2 (please refer to M-CP 10.3), a test with soil macro-organisms other than earthworms was triggered. Therefore, reproduction studies with BAS 500 06 F as well as with the metabolites BF 500-6 and BF 500-7 were carried out with *Folsomia candida*. Furthermore, a reproduction study with BAS 500 06 F and *Hypoaspis aculeifer* was carried out in order to gain additional information for the risk assessment. The chronic endpoints are summarized in Table 10.4.2-1. In addition, a study on effects of BAS 500 06 F on organic matter breakdown is available and shown in M-CP 10.4.2.2. However, since the assessment on collembolan and soil mites indicated low potential risk and the study type of organic matter break down is currently not mentioned as data requirement under Regulation (EC) 1107/2009, the study is added for completeness and not considered for risk assessment.

Table 10.4.2-1: Summary of chronic endpoints on *Folsomia candida* and *Hypoaspis aculeifer* for BAS 500 06 F

Test substance	Test species	Endpoint	Value [mg/kg dry soil]	Reference (BASF DocID)
BF 500-6 [1)]	*Folsomia candida*	NOEC	≥ 1000	2013/1068054
BF 500-7 [1)]	*Folsomia candida*	NOEC	≥ 800	2013/1224030
Pyraclostrobin in BAS 500 06 F [1)]	*Folsomia candida*	NOEC	23.9 [2)]	2008/1037495
Pyraclostrobin in BAS 500 06 F [1)]	*Hypoaspis aculeifer*	NOEC	≥ 17.3 [3)]	2012/1129444

1) Test was conducted with only 5% peat in the test substrate.
2) Based on a nominal content of BAS 500 06 F (200.0 g/L pyraclostrobin) and taken into account the density of 1.044 g/cm^3.
3) Based on a nominal content of BAS 500 06 F (200.0 g/L pyraclostrobin) and taken into account the density of 1.038 g/cm^3.

Risk assessment for other non-target soil meso- and macrofauna (other than earthworms)

For risk assessment the chronic toxicity data (NOEC for reproduction) are compared to the predicted environmental concentration considering long-term exposure following multi-year use of BAS 500 06 F. The results are presented in Table 10.4.2-2.

Table 10.4.2-2: Long-term TER values for Folsomia candida and Hypoaspis aculeifer

Test substance	Test species	NOEC [mg/kg dry soil]	PEC_{soil} [mg/kg dry soil]	TER_{LT}	TER trigger
BF 500-6	*Folsomia candida*	≥ 1000	0.121	≥ 8264	5
BF 500-7	*Folsomia candida*	≥ 800	0.073	≥ 10959	
Pyraclostrobin in BAS 500 06 F	*Folsomia candida*	23.9	0.228	105	
Pyraclostrobin in BAS 500 06 F	*Hypoaspis aculeifer*	≥ 17.3		≥ 76	

All long-term TER values exceed the Commission Regulation (EU) 546/2011 trigger value of 5, indicating that no unacceptable effects are expected for other non-target soil meso- and macrofauna (other than earthworms) when BAS 500 06 F is applied according to the proposed use pattern.

CP 10.4.2.1 Species level testing

Report: CP 10.4.2.1/1
Friedrich S., 2008b
Effects of BAS 500 06 F on the reproduction of the collembolans Folsomia candida in artificial soil with 5% peat
2008/1037495
Guidelines: ISO 11267 (1999)
GLP: yes
(certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

The effects of BAS 500 06 F on mortality and reproduction of Collembola *(Folsomia candida)* were investigated in a laboratory study over 28 days. Six application rates (15.7, 31.3, 62.5, 125.0, 250.0 and 500.0 mg BAS 500 06 F/kg dry soil) were incorporated into the soil (5% peat only) with 5 replicates per treatment (each containing 10 juvenile collembolans). An untreated control with 5 replicates was included. Assessment of adult springtail mortality and reproduction rate (number of juveniles) was carried out after 28 days.

A mortality of 4% was observed in the control group compared to 0 - 8% mortality at 15.7, 31.3, 62.5 and 125 mg BAS 500 06 F/kg dry soil. At the concentrations of 250 and 500 mg/kg dry soil statistically significant mortality of 52 and 80% was determined. In the control a mean of 575.4 juveniles was counted. In the treatment groups a mean number of juveniles of 535.8 to 19.0 was counted with statistically significant differences compared to the control for the two highest treatment groups.

In a 28-day collembolan reproduction study with BAS 500 06 F the NOEC based on mortality and reproduction was 125 mg BAS 500 06 F/kg dry soil. The EC_{50} was 189.6 mg BAS 500 06 F/kg dry soil, the LC_{50}.was determined to be 283.8 mg BAS 500 06 F/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. no. 304 428): 200 g/L (202.7 g/L analyzed), density: 1.044 g/cm³.

Test species: Collembola (*Folsomia candida*), juveniles (10-12 days old); source: in-house culture.

B. STUDY DESIGN

Test design: 28-day test in treated artificial soil according to ISO 11267 (5% peat only); artificial soil was filled in glass vessels after treatment with different concentrations of the test item before collembolans were introduced. 7 treatment groups (6 test item concentrations, control) were set up with 5 replicates for each and each containing 10 juvenile collembolans.
Assessment of adult collembolans mortality and reproduction rate (number of juveniles) was carried out after 28 days.

Endpoints: Mortality, reproduction rate.

Reference item: Betosip (phenmedipham, 114 g/L). The effects of the reference item were investigated in a separate study.

Test rates: Control, 15.7, 31.3, 62.5, 125.0, 250.0 and 500.0 mg BAS 500 06 F/kg dry soil (nominal).

Test conditions: Artificial soil according to ISO 11267 (with reduced content of peat: 5%); pH 6.1 at test initiation, pH 5.9 - 6.0 at test termination; water content at study initiation 59.6% - 59.8% of maximum water holding capacity (WHC) and 58.9% - 59.3% of maximum WHC at test termination; temperature: 20°C - 22°C; photoperiod: 16 h light : 8 h dark; light intensity: 570 lux; food: 2 mg granulated dry yeast at the start of the test and after 14 days.

Statistics: Descriptive statistics. Fisher-exact test for mortality, Welch-t-test for reproduction, Probit analysis for determination of the LC_{50}, Logit analysis for determination of the EC_{50}.

II. RESULTS AND DISCUSSION

A mortality of 4% was observed in the control group compared to 0 - 8% mortality at 15.7, 31.3, 62.5 and 125 mg BAS 500 06 F/kg dry soil. At the concentrations of 250 and 500 mg/kg dry soil a statistically significant mortality of 52 and 80% was determined (Fisher-exact test, $\alpha = 0.05$).
In the control a mean of 575.4 juveniles was counted. In the treatment groups a mean number of juveniles of 535.8 to 19.0 was counted with statistically significant differences compared to the control for the two highest treatment groups (Welch-t-test, $\alpha = 0.05$). The results are summarized in Table 10.4.2.1-1.

Table 10.4.2.1-1: Effect of BAS 500 06 F on Collembola (*Folsomia candida)* in a 28-day reproduction study

BAS 500 06 F [mg/kg dry soil]	**Control**	**15.7**	**31.3**	**62.5**	**125.0**	**250.0**	**500.0**
Mortality (day 28) [%]	4	4	0	2	8	52*	80*
No. of juveniles (day 28)	575.4	535.8	601.8	576.8	579.4	76.6*	19.0*
Reproduction in [%] of control (day 28)	--	93	105	100	101	13	3
Endpoints [mg/kg dry soil]							
$NOEC_{mortality,\ reproduction}$	125						
EC_{50}	189.6						
LC_{50}	283.8						

* = Statistically significant differences compared to the control (Fisher-exact test for mortality; Welch-t-test for reproduction, $\alpha = 0.05$).

III. CONCLUSION

In a 28-day collembolan reproduction study with BAS 500 06 F the NOEC based on mortality and reproduction was 125 mg BAS 500 06 F/kg dry soil. The EC_{50} was 189.6 mg BAS 500 06 F/kg dry soil, the LC_{50}.was determined to be 283.8 mg BAS 500 06 F/kg dry soil.

Report:	CP 10.4.2.1/2 Schulz L., 2012c BAS 500 06 F - Effects of BAS 500 06 F on the reproduction of the predatory mite Hypoaspis aculeifer 2012/1129444
Guidelines:	OECD 226 (2008)
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

The effects of BAS 500 06 F on mortality and reproduction of the soil mite *Hypoaspis aculeifer* were investigated in a chronic laboratory study over 14 days. The test item was mixed into artificial soils at rates of 5.6, 11.3, 22.5, 45.0 and 90.0 mg BAS 500 06 F/kg dry soil. Test item treatments were replicated four times each. As a control treatment, the soil remained untreated in eight replicates. Each treatment contained 10 adult soil mites. Reproduction and mortality assessments of the mites were carried out after 14 days of exposure.

No differences in behavior between mites in the control and the test item treatments could be observed.

Test item treatment groups had mortality rates of between 5.0 - 15.0%. The mortality rate in the control group was 5.0%. The observed mortality rates for adult mites in test item treatment groups were not statistically significantly different from those observed in control groups.

Reproduction rates in test item treatments were not statistically significantly different from reproduction rates in control groups and showed no adverse effects of BAS 500 06 F on reproduction in all tested concentrations.

In a 14-day reproduction study with BAS 500 06 F on predatory soil mites, the NOEC was determined to be 90.0 mg BAS 500 06 F/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 0003223026; content of a.s.: pyraclostrobin (BAS 500 F, Reg. no. 304 428): 200.0 g/L (nominal); 200.7 g/L (analyzed); density: 1.038 g/cm³.

Test species: *Hypoaspis aculeifer* (Canestrini), adult predatory mite (age difference 3 days); source: in-house culture, originally from Katz Biotech AG, Baruth, Germany.

B. STUDY DESIGN

Test design: 14-day laboratory test on effects of BAS 500 06 F on mortality and reproduction of soil mites. Artificial soil (5% peat) was treated with different concentrations of the test item and filled in glass vessels before predatory mites were introduced on top of the soil; 6 treatment groups (control, 5 test item concentrations); 8 replicates for control and 4 replicates for test item, each with 10 soil mites; assessment of dault mortality and reproduction rate (number of juveniles) after 14 days.

Endpoints: Mortality and reproduction rate after 14 days.

Reference item: Dimethoate EC 400 (411.7 g analyzed); trade product: Perfekthion. The effects of the reference item were investigated in a separate study.

Test rates: Untreated control (deionized water), 5.6, 11.3, 22.5, 45 and 90 mg BAS 500 06 F/kg dry soil.

Test conditions: Artificial soil according to OECD 226; pH 5.6 - 5.7 at test initiation, pH 5.2 - 5.3 at test termination; water content at test initiation 50.41% - 51.41% of maximum water holding capacity (WHC) and 48.88 - 50.38% of maximum WHC at test termination; temperature: 19.6°C - 21.4°C; photoperiod: 16 h light : 8 h dark; light intensity: 470 lux. food: cheese mites (*Tyrophagus putrescentiae*).

Statistics: Descriptive statistics; Fisher Exact Binominal Test with Bonferroni Correction for mortality (α = 0.05, one-sided greater), Dunnett-t test for reproduction (α = 0.05, one-sided smaller).

II. RESULTS AND DISCUSSION

Mortality rates of 5.0 to 15.0% were recorded in the test item treatments groups and 5.0% in the control group. The observed mortality rates for adult mites in test item treatment groups was not statistically significantly different from those observed in control groups (Fisher Exact Binominal Test with Bonferroni Correction, $\alpha = 0.05$, one-sided greater). No differences in behavior between mites in the control and the test item treatments could be observed.
Reproduction rates in the 5.6, 11.3, 22.5, 45.0 and 90.0 mg BAS 500 06 F/kg dry soil were 236.8, 251.8, 273.3, 227.8 and 215.8 juveniles, respectively. BAS 500 06 F caused no statistically significantly differences on the reproduction rates of *Hypoaspis aculeifer* at all tested concentrations (Dunnett-t test, $\alpha = 0.05$, one-sided smaller). The results are summarized in Table 10.4.2.1-2.

Table 10.4.2.1-2: Effects of BAS 500 06 F on predatory mites (*Hypoaspis aculeifer*) in a 14-day reproduction study

BAS 500 06 F [mg/kg dry soil]	**Control**	**5.6**	**11.3**	**22.5**	**45**	**90**
Mortality (day 14) [%]	5.0	10.0	7.5	5.0	7.5	15.0
No. of juveniles (day 14)	232.5	236.8	251.8	273.3	227.8	215.8
Reproduction [% of control] (day 14)	100	102	108	118	98	93
Endpoints [mg BAS 500 06 F/kg dry soil]						
$NOEC_{mortality\ and\ reproduction}$	≥ 90					
LC_{50}	> 90					
EC_{50}	> 90					

The reference item dimethoate was tested at concentrations of 4.10, 5.12, 6.40, 8.00 and 10.00 mg a.s./kg dry soil. In a separate study (BioChem project no. R 12 10 48 002 S), the EC_{50} (reproduction) for dimethoate was calculated to be 6.87 mg a.s./kg dry soil. The results of the reference item demonstrate the sensitivity of the test system.

III. CONCLUSION

In a 14-day reproduction study with BAS 500 06 F on predatory soil mites, the overall NOEC was determined to be ≥ 90.0 mg BAS 500 06 F/kg dry soil.

CP 10.4.2.2 Higher tier testing

Further studies are not triggered, however a litterbag study on organic matter breakdown is available. This study was a former requirement under Council Directive 91/414/EEC and SANCO/ 10329/2002 rev 2. However, under Regulation (EC) 1107/2009 it is not required anymore. Therefore, the study is considered as additional information.

Report:	CP 10.4.2.2/1 Luehrs U., Schabio S., 2010a Effects of BAS 500 06 F on the breakdown of organic matter in litter bags in the field 2010/1000081
Guidelines:	Roembke et al. (2003), OECD 56 (2006)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

The test item BAS 500 06 F was studied for its potential effects on the degradation of buried organic wheat straw compared to a water control after exposure of about 1, 3 and 6 months. The study was set up as randomized block design with an application on soil surface at 1.25 L BAS 500 06 F/ha. An incorporation of a plateau concentration was omitted for this test, because the active substance pyraclostrobin is not persistent (max. $DT_{50,field}$ of 37 days), and therefore does not build up a plateau concentration in soil even after long-term use.

The mass loss of the straw material in the untreated control was 80.5% at the end of the experiment after 179 days. In the treatment group exposing the soil to 1.25 L BAS 500 06 F/ha, the mean mass losses after the exposure phases of about 1, 3 and 6 months were only slightly different from those in the control, resulting in effects of -5.5, +0.2 and -0.1%, respectively. There were no statistically significant differences between this treatment group and the water treated control.

The results of this 6-month field study on an arable field site emphasize that BAS 500 06 F has no treatment-related ecologically relevant effects on the organic matter breakdown following application of 1.25 L BAS 500 06 F/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 500 06 F, batch no. 8265; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 202.7 g/L (nominal: 200.0 g/L); density: 1.044 g/cm^3.
Test species:	Naturally occurring non-target soil organisms.

B. STUDY DESIGN

Test site:	Arable crop site in Rossdorf (Darmstadt-Dieburg), Germany; total size about 1460 m², the site had not received chemical application since May 2008 and none was applied during the study apart from the test item.
Test design:	Randomized block design with two treatments (1 test item groups, water treated control) and six replicates each treatment. Exposure via application of the annual rate on the soil surface. An incorporation of a plateau concentration was omitted for this test because pyraclostrobin is not persistent (max. DT_{50} of 37 days). Within the plots (5 x 6 m plot size) the litter bags were randomly distributed in the upper soil layer (depth of about 5 cm). The treatments were assigned randomly to the plots within each replicate. The substances in all treatments were applied in a water volume equivalent to 400 L/ha. Application was performed using a movable plot sprayer with a distance between nozzles and soil of 0.5 m. Immediately after the application the test site was irrigated with 10.4 mm.
Endpoints:	Mean weight loss of organic matter based on ash-free dry weight per plot per treatment.
Test rates:	Treatment group 1: Untreated control; treatment group 2: 1.25 L BAS 500 06 F/ha (equivalent to 250 g a.s./ha).
Application dates:	Burying of litter bags: 04.05.2009; application: 05.05.2009.
Test conditions:	Natural field conditions; clayey silt/silty loam according to DIN 4220, 1.1% - 1.2% total organic carbon, pH 6.4 - 7.1. Air temperature: 9.6 to 19.6°C, soil temperature: 11.3 - 19.8°C, total precipitation per month: 17.1 - 110.2 L/m².

Litter bags:	Litter bags consisted of mesh material (100% polyester) with a mesh size of about 8 mm. The size of a bag was about 12 x 20 cm. Bags were filled with about 4.0 g (dry weight) of untreated dried wheat straw. Litter-bags were horizontally buried at a depth of about 5 cm, 1 day before application of the annual rate of BAS 500 06 F.
Sampling dates:	1st sampling: 29.05.2009 (after 25 days of exposure). 2nd sampling: 31.07.2009 (after 88 days of exposure). 3rd sampling: 30.10.2009 (after 179 days of exposure).
Sample processing:	Sampling was done at three different time intervals (25, 88 and 179 days of exposure). 8 bags were sampled per replicate per sampling date (48 bags per treatment), immediately transported to the laboratory and stored deep frozen until further processing. The enclosed straw material was cleaned and the bag content was oven-dried at 35°C for 12 hours and weighted. Finally, the straw was ashed at 600°C for 0.5 hours and ash-free weight was determined.
Analytics:	Soil samples were only analyzed for the active substance pyraclostrobin according to the analytical method M432.
Statistics:	Descriptive statistics, Student t test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Recovery rates for the active substance pyraclostrobin ranged from 51 to 92% of the expected soil concentration (mean 75%).

The mass loss of the straw material in the untreated control was 80.5% at the end of the experiment after 179 days. In the treatment group exposing the soil to 1.25 L BAS 500 06 F/ha, the mean mass losses after the exposure phases of about 1, 3 and 6 months were only slightly different from those in the control, resulting in effects of -5.5, +0.2 and -0.1%, respectively. There were no statistically significant differences between this treatment group and the water treated control (Student t-test, $\alpha = 0.05$). Effects on the degradation of buried wheat straw are summarized in Table 10.44.2.2-1.

Table 10.4.4.2.2-1: Mass loss [%] of wheat straw following exposure to BAS 500 06 F

Treatment	Mean mass loss [%]		
	Sampling 1	Sampling 2	Sampling 3
Control	16.9	54.1	80.5
1.25 L BAS 500 06 F/ha, % effect (mass loss)	17.8 (-5.5)	54.0 (+0.2)	80.6 (-0.1)

III. CONCLUSION

The results of this 6-month field study on an arable field site emphasize that BAS 500 06 F has no treatment-related ecologically relevant effects on the organic matter breakdown following application of 1.25 L BAS 500 06 F/ha.

CP 10.5 Effects on soil nitrogen transformation

The new representative formulation BAS 500 06 F was not evaluated within the previous Annex I inclusion process. It is an emulsifiable concentrate (EC) containing 200g/L pyraclostrobin.

The EU agreed endpoints for the soil metabolites of the active substance pyraclostrobin as described in the EU Review Report (SANCO/1420/2001-final, September 2004) plus endpoints from a new study with the new representative formulation BAS 500 06 F are used for the risk assessment on soil micro-organisms (see Table 10.5-1).

Table 10.5-1 Ecotoxicological endpoints for soil micro-organisms

Test substance	Test design [1)]	EU agreed endpoints	Endpoints used in risk assessment
Pyraclostrobin [2)]	C	NOEC = 3.33 mg a.s./kg dry soil, (equivalent to 2.5 kg a.s./ha)	--
	N	NOEC = 3.33 mg a.s./kg dry soil, (equivalent to 2.5 kg a.s./ha)	--
BF 500-6	C	NOEC = 1.0 mg/kg dry soil, equivalent to 0.75 kg/ha	
	N	NOEC = 1.0 mg/kg dry soil, equivalent to 0.75 kg/ha	NOEC = 1.0 mg/kg dry soil, equivalent to 0.75 kg/ha
BF 500-7	C	NOEC = 0.5 mg/kg dry soil, equivalent to 0.375 kg/ha	
	N	NOEC = 0.5 mg/kg dry soil, equivalent to 0.375 kg/ha	NOEC = 0.5 mg/kg dry soil, equivalent to 0.375 kg/ha
BAS 500 06 F	N	--	NOEC = 17.3 mg/kg dry soil (3.33 mg a.s./kg dry soil) [3)], equivalent to 12.5 L/ha

1) C = Carbon transformation, N = Nitrogen transformation.
2) Study was conducted with the pyraclostrobin solo-formulation BAS 500 00 F (250 g pyraclostrobin/L).
3) This study replaces also the old N-transformation study for the active substance pyraclostrobin, which was conducted with the former representative formulation BAS 500 00 F (see above).

Toxicity

The effects of BAS 500 06 F and the relevant metabolites to soil micro-organisms are summarized in Table 10.5-2. Further details on the studies on nitrogen transformation with the formulated product are given in the summary provided at the end of this chapter.

Table 10.5-2: Effects of BAS 500 06 F, BF 500-6 and BF 500-7 to soil micro-organisms

Test substance	Endpoint	NOEC	Reference (BASF DocID)
BF 500-6	Effects on nitrogen and carbon transformation	1.0 mg/kg dry soil	1999/11311 1999/11120
BF 500-7	Effects on nitrogen and carbon transformation	0.5 mg/kg dry soil	1999/11311 1999/11120
BAS 500 06 F	Effects on nitrogen transformation	17.3 mg/kg dry soil (equivalent to 12.5 L/ha)	2012/1129443

Exposure

Table 10.5-3: Critical use pattern of BAS 500 06 F

Crop	Application time (BBCH code)	Number of applications	Interval [d]	Application rate per treatment	
				Pyraclostrobin [g a.s./ha]	BAS 500 06 F [L/ha]
cereals	25 - 69	2	21	250	1.25
maize	30 - 65	1	--	200	1.0

The predicted environmental concentrations of pyraclostrobin and relevant metabolites in soil (PEC_{soil}) were calculated as described in M-CP 9.1. The resulting maximum PEC_{soil} values are presented in Table 10.5-4.

Table 10.5-4: PEC_{soil} values for pyraclostrobin and relevant metabolites *

Test substance	$PEC_{soil, max}$ [mg/kg dry soil]	$PEC_{soil, plateau}$ [mg/kg dry soil]	$PEC_{soil, accu}$ [mg/kg dry soil]
Pyraclostrobin	0.228	--	--
BF 500-6	0.065	0.057	0.121
BF 500-7	0.039	0.034	0.073

* Only worst-case scenario is presented.

Risk assessment for Soil Nitrogen Transformation

BAS 500 06 F had no significant effect on soil micro-organisms at 17.3 mg BAS 500 06 F/kg dry soil, corresponding to 3.33 mg pyraclostrobin/kg dry soil. This is approximately 15-times higher than the maximum $PEC_{soil, max}$ of 0.228 mg pyraclostrobin/kg dry soil. This supports the conclusion that under field conditions, the use of BAS 500 06 F in cereals and maize at the recommended rates poses no unacceptable risk to non-target soil micro-organisms.

Furthermore, the NOEC values for the metabolites of 1.0 mg BF 500-6/kg dry soil and 0.5 mg BF 500-7/kg dry soil are more than 8- and approximately 7-times higher than the maximum $PEC_{soil, accu}$ values of 0.121 mg BF 500-6/kg dry soil and 0.073 mg BF 500-7/kg dry soil, respectively.

It is concluded that the proposed use of BAS 500 06 F in cereals and maize will not pose an unacceptable risk to non-target soil micro-organisms, if applied according to the recommended use pattern.

Report:	CP 10.5/1 Schulz L., 2012b Effects of BAS 500 06 F on the activity of soil microflora (Nitrogen transformation test) 2012/1129443
Guidelines:	OECD 216 (2000)
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

In a soil microbial activity study, the effect of BAS 500 06 F on nitrogen transformation was tested in loamy sand soil. BAS 500 06 F was applied to samples of the soil at nominal test concentrations of 1.73 and 17.30 mg/kg dry soil. No adverse effects of BAS 500 06 F on nitrogen transformation in soil were observed in the test item concentration of 1.73 mg/kg dry soil after 28 days. Measured deviations of > 25% observed in the 17.30 mg/kg dry soil treatment group 28 days after application demanded extended test duration to 42 days of incubation. Only a small deviation from the control of +22.1% (at test concentration 17.30 mg/kg dry soil) was observed in the time interval of 0 – 42 days.

Based on the results of this study, BAS 500 06 F caused no adverse effects (< 25% deviation from control according to OECD 216) on the soil nitrogen transformation (measured as NO_3-N production) in a loamy sand soil tested up to a concentration of 17.30 mg/kg dry soil after 42 days of incubation.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch no. 0003223026, content of a.s.: pyraclostrobin (BAS 500 F, Reg. no.: 304 428): 200.7 g/L (nominal: 200.0 g/L); density: 1.038 g/cm^3.

Test soil: Biologically active agricultural soil: loamy sand (DIN 4220) / sandy loam (USDA), soil pH 6.5, C_{org} 1.45%, WHC: 33.45 g/100 g dry soil.

B. STUDY DESIGN

Test design: Determination of the N-transformation (NO_3-nitrogen production) in soil enriched with lucerne meal (concentration in soil 0.5%). Three treatment groups were set up (untreated control, two test item concentrations) with three replicates per treatment. Comparison of test item treated soil with a non-treated soil. NH_4-nitrogen formed from organically bound nitrogen and NO_3-nitrogen formed from the nitrification process was determined by using an Autoanalyzer (Bran and Luebbe). Sampling scheme: 0, 7, 14, 28 and 42 days after treatment; sub-samples were withdrawn from the bulk batches and subjected to the measurement.

Endpoints: Effects on the NO_3-nitrogen production 0, 7, 14, 28 and 42 days after exposure.

Test rates: Control, 1.73 and 17.30 mg BAS 500 06 F/kg dry soil (equivalent to 0.33 and 3.33 mg a.s./kg dry soil, respectively).

Reference item: Dinoterb (purity: 98.0 ± 0.5%). The reference item was tested in a separate study at rates of 6.8, 16.0 and 27.0 mg/kg dry soil.

Test conditions: Water content: approx. 45% of maximum water holding capacity; measured water content: 14.02% – 14.67%; pH 5.8 - 6.2. Soil samples were incubated at 19.2°C – 21.0°C while stored in glass flasks in the dark.

Statistics: Descriptive statistics.

II. RESULTS AND DISCUSSION

No adverse effects of BAS 500 06 F on nitrogen transformation in soil was observed in the test item concentration of 1.73 mg/kg dry soil after 28 days. Only a negligible deviation from the control of +20.1% (at test concentration 1.73 mg/kg dry soil) was observed in the time interval of 0 – 28 days.
Measured deviations of > 25% observed in the 17.30 mg/kg dry soil treatment group 28 days after application demanded extended test duration to 42 days of incubation. Only a negligible deviation from the control of +22.1% (at test concentration 17.30 mg/kg dry soil) was observed in the time interval of 0 – 42 days. The results are summarized below in Table 10.5-5.

Table 10.5-5: Effects of BAS 500 06 F on soil micro-organisms (nitrogen transformation) on days 7, 14, 28 and 42 of incubation

Soil (days)	Control	1.73 mg BAS 500 06 F/kg dry soil		17.30 mg BAS 500 06 F/kg dry soil	
	NO_3-N [mg/kg dry soil]	NO_3-N [mg/kg dry soil]	% Deviation from control [1)]	NO_3-N [mg/kg dry soil]	% Deviation from control [1)]
Loamy sand (0 - 7 d)	11.33	12.20	+7.6	17.43	+53.8
Loamy sand (0 - 14 d)	14.77	18.40	+24.6	23.70	+60.5
Loamy sand (0 - 28 d)	24.43	29.33	+20.1	32.87	+34.5
Loamy sand (0 - 42 d)	32.67	--[2)]	--[2)]	39.90	+22.1

1) Based on NO_3-nitrogen production; - = inhibition, + = stimulation.
2) No analysis performed.

In a separate study the reference item Dinoterb produced a stimulation of nitrogen transformation of +40.4, +68.1 and +83.5% at 6.8 mg, 16.0 mg and 27.0 mg/kg dry soil after 28 days incubation, respectively.

III. CONCLUSION

Based on the results of this study, BAS 500 06 F caused no adverse effects (< 25% deviation from control according to OECD 216) on the soil nitrogen transformation (measured as NO3-N production) in a loamy sand soil tested up to a concentration of 17.30 mg/kg dry soil after 42 days of incubation.

CP 10.6 Effects on terrestrial non-target higher plants

The new representative formulation BAS 500 06 F was not evaluated within the previous Annex I inclusion process. It is an emulsifiable concentrate (EC) containing 200g/L pyraclostrobin.

Endpoints from two new studies with the new representative formulation BAS 500 06 F are used for the risk assessment on non-target higher plants (see Table 10.6-1).

Table 10.6-1: Ecotoxicological endpoints for non-target higher plants

Test substance	Test system	Test species	EU agreed endpoints	Endpoints used in risk assessment
BAS 500 06 F	Vegetative vigor, greenhouse	Carrot, lettuce, oilseed rape, cabbage, soybean, tomato, onion, rye grass, oat, maize	--	ER_{50} > 1.25 L/ha
	Seedling emergence, greenhouse	Carrot, lettuce, oilseed rape, cabbage, soybean, tomato, onion, rye grass, oat, maize	--	ER_{50} > 1.25 L/ha

Toxicity

The potential effects of BAS 500 06 F on vegetative vigor and seedling emergence have been tested in two studies. There were no unacceptable effects on vegetative vigor and seedling emergence at rates up to and including 1.25 L BAS 500 06 F/ha for all ten species tested. Further details of the studies are given in M-CP 10.6.2.

Table 10.6-2: Summary of effects on terrestrial non-target plants following exposure to BAS 500 06 F

Test substance	Test species	Test system	ER_{50} plant dry weight, plant height [L/ha]	ER_{50} seedling emergence [L/ha]	Reference (BASF DocID)
BAS 500 06 F	Carrot, lettuce, oilseed rape, cabbage, soybean, tomato, onion, rye grass, oat and maize	Vegetative vigour	> 1.25	--	2012/1115894
		Seedling emergence	--	> 1.25	2012/1115895

Exposure

Table 10.6-3: Critical use pattern

Crop	Application time (BBCH growth stage)	Number of applications	Interval [d]	Application rate per treatment	
				Pyraclostrobin [g a.s./ha]	BAS 500 06 F [L/ha]
cereals	25 - 69	2	21	250	1.25
maize	30 - 65	1	--	200	1.0

Effects on non-target plants are of concern in the off-field environment, where they may be exposed to spray drift. The amount of spray drift reaching off-crop habitats is calculated using the 90th percentile estimates derived by the BBA [*BBA (2000) Bundesanzeiger Jg. 52 (Official Gazette), Nr 100, S. 9879-9880 (25.05.2000) Bekanntmachung über die Abtrifteckwerte, die bei der Prüfung und Zulassung von Pflanzenschutzmitteln herangezogen werden.*] from the spray-drift predictions of Ganzelmeier & Rautmann (2000) [*Ganzelmeier H., Rautmann D. (2000) Drift, drift-reducing sprayers and sprayer testing. Aspects of Applied Biology 57, 2000, Pesticide Application*]. Only a single application was considered, because factors like plant growth will reduce residues per unit area between multiple applications.
For a single application to field crops, 2.77% of the application rate was assumed to reach areas at 1 m from the edge of the crop (worst-case scenario). The highest single application rate of BAS 500 06 F is 1.25 L product/ha, giving a maximum off-field predicted environmental rate ($PER_{off\text{-}field}$) of 0.0346 L product/ha.

Risk assessment for terrestrial non-target higher plants

BAS 500 06 F is a fungicide and therefore this product is not expected to have any significant herbicidal activity. Profiling studies of the effects on pre- and post-emergence of non-target higher plants were conducted and showed no unacceptable effects on any of the ten species tested at rates up to and including 1.25 L BAS 500 06 F/ha.

According to the Terrestrial Guidance Document [*Anonymous (2002b). Guidance Document on terrestrial ecotoxicology under council directive 91/414/EEC. SANCO/10329/2002. 17 October 2002*], the risk to non-target plants should be considered acceptable if less than 50% effect on all ten species is seen at the maximum single application rate. Less than 50% effect on vegetative vigor and seedling emergence were observed on all tested species at the highest tested rate of 1.25 L BAS 500 06 F/ha. Therefore, it can be concluded that the proposed use of BAS 500 06 F poses no unacceptable risk to non-target plants.

The calculated maximum $PER_{off\text{-}field}$ of 0.0346 L product/ha is by far below the level found to have no effects on the non-target higher plants. Based on the drift values it can be concluded that the use of BAS 500 06 F in cereals and maize poses no unacceptable risk to non-target higher plants, too.

In conclusion, BAS 500 06 F poses no unacceptable risk to terrestrial non-target plants in off-crop areas following the intended use in cereals and maize.

CP 10.6.1 Summary of screening data

Tests on non-target plants have been conducted. The data point is covered by M-CP 10.6.2.

CP 10.6.2 Testing on non-target plants

Report:	CP 10.6.2/1 Stroemel C. et al., 2013a Effect of BAS 500 06 F on vegetative vigour of ten species of terrestial plants under greenhouse conditions 2012/1115894
Guidelines:	OECD 227 July 2006, EPA 850.4150
GLP:	yes (certified by Land Brandenburg Ministerium fuer Umwelt, Gesundheit und Verbraucherschutz, Potsdam, Germany)

Executive Summary

In a vegetative vigor test, six species of dicotyledonous plants (carrot, lettuce, oilseed rape, cabbage, soybean and tomato) and four species of monocotyledonous plants (onion, rye grass, oat and maize) were exposed to BAS 500 06 F. BAS 500 06 F was applied post-emergence at test rates of 0.078, 0.156, 0.313, 0.625 and 1.25 L BAS 500 06 F/ha. Assessments for phytotoxicity, survival and plant length were done 7, 14 and 21 days after application (DAT). Plant biomass (shoot dry weight) was determined 21 DAT.

After treatment with BAS 500 06 F, carrot, lettuce, onion, ryegrass and oat showed no phytotoxic symptoms. Only slight damage occurred in oilseed rape, cabbage, soybean, tomato and maize. No plant mortality was observed for all tested species after application of BAS 500 06 F up to a rate of 1.25 L/ha. Plant length at 21 DAT was not significantly affected by BAS 500 06 F up to a rate of 1.25 L/ha. No influence of BAS 500 06 F on plant biomass was observed for all tested species, except for cabbage, showing a significantly reduced biomass by 8% at a rate of 1.250 L BAS 500 06 F/ha. In onion, statistically significantly reduced biomass was found at a rate of 0.313 L/ha, but not at higher test rates, indicating that this difference was not related to the test item. In summary, BAS 500 06 F did not cause adverse effects to the tested species.

The NOER based on plant survival, phytotoxicity, plant length and plant dry weight was determined to be ≥ 1.25 L BAS 500 06 F/ha for all tested species except for maize (NOER phytotoxicity: 0.625 L/ha) and cabbage (NOER plant biomass: 0.625 L/ha). Both, ER_{25} and ER_{50} were determined to be > 1.25 L BAS 500 06 F/ha, the highest tested rate in this study.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch No. 0004863761; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 201.0 g/L (nominal 200.0 g/L); density: 1.037 g/cm^3.

Test species: Carrot (*Daucus carota* L.), lettuce (*Lactuca sativa* L.), oilseed rape (*Brassica napus* L.), cabbage (*Brassica oleracea* L. var. *capitata L. f. alba*), soybean (*Glycine max* L.), tomato (L*ycopersicum esculentum* Mill.), onion (*Allium cepa* L.), ryegrass (*Lolium perenne* L.), oat (*Avena sativa* L.) and maize (*Zea mays* L.).

B. STUDY DESIGN

Test design: 6 treatment groups (one untreated control and 5 treatment rates per species); 4 – 6 replicates per treatment; 5 – 10 plants per pot (depending on plant species); greenhouse cultivation over a 21 days period, dose-response design; application post emergence (BBCH 12 – 14); assessments for plant damage (phytotoxicity), survival and length was done 7, 14 and 21 days after treatment (DAT); shoot dry weight was determined at study termination 21 DAT.

Endpoints: ER_{25}, ER_{50}, NOER.

Test rates: Untreated control, 0.078, 0.156, 0.313, 0.625 and 1.250 L BAS 500 06 F/ha; applied in a water volume of 223 L/ha using a laboratory spray cabin.

Test conditions: Temperatures between 20.5°C and 26.3°C; humidity: 47.8% to 73.3%; photoperiod: ≥ 16 h light; additional light when daylight was less than 10 klux.

Statistics: Descriptive statistics; ANOVA followed by Welch-t test or Dunnett's t-test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

All control plants remained healthy throughout the trial period and no mortality was observed. Carrot, lettuce, onion, ryegrass and oat showed no phytotoxic symptoms at all. Only slight damage occurred in oilseed rape, cabbage, soybean, tomato and maize.
No plant mortality was observed for all tested species after application of BAS 500 06 F up to a rate of 1.25 L/ha. Plant length at 21 DAT was not statistically significantly affected by BAS 500 06 F up to and including a rate of 1.25 L/ha. No influence of BAS 500 06 F on plant biomass was observed for all tested species, except for cabbage, showing a statistically significantly reduced biomass of 8% at a rate of 1.25 L BAS 500 06 F/ha (Dunnett's t-test, $\alpha = 0.05$). In onion, statistically significantly reduced biomass was found at a rate of 0.313 L/ha (Dunnett's t-test, $\alpha = 0.05$) but not at higher test rates, indicating that this difference was not related to the test item. In summary, BAS 500 06 F did not cause adverse effects to the tested species. The results are summarized in Table 10.6.2-1 and Table 10.6.2-2.

III. CONCLUSION

The NOER based on plant survival, phytotoxicity, plant length and plant dry weight was determined to be ≥ 1.25 L BAS 500 06 F/ha for all tested species except for maize (NOER phytotoxicity: 0.625 L/ha) and cabbage (NOER dry weight: 0.625 L/ha). Both, ER_{25} and ER_{50} were determined to be > 1.25 L BAS 500 06 F/ha, the highest tested rate in this study for all tested species.

Report:	CP 10.6.2/2 Stroemel C. et al., 2012a Effect of BAS 500 06 F on seedling emergence and seedling growth of ten species of terrestrial plants under greenhouse conditions 2012/1115895
Guidelines:	OECD 208 (2006), EPA 850.4100
GLP:	yes (certified by Land Brandenburg Ministerium fuer Umwelt, Gesundheit und Verbraucherschutz, Potsdam, Germany)

Executive Summary

In a seedling emergence test, six species dicotyledonous plants (carrot, lettuce, oilseed rape, cabbage, soybean, tomato) and four species of monocotyledonous plants (onion, ryegrass, oat, maize) were exposed to BAS 500 06 F to evaluate the phytotoxic potential. BAS 500 06 F was applied pre-emergence in a dose-response design at test rates of 0.078, 0.159, 0.313, 0.625 and 1.25 L/ha. Assessments for seedling emergence, phytotoxicity, plant survival and plant length were done 7, 14 and 21 days after application (DAT) (carrot and onion: 14, 21 and 28 days). Plant dry weight was determined at study termination 21 DAT (28 days for carrot and onion).

Based on the results of this study, conducted under greenhouse conditions, it can be concluded that the fungicide BAS 500 06 F did not cause adverse effects to the seedling emergence, plant survival, phytotoxicity, plant length and dry biomass production of the tested plant species.

The NOER based seedling emergence, plant survival, dry weight and height was determined to be 1.25 L BAS 500 06 F/ha for all tested plant species except for onion (0.313 L BAS 500 06 F/ha). For all tested plant species, the ER_{50} was determined to be > 1.25 L BAS 500 06 F/ha, the highest rate tested.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 500 06 F, batch No. 0004863761, content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 201.0 g/L (nominal 200.0 g/L); density 1.037 g/cm³.

Test species: Carrot, (*Daucus carota* L.), lettuce (*Lactuca sativa* L.), oilseed rape (*Brassica napus* L.), cabbage (*Brassica oleracea* L. var. *capitata L. f. alba*), soybean (*Glycine max* L.), tomato (L*ycopersicum esculentum* Mill.), onion (*Allium cepa* L.), ryegrass (*Lolium perenne* L.), oat (*Avena sativa* L.) and maize (*Zea mays* L.).

B. STUDY DESIGN

Test design: 6 treatment groups (5 test item rates, control); 4 – 5 replicates per treatment; 7 – 12 plants per pot (depending on plant species); dose-response design under greenhouse conditions; BAS 500 06 F was applied pre-emergence using a laboratory sprayer at a water rate of 223 L/ha for soybean and onion, and 233 L/ha for the remaining test species; assessments for seedling emergence, plant damage (phytotoxicity), survival and plant length were done 7, 14 and 21 days after treatment (DAT) (carrot and onion 14, 21 and 28 days); shoot dry weight was determined at study termination 21 DAT (carrot and onion: 28 DAT).

Endpoints: NOER, ER_{25}, ER_{50}.

Test rates: Untreated control (tap water), 0.078, 0.156, 0.313, 0.625 and 1.250 L BAS 500 06 F/ha for all tested species.

Test conditions: Temperatures between 17.4°C and 28.8°C; humidity: 42.4% to 73.3%; photoperiod: > 16 h light, additional light was automatically applied when outdoor illumination was < 10 klux.

Statistics: Descriptive statistic, ANOVA followed by Welch-t test or Dunnett's-test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

No adverse dose response effects of BAS 500 06 F on seedling emergence, plant survival, phytotoxicity, plant length and biomass (dry weight) were observed on any of the ten species tested.
None of the tested species was adversely affected concerning seedling emergence and plant survival after pre-emergence application of BAS 500 06 F. All species reached a required emergence rate of 50% at 7 DAT except carrot and onion at 14 DAT. The NOER, ER_{25} and ER_{50} for seedling emergence and plant survival were 1.25, > 1.25 and > 1.25 L BAS 500 06 F/ha for all tested species, respectively.
For none of the tested species, reduction in plant length was observed except for onion. Plant length of onions was statistically significantly reduced by 8 and 9% at 0.625 and 1.25 L BAS 500 06 F/ha (Dunnett's t-test, $\alpha = 0.05$). The NOER, ER_{25} and ER_{50} for plant length were 1.25, > 1.25 and > 1.25 L BAS 500 06 F/ha for all tested species except for onion with a NOER of 0.313 L BAS 500 06 F/ha, respectively.
BAS 500 06 F did not adversely affect plant biomass development in all tested species. Statistically significant differences found in onion only occurred at 0.156 and 0.625 L BAS 500 06 F/ha (Dunnett's t-test, $\alpha = 0.05$), but not at the highest test rate and can thus be assumed not to be treatment-related. The NOER, ER_{25} and ER_{50} for plant biomass were 1.25, > 1.25 and > 1.25 L BAS 500 06 F/ha for all tested species, respectively. In summary, BAS 500 06 F did not cause adverse effects to the tested species. The results are summarized in Table 10.6.2-3 and Table 10.6.2-4.

[1)] Carrot and onion were cultivated over 28 days.

III. CONCLUSION

The NOER based on seedling emergence, plant survival, dry weight and height was determined to be 1.25 L BAS 500 06 F/ha for all tested plant species except for onion (0.313 L BAS 500 06 F/ha). For all tested plant species, the ER_{50} was determined to be > 1.25 L BAS 500 06 F/ha, the highest rate tested.

CP 10.6.3 Extended laboratory studies on non-target plants

Further tests on non-target plants are not triggered.

CP 10.6.4 Semi-field and field tests on non-target plants

Further tests on non-target plants are not triggered.

CP 10.7 Effects on other terrestrial organisms (flora and fauna)

Further studies are not triggered.

CP 10.8 Monitoring data

According to the knowledge of the applicant, there are currently no monitoring studies available, which are assessing ecotoxicological effects of BAS 500 06 F.

Table of Contents

CP 12 CLASSIFICATION AND LABELLING OF THE PLANT PROTECTION PRODUCT

Physico-chemical properties

Table 12-1: Physico-chemical data relevant for classification of BAS 500 06 F

Parameter	Findings (triggered risk phrase)	Reference (BASF DocID)
Explosive properties	The product has no explosive properties.	2004/1004104
Oxidizing properties	The product has no oxidizing properties.	2004/1004104
Flammability	Flash point: 104°C Auto-ignition temperature: 450°C	2004/1010381 2004/1004104
Content of hydrocarbons	> 10 % **(H304 required, R65 not required, see remark below)**	Doc JCP 1.4.1
Viscosity	The kinematic viscosity (at 40°C) was determined to be 12.9 x 10^{-6} m^2/s. Viscosity (at D=100s^{-1}): 31.4 mPa s at 20°C (Flow behaviour: Newtonian) **(see remark below)**	2004/1010381
Surface tension	36.6 mN/m at 0.06%, 33.4 mN/m at 0.8% and 36.3 mN/m undiluted (all at 20°C) **(see remark below)**	2004/1010381

Remarks:

H 304:
A classification with H304 is triggered for BAS 500 06 F by its physical/chemical properties according to Regulation (EC) No. 1272/2008 (CLP):

- hydrocarbon content: > 10 % (w/w)
- kinematic viscosity at 40°C: < 20.5 x 10^{-6} m^2/s

R 65:
Due to the different trigger values a classification with R65 is not required for BAS 500 06 F by its physical/chemical properties (EU Directives 67/548/EEC and 2001/59/EC):

- hydrocarbon content: > 10 % (w/w)
- kinematic viscosity at 40°C: > 7 x 10^{-6} m^2/s
- surface tension: ≥ 33 mN/m

Toxicology

Table 12-2: Toxicological data relevant for classification of BAS 500 06 F

Study type/species	Results	Classification		Reference
		EU Dir. 67/548/EEC 2001/59/EC	Reg. EC 1272/2008 (CLP)	(BASF DocID)
Acute oral toxicity, rat	LD_{50} ~ 500 mg/kg bw	R22	H302	2007/1053390
Acute dermal toxicity, rat	LD_{50} > 5000 mg/kg bw	-	-	2009/1084157
Acute inhalation toxicity, rat	LC_{50} = 4.48 mg/L (both sexes) LC_{50} = 4.78 mg/L (males) LC_{50} = 4.55 mg/L (females)	R20	H332	2009/1122167
Skin irritation, rabbit	Irritating to rabbit skin	R38	H315	2009/1100358
Eye irritation, rabbit	Irritating to rabbit eye	-	H319	2009/1100359
Skin sensitization LLNA assay, mouse Maximization test, guinea pig	Sensitizing	R43	H317	2007/1053391 2009/1018498

Remarks:
A full acute toxicity data package for BAS 500 06 F is available. BAS 500 06 F is moderately toxic by the oral and inhalation route of exposure and non-toxic by the dermal route. It is irritant to the skin and the eye and may cause skin sensitization.
Neither the classification of the active substance nor the classification of individual co-formulants has any further influence on the classification of the product BAS 500 06 F. Detailed information about the co-formulants is given in Documents JCP and JGH.

Ecotoxicology/Environment

Table 12-3: Ecotoxicological data relevant for classification of BAS 500 06 F

Study type/species	Results	Classification		Reference
		EU Dir. 67/548/EEC 2001/59/EC	Reg. EC 1272/2008 (CLP)	(BASF DocID)
Rainbow trout (96 h)	LC_{50} = 0.036 mg/L	R50	H400	2008/1018046
D. magna (48 h)	EC_{50} = 0.065 mg/L	R50	H400	2004/1004393
Green alga (72 h)	E_RC_{50} = 14.2 mg/L	R52	-	2008/1009325
Biodegradation	Not readily biodegradable	R53	H410	1999/10655

Remarks:
Ecotoxicological studies were conducted with BAS 500 06 F as shown in the table above. The statement on biodegradation has been derived from the properties of the active substance (pyraclostrobin is not readily biodegradable). Neither the classification of the active substance nor the classification of individual co-formulants has any further influence on the classification of the product BAS 500 06 F. Detailed information about the co-formulants is given in Documents JCP and JGH.

Label Elements

Table 12-4: Proposed Risk and Safety Phrases according to Directive 67/548/EEC or 1999/45/EC

Pictogram(s)		
Hazard symbol(s):	Xn, N	
Indication(s) of danger:	Harmful, Dangerous for the environment	
Risk phrases:	R20/22	Harmful by inhalation and if swallowed.
	R38	Irritating to skin.
	R43	May cause sensitization by skin contact.
	R50/53	Very toxic to aquatic organisms, may cause long-term adverse effects in the aquatic environment.
Safety phrases	S2	Keep out of the reach of children.
	S13	Keep away from food, drink and animal feeding stuffs.
	S20/21	When using do not eat, drink or smoke.
	S24	Avoid contact with skin.
	S29	Do not empty into drains.
	S35	This material and its container must be disposed of in a safe way.
	S37	Wear suitable gloves.
	S46	If swallowed, seek medical advice immediately and show this container or label.
	S57	Use appropriate container to avoid environmental contamination.

Table 12-5: Proposed Hazard and Precautionary Statements according to Globally Harmonized System/Regulation (EC) No 1272/2008 [CLP]

Pictogram(s)		
Signal word	Danger	
Hazard statements	H319	Causes serious eye irritation.
	H315	Causes skin irritation.
	H332	Harmful if inhaled.
	H302	Harmful if swallowed.
	H317	May cause an allergic skin reaction.
	H304	May be fatal if swallowed and enters airways.
	H400	Very toxic to aquatic life.
	H410	Very toxic to aquatic life with long lasting effects.
	EUH401	To avoid risks to human health and the environment, comply with the instructions for use.
Precautionary Statements*		
Prevention	**P280**	Wear protective gloves/clothing.
	P261	Avoid breathing vapours.
	P264	Wash contaminated body parts thoroughly after handling.
	P270	Do not eat, drink or smoke when using this product.
	P271	Use only outdoors or in a well-ventilated area.
	P272	Contaminated work clothing should not be allowed out of the workplace.
Response	**P301 + P310**	IF SWALLOWED: Immediately call a POISON CENTER or doctor/physician.
	P331	Do NOT induce vomiting.
	P305 + P351 + P338	IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing.
	P302 + P352	IF ON SKIN: Wash with plenty of soap and water.
	P333 + P313	If skin irritation or rash occurs: Get medical advice/attention.
	P330	Rinse mouth.
	P304 + P340	IF INHALED: Remove victim to fresh air and keep at rest in a position comfortable for breathing.
	P361	Remove/Take off immediately all contaminated clothing.
	P391	Collect spillage.
Storage	-	-
Disposal	**P501**	Dispose of contents/container to hazardous or special waste collection point.

***** P-statements in **bold** are recommended for product label

OCP Evaluation Form Plant Protection Product
for use in checking that all test and study reports required in accordance with SANCO/11803 have been provided

Active Substance: Pyraclostrobin Applicant: BASF SE Date: 18/Jul/2014

Preparation: BAS 500 06 F

As the representative formulation has changed from the original dossier to the supplementary dossier, all studies and references for BAS 500 06 F submitted within the supplementary dossier are new and are therefore not individually identified as new.

SANCO/ 11803 data point	Information, test or study	Information, test or study provided	Justification provided	Undertaking provided	*Data gap*
1	Identity of the plant protection product				
1.1	Applicant	yes			☐
1.2	Producer of the plant protection product and the active substances	yes			☐
1.3	Trade name or proposed trade name and producer's development code number of the plant protection product if appropriate	yes			☐
1.4	Detailed quantitative and qualitative information on the composition of the plant protection product				
1.4.1	Composition of the plant protection product	yes			☐
1.4.2	Information on the active substances	yes			☐
1.4.3	Information on safeners, synergists and co-formulants	yes	Doc J		☐
1.5	Type and code of the plant protection product	yes			☐
1.6	Function	yes			☐
2	Physical and chemical properties of the plant protection product

CP 1.2 Producer of the plant protection product and the active substances

Manufacturer of BAS 516 07 F (legal entity):

BASF SE
67056 Ludwigshafen
Germany
Crop Protection Division:
P.O. Box 120
67114 Limburgerhof
Germany

Contact person: Please refer to CP 1.1 Applicant.

Location of the manufacturing site of BAS 516 07 F:

Confidential information - data provided in Document J.

Manufacturer of pyraclostrobin and boscalid (legal entity):

BASF SE
67056 Ludwigshafen
Germany
Crop Protection Division:
P.O. Box 120
67114 Limburgerhof
Germany

Contact person: Please refer to CP 1.1 Applicant.

Location of the manufacturing sites of pyraclostrobin and boscalid:

Confidential information - data provided in Document J.

CP 1.3 Trade names or proposed trade name and producer's development code number of the plant protection product if appropriate

Code number: BAS 516 07 F

Trade Names: Aragon, Bellis Drupacee, Gringo, Signum, Signum S, Signum 26.7/6.7 WG, Signum 33 WG, Signum WG, Terminett, Trigramm 26.7/6.7

CP 1.4 Detailed quantitative and qualitative information on the composition of the plant protection product

Pyraclostrobin pure active substance:
Minimum purity: 975 g/kg

Boscalid pure active substance:
Minimum purity: 960 g/kg

CP 1.4.1 Composition of the plant protection product

Pure active substance

content of pure pyraclostrobin:	**67.0 g/kg**	**(6.70% w/w)**
limits:	60.30 – 73.70 g/kg	(6.03 – 7.37% w/w)
content of pure boscalid:	**267.0 g/kg**	**(26.70% w/w)**
limits:	250.98 – 283.02 g/kg	(25.10 – 28.30% w/w)

Technical active substance[1)]

content of technical pyraclostrobin:	**69.79 g/kg**	**(6.98% w/w)**
limits:	62.81 – 76.77 g/kg	(6.28 – 7.68% w/w)
content of technical boscalid:	**273.85 g/kg**	**(27.39% w/w)**
limits:	257.42 – 290.28 g/kg	(25.74 – 29.03% w/w)

[1)] at a minimum purity of technical pyraclostrobin of 97.5% and technical boscalid of 96.0%

Safeners, synergists and co-formulants

Confidential information - data provided in Document J.

CP 1.4.2 Information on the active substances

Type	Name/Code Number
ISO common name	pyraclostrobin
CAS No	175013-18-0
EC No	n.a.
CIPAC No	657
salt, ester anion or cation present	none

Type	Name/Code Number
ISO common name	boscalid
CAS No	188425-85-6
EC No	n.a.
CIPAC No	673
salt, ester anion or cation present	none

CP 1.4.3 Information on safeners, synergists and co-formulants

Confidential information - data provided in Document J.

CP 1.5 Type and code of plant protection product

Nature: Water dispersible granules [Code: WG]

CP 1.6 Function

Fungicide

Table of Contents

CP 2 PHYSICAL AND CHEMICAL PROPERTIES OF THE PLANT PROTECTION PRODUCT

BAS 516 07 F is a new representative formulation, which has not been evaluated during a previous Annex I inclusion process.

All tests have been performed in GLP-certified laboratories.

Test or study & Data point	Guideline and method	Test material purity and specification	Findings	GLP Y/N	Reference
CP 2.1 Appearance	Visual assessment and organoleptic determination	BAS 516 07 F 1779 Boscalid: 26.65%; Pyraclostrobin: 6.78%	BAS 516 07 F is a brown fine granule with a smoky odour (remains unchanged after accelerated storage test).	Y	[see 2004/1024836 Kaestel R. 2004 a]
CP 2.2 Explosive and oxidising properties	OECD 113, Differential Scanning Calorimetry (DSC) 92/69/EEC A.14 92/69/EEC A.17 92/69/EEC A.16	BAS 516 07 F 1789 Boscalid: 26.7%; Pyraclostrobin: 6.8%	DSC in a temperature range from 30°C to 500°C yielded two peaks: 1.Peak: Onset: 150°C Peak temperature: 207°C Energy release: 130 J/g 2.Peak: Onset: 335°C Peak temperature: 393°C Energy release: 130 J/g The exothermic decomposition energy is less than 500 J/g. BAS 516 07 F does not react explosively to thermal and mechanical stress or to friction.	Y Y	[see 2005/1011601 Bitterlich S. 2005 a] [see 2011/1065573 Loehr S. 2011 a]

Test or study & Data point	Guideline and method	Test material purity and specification	Findings	GLP Y/N	Reference
			A preliminary experiment was conducted to determine if the test item burns at a rate faster than that of the reference sample. From the result of the preliminary test it cannot be concluded that the test substance is without doubt an oxidising substance. Therefore the main test had to be conducted. The highest burning rate determined in the first test and in the repetition tests was 1.4 mm/s. The burning rate of the reference mixture (a barium nitrate/cellulose mixture containing 70% weight of oxidiser) was determined to be 3.6 mm/s.		
CP 2.3 Flammability and self-heating	92/69/EEC A.10 92/69/EEC A.12 92/69/EEC A.16	BAS 516 07 F 1789 Boscalid: 26.7%; Pyraclostrobin: 6.8%	Flammability (solids): The substance in its commercial form is made into a pile. An attempt is then made to ignite the sample under defined conditions and the burning time is measured. Result: Brief burning and rapid extinction was observed. Flammability (in contact with water): It is determined whether the reaction of the substance with water leads to the development of dangerous amounts of highly flammable gases. The substance was tested according to a step by step sequence. In three steps there was no gas evolution. The relative self-ignition temperature is 246°C.	Y Y	[see 2005/1011601 Bitterlich S. 2005 a] [see 2011/1065573 Loehr S. 2011 a]

Test or study & Data point	Guideline and method	Test material purity and specification	Findings	GLP Y/N	Reference
CP 2.7 Storage Stability and shelf-life: effects of temperature on technical characteristics of the plant protection product	CIPAC MT 46.3 CLI Technical Monograph No. 17	BAS 516 07 F 1779 Boscalid: 26.65%; Pyraclostrobin: 6.78% BAS 516 07 F 08-120050 Boscalid: 26.6%; Pyraclostrobin: 6.9% (data from study 367105_1)	The relative content of the active substances does not decrease >5% during accelerated storage. Thus the product is considered to be stable. Content of pyraclostrobin (HPLC method CF-A598): 6.78% w/w before after storage for 14 days at 54°C Content of boscalid (HPLC method CF-A598): 26.65% w/w before and after storage for 14 days at 54°C Content of Dimethyl sulfate: Not tested. The impurity originates from pyraclostrobin technical, is diluted during the formulation process and reacts with water, resulting in its absence in BAS 516 07 F. Therefore this impurity is not formed during the production process of the formulation. Its content in the formulation does not increase during storage, because it is a molecule with a high energy content. No significant changes of the physical properties: appearance, odour, pH-value, wettability, suspension stability, suspensibility, dry sieve test, wet sieve test, dustiness, attrition resistance and flowability (see corresponding Annex points) were found after the accelerated storage stability test in glass bottles. After storage for 104 weeks at 23°C, the formulation showed good chemical and physical stability: Content of pyraclostrobin (AFL0598/01): 6.9% w/w before and after storage for 2 years at 23°C Content of boscalid (AFL0598/01): 26.6% w/w before and after storage for 2 years at 23°C	Y Y	[see 2004/1024836 Kaestel R. 2004 a] [see 2011/1102466 Keller M. 2011 a]

Test or study & Data point	Guideline and method	Test material purity and specification	Findings	GLP Y/N	Reference
CP 2.9 Physical and chemical compatibility with other products including other plant protection products with which its use is to be authorised	ASTM method E 1518-93	BAS 516 00 F 2000-1	Test product: BAS 516 00 F (WG) Note: The tested product is the predecessor formulation of BAS 516 07 F. Both products are very similar. Therefore the test is considered to be also valid for BAS 516 07 F. The composition of both products is given in Document J. Tank mix partners: Acrobat Plus (WG), Polyram WG (WG), Decis (EC), Fastac 100 EC (EC), Stratos Ultra (EC) In total five mixtures of BAS 516 00 F with other plant protection products of the types WG and EC were tested. All mixtures were determined to be physically compatible and can be used in spray application. In all mixtures no lumping and no flocculation occurred, but a running agitator should be used in all mixtures. No phase separation and no significant sediment were formed. The mixtures were detected to be homogeneous. In some mixtures it could be useful to add a foam protection agent. There were no indications of any chemical reaction between the mixed products. While performing the tests no significant effect of heating or cooling of the mixtures occurred. No significant screen residues were found or remained in the test vessel. No chemical interactions between BAS 516 00 F and the tank mix partners were observed. Therefore BAS 516 00 F and consequently BAS 516 07 F are apparently chemically compatible with the tested products.	N	[see 2001/1001884 Schneider K.-H. 2001 a]

Table of Contents

CP 3 DATA ON APPLICATION

BAS 516 07 F is a new representative formulation, which has not been evaluated during a previous Annex I inclusion process.

CP 3.1 Field of use envisaged

Please see below efficacy information according to SANCO/2012/11251 (chapter 3).

CP 3.2 Effects on harmful organisms

Please see below efficacy information according to SANCO/2012/11251 (chapter 8).

CP 3.3 Details of intended use

Please see below Table 2 in the efficacy information according to SANCO/2012/11251 (following chapter 8).

CP 3.4 Application rate and concentration of active substance

Please see below Table 2 in the efficacy information according to SANCO/2012/11251 (following chapter 8).

CP 3.5 Method of application

Please see below efficacy information according to SANCO/2012/11251 (chapter 7).

CP 3.6 Number and timing of applications and duration of protection

Please see below for general information M-CP 3.8 and for detailed information Table 2 (following chapter 8) of the efficacy information given according to SANCO/2012/11251.

BAS 516 07 F is recommended with a spray interval up to 21 days depending on weather conditions, disease pressure and other factors. A sufficient level of protection can be expected for this period.

CP 3.7 Necessary waiting periods or other precautions to avoid phytotoxic effects on succeeding crops

Pyraclostrobin and boscalid have been applied since many years with a several different formulations across a wide range of crops without any reports of phytotoxic effects on succeeding crops. Due to the broad range of crops in which the product has been used, most rotational crop possibilities have been appeared in practice. Therefore no negative impact on succeeding crops is to be expected. Consequently, there is no necessity for restrictions in the choice of following crops, even in the event of crop failure on a field which has been treated with BAS 516 07 F.

CP 3.8 Proposed instructions for use

BAS 516 07 F is a fungicide used in potatoes mainly for the control of Alternaria spp.. Besides potatoes the product is also used against a broad spectrum of diseases in fruits and vegetables.

Time of application

Apply BAS 516 07 F in potatoes at the start of disease attack with Alternaria spp.. Typically the best point in time to start the applications is 6-8 weeks after emergence of the potatoes and the last application should be done latest 3 days before harvest. The recommended spray interval is about 10 – 21 days depending on disease pressure and the general spray program strategy.

Number and rate of application

Apply in potatoes maximum 4 times 0.2 – 0.25 kg BAS 516 07 F in a water volume of 150 – 400 L of water per ha.

On the specific country labels additional detailed guidance for the use of the product e.g. with regard to filling and application, tank cleaning and field use are given considering the local requirements. These instructions will be covered by the dRRs to be submitted for the re-registration of the plant protection product BAS 516 07 F following the renewal of approval for the active substance pyraclostrobin.

Further information can be found in Document C.

Efficacy Information

Active Substance: Pyraclostrobin

Product Code: BAS 516 07 F
67 g pyraclostrobin/kg
267 g boscalid/kg
WG

Applicant: BASF SE
Date: 09/June/2015

Statement

Pyraclostrobin, one of the active substances contained in the plant protection product BAS 516 07 F, has been tested in field development trials which demonstrated efficacious activity against a broad range of fungal diseases. It was included in Annex I of Directive 91/414/EEC on 1 June 2004 (entry into force) under Inclusion Directive 2004/30/EC for the use as fungicide. This use was amended on 22 April 2009 (entry into force) by Inclusion Directive 2009/25/EC to the use as fungicide or plant growth regulator.

BAS 516 07 F is registered in potatoes in many EU countries (for details please see Table 1) based on detailed national assessments of the efficacy data package in compliance with Regulation (EC) No 545/2011 and according to the Uniform Principles as given in Regulation (EC) No 546/2011.

1. INTRODUCTION

This document summarises the information related to the efficacy of the representative formulation BAS 516 07 F containing pyraclostrobin and boscalid as active substances.

2. FUNCTION

BAS 516 07 F is used as a fungicide to control harmful diseases in potatoes and other crops. It shows local systemic and translaminar activity.

3. FIELD OF USE

BAS 516 07 F is used in agriculture in many crops (potatoes, fruits, vegetables) for the control of a broad range of harmful and economically important pathogens.

4. SUPPORTED USES

BAS 516 07 F in potatoes had been identified as representative use to support the renewal of approval for the active substance pyraclostrobin (for details see Tables 1 and 2).

This use is representative because of

- its wide geographical distribution covering the Southern, Central and Northern Zone
- its different application timings during the year
- its agricultural importance in the EU
- its importance in the human diet
- the potato belonging to the solanacea crop group, to which for example also important crops like tomato, eggplant and pepper belong

BAS 500 06 F in cereals and maize had been identified as additional representative uses to support the renewal of approval for the active substance pyraclostrobin (for details see separate dossier for BAS 500 06 F).

5. OVERVIEW OF CURRENT REGISTRATIONS

Current registrations of BAS 516 07 F in the EU for the representative use potatoes are shown in Table 1.
Besides the use of BAS 516 07 F in potatoes, many other uses of pyraclostrobin containing plant protection products are registered covering all EU member states and most of the crops professionally cultivated (further information on these additional uses treated with pyraclostrobin can be found in M-CA 3.5). In addition to various solo formulations other active substances such as boscalid, dimethomorph, dithianon, epoxiconazole, fenpropimorph, fluxapyroxad, folpet and metiram are used in pyraclostrobin containing mixture formulations (further information on these uses can be found in document D2).

6. HARMFUL ORGANISMS CONTROLLED AND CROPS TREATED

Harmful organisms controlled by BAS 516 07 F in potatoes are given in chapter 8 below. An overview on additional harmful organisms controlled by pyraclostrobin and on additional crops treated in the EU with pyraclostrobin-containing formulations can be found in M-CA 3.5.

7. METHOD OF APPLICATION

BAS 516 07 F is applied in potatoes by broadcast foliar spraying using water as carrier. The water volume varies between 150 – 1000 L/ha.

8. MODE OF ACTION - EFFECTS ON HARMFUL ORGANISMS

The **mode of action** for the active substance pyraclostrobin is described below for the use as fungicide and the use as plant growth regulator.

Use as fungicide

Pyraclostrobin belongs to the QoI group of fungicides. The mode of action is the inhibition of mitochondrial respiration resulting from a blockage of the electron transport from ubihydroquinone to cytochrome c by means of a binding to the ubihydroquinone oxidation centre (Qo) of the cytochrome bc1 complex (Complex III). This disrupts the mitochondrial electron transport chain, thus blocking phosphorylation further down in the respiratory chain. In consequence, this leads to a reduction of energy-rich ATP which is required to support a range of essential processes in the fungal cell such as maintenance of membrane potentials and concentration gradients up to DNA, RNA and protein biosynthesis. In the end, the various fungal development processes of spore germination, formation of infection structures, mycelium growth and sporulation are permanently disrupted.

Use as plant growth regulator

In addition to the effects on yield through inhibition of fungal pathogens, pyraclostrobin also delivers a positive effect on yield through influence on the plant metabolism and physiology.
A decrease in ethylene levels has been demonstrated in several lab studies after treatment with pyraclostrobin. This can explain the observed delay in senescence. The reduction in ethylene levels can result in a variety of cellular changes being involved in yield gain (e.g. by an increased and longer photosynthetic performance during the vegetation period of a treated crop):

- enhancement of cytokinin levels resulting in increased chlorophyll concentrations in the leaves
- higher catalase and superoxide dismutase (SOD) activities reducing reactive $O_2^{\cdot}$-levels producing e.g. H_2O_2, resulting in reduced chlorophyll degradation

Furthermore, studies demonstrated that pyraclostrobin increases nitrate reductase, improving nitrogen assimilation and nitrogen use efficiency.

In the following, information on the **foliar uptake** of pyraclostrobin and a description of its **general effects on harmful organisms** are given.

After application to the plant, the active ingredient is taken up via the leaf and then translocated at low rates via the transpiration flow. Due its relatively low mobility, it shows local systemic and translaminar activity. Because of its very high intrinsic activity, pyraclostrobin has been observed to have systemic effects in a number of authorized uses. By that, it can control fungal stages which have already become established in deeper tissue layers. Pyraclostrobin is thus suitable for preventative and curative treatments. Since the vapour pressure of pyraclostrobin is very low, a marked gas phase activity was not observed.

Pyraclostrobin is active against different fungal stages on and in the plant. When applied protectively, pyraclostrobin prevents not only the germination of fungal spores landing on the plant surface but also re-infection, since during these extremely energy-consuming phases fungi react very sensitively to disturbances of their mitochondrial respiratory chain. Due to its ability to penetrate into the leaf and its further translocation as well as its high intrinsic activity, it can also control fungal stages which have already become established in deeper tissue layers.

BAS 516 07 F is a fungicide to control the different Alternaria species (mainly *Alternaria solani* and *Alternaria alternata*) in potatoes.

Furthermore, it controls a broad range of harmful and economically important pathogens in many fruits and vegetables.

Table 1: Supported representative uses for BAS 516 07 F currently registered in the EU

	Representative Uses (for application details see Table 2)				Existing Authorisations

Table of Contents

CP 4 FURTHER INFORMATION ON THE PLANT PROTECTION PRODUCT

BAS 516 07 F is a new representative formulation, which has not been evaluated during a previous Annex I inclusion process.

CP 4.1 Safety intervals and other precautions to protect humans, animals and the environment

Pre-harvest interval (in days) for each relevant crop:
For potatoes the application is intended with a pre-harvest interval of 0-3 days.

Re-entry period (in days) for livestock, to areas to be grazed:
Because pyraclostrobin is not intended to be used in areas to be grazed, no re-entry period for livestock has to be defined.

Re-entry period (in hours or days) for man to crops, buildings or spaces treated:
The re-entry assessment is discussed in M-CP 7.2. Re-entry is possible after the spray deposits on the crops have dried given the worker is wearing adequate work clothing.

Withholding period (in days) for animal feeding stuffs:
Due to the favorable residue situation in potatoes with residues consistently below LOQ no withholding period is needed.

Waiting period (in days) between application and handling of treated products:
This is not relevant here since a post-harvest treatment is not intended for potatoes.

Waiting period (in days) between last application and sowing or planting succeeding crops:
No minimum waiting periods needs to be considered for phytotoxicity or for residues in follow-crops.

Information on specific conditions under which the preparation may or may not be used:
Not relevant

CP 4.2 Recommended methods and precautions

Report:	CP 4.2/1 Anonymous, 2015 a Safety data sheet - Signum 2015/1260817
Guidelines:	EEC 1907/2006
GLP:	no

Precautions for safe handling

No special measures necessary if stored and handled correctly. Ensure thorough ventilation of stores and work areas. When using do not eat, drink or smoke. Hands and face should be washed before breaks and at the end of the shift.

Protection against fire and explosion:
Avoid dust formation. Dust can form an explosive mixture with air. Prevent electrostatic charge. Sources of ignition should be kept well clear. Fire extinguishers should be kept handy.

Conditions for safe storage including any incompatibilities

Segregate from foods and animal feeds.
Further information on storage conditions:
Keep away from heat. Protect against moisture. Protect from direct sunlight.

Storage stability:
Storage duration: 60 months
Protect from temperatures above 40 °C.
Changes in the properties of the product may occur if the product is stored above the indicated temperature for extended periods of time.

Exposure controls

Personal protective equipment

Respiratory protection:
Respiratory protection not required.

Hand protection:
Suitable chemical resistant safety gloves (EN 374) with prolonged, direct contact. Recommended is protective index 6 corresponding to > 480 minutes of permeation time according to EN 374, e.g. nitrile rubber (0.4 mm), chloroprene rubber (0.5 mm), butyl rubber (0.7 mm) etc.

Eye protection:
Safety glasses with side-shields (frame goggles), e.g. EN 166

Body protection:
Body protection must be chosen depending on activity and possible exposure, e.g. apron, protecting boots, chemical-protection suit (according to EN 14605 in case of splashes or EN ISO 13982 in case of dust).

General safety and hygiene measures
The statements on personal protective equipment in the instructions for use apply when handling crop-protection agents in final consumer packing. Wearing of closed work clothing is recommended. Store work clothing separately. Keep away from food, drink and animal feeding stuffs.

Contaminated packaging should be emptied as far as possible and disposed of in the same manner as the product.

Report: CP 4.2/2
Ohnsorge U., 2001a
BAS 516 00 F (preliminary designator): Effectiveness of procedures for cleaning application equipment and protective clothing
2001/1001819
Guidelines: none
GLP: no

Note 1: This study was erroneously not contained in the application. It needs to be submitted, because BAS 516 07 F is a new representative formulation, which has not been evaluated during a previous Annex I inclusion process.

Note 2: The above described document is based on BAS 516 00 F, the predecessor formulation of BAS 516 07 F. Both products are very similar. Therefore, the document is considered to be also valid for BAS 516 07 F. The composition of both products is given in Document J.

Any surplus spray solution containing BAS 516 07 F should be diluted with water at a ratio of 1:10 and sprayed onto the previously treated area according to the use instructions.

The spray equipment should be cleaned thoroughly immediately after use by draining the system completely and by rinsing spray tank, boom and nozzles two to three times with clean water, so that foam and remainders of BAS 516 07 F will be sufficiently removed. No plant damage can be caused when the equipment is used subsequently for other applications.

Protective clothing will be cleaned effectively when washed with usual laundry detergents.

CP 4.3 Emergency measures in the case of an accident

Report:	CP 4.3/1 Anonymous, 2015 a Safety data sheet - Signum 2015/1260817
Guidelines:	EEC 1907/2006
GLP:	no

First aid measures

Remove contaminated clothing.

If inhaled:
Keep patient calm, remove to fresh air.

On skin contact:
Wash thoroughly with soap and water.

On contact with eyes:
Wash affected eyes for at least 15 minutes under running water with eyelids held open.

On ingestion:
Rinse mouth and then drink plenty of water.

Most important symptoms and effects, both acute and delayed
No significant reactions of the human body to the product known.

Indication of any immediate medical attention and special treatment needed
Treat according to symptoms (decontamination, vital functions).

Fire-fighting measures

Suitable extinguishing media
Dry powder, foam, water spray

Unsuitable extinguishing media for safety reasons
Carbon dioxide

Special hazards arising from the product
The following substances or groups of substances can be released in case of fire:
Carbon monoxide, hydrogen chloride, carbon dioxide, nitrogen oxides, organochloric compounds

Advice for fire-fighters
Special protective equipment:
Wear self-contained breathing apparatus and chemical-protective clothing.
Further information:
Collect contaminated extinguishing water separately, do not allow to reach sewage or effluent systems. Dispose of fire debris and contaminated extinguishing water in accordance with official regulations. In case of fire and/or explosion do not breathe fumes. Keep containers cool by spraying with water if exposed to fire.

Accidental release measures

Personal precautions, protective equipment and emergency procedures
Avoid dust formation. Use personal protective clothing. Avoid contact with skin, eyes and clothing.

Environmental precautions
Do not discharge into subsoil or soil. Do not discharge into drains, surface waters or ground-water.

Methods and material for containment and cleaning up
For small amounts:
Contain with dust binding material and dispose of.
For large amounts:
Sweep/shovel up. Avoid raising dust. Dispose of absorbed material in accordance with regulations. Collect waste in suitable containers, which can be labeled and sealed. Clean contaminated floors and objects thoroughly with water and detergents, observing environmental regulations.

CP 4.4 Packaging, compatibility of the plant protection product with proposed packaging materials

BAS 516 07 F is marketed in mold blown high-density polyethylene containers (HDPE). They are sealed by foil seals, protected by screw caps of polypropylene.

0.5 litre bottle	material:	HDPE
(0.3 kg)	shape/size:	cylindrical / approx. 69 mm diameter x 185.5 mm
	opening:	42 mm inner diameter
	closure:	polypropylene screw cap
	seal:	HF-seal
1 litre bottle	material:	HDPE
(0.5kg)	shape/size:	cylindrical / approx. 91 mm diameter x 234 mm
	opening:	42 mm inner diameter
	closure:	polypropylene screw cap
	seal:	HF-seal
2 litre bottle	material:	HDPE
(1 kg)	shape/size:	Rectangular, 142 x 97 x 226 mm (LxBxH)
	opening:	42 mm inner diameter
	closure:	polypropylene screw cap
	seal:	HF-seal
5 litre container	material:	HDPE
(2.5 kg)	shape/size:	rectangular / approx. 190 mm x 140 mm x 313 mm
	opening:	54 mm inner diameter
	closure:	polypropylene screw cap
	seal:	HF-seal
10 litre container	material:	HDPE
(5 kg)	shape/size:	rectangular / approx. 230 mm x 165 mm x 375 mm
	opening:	54 mm inner diameter
	closure:	polypropylene screw cap
	seal:	HF-seal

Report:	CP 4.4/1 Schreiner B., 2009a EU-Performance-Test of BAS 516 07 F, Bottle, rectangular, 1 Kg (PE-HD) 2009/1052799
Guidelines:	none
GLP:	no

ADR-test 6.1.5.3 was performed for drop resistance. In this test, the tightness of the bottles was successfully tested. The leak test (ADR 6.1.5.4), an internal pressure test (hydraulic test, ADR 6.1.5.5) and the test for permeation (ADR 6.1.5.7) were not applicable since the product is a solid. Also the stacking test (ADR 6.1.5.6) was not applicable (bottles are part of combination packaging). Packagings are supplied in UN-approved combination packs (ADR 6.1.4.21).

These packagings meet the requirements for packaging group III as specified by the ADR/RID regulations for the transport of hazardous goods.

Report:	CP 4.4/2 Keller M., 2011a Boscalid/Pyraclostrobin 26.7/6.7 % WG - chemical and physical stability of formula BAS 516 07 F when stored at 23°C up to 3 years in commercial packs (HDPE-bottle) 2011/1102466
Guidelines:	CLI Technical Monograph No. 17,EEC 91/414 Annex III,EPA Product Properties Test Guidelines,OECD Principles of Good Laboratory Practice,GLP Principles of the German Chemikaliengesetz (Chemicals Act)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Note: In the application this study was only mentioned in section 2.

The study results prove that the original container material and the closure/seal resists to the product BAS 516 07 F. No corrosion of the container could be observed during the storage time.

CP 4.5 Procedures for the destruction or decontamination of the plant protection product and its packaging

CP 4.5.1 Neutralisation procedure

The pH of BAS 516 07 F is in a range between 5.6 and 6.3 in aqueous solution. Therefore, the proposal of a neutralisation procedure is not considered to be necessary. Any spilled product and contaminated soil or water has to be absorbed and disposed according to the use instructions.

CP 4.5.2 Controlled incineration

For purposes of disposal, combustion of BAS 516 07 F in a licensed incinerator is recommended. This method of disposal applies also to contaminated packages, which cannot be cleaned or reused.

Although it is possible to incinerate the product at lower temperatures, combustion at approximately 1100°C with a residence time of about 2 seconds is advised. By doing so, i.e. operating the incinerator according to the conditions laid down in council directive 94/67/EEC resp. directive 2000/76/EC of the European Parliament, one will achieve complete combustion and minimize the formation of undesired by-products in the off-gases.

Users are requested to triple rinse empty primary packages as described in the ECPA "Guidelines for the rinsing of agrochemical containers", 1993.

Pressure rinsing or integrated pressure rinsing of the packaging material achieves a similar or even better result. The rinsing water must be added to the spray liquid.

To minimize waste of packages it is recommended that empty and rinsed containers are delivered to local container collection stations. If these do not exist, empty and rinsed containers must be rendered unusable and disposed according to local regulations.

Summary
The active substances of BAS 516 07 F can be quantified using the analytical reversed phase-HPLC method CF-A 598. This method was developed for quantifying pyraclostrobin and boscalid in BAS 516 00 F, but specific chromatograms prove the applicability for BAS 516 07 F as well (BASF DocID 2009/1050295, study summary shown below).

The method CF-A 598 is a reversed phase-HPLC method with UV-detection and external calibration to determine boscalid and pyraclostrobin in water dispersible granules (WG).

Method description

Method Principle:

Method CF-A 598 is applicable for the determination of boscalid and pyraclostrobin in WG formulations, e.g. in BAS 516 07 F. The validation was carried out on BAS 516 00 F, the applicability of this method for BAS 516 07 F is proven by specific chromatograms. The analytes are determined by reversed phase HPLC on a J'sphere ODS-H80 column (250 x 4.6 mm, dp = 4 µm) at room temperature, using external calibration. Injection volume is 5 µL. The separation is achieved by using gradient conditions for the detection and quantification of the actives (flow rate: 1 mL/min). Detection is performed with a HPLC UV detector with variable wavelength adjustment. The mobile phase A consists of 580 mL acetonitrile, 420 mL water and 771 mg ammonium acetate. The mobile phase B consists of 900 mL acetonitrile, 100 mL water and 771 mg ammonium acetate.
The analytes are quantified by comparing the specific response ratios of the samples with those of standards of known quality.

Findings:

The validation data of method CF-A 598 with respect to precision, accuracy, linearity and specificity prove that the method is suitable for the determination of pyraclostrobin and boscalid in WG-formulations, e.g. in BAS 516 00 F or BAS 516 07 F (proved by specific chromatograms as shown in BASF DocID 2009/1050295).

Enforcement analytical methodology:

Specificity: The specificity of the method was demonstrated by spectrometric examination, i.e. by HPLC analysis of the species. It was verified by comparing the retention times of the active ingredients in the preparation with the reference substances, checking the chromatograms of the blank formulation and the technical active ingredients for interference and comparing the UV-spectra of the active ingredient-peaks in the product and the peaks of the reference substances.
There were no indications of interferences. Identical UV-spectra of the active ingredient-peaks in the preparation and the reference substances were measured.

Linearity: BAS 516 00 F was weighed five times in ascending concentrations and analysed in each case in accordance with the present analytical method. The weigh-in weights of this series of concentrations are approximately 0.5 to 1.5 times of the nominal concentrations.

The regression curve data are listed below:

Boscalid:

Slope (m):	70
y axis intercept (b):	4
Correl. coeff. (r^2):	1.0000

Pyraclostrobin:

Slope (m):	71
y axis intercept (b):	1
Correl. coeff. (r^2):	1.0000

Accuracy: The accuracy of the procedure was assessed by preparation and analysis of six samples containing known weights of the analytes, i.e. known amounts of boscalid and pyraclostrobin were added to the blank formulation. The amount of blank formulation was equivalent to the amount in the original formulation BAS 516 00 F.
The average recovery was found to be 100.17% (RSD = 0.399%) for pyraclostrobin and 100.55% (RSD = 0.386%) for boscalid.

Outliers or stragglers could not be determined.

Repeatability: The repeatability (precision) of the method was determined by weighing six samples of BAS 516 00 F (batch 2000-2). Each sample was analysed using method CF-A 598.
Results for the formulation BAS 516 00 F:

Active ingredient	Weight (min, max) [%]	Average [%]	RSD [%]
Pyraclostrobin	6.775 – 6.824	6.80	0.299
Boscalid	27.240 – 27.358	27.29	0.162

It is situated in a range which can be expected by the used equipment and the analytical method in general. The RSD values meet the requirements given by the modified Horwitz equation (Horwitz RSDR * 0.67).
Outliers could not be observed.

Report: CP 5.1.1/3
Euler K., 2009a
Final report: Supplement to the development and validation of the analytical method CF-A 598, Study No. 09L00088
2009/1050295

Guidelines: OECD Principles of Good Laboratory Practice, GLP Principles of the German Chemikaliengesetz (Chemicals Act)

GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

In order to prove the applicability of CF-A 598 to BAS 516 07 F, specific chromatograms were generated.
The chromatograms demonstrate that the analytical method CF-A 598 is applicable to determine the active ingredients in the formulation BAS 516 07 F.

(b) Methods for determination of relevant impurities identified in the technical material or which may be formed during manufacture of the plant protection product or from degradation of the plant protection product during storage

Boscalid does not contain any impurity of toxicological or ecotoxicological concern.

Pyraclostrobin contains < 1mg/kg dimethyl sulfate. Information on the analytical method for determination of this impurity in the technical material can be found in M-CA 4.1.1. In the following, the method for determination of dimethyl sulfate in BAS 516 07 F is outlined.

Report: CP 5.1.1/4
Stegmaier W., 2009a
Analytical method AM/01120/01e, gas chromatographic determination of dimethyl sulfate in BAS 516 07 F
2009/1105184

GLP:	yes

Summary
The GC method AM/01120/01e is suitable to determine the impurity dimethyl sulfate in the formulation BAS 516 07 F with quantification by means of standard addition.
The analytical method AM/01120/01e is a GC method equipped with headspace autosampler and a mass spectrometer detector.

Method description

Method Principle:

Method AM/01120/01e is applicable for the determination of the impurity dimethyl sulfate in the WG formulation BAS 516 07 F. The analyte, dissolved in toluene, is determined by headspace gas chromatography utilising a ZB-1701 (Phenomenex) - column (30 m; 0.25 mm id; film thickness 0.25 µm); temperature programmed.
Duration of injection is 0.75 s at a transfer line temperature of 150°C and the final headspace pressure is 2 bar.
The column head pressure is 0.75 bar and carrier gas is helium.
Detection is performed with a MSD (detection of selected ions: m/z = 95.0, 96.0, 125.0).
Quantification is by means of standard addition.

Findings:

The validation data of method AM/01120/01e with respect to precision, accuracy, linearity and specificity prove that the method is suitable for the determination of the impurity dimethyl sulfate in the WG-formulation BAS 516 07 F.

Enforcement analytical methodology:

Specificity/ selectivity: Peaks in the gas chromatogram are assigned to the analyte dimethyl sulfate by comparison of retention times and by the selection of characteristic ions in MS-detection. Constituents of the sample which coelute with the analyte and which yield the same ions as selected for dimethyl sulfate give rise to excessively high mass fractions.

No dimethyl sulfate could be detected in toluene (solvent blank).

Linearity: Linearity was proved for standard additions to the test item (with influence of active agents) and to BAS 516 AA F (without influence of active agents).

Linearity of calibration for standard addition to the test item: Calibration was performed on 6 concentration levels in the range of 0.248 µg/g and 9.78 µg/g.
The calibration points for 0.473 µg/g and 1.00 µg/g were not considered for evaluation. Although they cannot be regarded as outliers according to Dixon's test it is obvious that they do not fit on the regression line through the other calibration points.
Maybe this can be traced back to the fact that calibrations were run on different days and the MSD response altered in between.
The regression curve data are listed below:

Dimethyl sulfate:

Slope:	350894
y axis intercept (b):	9200
Correl. coeff. (R^2):	0.9998 (4 calibration levels)

Linearity of calibration for standard addition to BAS 516 AA F: Calibration was performed on 6 concentration levels in the range of 0.253 µg/g and 9.77 µg/g.
The regression curve data are listed below:

Dimethyl sulfate:

Slope:	625976
y axis intercept (b):	-31405
Correl. coeff. (R^2):	0.9984

Mass fraction of dimethyl sulfate in the test item:

The test item was analyzed without fortification of the analyte.
Dimethyl sulfate could not be detected.

Accuracy:

Accuracy was verified twice. Fortifications of approx. 1µg/g dimethyl sulfate to the test item and to BAS 516 AA F were determined with mean recoveries of 122% (test item) and 103% (BAS 516 AA F).

Precision, repeatability:

Due to the poor solubility of the test item in toluene it was not possible to prepare a homogeneous fortified solution which could have been divided in 6 subsamples in order to test precision. Alternatively precision had to be deduced from the standard deviation of the recoveries of the 6 samples spiked with approx. 1µg/g each.
Determinations 5 and 6 were not considered for evaluation.
Although they cannot be regarded as outliers according to Dixon's test it is obvious that they are far away from the other values.

Results for the spiked test item:

Mean recovery [%]	Standard deviation [%]	Relative standard deviation [%]	Measurement uncertainty [%]
122	4.8	3.9	11.7

Results for spiked BAS 516 AA F:

Mean recovery [%]	Standard deviation [%]	Relative standard deviation [%]	Measurement uncertainty [%]
103	4.1	4.0	12.0

As shown by fortification tests, the analysis of the relevant impurity dimethyl sulfate in the end-product BAS 516 07 F is possible. The fortifications could be detected.

Based on the production process of the formulation BAS 516 07 F in which the active ingredients are mixed with the formulants in the presence of water to get a spray-dryable suspension, the traces of dimethyl sulfate (remaining in the technical active substance pyraclostrobin) react with water.
The analytical method proves that dimethyl sulfate is not present in the end-use product BAS 516 07 F.

(c) Methods for the determination of relevant co-formulants or components of co-formulants, where required by the national competent authorities

Currently not required by EU legislation

CP 5.1.2 Methods for the determination of residues

Methods for the determination of residues are submitted and summarized in M-CA 4.1.2.

CP 5.2 Methods for post-authorisation control and monitoring purposes

Methods for the determination of residues in or on plants, plant products, processed food commodities, food and feed of plant and animal origin

Monitoring methods for plant and animal matrices are discussed in M-CA 4.2.

Methods for the determination of residues in body fluids and tissues

Monitoring methods for body fluids are discussed in M-CA 4.2.

Methods for the determination of residues in soil

Monitoring methods for soil are discussed in M-CA 4.2.

Methods for the determination of residues in water

Monitoring methods for water are discussed in M-CA 4.2.

Methods for the determination of residues in air, unless the applicant shows that exposure of operators, workers, residents or bystanders is negligible

As pyraclostrobin has a very low vapour pressure of 2.6 x 10^{-8} Pa (for details see M-CA 2.2), it is considered to be non-volatile. Consequently, inhalation exposure of operators, workers, residents or bystanders to vapours of pyraclostrobin is negligible. Further information can be found in M-CP 7.2.

CP 7 TOXICOLOGICAL STUDIES ON THE PLANT PROTECTION PRODUCT

BAS 516 07 F is a new representative formulation, which has not been evaluated during previous Annex I inclusion processes.

This document reviews the toxicological studies for BAS 516 07 F, an WG formulation containing 67 g/kg pyraclostrobin and 667 g/kg boscalid. In addition, a full risk assessment is provided, which shows that BAS 516 07 F is safe for operators, workers, bystanders and residents (for details please see M-CP 7.2).

CP 7.1 Acute toxicity

The acute toxicity of BAS 516 07 F is assessed using the studies listed below in Table 7.1-1. Some of the studies have been conducted with BAS 516 00 F, a formulation that is very similar to BAS 516 07 F. Therefore, studies performed with BAS 516 00 F are considered to be also valid for BAS 516 07 F. Information on the detailed composition of BAS 516 00 F and BAS 516 07 F can be found in the confidential part of the dossier (Document J).

BAS 516 07 F is of low toxicity by the oral, dermal and inhalation route of exposure. It is non-irritant to the skin and the eye and does not cause skin sensitization.

Table 7.1-1: Summary of acute toxicity studies relevant for BAS 516 07 F

(certified by Groupe Interministeriel des Produits Chimiques, France)

Executive Summary

In an acute oral toxicity study two groups of each 3 fasted female Sprague Dawley rats were administered single doses of 2000 mg/kg bw of BAS 516 07 F. The test substance was administered undiluted at a volume of 10 mL/kg. The observation period was 14 days. All animals were subjected to necropsy.

Administration of 2000 mg/kg bw of BAS 516 07 F resulted in no unscheduled mortality during the study. Accordingly, the oral LD_{50} was higher than 2000 mg/kg bw.

oral LD_{50} > 2000 mg/kg bw

All animals showed piloerection and hypoactivity (3/6 animals) on day 1 after administration. At necropsy, no apparent abnormalities were observed in any animal.

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 516 07 F is not to be classified for acute oral toxicity.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 516 07 F

Description:	brown granules
Density:	not given
Lot/Batch #:	1789
Purity/content:	Pyraclostrobin (= BAS 500 F): 6.84% Boscalid (= BAS 510 F): 26.7%
Stability of test compound:	Stable: expiry date 21-Mar-2009

2. Vehicle and/or positive control: 0.5% methylcellulose in bidistilled water

3. Test animals:

Species:	Rat
Strain:	Sprague-Dawley Rj:SD(IOPS Han)
Sex:	female
Age:	approx. 8 weeks
Weight at dosing (mean):	212 ± 15 g
Source:	Janvier, Le Genest-Saint-Isle, France
Acclimation period:	At least 5 days
Diet:	SsniffR/M-H pelleted diet (SSNIFF Spezialdiäten GmbH, Soest, Germany), ad libitum
Water:	drinking water filtered by a FG Millipore membrane (0.22 micron), ad libitum
Housing:	three animals in cages with stainless steel lid

Environmental conditions:

Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	approx. 12 cycles/hour
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 17-Jan-2008 to 13-Feb-2008

2. Animal assignment and treatment:
Groups of 3 female rats received a single dose of 2000 mg/kg bw. After the first assay, as no mortality occurred, the results were confirmed in three other females at the dose level of 2000 mg/kg bw. BAS 516 07 F was administered by oral gavage under a volume of 10 mL/kg bw. Prior to administration the animals were deprived of food for approximately 18 hours, however had free access to water. Animals were observed for clinical signs and mortality several times on the day of administration, and at least once each workday for the remainder of the 14-day observation period. Body weights were recorded at day 0 (prior to dosing), and then on days 7 and 14. Necropsy with gross-pathology examination was performed on the last day of the observation period. The animals were sacrificed by CO_2-inhalation.

II. RESULTS AND DISCUSSION

A. MORTALITY

No mortality was observed after administration of 2000 mg/kg bw in two independent experiments (see Table 7.1.1-1).

Table 7.1.1-1: Mortality of rats administered BAS 516 07 F by the oral route

Sex	Dose [mg/kg bw]	No. of administration	Cumulative mortality	Time of deaths
Female	2000	1st	0/3	-
	2000	2nd	0/3	-

h = hour after administration, d1 = day after administration

B. CLINICAL OBSERVATIONS

Piloerection was observed in all animals until 2 hours after administration. In three of six animals hypoactivity was seen at least until six hours after administration. The type, incidence and duration of clinical signs are given in Table 7.1.1-2.

Table 7.1.1-2: Clinical signs in rats administered BAS 516 07 F by the oral route (incidence / duration)

Dose [mg/kg bw]	2000	2000
Total number of animals	**3**	**3**
Administration	**1st**	**2nd**
- Piloerection	3 / h0 – h2	3 / h0 – d1
- Hypoactivity		3 / h0 – d1

h = hour; - not observed

C. BODY WEIGHT

Compared to historical control animals, a slightly lower body weight gain was noted in 2/6 animals between day 1 and day 8, which returned to normal thereafter. The body weight gain of the other animals was not affected by the test item.

D. NECROPSY

Macroscopic examination of the main organs of the animals revealed no apparent abnormalities.

III. CONCLUSION

Under the conditions of this study the oral LD_{50} in rats for BAS 516 07 F was determined to be higher than 2000 mg/kg bw.

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 516 07 F is not to be classified for acute oral toxicity.

CP 7.1.2 Dermal toxicity

Report: CP 7.1.2/1
[redacted] 2001a
BAS 516 00 F - Acute dermal toxicity study in rats
2001/1003723
Guidelines: OECD 402, EEC 92/69 B 3, EPA 870.1200
GLP: yes
(certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In an acute dermal toxicity study groups of 5 male and 5 female Wistar rats were administered a single dose of 2000 mg/kg bw of BAS 516 00 F to the clipped skin under semi-occlusive conditions for 24 hours. The formulation was applied diluted in 0.5% aqueous carboxymethylcellulose (4.0 mL/kg bw). The animals were observed for 14 days after administration. Based on the absence of mortality in this study the acute dermal LD_{50} was determined to be

dermal LD_{50} > 2000 mg/kg bw

No clinical observations of systemic toxicity or local signs were made. At necropsy no deviations from normal morphology were observed. Due to the similar composition of BAS 516 00 F and BAS 516 07 F, the study performed with BAS 516 00 F is considered to be valid for BAS 516 07 F, too.

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 516 07 F is not to be classified for acute dermal toxicity.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 516 00 F

Description:	solid / brown
Lot/Batch:	2000-2
Purity:	nominal concentration: BAS 500 F (pyraclostrobin): 6.7% (w/w); BAS 510 F (boscalid): 26.7% (w/w); Analytical concentration: BAS 500 F (pyraclostrobin): 6.6% (w/w); BAS 510 F (boscalid): 27.9% (w/w)
Stability of test compound:	The homogeneity of the test substance was confirmed by analysis. The stability of the test substance in the vehicle was confirmed by analysis over a time period of 4 hours.

2. Vehicle and/or positive control: 0.5% carboxymethylcellulose in bi-distilled water

3. Test animals:

Species:	Rat
Strain:	Wistar (Crl:WI (GLX/BRL/HAN)IGS BR)
Sex:	Male and female (nulliparous and non-pregnant)
Age:	Young adult animals, males about 8-12 weeks, females about 14-18 weeks
Weight at dosing:	Mean of dose groups: 247 g for males and 220 g for females
Source:	Charles River Laboratories, D-97633 Sulzfeld, FRG
Acclimation period:	At least one week
Diet:	Kliba-Labordiät Provimi Kliba SA, CH-4303 Kaiseraugst, Switzerland, ad libitum
Water:	Tap water ad libitum
Housing:	Stainless steel wire mesh cages, Type DK-III (Becker & Co., Castrop-Rauxel, FRG)

Environmental conditions

Temperature:	20 - 24°C
Humidity:	30 - 70%, relative
Air changes:	Fully air-conditioned rooms
Photo period:	12 h light / 12 h dark (6.00 a.m. – 6.00 p.m. / 6.00 p.m. – 6.00 a.m.)

B. STUDY DESIGN AND METHODS

1. Dates of work: 03-Aug-2000 (date of administration) to 17-Aug-2000 (date of necropsy)

2. Animal assignment and treatment:
Single administration of the test substance preparation in 0.5% carboxymethylcellulose in aqua bidest to five male and five female Wistar rats for 24 hours under semi-occlusive dressing at a dose level of 2000 mg/kg bw at a volume of 4 mL/kg bw. The application was performed to the clipped epidermis (dorsal and dorsolateral parts of the trunk) and covered by a semi-occlusive dressing for 24 hours. The application area was about 40 cm^2 (corresponding to at least 10% of the body surface area). The animals were observed for 14 days. Animals were checked for clinical signs of toxicity several times on the day of administration, and at least once each workday for the remainder of the study. A check for any dead or moribund animals was made twice each workday and once on Saturday, Sunday and on public holidays. Body weights were recorded at day 0 (prior to dosing), weekly thereafter and at the end of the study. Individual readings of skin findings were performed according to the Draize scheme 30-60 minutes after removal of the semi-occlusive dressing, weekly thereafter and at the end of the study. Necropsy with gross-pathology examination was performed on the last day of the observation period after killing by CO_2-inhalation.

II. RESULTS AND DISCUSSION

A. MORTALITY
No mortality occurred during the 14 days post application observation period.

B. CLINICAL OBSERVATIONS
No clinical signs of systemic toxicity and local effects were observed.

C. BODY WEIGHT
The mean body weights of all animals increased throughout the study period.

D. NECROPSY
No macroscopic pathological abnormalities were detected in the animals at the termination of the study.

III. CONCLUSION

The dermal LD_{50} of BAS 516 00 F was determined to be greater than 2000 mg/kg body weight for male and female animals. Due to the similar composition of BAS 516 00 F and BAS 516 07 F, the study performed with BAS 516 00 F is considered to be valid for BAS 516 07 F, too. Information on the detailed composition of BAS 516 00 F and BAS 516 07 F can be found in the confidential part of the dossier (Document J).

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 516 07 F is not to be classified for acute dermal toxicity.

CP 7.1.3 Inhalation toxicity

Report: CP 7.1.3/1
[redacted] 2001b
BAS 516 00 F - Acute inhalation toxicity study in Wistar rats 4-hour dust exposure
2001/1001824
Guidelines: OECD 403, EEC 93/21, EPA 870.1300, EEC 92/69 B 2
GLP: yes
(certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In an acute inhalation toxicity study, groups of 5 male and 5 female Wistar rats were exposed to dust aerosol of BAS 516 00 F at an actual concentration of 5.57 ± 0.16 mg/L for 4 hours. The animals were observed for 14 days after exposure. Based on the absence of mortality in this study the acute inhalation LC_{50} was determined to be

LC_{50} (both sexes combined) > 5.6 mg/L

Clinical signs of toxicity in animals exposed to the test substance comprised attempts to escape, visually accelerated respiration, squatting posture and smeared fur, but animals appeared normal from post exposure day 7 onwards. No gross pathological abnormalities were detected in the animals that were necropsied at termination of the study.
The mass mean aerodynamic diameters (MMAD) were 3.1 and 4.1 µm with geometric standard deviations (GSD) of 2.6. 37 to 49% of the particles had a diameter of ≤ 3.0 µm and thus may have reached the alveolar space of the lung.

Due to the similar composition of BAS 516 00 F and BAS 516 07 F, the study performed with BAS 516 00 F is considered to be valid for BAS 516 07 F, too.

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 516 07 F is not to be classified for acute inhalation toxicity.

2. Vehicle and/or positive control: Exposure as dust aerosol

3. Test animals:

Species:	Rat
Strain:	Wistar (Crl:WI (GLX/BRL/HAN)IGS BR)
Sex:	Male and female (nulliparous and non-pregnant)
Age:	Young adult animals, about 8-9 weeks old
Weight at day of exposure:	Mean of dose groups: 241 g for males and 165 g for females
Source:	Charles River Laboratories, D-97633 Sulzfeld, FRG
Acclimation period:	At least one week
Diet:	Kliba-Labordiät Provimi Kliba SA, CH-4303 Kaiseraugst, Switzerland, ad libitum
Water:	Tap water ad libitum
Housing:	Stainless steel wire mesh cages, Type DK-III (Becker & Co., Castrop-Rauxel, FRG)

Environmental conditions

Temperature:	20-24°C
Humidity:	30-70%, relative
Air changes:	Fully air-conditioned rooms
Photo period:	12 h light / 12 h dark (6.00 a.m. – 6.00 p.m. / 6.00 p.m. – 6.00 a.m.)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 13-Jun-2000 to 27-Jun-2000

2. Animal assignment and treatment:
Five male and five female Wistar rats were exposed to a dust aerosol of the test material for four hours in a head/nose inhalation system at a mean analytical concentration of 5.6 mg/L. The animals were randomly selected from a pool of animals.

3. Clinical examination:
Animals were observed for clinical signs of toxicity several times on the day of administration, and at least once each workday for the remainder of the study. A check for any dead or moribund animals was made twice each workday and once on Saturday, Sunday and on public holidays. Body weights were recorded at day 0 (prior to exposure), weekly thereafter and at the end of the study.

4. Pathology:
Necropsy with gross-pathology examination was performed on the last day of the observation period after killing by CO_2-inhalation.

5. Statistics/Calculations:
The statistical evaluation of the concentration-response relationship was carried out using a computer program. Depending on the data of the concentration-response relationship obtained by the experiment, this program is used to estimate the LC_{50} or to perform a Probit analysis[1].
The calculation of the particle size distribution was carried out in the inhalation laboratory on basis of mathematical methods for evaluating particle measurements[2].

[1] FINNEY, D.J. (1971): "Probit Analysis" Cambridge University Press, pp. 1 - 50

[2] DIN 661 41: Darstellung von Korngrößenverteilungen, DIN 661 61: Partikelgrößenanalyse (Beuth-Vertrieb GmbH, Berlin 30, FRG und Köln 1, FRG)

6. Generation of the test atmosphere / chamber description:
After des-agglomeration of the test substance the inhalation atmosphere was generated by means of a dosing wheel dust generator combined with a dust pre-chamber. From the pre-chamber the dust was passed into the inhalation system by means of compressed air.
The exposure system was located inside an exhaust cabin in an air-conditioned laboratory. A supply airflow (compressed air) of 1.5 m^3/h was used for the exposure. The exhaust airflow was set to 1.35 m^3/h. An air change of about 27 times per hour can be calculated by dividing the supply air flow by the volume of the inhalation system. The lower amount of exhaust air, which was adjusted by means of a separate exhaust air system, achieved a positive pressure inside the exposure system. This ensured that the mixture of test substance and air was not diluted with laboratory air in the breathing zones of the animals.
The animals were exposed to the inhalation atmosphere for 4 hours plus an equilibration time for the inhalation system of about 10 minutes.

7. Analytical investigation:

The flows of supply and exhaust air were adjusted and continuously measured with a flow meter. Air flows, the temperature and the humidity in the exposure system measured were at about 1-hour intervals.
The oxygen content in the inhalation system was not measured. The air change was judged to be sufficient to prevent oxygen depletion by the breathing of the animals, and the concentrations of the test substance used could not have a substantial influence on oxygen partial pressure.
The nominal concentration was calculated from the amount of substance dosed and the supply airflow.
The sampling for determination of the actual dust aerosol concentration was performed with following equipment and procedure:

- Vacuum pump (Millipore)
- Filtration equipment with probe, internal diameter: 7 mm (Millipore)
- Filter: MN 85/90BF (d = 4.7 cm)
- Sampling position: immediately adjacent to the animals' noses
- Sampling flow: 1 L/min
- Sampling velocity: 1.25 m/s
- Sampling frequency: 4 samples at about hourly intervals
- Sample volume: 2 L

Gravimetric determination of the inhalation atmosphere concentration was done with a balance (Mettler AT 250). Pre-weighed filters were placed into the filtration equipment. By means of the vacuum pump metered volumes of the dust were drawn through the filter. The dust concentration in mg/L was calculated from the difference between the pre-weighed of the filter and the weight of the filter after sampling, with reference to the sample volume of the inhalation atmosphere.
The particle size analysis was done using a Stack Sampler Mark III (Andersen) and a vacuum pump (Millipore). The sampling probe had an internal diameter of 6.9 mm.
Before sampling, the impactor was assembled with pre-weighed glass-fiber collecting discs, and a backup particle filter. The impactor was connected to the vacuum pump. Two samples were taken from the breathing zone of the animals starting not earlier than 30 minutes after the beginning of the exposure. The sample volume was 6 L. After sampling the impactor was taken apart. The collecting disc and the backup particle filter were re-weighed. Additionally, material absorbed on the walls of the impactor and the sampling probe (wall losses) were also determined quantitatively.

II. RESULTS AND DISCUSSION

A. MORTALITY

No mortality occurred at the tested concentration of 5.6 mg/L during the study period of 14 days. Therefore, the study satisfied the criteria of a limit test.

B. CLINICAL OBSERVATIONS

Clinical signs of toxicity consisted of attempts to escape, visually accelerated respiration, squatting posture and smeared fur. The animals appeared normal from post exposure day 7 onwards. The maximum incidence and duration of the observations are indicated in Table 7.1.3-1.

Table 7.1.3-1: Clinical signs in rats exposed for 4 hours to a liquid aerosol of BAS 516 00 F (incidence/duration)

Dose [mg/L]	5.6	5.6
Sex	**Males**	**Females**
- Total number of animals	5	5
- Respiration, visually accelerated	≤ 2h – d3	≤ 2h – d3
- Attempts to escape	≤ 1h	≤ 1h
- Squatting posture	d0 – d6	d0 – d6
- Fur, smeared	d0 – d3	d0 – d3

C. BODY WEIGHT

Body weight development in the male animals was slightly depressed in the first post exposure week, but recovered in the second. The female animals showed a slight reduction of body weight development throughout the post observation period.

D. NECROPSY

In the animals examined at the end of the post exposure observation period, no gross pathological abnormalities were detected.

E. ATMOSPHERE ANALYSIS

The exposure conditions are summarized in Table 7.1.3-2.

Table 7.1.3-2: Exposure conditions

Supply air [m³/h]	Exhaust air [m³/h]	Substance flow (g/h)	Temp. [°C]	Relative humidity [%]
1.5	1.35	511.44	22.9	5.5

The low relative humidity resulted from the need to use compressed air for dust generation. This deviation from the guideline recommendations (30 - 70% relative humidity; especially low humidity in dust) are considered not to be of influence for the test results, because of the relatively short exposure time.

The results of the concentration measurements (mean of 4 measurements) are presented in Table 7.1.3-3.

Table 7.1.3-3: Measurement of concentrations (4 hourly measurements)

Mean concentration [mg/L]	Standard deviation	Nominal concentration [mg/L]
5.6	0.16	341.0

The measurements of particle-size distribution revealed mass mean aerodynamic diameters (MMAD) of 3.1 to 4.1 µm with geometric standard deviation of 2.6 (see Table 7.1.3-4).

37 and 49% of the particles had a diameter of ≤ 3.0 µm and thus may have reached the alveolar space of the lung.

Table 7.1.3-4: Particle size measurements

Sample	% ≤ 3 µm	MMAD [µm]	Geometric standard deviation
1	49	3.1	2.6
2	37	4.1	2.6

III. CONCLUSION

The inhalation LC_{50} was determined to be > 5.6 mg/L (4 h) for male and female rats. Due to the similar composition of BAS 516 00 F and BAS 516 07 F, the study performed with BAS 516 00 F is considered to be valid for BAS 516 07 F, too. Information on the detailed composition of BAS 516 00 F and BAS 516 07 F can be found in the confidential part of the dossier (Document J).

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 516 07 F is not to be classified for acute inhalation toxicity.

CP 7.1.4 Skin irritation

Report: CP 7.1.4/1
[redacted]2007a
BAS 516 07 F: Acute dermal irritation / corrosion in rabbits
2007/1056989

Guidelines: OECD 404, EEC 2004/73 B.4, EPA 870.2500, JMAFF No 12 Nosan No 8147

GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a primary dermal irritation study the skin irritation/corrosion potential of BAS 516 07 F was tested. An area of 6.25 cm² of clipped skin of 3 New Zealand White rabbits was exposed to 0.5 g of the test-substance for 4 hours under semi-occlusive conditions. The rabbits were observed for 7 days after removal of the dressings. Signs of skin irritation were scored using the Draize scheme.

Administration of BAS 516 07 F to the skin of rabbits caused up to grade 2 (slight to moderate) erythema and no edema. The cutaneous reaction was fully reversible in all animals within 7 days after removal of the patch. The overall 24 to 72 hour skin irritation scores were 1.1 for erythema and 0.0 for edema.

Based on the results of the study no classification as skin irritant is warranted for BAS 516 07 F according to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP).

Stability of test compound:	The stability was guaranteed for the duration of the study

2. Vehicle and/or positive control: none

3. Test animals:

Species:	Rabbit
Strain:	New Zealand White, A 1077 INRA (SPF)
Sex:	male and female
Age:	6 – 7 months
Weight at dosing (mean):	3.83 – 4.00 kg
Source:	Centre Logo S.A., 01540 Vonnas, France
Acclimation period:	At least 5 days
Diet:	Kliba Laboratory Diet, Provimi Kliba SA, Kaiseraugst, Basel, Switzerland (approx. 130 g/animal/day)
Water:	Tap water, ad libitum
Housing:	Single housing in stainless steel wire mesh cages with grating, floor area 3000 cm²
Environmental conditions:	
Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	Fully air-conditioned rooms; number of air-changes not indicated in the report
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 23-Oct-2007 to 12-Nov-2007

2. In-vitro pre-test:
No in-vitro pre-test was performed.

3. Animal assignment and treatment:
The potential of BAS 516 07 F to cause acute dermal irritation or corrosion was assessed by a single topical application of 0.5 mg of minimally moistened test substance for 4 hours to the intact skin of two male and one female New Zealand White rabbits.

At least 24 hours before treatment, the dorsolateral part of the trunk of the animals was clipped. Only animals without obvious signs of skin irritation were used in the study. A dose of 0.5 mg minimally moistened with doubly distilled water was applied to a 2.5 x 2.5 cm test patch and applied to the flank for 4 hours. The gauze patch was held in place by means of an adhesive semi-occlusive dressing. After a 4 hour exposure period the patch was removed and the application area was washed with Lutrol® (PEG 400) and Lutrol®/water (1:1).
The cutaneous reactions were assessed immediately after removal of the patch, approximately 1, 24, 48 and 72 hours as well as 7 days after removal of the patch.
Body weights were measured shortly prior to application and after the last reading. The animals were checked for mortality, morbidity and clinical signs twice on working days and once on weekends and public holidays.

II. RESULTS

Administration of BAS 516 07 F to the skin of rabbits caused up to moderate erythema (grade 2). No edema were observed (see Table 7.1.4-1). The cutaneous reactions were reversible latest within 7 days after removal of the patch.

Table 7.1.4-1: Individual and mean skin irritation scores after 4 hour dermal application of BAS 516 07 F

III. CONCLUSION

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 516 07 F is not to be classified for skin irritation.

CP 7.1.5 Eye irritation

Report: CP 7.1.5/1
[redacted] 2007b
BAS 516 07 F: Acute eye irritation in rabbits
2007/1056988
Guidelines: OECD 405, EEC 2004/73 B.5, EPA 870.2400, JMAFF No 12 Nosan No 8147
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a primary eye irritation study, the eye irritation/corrosion potential of BAS 516 07 F was determined by instillation of 0.1 mL (about 47 mg) of the test substance into the conjunctival sac of the right eye of three rabbits (stepwise procedure starting with one animal and supplementing two additional animals). The left eye, which remained untreated, served as a control. The eyes were rinsed 24 hours after administration of the test substance.
The ocular reactions were assessed approximately 1, 24, 48 and 72 hours after the administration of the test substance.
Signs of ocular irritation consisted of up to grade 2 conjunctival redness and up to grade 2 chemosis with slight to moderate discharge. No effects on the cornea or iris were observed. All signs of ocular irritation were reversible within 72 hours. The mean scores calculated for all animals over 24, 48 and 72 hours were 0.0 for corneal opacity and for iris lesions, 0.9 for redness of the conjunctiva and 0.2 for chemosis.

Based on the results of the study no classification as eye irritant is warranted for BAS 516 07 F according to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP).

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 24-Sep-2007 to 12-Nov-2007

2. In-vitro pre-test:
No in-vitro pre-test was performed.

3. Animal assignment and treatment:
The potential of BAS 516 07 F to cause acute eye irritation was assessed by instillation of 0.1 mL bulk volume (about 47 mg of the milled test substance) into the conjunctival sac of the right eye. The left eye, which remained untreated, served as a control. The eyes were rinsed with tap water 24 hours after administration of the test substance.
The ocular reactions were assessed approximately 1, 24, 48 and 72 hours after the administration of the test substance.
Body weights were measured shortly prior to application and after the last reading. The animals were checked for mortality, morbidity and clinical signs twice on working days and once on weekends and public holidays.

II. RESULTS AND DISCUSSION

Moderate conjunctival redness (grade 2) was noted in all animals 1 hour after application and persisted in two animals until the 24-hour reading. Slight conjunctival redness (grade 1) was observed in one animal 24 hours after application and in all animals at the 48-hour reading. Slight or moderate conjunctival chemosis (grade 1 or 2) was noted in all animals 1 hour after application. Slight conjunctival chemosis persisted in two animals until 24 hours. Slight or moderate discharge (grade 1 or 2) was noted in all animals only 1 hour after application. In addition, injected scleral vessels in a circumscribed area were noted during the observation period. The ocular reactions were reversible in all animals within 72 hours after application.
Mean scores calculated for each animal over 24, 48 and 72 hours were 0.0 for corneal opacity and for iris lesions, 0.7, 1.0 and 1.0 for redness of the conjunctiva and 0.0, 0.3 and 0.3 for chemosis, respectively (see Table 7.1.5-1).

Table 7.1.5-1: Individual and mean eye irritation scores after ocular application of BAS 516 07 F

Readings	Animal	Cornea		Iris	Conjunctiva			Additional findings
		Opacity	Area involved		Redness	Chemosis	Discharge	
1 h	01 (♂)	0	0	0	2	1	2	48

III. CONCLUSION

According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 516 07 F is not to be classified for eye irritation.

CP 7.1.6 Skin sensitization

Report:	CP 7.1.6/1 [redacted] 2014a BAS 516 07 F - Skin sensitisation: Local lymph node assay 2014/1001403
Guidelines:	OECD 429 (2010), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.42
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

For the determination of potential sensitizing properties of the formulation BAS 516 07 F the Murine Local Lymph Node Assay (LLNA) was conducted.
Groups of 5 female mice were treated with three different concentrations of the test substance (5, 10 and 25% (w/w) in DMSO) or with the vehicle alone for three consecutive days.
A skin sensitizing effect for BAS 516 07 F is not considered since Stimulation Indices (S.I.) of 1.86, 2.55 and 2.68 were determined with BAS 516 07 F at concentrations of 5, 10 and 25% (w/w) in DMSO, respectively. A slight dose response was observed, but an EC3 could not be calculated.
A statistically significant increase in lymph node weight and – cell count was obtained in all dose groups in comparison to the vehicle control group. The cut-off value for a positive response regarding the lymph node cell count index (1.55) was exceeded in the mid and high dose groups. However, this was not considered as biological relevant as the S.I.s determined for all concentrations did not exceed the threshold value of 3.
Erythema score 1-2 was observed in all test substance groups. A statistically significant increase in ear weights was observed in all treated groups compared to the vehicle control. The cut-off value of 1.1 for the ear weight index for a positive response regarding ear skin irritation was reached in all animals treated with the test item. The threshold value of 25% increase in ear weights for excessive local skin irritation mentioned in OECD guideline 429 was exceeded in the low and high dose group. The increased ear weights were attributed to irritant properties of the test item.
No signs of systemic toxicity and no mortalities were observed.

Based on the results of this study it is concluded that BAS 516 07 F does not have sensitizing properties in the Murine Local Lymph Node Assay under the test conditions chosen. According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 516 07 F is not to be classified as skin sensitizer.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 516 07 F

Description:	Brown solid
Lot/Batch #:	12-000110
Purity/content:	Pyraclostrobin, BAS 500 F: 6.7% Boscalid, BAS 510 F: 27.1%
Stability of test compound:	Stable: Expiry date 01.03.2015

2. Vehicle/ positive control: DMSO

3. Test animals:

Species:	Mouse
Strain:	CBA/ CaOlaHsd
Sex:	Female
Age:	8 to 10 weeks
Weight at dosing:	20.4 g ± 0.8 g
Source:	Harlan Laboratories B.V., Postbus 6174, 5960 AD Horst / The Netherlands
Acclimation period:	at least 5 days
Diet:	2018C Teklad Global 18% protein rodent diet (certified), ad libitum
Water:	tap water, ad libitum
Housing:	group housing in Makrolon Type II (pre-test) / III (main study), with wire mesh top
Environmental conditions:	
Temperature:	20 - 24°C
Humidity:	45 - 65%
Air changes:	not indicated
Photo period:	Alternating 12-hour light and dark cycles, artificial light from 6 am to 6 pm.

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 15-Jan-2014 to 18-Feb-2014

2. Animal assignment and treatment:
The skin sensitizing potential of BAS 516 07 F was assessed using the Murine Local Lymph Node Assay. To determine the highest non-irritant test concentration that at the same time did not induce signs of systemic toxicity, a pre-test was performed in two animals with test item concentrations of 10 and 25% (highest concentration, which could be technically achieved) applied once daily each on three consecutive days. At the tested concentrations the animals did not show any signs of systemic toxicity. The animal treated with 10 and 25% test item concentration showed erythema of the ear skin (score 1 on days 1 and 6, score 2 on day 5 after application). Increase in ear weights was 11.1 and 15.3%, respectively, compared to historical vehicle data. Both animals showed substance residues during the observation period, thus the increase in ear weights was partially attributed to the residues.

Thus, the test item in the main study was assayed at 5, 10 and 25% and female mice were randomly allocated to groups of 5 animals.
The groups were treated either with

- the vehicle (DMSO),
- a 5% (w/w) dilution in DMSO,
- a 10% (w/w) dilution in DMSO, or
- a 25% (w/w) dilution in DMSO.

The application solutions were prepared individually and shortly before treatment.

3. Analysis of treatment solutions:
A concentration control and homogeneity analysis of all three doses was performed as a separate study that confirmed that test substance preparation concentrations were adequate and homogenous.

4. Clinical observation:
Mortality was checked at least once daily from experimental start to necropsy. Clinical signs (local irritation at the application site or systemic toxicity) were recorded at least once daily. Especially the treatment sites were observed carefully.

5. Body weights:
Body weights were determined prior to the first application and prior to treatment with radioactive ^{3}H-methyl thymidine (^{3}HTdR).

6. Treatment of animals:
Each test group was treated with the item preparations by topical application to the dorsal surface of each ear at a volume of 25 µL per ear for three consecutive days. A further group of mice (control animals) was treated with an equivalent volume of the relevant vehicle alone. Five days after the first topical application, 20.2 µCi of ^{3}H-methyl thymidine in 250 µL of phosphate-buffered saline were injected into the tail vein of each mouse.

7. Terminal procedures:

Approximately 5 hours after ^{3}H-thymidine injection the animals were euthanised by using CO_2, which was, after harvesting of the lymph nodes, followed by cervical dislocation to ensure death. The draining lymph nodes were rapidly excised and pooled per animal (2 nodes per animal). Single cell suspensions in phosphate buffered saline of pooled lymph node cells were prepared by gentle mechanical disaggregation through stainless steel gauze (200 µm mesh size). After washing two times with phosphate buffered saline the lymph node cells were resuspended in 5% trichloroacetic acid and incubated at approximately +4°C for at least 18 hours for precipitation of macromolecules. The precipitates were then resuspended in 5% trichloroacetic acid and transferred to scintillation vials. The level of ^{3}HTdR incorporation was then measured in a β-scintillation counter. The β-scintillation counter expresses ^{3}HTdR incorporation as the number of radioactive disintegrations per minute.
After excision, the lymph nodes were pooled per animal and weighed immediately. Furthermore, the lymph node cell count was determined for each animal. For this, the volume of the cell suspensions was adjusted to an equal final volume and vortexed. Subsequently, individual cell counts were determined using a cell counter. After the lymph nodes had been excised, both ears of mice were punched at the apical area using a biopsy punch (Ø 8 mm corresponding to 0.5 cm^2) and immediately weighed (pooled per animal).

8. Calculations:

The stimulation indices of cell count, ^{3}H-thymidine incorporation, lymph node weight, and ear weight were calculated as the ratio of the test group values for these parameters divided by those of the vehicle control group.

9. Data evaluation and interpretation:

The lymph node cell count and the ^{3}H-thymidine incorporation into the lymph node cells as well as to a certain extent lymph node weight are used to determine the potential sensitizing properties of a test article. Because not only sensitization but also irritation of the ear skin by the test substance may induce lymph node responses, the weight of ear punches taken from the area of test-substance application is determined as a parameter for inflammatory ear swelling as an indicator for the irritant action of the test substance.

Stimulation indices of >1.55 for cell count and/or of ≥ 3 for ^{3}H-thymidine incorporation compared to the concurrent vehicle control group are generally considered as indicative for a sensitizing potential of a test substance. If applicable, the EC (estimated concentration) leading to the respective SI values were calculated by linear or semi-logarithmical regression.

If the increase in cell count, ^{3}H-thymidine incorporation and/or lymph node weight is accompanied by a biologically relevant increase in ear weights (cut-off: 1.1) it cannot be ruled out that the lymph node response was caused by irritation and not by skin sensitization. Depending on the magnitude of lymph node response, based on expert judgment, the evaluation of the sensitizing potential may be modified or additional studies might be necessary.

10. Positive controls:
A concurrent positive control (reliability check) with a known sensitizer was not included into this study. Studies using the positive control substance alpha-hexylcinnamaldehyde are regularly performed in the laboratory in order to show that the test system is able to detect sensitizing compounds under the test conditions chosen.

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

No deaths and no signs of systemic toxicity occurred during the study period.

B. BODY WEIGHTS

The expected body weight gain was generally observed in the course of the study.

C. STIMULATION INDICES

In this study, Stimulation Indices (S.I.) of 1.86, 2.55 and 2.68 were determined with test item concentrations of 5, 10 and 25%, respectively. A slight dose response was observed but an EC3 value could not be calculated since all S.I.'s were below the threshold value of 3. A statistically significant increase in DPM values was not observed in any of the dose groups in comparison to the vehicle group.

A statistically significant increase in lymph node weights and –cell count was obtained in all dose groups in comparison to the vehicle control group. Moreover, the cut-off value for a positive response regarding the lymph node cell count index (1.55) was exceeded in the mid and high dose groups (Table 7.1.6-1). This was considered as not biologically relevant as the S.I.s determined for all concentrations did not exceed the threshold value of 3.

Animals treated with 5% of the test item showed a very slight erythema of the ear skin (score: 1 on days 2-4). Animals treated with 10% of the test item showed an erythema of the ear skin as well (score: 1 on days 2-5). Animals treated with the high dose (25%) of the test item showed an erythema of the ear skin (score: 2 on days 2 and 3, score: 1 on days 4 and 5).

A statistically significant increase in ear weights was observed in all treated groups in comparison to the vehicle control group. The cut-off value (1.1) of the ear weight index for a positive response regarding ear skin irritation was exceeded in all test item treated groups. The threshold value of 25% increase in ear weights for excessive local skin irritation mentioned in OECD guideline 429 was exceeded in the low and high dose group, thus indicating the irritant properties of the test item.

Based on the above-mentioned findings regarding ear skin irritation, an influence of irritation on lymphocyte proliferation cannot be excluded. Details of the test group mean values and stimulation indices are summarized in Table 7.1.6-1.

Table 7.1.6-1: Stimulation indices for cell counts, ^{3}H-thymidine incorporation, lymph node, and ear weight in mice after treatment with BAS 516 07 F

Test Group	Treatment	Parameter evaluated	Stimulation index (S.I.)[1]
		Cell count [counts x10^6/lymph node pair]	
1	vehicle (DMSO)	13.3 ± 2.9	1.00
2	5% (w/w) in DMSO	19.1 ± 2.0*	1.44
3	10% (w/w) in DMSO	23.3 ± 4.0*	1.76
4	25% (w/w) in DMSO	26.4 ± 1.8*	1.99
		^{3}H-Thymidine incorporation [DPM/lymph node pair]	
1	vehicle (DMSO)	1853.1 ± 743.4	1.00
2	5% (w/w) in DMSO	3455.3 ± 602.3	1.86
3	10% (w/w) in DMSO	4724.3 ± 2453.9	2.55
4	25% (w/w) in DMSO	4966.9 ± 2532.6	2.68
		Lymph node weight [mg/lymph node pair]	
1	vehicle (DMSO)	6.7 ± 1.5	1.00
2	5% (w/w) in DMSO	8.4 ± 1.1*	1.26
3	10% (w/w) in DMSO	10.2 ± 0.9*	1.52
4	25% (w/w) in DMSO	10.6 ± 1.1*	1.58
		Ear weight [mg/animal]	
1	vehicle (DMSO)	27.5 ± 1.7	1.00
2	5% (w/w) in DMSO	34.4 ± 4.8*	1.25
3	10% (w/w) in DMSO	32.1 ± 2.0*	1.17
4	25% (w/w) in DMSO	37.3 ± 1.7*	1.35

[1] test group x / test group 1 (vehicle control)

* Mean cell count, lymph node weight and ear weight for the group was according to the ANOVA (Dunnett-test) significantly higher than the corresponding control value. The p value for the analysis was $p < 0.05$.

D. POSITIVE CONTROL

The sensitivity of mice and the reliability of experimental techniques are assessed regularly in the test laboratory using a known sensitizer. Positive results were consistently obtained over the years. Results of the positive control studies are presented in Table 7.1.6-2.

Table 7.1.6-2: Positive control LLNA studies performed

Positive control Substance	Date	Concentration / Vehicle	S.I. values
Alpha-hexylcinnamaldehyde	October 2013	25% in acetone:olive oil (4+1, v/v)	5.8
	April 2013		5.9
	October 2012		5.7
	April 2012		3.7
	February 2012		4.7
	January 2012		10.8
	January 2012		7.1
	December 2011		5.9
	November 2011		5.3
	October 2011		6.1

III. CONCLUSION

Based on the results of this study it is concluded that BAS 516 07 F does not have sensitizing properties in the Murine Local Lymph Node Assay under the test conditions chosen. According to the 28th ATP of Council Directive 67/548/EEC (Commission Directive 2001/59/EC) and Regulation (EC) No 1272/2008 (CLP), BAS 516 07 F is not to be classified as skin sensitizer.

CP 7.1.7 Supplementary studies on the plant protection product

No supplementary studies on the plant protection product were deemed necessary and thus none were conducted. However, a publication of Cayir et al. 2012 on the genotoxicity of pyraclostrobin, boscalid and **BAS 516 07 F** has been evaluated and is discussed in M-CA 5.4.

CP 7.1.8 Supplementary studies for combinations of plant protection product

No studies for combinations of BAS 516 07 F with other plant protection products product were deemed necessary and thus none were conducted.

CP 7.2 Data on exposure

Exposure assessments and risk evaluations for operators, workers, bystanders and residents are presented below for the new representative formulation BAS 516 07 F, which has not been evaluated during a previous Annex I inclusion process.

CP 7.2.1 Operator exposure

The plant protection product BAS 516 07 F is already registered for the use as fungicide in the representative crop potatoes. Information on the critical use pattern relevant for operator exposure is summarized in Table 7.2.1-1.
The formulation is a water dispersable granule (WG) containing 67 g/kg pyraclostrobin and 267 g/kg boscalid. It is mainly commercialized in 1, 2.5 and 5 kg containers.

Table 7.2.1-1: Summary of critical use pattern

Crop (indoor / field)	**Application rate** (g as/ha)		**Minimum spray dilution** (L/ha)	**Application equipment**	**Number of applications**
Potatoes (field)	Pyraclostrobin	17	200	Tractor mounted boom sprayers	4
	Boscalid	67			

The critical use pattern has been defined based on the already registered uses in potatoes (for details see M-CP 3 Table 2). The GAP registered in DE was used as basis for the risk assessment.

Estimations of potential operator exposure have been undertaken for BAS 516 07 F using the intended use shown above and the following predictive models:

- Uniform Principles for Safeguarding the Health of Applicators of Plant Protection Products (Uniform Principles for Operator Protection), Mitteilungen aus der Biologischen Bundesanstalt, Heft 277, Berlin 1992 ("German model").

- Revised UK POE Model, as available on http://www.pesticides.gov.uk/uploadedfiles/Web_Assets/PSD/UK_POEM1.xls [UK Predictive Operator Exposure Model (POEM): Estimation of Exposure and Absorption of Pesticides by Spray Operators, Scientific subcommittee on Pesticides and British Agrochemical association Joint Medical Panel Report (UK MAFF), 1986 and the Predictive Operator Exposure Model (POEM) V 7 of 2008, (UK MAFF), 1992 ("UK Model").

Risk assessment for operator

The toxicological reference values (Acceptable Operator Exposure Level) for pyraclostrobin and boscalid as well as dermal absorption values appropriate for BAS 516 07 F, which were used in the operator risk assessment are shown in Table 7.2.1-2.

Table 7.2.1-2: Endpoints for pyraclostrobin and boscalid used in operator risk assessment

Endpoint	Value	Reference
Pyraclostrobin		
Dermal penetration - Concentrate - Spray dilutions	0.2% 5%	BASF DocID 2014/1001402 (for details see M-CP 7.3 of this dossier)
AOELsystemic	0.015 mg/kg bw/day	EU Review Report SANCO/1420/2001-Final, 8. September 2004
Boscalid		
Dermal penetration - Concentrate - Spray dilutions	0.5% 4%	BASF DocID 2014/1001401 (for details see M-CP 7.3 of this dossier)
AOELsystemic	0.1 mg/kg bw/day	EU Review Report SANCO/3919/2007-rev.5, 21. January 2008

The estimated operator exposure to pyraclostrobin and boscalid for the use of BAS 516 07 F in potatoes without using PPE is shown in Table 7.2.1-3 below. The values reflecting this use including PPE can be found in chapter 7.2.1.1.

Table 7.2.1-3: Estimated operator exposure to pyraclostrobin and boscalid in BAS 516 07 F

Model data	Level of PPE	Active substance	Total absorbed dose (mg/kg bw/day)[1]	% of AOEL[2]	Reference in Appendix
outdoor tractor operated boom sprayer application with hydraulic nozzles to field crops 0.25 kg BAS 516 07 F/ha corresponding to 17 g pyraclostrobin and 67 g boscalid per ha					
German Model - 20 ha/day - 70 kg operator	None	Pyraclostrobin	0.0006	3.7	**7.2-1**
		Boscalid	0. 002	1.9	**7.2-2**
UK POEM - 30 ha/day - 60 kg operator		Pyraclostrobin	0.003	23	**7.2-3**
		Boscalid	0. 0117	12	**7.2-4**

[1] systemic exposure based on dermal absorption: 0.2% for mixing/loading and 5% for application for pyraclostrobin as well as 0.5% for mixing/loading and 4% for application for boscalid
[2] based on a systemic AOEL of 0.015 and of 0.1 mg/kg bw/day for pyraclostrobin and boscalid, respectively

Results and discussion
Following the operator exposure and risk evaluation based on models a safe use could be shown for both the BBA model and UK POEM estimates.

In conclusion operators are considered to be at acceptable risk when exposed to pyraclostrobin and boscalid under the use conditions of BAS 516 07 F in potatoes.

CP 7.2.1.1 Estimation of operator exposure

BAS 516 07 F is applied in field crops (potatoes), which is professional use only. The relevant application scenario is outdoor tractor operated boom sprayer with hydraulic nozzles. Risk assessments are presented based on the BBA model and the UK POEM with consideration of the following input parameters.

Table 7.2.1.1-1: German model input parameters for tractor mounted boom sprayer application in potatoes

Application method:	tractor-mounted boom sprayers with hydraulic nozzles, field crop	
Treated area:	20 ha/day	
Max. dose rate:		0.25 kg BAS 516 07 F/ha
	corresponding to:	0.017 kg pyraclostrobin/ha 0.067 kg boscalid/ha
Operator body weight:	70 kg	

Table 7.2.1.1-2: UK POEM input parameters for tractor mounted boom sprayer application in potatoes

Application method:	Tractor-mounted/trailed boom sprayer: hydraulic nozzles	
Treated area:	30 ha/day*	
Max. dose rate:		0.25 kg BAS 516 07 F/ha
	corresponding to:	0.017 kg pyraclostrobin/ha 0.067 kg boscalid/ha
Spray volume:	200 L/ha	
Duration:	6 h	
Operator body weight:	60 kg	
*Default value for row crops		

Estimation of operator exposure without personal protective equipment

Exposure predictions for operators using no protective equipment (PPE) are summarized Table 7.2.1.1-3.

Table 7.2.1.1-3: Estimated operator exposure to pyraclostrobin and boscalid in BAS 516 07 F without using PPE

Model data	Level of PPE	Active substance	Total absorbed dose (mg/kg bw/day)[1]	% of AOEL[2]	Reference in Appendix
outdoor tractor operated boom sprayer application with hydraulic nozzles to field crops 0.25 kg BAS 516 07 F/ha corresponding to 17 g pyraclostrobin per ha and 67 g boscalid/ha					
German Model - 20 ha/day - 70 kg operator	None	Pyraclostrobin	0.0006	3.7	**7.2-1**
		Boscalid	0. 002	1.9	**7.2-2**
UK POEM - 30 ha/day - 60 kg operator		Pyraclostrobin	0.003	23	**7.2-3**
		Boscalid	0. 0117	12	**7.2-4**

[1] Systemic exposure based on dermal absorption: 0.2% for mixing/loading and 5% for application for pyraclostrobin as well as 0.5% for mixing/loading and 4% for application for boscalid

[2] based on a systemic AOEL of 0.015 and of 0.1 mg/kg bw/day for pyraclostrobin and boscalid, respectively

A safe use could be shown for operators without personal protective equipment with any of the models chosen. Detailed information is presented in appendix 7.2-1 to 7.2-4.

Estimation of operator exposure <u>with personal protective equipment</u>

Although a safe use was already shown for operators without personal protective equipment, exposure predictions for operators using protective equipment are summarized Table 7.2.1.1-4 for completeness.

Table 7.2.1.1-4: Estimated operator exposure to pyraclostrobin and boscalid in BAS 516 07 F with using PPE

Model data	Level of PPE	Active substance	Total absorbed dose (mg/kg bw/day)[1]	% of AOEL[2]	Reference in Appendix
outdoor tractor operated boom sprayer application with hydraulic nozzles to field crops 0.25 kg BAS 516 07 F/ha corresponding to 17 g pyraclostrobin per ha and 67 g boscalid/ha					
German Model - 20 ha/day - 70 kg operator	Gloves during mixing/loading and gloves, coverall and sturdy footwear during application	Pyraclostrobin	0.00001	0.5	**7.2-5**
		Boscalid	0.00028	0.3	**7.2-6**
UK POEM - 30 ha/day - 60 kg operator	Gloves during mixing/loading and gloves during application	Pyraclostrobin	0.001	6	**7.2-7**
		Boscalid	0. 003	3	**7.2-8**

[1] Systemic exposure based on dermal absorption: 0.2% for mixing/loading and 5% for application for pyraclostrobin as well as 0.5% for mixing/loading and 4% for application for boscalid

[2] based on a systemic AOEL of 0.015 and of 0.1 mg/kg bw/day for pyraclostrobin and boscalid, respectively

A safe use could be shown for operators with personal protective equipment. Detailed information is presented in appendix 7.2-5 to 7.2-8.

CP 7.2.1.2 Measurement of operator exposure

Since the risk assessments performed indicate that the health-based limit value (AOEL) will not be exceeded under practical conditions of use for pyraclostrobin and boscalid, further refinement of exposure predictions is not necessary and has thus not been performed.

CP 7.2.2 Bystander and resident exposure

The plant protection product BAS 516 07 F is already registered for the use as fungicide in the representative crop potatoes. Information on the formulation and the critical use pattern relevant for the bystander and resident risk assessment can be found in chapter 7.2.1. The critical GAP is summarized in Table 7.2.1-1.

Exposure assessments and risk evaluations for bystanders and residents for the representative formulation BAS 516 07 F are presented below. According to the EU requirements they have been based on the following model:

- Martin S. et al. (2008): Guidance for Exposure and Risk Evaluation for Bystanders and Residents exposed to Plant Protection Products during and after Application. J. Verbr. Lebensm., drift distances adopted according to the recommendation published by the German BVL: B. Nolting (2012) Bekanntmachung ueber Mindestabstaende, die bei der Anwendung von Pflanzenschutzmitteln zum Schutz von Umstehenden und Anwohnern einzuhalten sind. Bundesanzeiger 2012 No. 4 Pp. 75-76 for the bystander and resident.

Risk assessment for bystander and resident

A summary of the bystander risk assessment is provided in Table 7.2.2-1.

Table 7.2.2-1: Summary of bystander exposure during application of BAS 516 07 F in potatoes

	Active Substance			
	Pyraclostrobin		Boscalid	
	AOEL = 0.015 mg/kg bw/day		AOEL = 0.1 mg/kg bw/day

Conclusion
It is concluded that there is no unacceptable risk to bystanders or residents after accidental exposure to BAS 516 07 F.

CP 7.2.2.1 Estimation of bystander and resident exposure

Bystanders and residents are not involved in application or handling of plant protection products or the professional handling of treated crops. Therefore, exposure differs significantly from operator exposure levels. The exposure assessment presented below is based on the German guidance paper for evaluation of bystander and resident exposure (Martin S. et al., 2008) with adopted drift distances (B. Nolting, 2012).

A. Bystander exposure

The presence of bystanders is incidental within or directly adjacent to an area where plant protection products are applied. A situation in which bystander exposure could occur would be a person walking alongside an area being treated at the same time. Under these conditions the bystander would never walk directly next to the outer spraying nozzle. A distance of some meters from the spraying device can always be expected. It can further be assumed that any bystander, as soon as becoming aware of an exposure will leave the spraying area. Therefore, bystander exposure is of short duration, typically a matter of minutes. Thus, the exposure duration of 5 minutes is assumed.

Bystander exposure results from spray drift that deposits on the body surface or passes the breathing zone. Assuming that bystanders wear only light clothing (i.e. short-sleeved shirt and shorts), the exposed, uncovered body surface of an adult (head, face, neck front and back, forearms, half upper arms, hands, lower half of thighs, lower legs and feet) is amounting to about 1 m². For children the exposed body surface with the same level of clothing amounts to 0.21 m².

For the scenario of professional agricultural use it is assumed that the bystander is located at a distance of 1 m, downwind from the spraying source. The extent of spray drift and the consequent deposition depends on the plant protection product application rate, the particular crop being treated and the method of application. Measurements of spray drift following different crop/equipment combinations are available from Rautmann D. et al., 2001: New basic drift values in the authorisation procedure for plant protection products. In: Forster, B. and Streloke, M. (eds.), Workshop on Risk Assessment and Risk Mitigation Measures (WORMM). 27–29 September 1999, Mitteilungen aus der Biologischen Bundesanstalt für Land- und Forstwirtschaft, booklet 383, 2001; actual version of 27th March 2006: Rautmann, D., 2006: Aktuelle Abdrifteckwerte (Current Drift Values). http://www.jki.bund.de/cln_045/nn_926124/SharedDocs/10_FA/Publikationen/Pflanzenschutzgeraete/abdrifteckwerte_xls.html.
Thus, for the corresponding application scenario in cereals the proposed drift value at 1 m distance of 2.77% (90th percentile value) is used for estimations of dermal exposure. However, the drift deposition data by Rautmann D. et al., 2001 cannot easily be transposed into airborne concentrations and consequent inhalation exposure values. Therefore, to ensure a conservative evaluation, measured inhalation exposure data for the unprotected operator during spray applications (Lundehn J.R. et al., 1992, German BBA model) are used for the bystander inhalation exposure estimation.

The parameters used for bystander exposure calculations are summarized in Table 7.2.2.1-1.

Table 7.2.2.1-1: Parameters used for bystander exposure calculations

	Parameter	Pyraclostrobin	Boscalid
AR	Maximum application rate (kg a.s./ha)	0.017	0.067
ar	Maximum application rate (mg a.s./m²)	1.7	6.7
DA	Dermal absorption (%)	5	4
IA	Inhalation absorption (%)	100	
		Default values	
D	Drift at 1 meter distance for field crop (% of application rate)	2.77	
TB	Exposure duration bystander (minutes)	5	
TO	Exposure duration operator (hours)	6	
TF	Exposure duration factor (TB / TO) [1]	0.0139	
A	Area treated (ha/day)	50	
		Adults	Children
BSA	Exposed body surface (m²)	1	0.21
IA	Specific inhalation exposure (mg a.s./kg a.s. handled) [2]	0.001	0.00057
BW	Bystander body weight (kg)	60	16.15

[1] Since the German model values are based on an application period of 6 hours/day, adjustment to 5 minutes is required for exposure calculations.
[2] based on geometric mean values proposed by the German BBA Model (Lundehn et al., 1992) and inhalation rates of 1.74 and 1.0 m³/h for adults and children, respectively

Bystander exposure for adults and children is estimated according the following equations:

Systemic dermal exposure $$SDE_B = \frac{ar \times D \times BSA \times DA}{BW}$$

Systemic inhalation exposure $$SIE_B = \frac{I_A \times AR \times A \times TF \times IA}{BW}$$

Total systemic exposure $$SE_B = SDE_B + SI_B$$

Assessment

For the exposure of a bystander passing by the field treated with BAS 516 07 F the systemic exposure to pyraclostrobin and boscalid was assessed based on 5 minutes exposure applying generic spray drift deposits of 2.77% of the application rate at 1 meter distance and air borne spray concentrations of 0.001 and 0.00057 mg/kg a.s./person for adults and children, respectively.

The result of the bystander exposure estimation is presented in Table 7.2.2.1-2. Details of the estimations are presented in Appendix 7.2-9 (for pyraclostrobin) and in Appendix 7.2-10 (for boscalid).

Table 7.2.2.1-2: Estimated bystander exposure to pyraclostrobin and boscalid in % of the AOEL

	Active Substance			
	Pyraclostrobin		**Boscalid**	
	AOEL = 0.015 mg/kg bw/day		**AOEL = 0.1 mg/kg bw/day**	
	Adults	**Children**	**Adults**	**Children**
Systemic exposure via dermal route (mg/kg bw/day)	0.00004	0.000031	0.000124	0.0001
Systemic exposure via inhalation (mg/kg bw/day)	0.0000001	0.0000002	0.0000003	0.000001
Total systemic exposure (mg/kg bw/day)	**0.00004**	**0.000031**	**0.0001243**	**0.000101**
% of AOEL	**0.26**	**0.21**	**0.12**	**0.10**

[1] according to the German model for bystander and resident exposure assessment; Martin S. et al. (2008)
[2] based on a systemic AOEL of 0.015 and 0.1 mg/kg bw/day for pyraclostrobin and boscalid, respectively

The estimates result for adults in 0.26 and 0.12% of the AOEL for pyraclostrobin and boscalid, respectively. For children the corresponding estimates are 0.21% of the AOEL for pyraclostrobin and 0.1% for boscalid. Thus, the exposure of adult and child bystanders passing by a field treated with BAS 516 07 F is considered to be safe.

In conclusion, bystanders are not considered to be at risk when exposed to spray drift of pyraclostrobin and boscalid under the use conditions of BAS 516 07 F in potatoes.

B. Resident exposure

Residents are persons who live, work or attend any institution adjacent to an area that has been treated with a plant protection product. Possible situations are persons who are standing, working, or sitting in a garden in the vicinity of the application. They may be exposed to the plant protection products mainly via the dermal route from spray drift deposits and by inhalation of vapour drift depending on the vapour pressure of the active substances. For infants and toddlers oral exposure via hand-to-mouth transfer or object-to-mouse transfer has to be considered, too.
As for the bystander it can be assumed that residents are unlikely to take actions to avoid or control exposure, and they wear only light clothing and no protective equipment. In addition, as conservative approach it is assumed that residents are located directly downwind of the centre of the treatment area from the point of spray emission caused by professional agricultural uses.
The field crop application is here considered to represent the worst case scenario for which a distance of 1 m from the spraying device is taken into consideration.

It can be assumed that the exposure duration of residents being in a garden is longer than the exposure duration of bystanders. Therefore, the default exposure duration of 2 hours is adopted for risk evaluations.

According to the German model for bystander and resident exposure assessments, inhalation exposure has only to be considered for semi-volatile and volatile active substances (vapour pressures of $1 \times 10^{-5} - 5 \times 10^{-3}$ Pa and $> 5 \times 10^{-3}$ Pa, respectively). As pyraclostrobin has a vapour pressure of 2.6×10^{-8} Pa it is considered non-volatile. The same applies to boscalid having a vapour pressure of 7.2×10^{-7} Pa. Consequently, inhalation exposure to vapours is therefore not taken into account.

For assessment of the oral exposure of children and toddlers in a first-tier approach the default values proposed by the German model for bystander and resident exposure assessments are used (Martin S. et al. (2008) as derived from a US-EPA policy paper). Table 7.2.2.1-3 summarizes the parameters used for resident exposure of adults and children.

Table 7.2.2.1-3: Parameters used for resident exposure estimations

	Parameter	Pyraclostrobin	Boscalid
	Vapour pressure (Pa)	2.6×10^{-8}	7.2×10^{-7}
	Volatility	non-volatile	non-volatile
	Maximum application rate (kg a.s./ha)[1]	0.017	0.067
	Maximum number of applications	4	4
AR	Application rate relevant for resident (kg a.s./ha)	0.034	0.134
Ar	Maximum application rate (mg a.s./cm²)	3.4	13.4
DA	Dermal absorption (%)	5	4
IA	Inhalation absorption (%)	100	
OA	Oral absorption (%)	50	44
ACV	Airborne concentration of vapour (mg/m³) [2]	-	-
		Default values	
D	Drift (%) at 1 m distance - 90th percentile values[3] for field crop	2.77	
H	Duration (hours)	2	
		Adults	Children
TTR	Turf transferable residues hand (%)	5	5
TC	Transfer coefficient (cm²/hour)	7300	2600
IR	Inhalation rate (m³/day)	16.57	8.31
SE	Salivation extraction factor (%)		50
SA	Surface area of hands (cm²)		20
Freq	Frequency of hand-to-mouth events (events/hour)		20
DFR	Dislodgeable foliar residue object to mouth (%)		20
IgR	Ingestion rate for mouthing of grass (cm²)		25
BW	Resident body weight (kg)	60	16.15

[1] As BAS 516 07 F will be applied 4 times per season at maximum, the double application rate is considered relevant for residential exposure according to the German model for bystander and resident exposure assessment.
[2] Since pyraclostrobin and boscalid are non-volatile, i.e. the vapour pressures are 2.6 x 10-8 and 7.2 x 10-7 Pa, the ACV value is 0.0 mg/m³.
[3] 90th percentile of drift recommended for one application, 82nd percentile of drift for double application rate recommended for more than one application according to Martin S. et al. (2008)

Resident exposure for adults and children is estimated according the following equations:

Systemic dermal exposure $$SDE_R = \frac{AR \times D \times TTR \times TC \times H \times DA}{BW}$$

Systemic inhalation exposure $$SIE_R = \frac{AC \times IR \times IA}{BW}$$

Systemic exposure due to hand-to-mouth transfer (children only) $$SOE_H = \frac{AR \times D \times TTR \times SE \times SA \times F \times H \times OA}{BW}$$

Systemic exposure due to mouthing (children only) $$SOE_O = \frac{AR \times D \times DFR \times IgR \times OA}{BW}$$

Total systemic exposure (adults) $$SE_R = SDE_R + SIE_R$$

Total systemic exposure (children) $$SE_R = SDE_R + SIE_R + SOE_H + SOE_O$$

The resulting predicted exposures are summarized below.

Assessment

For the exposure of a resident located next to a field treated with BAS 516 07 F the systemic exposure to pyraclostrobin and boscalid was assessed based on 2 hour exposure to spray drifts via dermal and oral route. Exposure to airborne concentration of vapour for non-volatile compounds such as pyraclostrobin and boscalid is not considered.

The results of the resident exposure calculations are summarized in Table 7.2.2.1-4 below. Details of the estimations are presented presented in Appendix 7.2-11 (for pyraclostrobin) and in Appendix 7.2-12 (for boscalid).

Table 7.2.1.1-4: Estimated resident exposure to pyraclostrobin and boscalid in % of the AOEL

	Active Substance			
	Pyraclostrobin		**Boscalid**	
	AOEL = 0.015 mg/kg bw/day		**AOEL = 0.1 mg/kg bw/day**	
	Adults	**Children**	**Adults**	**Children**
Systemic exposure via dermal route (mg/kg bw/day)	0.000005	0.000007	0.000016	0.000021
Systemic exposure via inhalation (mg/kg bw/day)	-	-	-	-
Systemic exposure via oral route (mg/kg bw/day)	-	0.000006	-	0.000022
Total systemic exposure (mg/kg bw/day)	0.000005	0.000013	0.000016	0.000043
% of AOEL	**0.033**	**0.09**	**0.02**	**0.04**

[1] based on the German model for bystander and resident exposure assessment; Martin S. et al. (2008)
[2] based on a systemic AOEL of 0.015 and 0.1 mg/kg bw/day for pyraclostrobin and boscalid, respectively

The predicted resident exposure for adults is 0.033 and 0.02% of the AOEL for pyraclostrobin and boscalid, respectively. For children the estimated exposure is 0.09% of the AOEL for pyraclostrobin and 0.04% of the AOEL for boscalid.

In conclusion, residents are not considered to be at risk when exposed to spray drift of pyraclostrobin and boscalid under the use conditions of BAS 516 07 F in potatoes.

CP 7.2.2.2 Measurement of bystander and resident exposure

Since the risk assessment performed indicates that the health-based limit values (AOEL) will not be exceeded under practical conditions of use, studies to provide field data on bystander or residential exposure to BAS 516 07 F were not considered to be necessary and were thus not performed.

CP 7.2.3 Worker exposure

The plant protection product BAS 516 07 F is already registered for the use as fungicide in the representative crop potatoes. Information on the formulation and the critical use pattern relevant for the re-entry worker risk assessment can be found in chapter 7.2.1. The critical GAP is summarized in Table 7.2.1-1.

Exposure assessments and risk evaluations for re-entry workers for the representative formulation BAS 516 07 F are presented below. Estimations of potential worker exposure have been undertaken applying the following guidance for exposure prediction:

- EUROPOEM - Re-entry exposure model final draft adopted by more specific US EPA agricultural transfer coefficients

Risk assessment for worker

A summary of the worker risk assessment is provided in Table 7.2.3-1.

Table 7.2.3-1: Summary of re-entry worker exposure following application of BAS 516 07 F without protective equipment (standard assessment)

	Active ingredient	Estimated worker exposure (mg/kg bw/day)	% of AOEL[1]	Reference in Appendix
2 hour/day scouting and crop inspection in potatoes	pyraclostrobin	0.0005	3.3	7.2-13
	boscalid	0.0016	1.6	7.2-14

[1] based on a systemic AOEL of 0.015 and 0.1 mg/kg bw/day for pyraclostrobin and boscalid, respectively

Conclusion
It is concluded that there is no unacceptable risk anticipated for the worker wearing adequate working clothing when re-entering potatoes treated with BAS 516 07 F after the spray dilute has dried.

CP 7.2.3.1 Estimation of worker exposure

Worker exposure to pyraclostrobin and boscalid for the product BAS 516 07 F

BAS 516 07 F will be used as a fungicde in potatoes during growth stages BBCH 51-89 with a maximum of four applications per season. Thus, the considered reasonable worst case for the maximum applied amount of product per season is 1kg/ha corresponding to 0.067 kg pyraclostrobin and 0.267 kg boscalid per ha.

Hand operations in potatoes, which may result in re-entry exposure do not belong to standard growing procedures after the application of the product. Exposure scenarios one may think of as a worst case is scouting and crop inspection. These operations are considered to be of limited duration and of limited direct contact to the treated plants. For these operations a working period of 2 hours per day is considered as a reasonable approach.

Exposure Estimation Models used

The exposure estimation of the re-entry worker presented below is based on the:

- EUROPOEM - Re-entry exposure model final draft adopted by more specific US EPA agricultural transfer coefficients

The default exposure assessment is based on the following assumptions:

- Re-entry exposure is predominantly via the dermal route (contact with the foliage)
- Residues on the foliage depend on:
  - application rate
  - the crop habitat (total size of foliage compared to surface area, Leaf Area Index (LAI))
- Transfer of residues from the foliage to clothes or skin of workers is more or less independent of the product applied, but depend mainly on the intensity of contact with foliage (work activity).
- Activities with a similar pattern can be grouped and generic Transfer Coefficients (TC) can be used for one group.
- Based on the EUROPOEM proposal an Dislodgeable Foliar Residue (DFR) default value of 3 µg a.s./cm² is taken into account.

It is reasonably presumed that workers re-enter the treated crop after the spray has dried.

For pyraclostrobin an application rate of 0.067 kg a.s./ha and for boscalid the application rate of 0.267 kg a.s./ha is taken into account.

Within the EU, there are no commonly accepted specific transfer coefficients (TC) available to assess scouting and crop inspection activities in potatoes. Whereas the RMS widely accepted a TC of 1500 cm²/hour for crop inspection, the EFSA draft guidance on operator, bystander, resident and worker exposure assessment has proposed a 1100 cm²/hour for crop inspection activities instead.
Following the US EPA agricultural transfer coefficient, a TC of 1500 cm²/hour based on Central value from ARF021 -- scouting dry peas (range 486 to 2760) has been used in this evaluation as the more conservative approach.

In the following Table 7.2.3.1-1 the parameters used in the re-entry worker risk assessment are presented.

Table 7.2.3.1-1: Parameters used for the worker risk assessment

	Parameter	**Pyraclostrobin**	**Boscalid**	
MR	Application rate considered for default worker exposure	0.067	0.267	kg a.s./ha
DF	Dermal absorption[1]	5	4	%
DFR	Default dislodgeable foliar residue	3		µg/cm² x kg a.s. applied
		Default values		
BW	Re-entry worker body weight	60		kg
TC	Transfer coefficient[2]	1,500		cm²/h x person
A	Working period	2		h/day
TR	Transmission to skin for unprotected worker	1.00		(factor, equal to 100%)

[1] The given values for dermal absorption of pyraclostrobin and boscalid represent the estimates for spray dilutes. Exposure during re-entry occurs to dry residues for which it is adequate to expect a very low dermal absorption. Therefore, it is considered to be a conservative approach to use the dermal absorption values determined for the liquid spray dilutes.
[2] A TC of 1500 cm²/h x person was used (according to US EPA agricultural transfer coefficients) for activities like scouting and irrigation in potatoes based on recommendations for Central value from ARF021 -- scouting dry peas (range 486 to 2760).

Based on the assumptions and consideration made above, worker exposure is calculated as follows:

External dermal exposure ED_W

$$ED_W = MR \times A \times DFR \times TC \times TR$$

Total systemic exposure SE_W

$$SE_W = \frac{ED_W}{BW} \times DF$$

Estimatimation of worker exposure without personal protective equipment

The results of the re-entry worker risk assessment without PPE is presented in Table 7.2.3.1-2 below, details are given in Appendix 7.2-13 (for pyraclostrobin) and in Appendix 7.2-14 (for boscalid).

Table 7.2.3.1-2: Estimated worker exposure to pyraclostrobin and boscalid following application of BAS 516 07 F in potatoes (standard assessment)

		Exposure parameter	
Active substance	**AOEL (mg/kg bw/day)**	**Absorbed dose (mg/kg bw/day)**	**% of AOEL**
unprotected worker[1]			
Pyraclostrobin	0.015	0.0005	3.3
Boscalid	0.1	0.0016	1.6

[1] worker wearing working clothing

The predicted exposure to pyraclostrobin is 3.3% of the AOEL and to boscalid is 1.6% of the AOEL. Thus, for a worker performing post-treatment activities (potatoes: scouting and crop inspection) without gloves or protective clothing for 2 hours, the estimated worker exposure levels for pyraclostrobin and boscalid are within the acceptable range.

It is concluded that there is no unacceptable risk anticipated for the worker wearing adequate working clothing when re-entering potatoes treated with BAS 516 07 F after the spray dilute has dried.

CP 7.2.3.2 Measurement of worker exposure

Since the risk assessment performed indicates that the health-based limit value (AOEL) will not be exceeded under practical conditions of use, studies to provide field data on worker exposure to pyraclostrobin and boscalid in BAS 516 07 F were not considered to be necessary and were thus not performed.

Appendix 7.2-13: Estimated exposure and risk assessment for an unprotected worker exposed to pyraclostrobin from the product BAS 516 07 F (standard assessment)

Product:	BAS 516 07 F	**Active ingredient:**		Pyraclostrobin	
Maximum application rate (MR):	0.067 kg a.i. per ha	**AOELsys:**		0.015	mg/kg bw/day
Crop:	Potatoes	**Assessment factor:**		100	
Growth stage BBCH:	*51-89*	**Dermal absorption (DF):**		5%	
Activity:	Scouting and crop inspection	**Working duration (A):**		2	hours/day
		Worker bodyweight:		60	kg
Dislodgeable Foliar Residue (DFR):	0.003 mg/cm²	**Transfer coefficient (TC):**		1,500	cm²/hour
Protective clothing:	**None**	**Transmission to skin (TR):**		100%	
Dermal exposure (mg/person/d):		MR x A x DFR x TC x TR	=	0.603	mg/person/day
Systemic exposure (mg/person/d):		MR x A x DFR x TC x TR x DF	=	0.0302	mg/person/day
Total systemic exposure (assuming person of 60 kg):				**0.0005**	**mg/kg bw/day**
Total exposure (% AOEL):				**3.3%**	

Based on the Europoem - Re-entry exposure model final draft adopted by more specific US EPA agricultural transfer coefficients.

Appendix 7.2-14: Estimated exposure and risk assessment for an unprotected worker exposed to boscalid from the product BAS 516 07 F (standard assessment)

Product:	BAS 516 07 F	**Active ingredient:**		Boscalid	
Maximum application rate (MR):	0.267 kg a.i. per ha	**AOELsys:**		0.015	mg/kg bw/day
Crop:	potatoes	**Assessment factor:**		100	
Growth stage BBCH:	*51-89*	**Dermal absorption (DF):**		4%	
Activity:	Scouting and crop inspection	**Working duration (A):**		2	hours/day
		Worker bodyweight:		60	kg
Dislodgeable Foliar Residue (DFR):	0.003 mg/cm²	**Transfer coefficient (TC):**		1,500	cm²/hour
Protective clothing:	**None**	**Transmission to skin (TR):**		100%	
Dermal exposure (mg/person/d):		MR x A x DFR x TC x TR	=	2.403	mg/person/day
Systemic exposure (mg/person/d):		MR x A x DFR x TC x TR x DF	=	0.09612	mg/person/day
Total systemic exposure (assuming person of 60 kg):				**0.0016**	**mg/kg bw/day**
Total exposure (% AOEL):				**1.6%**	

Based on the Europoem - Re-entry exposure model final draft adopted by more specific US EPA agricultural transfer coefficients.

CP 7.3 Dermal absorption

Report: CP 7.3/1
Hassler S., 2014(a)
Radiolabeled BAS 510 F in BAS 516 07 F - In vitro study to investigate the dermal penetration through human skin
2014/1001401

Guidelines: OECD Guideline for testing of chemicals No. 428 (Skin absorption: In vitro method (2004)), (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.45

GLP: yes
(certified by Swiss Federal Office of Public Health, Berne, Switzerland)

Executive Summary

In an in-vitro experiment, the dermal penetration of boscalid (BAS 510 F) formulated as BAS 516 07 F through human skin was determined. For this a high dose (formulation 'concentrate' – 1:2 aqueous slurry feasible for application; nominal dose 945 µg bocalid per cm²), a mid dose (1:150 aqueous dilution; 17 µg boscalid per cm²) and a low dose (1:1200 aqueous dilution; 2.1 µg boscalid per cm²) was applied to human dermatomed skin at 10 µL/cm². The skin membranes were set up in flow through diffusion cells. The exposure of the skin to the test material lasted 8 hours; thereafter the skin was thoroughly washed. Further penetration of the remaining test item after removal was measured for additional 16 hours. The receptor fluid (water/ethanol 9:1 (v/v) for low and middle doses, and water/ethanol 7:3 (v/v) for the high dose level) was collected in hourly intervals between 0-8 hours and thereafter in 2 hour intervals until the end of the experiments.

In summary, boscalid, applied as BAS 516 07 F to human skin membrane, penetrated at a very low extent at all concentrations tested. Summing up the absorbed dose with that associated to the skin membrane, the following dermal absorption estimates are proposed for boscalid: 0.23 ± 0.30% for the formulation concentrate as well as 1.05 ± 1.18% and 3.00 ± 0.91% for the mid and low dose, respectively. The dermal penetration estimates to be used for risk assessment were therefore calculated to be 0.5% and 4% for the formulation concentrate and the aqueous spray dilutions, respectively.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

	a) ^{14}C-BAS 510 F (pyridin-3-C14)
	b) BAS 516 CO F (BAS 516 07 F blank formulation, without BAS 510 F)
	c) unlabeled BAS 510 F
Description:	a) solution in acetonitril
	b) solid, brownish
	c) solid, white
Lot/Batch #:	a) 640-2201
	b) FD-131202-0032
	c) N37
Purity:	a) radiochemical purity: 99.7%; specific activity: 5.34 MBq/mg
	b) BAS 516 07 F, but without BAS 510 F
	c) 94.4%
Stability of test compound:	a) The storage stability of the test substance was confirmed by HPLC analysis.
	b) The storage stability of the test substance in the formulation was confirmed by HPLC analysis.
	c) Stable: Expiry date 30.06.2018

2. Vehicle: water

3. Human skin preparations:

Source:	Institute for Pathology, Kantonspital Basel, Switzerland
Preparation:	Dermatomed (split thickness) human skin membranes with a thickness of about 400 µm were prepared.
Storage of skin samples:	Human skin samples were stored at -20°C wrapped until preparation of the split thickness skin membranes and the skin membranes were stored refrigerated (+5°C) until use.

4. Reagents:

Receptor fluid:	Water/ethanol (7:3 (v/v); boscalid solubility 68 mg/L) for the high dose formulation
	Water/ethanol (9:1 (v/v); boscalid solubility 44 mg/L) for the low and mid dose
Extraction media:	none
Washing solution:	mild shower gel solution: Nivea douche fitness, Beiersdorf, Germany (1% in tap water)

5. Preparation of the dosing solutions

High dose A3 (formulation 'concentrate', 1:2 aqueous slurry):
The formulation 'concentrate' was diluted in the lowest possible amount of water (1 part formulation + 2 parts water) feasible for dermal application with a pipette. An amount of 266 mg unlabeled BAS 510 F was weighed in a flask and a volume (260 µL) of the stock solution containing 1.0 mg [^{14}C]-BAS 510 F was added and further diluted with 4.74 mL of dichloromethane. This procedure led to a final specific activity of 20 kBq/mg. An amount (733 mg) of BAS 516 CO F blank formulation was added. The organic solvent was removed using a rotary evaporator. The dry formulation was then suspended in 2 ml water. The final formulation had a concentration of 107.5 mg [^{14}C] BAS 510 F/mL. The concentration of radioactivity was 2151 kBq/mL (measured). A density of 1.14 g/mL was determined in the final formulation.

Mid dose A2 (1:150 aqueous dilution):
An amount of 16.7 mg unlabeled BAS 510 F was weighed in a flask and a volume (2600 µL) of the stock solution containing 10.1 mg [^{14}C]-BAS 510 F was added and further diluted with 2.4 mL of dichloromethane. This procedure led to a final specific activity of 2017 kBq/mg. An amount of 73.3 mg of BAS 516 CO F blank formulation was added. The organic solvent was removed using a rotary evaporator. This formulation was further diluted with 15.0 mL water according to a ratio of 1:150. The final preparation had a concentration of radioactivity of 3451 kBq/mL corresponding to 1.71 mg [^{14}C]-BAS 510 F/mL.

Low dose A1 (1:1200 aqueous dilution):
A volume of the middle dose formulation A2, i.e. 1.5 mL containing about 0.01 g BAS 516 07 F, was further diluted with 10.5 mL water to a total volume of 12 mL in order to achieve a dilution ratio of 1:1200. The final formulation had a concentration of radioactivity of 462 kBq/mL corresponding to 0.23 mg [^{14}C]-BAS 510 F/mL.

Analyses:
Liquid scintillation counting and/or HPLC verified the homogeneity and accuracy of the test substance preparations. Taking and analyzing samples at time of application confirmed the stability of the test-substance in the preparation.

The conditions of the HPLC analysis are described in the table below:

Column:	Nucleosil 120-5 C18 (incl. pre-column RP18) 5µm, 250 mm x 4 mm (l x i.d.)
Mobile Phase: Eluent A:	Water/acetonitrile/sulfuric acid (500/500/0.5 v/v/v)
Flow:	1 mL/min
Gradient: 0-40 min	100% A (isocratic)
Wavelength:	254 nm
Detection:	UV-detector (Merck-Hitachi Model L-4000), Radiomatic 500TR radioactivity flow monitor

B. TEST PERFORMANCE

1. Dates of experimental work: 13-Jan-2014 - 20-Jan-2014

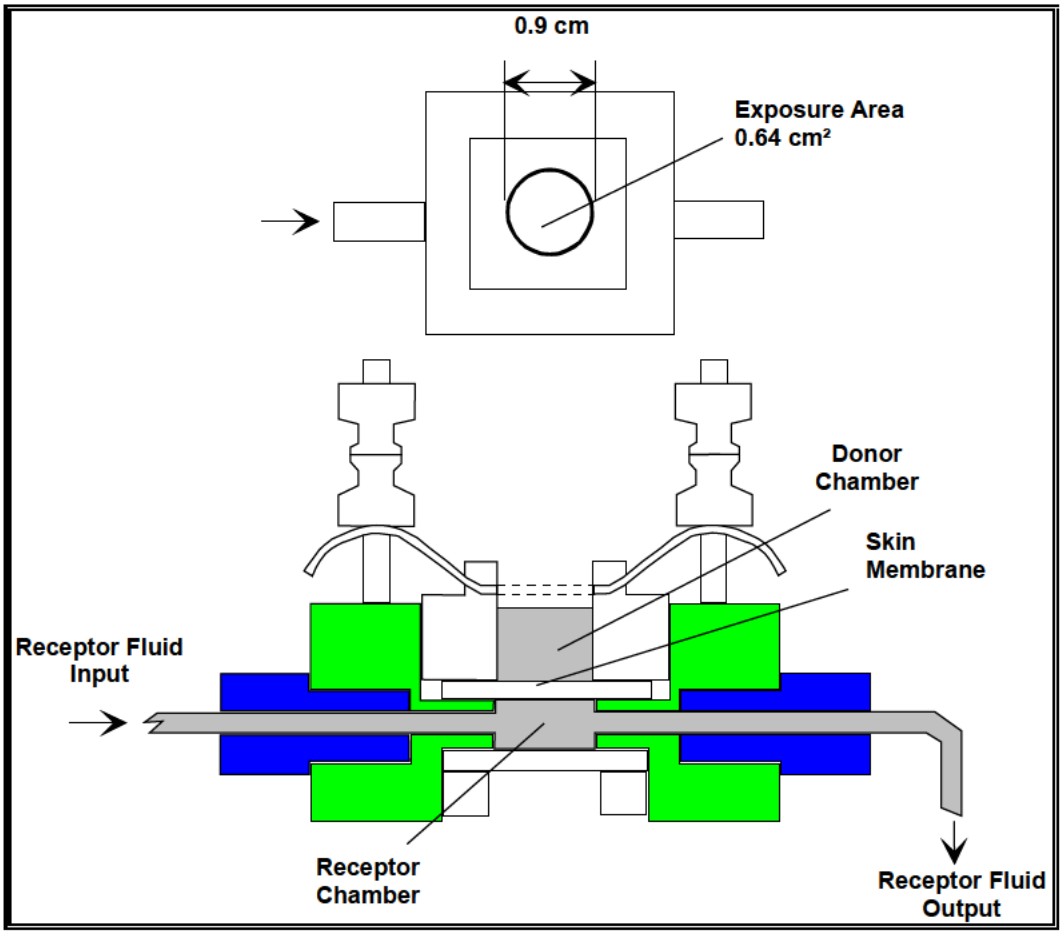
2. Study design:

The penetration of BAS 510 F through human dermatomed skin was determined using an automated flow through cell system (see Figure 7.3-1). Seven flow-through diffusion cells were placed in one aluminium manifold connected to a water bath to maintain the temperature of the skin membranes at 32 ± 1°C. Each diffusion cell consisted of a donor and receptor chamber. The area of skin membrane exposed to the donor chamber was 0.64 cm^2. The receptor chambers were connected to a multi-channel peristaltic pump. The pump speed was adjusted to about 3 mL/h. During the given time intervals, the effluent from the cell was collected directly into vials on a fraction collector.

Pieces of the skin membranes (approximately 1.8 x 1.8 cm) were cut and mounted in the diffusion cells between the donor and receptor chamber, 7 cells per formulation each. The cells were placed in the manifolds and connected to the peristaltic pump. For an equilibration period of 0.5 – 1 hour, saline (0.9% NaCl w/v) was pumped through the receptor chamber at a flow rate of about 3 mL/h.

The integrity of the skin membranes was checked by applying 50 µl tritium water (about 200000 dpm) to the skin membrane surface. The donor chamber was covered with adhesive tape (occluded conditions). The cumulative penetration was determined over 6 hours by collecting hourly fractions. The permeability coefficient (K_p) of each skin membrane was calculated for the 3 - 6 hours interval. Human membranes with $K_p > 3.0 \cdot 10^{-3}$ cm/h were excluded from the subsequent experiment.
After 6 hours, adhesive tape was removed from the donor cell chamber and the cells left open overnight with the saline flowing through the receptor chamber.

Figure 7.3-1: Schematic depiction of a flow-through diffusion cell



Those cells with skin membranes of acceptable K_p values in the integrity test were arranged on the manifold. Skin from a total of 5 donors was used and skin from 4 different donors were used per dose group. An aliquot of 6 µl of the application solution was applied to the surface of the skin membranes. The donor chambers were covered by a permeable tape (non-occluded conditions). The receptor fluid water/ethanol (9:1 v/v for the 1:150 and 1:1200 dilution and 7:3 v/v for formulation 'concentrate'), was delivered at a flow rate of about 3 mL/h. The perfusates were collected at ambient temperature in time intervals as follows:

0 - 8 hours:	1 hour intervals	(8 intervals)
8 - 24 hours:	2 hours intervals	(8 intervals)

At the end of the exposing period, i.e. 8 hours after start of exposure, the surface of the skin membrane was thoroughly rinsed (3 times / 0.5 mL) with a mild shower gel solution (1% in tap water), then the skin membrane was gently brushed with cotton swabs wetted with the mild shower gel solution (2 times). The skin membrane was finally rinsed once with 0.5 mL water and dried with one cotton swab. The skin membrane rinse and the used cotton swabs were combined to one specimen and analyzed for radioactivity (skin membrane wash 8 h). The donor chamber was covered again with a permeable tape (non-occluded conditions) until end of experiment (24 hours).

Twenty-four hours after application the perfusate sampling was terminated. The skin membrane surface was washed again as described after the exposure period. The skin membrane rinse and the used cotton swabs were combined to one specimen and analysed for radioactivity (skin membrane wash 24 h). The skin membranes were removed from the diffusion cell and consecutively stripped with adhesive tape until the stratum corneum/epidermis was removed from the skin membrane, i.e. 15 tape strips were needed. The first five stripping tapes were analysed individually (Tape Strips I-V) and the stripping tape 6 to 10 and 11 to 15 were combined to a specimen pool of five tape strips each, i.e. Tape Strips VI and VII.

Aliquots of each specimen were measured for radioactivity after solubilization with tissue solubilizer (Solvable). The skin membranes remaining after stripping were digested in tissue solubilizer (Solvable) and the radioactivity was determined by LSC.
The donor cell was finally washed with 15 ml ethanol/water (1:1) and the radioactivity in the donor cell wash was determined by LSC.

II. RESULTS AND DISCUSSION

A. STABILITY, HOMOGENEITY AND CONTENT

The stability, homogeneity and content of boscalid in the application medium were confirmed by analysis. The radiochemical purity was in the range of 96.7 to 97.7%.

B. INTEGRITY TEST OF SKIN SAMPLES

All skin samples passed the integrity test. The mean permeability coefficients for the formulation ‘concentrate’ and the 1:150 and 1:1200 aqueous dilutions were 1.77 ± 0.61, 1.63 ± 0.41 and 1.87 ± 0.38, respectively.

C. APPLIED AND RECOVERY OF DOSE

A 6µL aliquot of the application solution was applied manually to each skin membrane preparation. The doses applied and the respective concentrations of the application solution are given in Table 7.3-1.

Table 7.3-1: Applied doses

Dose group	Actual nominal dose [µg/cm²]	dpm/cell	Concentration [mg/cm³]
A1 Low dose	2.1	166145	0.23
A2 Mid dose	16.0	1242332	1.71
A3 High dose	1008	774281	107.5

The mean recoveries were 100.1, 102.3 and 104.0% for the high, mid and low dose levels, respectively (see Table 7.3-2). As group mean total recovery for all dose groups were > 95% - in agreement with the EFSA Guidance on Dermal Absorption - no adjustment of the dermal penetration values were necessary. The individual recovery for the high, mid and low dose was in the range of 94.2 – 108.2%, 96.7 – 105.9% and 96.8 – 106.2%, respectively. At the low dose, cell #3 was excluded from the calculations of means because of a too high recovery (128.9%).

In the high (formulation 'concentrate') and mid dose groups (1:150 aqueous dilution) absorption was not essentially completed. After 12 hours 64.8% and 61% of the total penetrated radioactivity, respectively, was recovered in the receptor media (see Table 7.3-3). Accordingly, only the first two tape strips were not added to the absorption estimate. In the low dose group absorption was essentially complete. After 12 hours 80% of the total penetrated radioactivity, respectively, was recovered in the receptor media (see Table 7.3-3). Accordingly, none of the tape strips were added to the absorption estimate.

Nearly the entire dose, i.e. 99.9% was recovered from the skin washing, donor chamber and tape strips (1st pool) at the high dose. In case of the cells treated with the mid and low dose, this value was 101.2 and 100.5%, respectively. The amount associated with the skin preparations was 0.08, 0.21 and 0.24% for the high, mid and low dose, respectively.

The absorbed dose, i.e. the sum of perfusates, amounted to < 0.05, 0.62 and 2.76% at the high, mid and low doses, respectively.

The total amount of boscalid recovered in the cumulative penetration after 24 hours was 0.494 µg/cm², 0.099 µg/cm² and 0.059 µg/cm² for the high, mid and low dose, respectively. Since the skin membrane area was 0.64 cm² following amounts of BAS 510 F were found after 24 h: 0.316 µg, 0.063 µg and 0.038 µg for the high, mid and low dose, respectively. When compared to the maximum solubilisation capacity in the total receptor medium volume of 72 mL (3 mL/h for 24 h) of 4896 µg and 3168 µg, the solubility in the receptor media was about 15494, 50286 and 83368-fold higher than actually needed for the high, mid and low dose, respectively. These results show that the maximum concentration of the test substance in the receptor chamber does not exceed 10% of the saturation concentration as recommended by EFSA.

Table 7.3-2: In-vitro dermal penetration of boscalid formulated as BAS 516 07 F through human skin - Recovery data

Dose group	High dose		Mid dose		Low dose	
	A3		A2 (1:150)		A1 (1:1200)

Absorption estimates used for risk assessment[c]	**0.5**		**2**		**4**	

[#] Values may not calculate exactly due to rounding of figures

[a] Grouping is different than in the report: In accordance with the EFSA Guidance on Dermal Absorption (EFSA Journal 2012;10(4):2665) the radioactivity in the second tape-strip pool (3rd to 6th tape strip) is considered potentially absorbable if less than 75% of the absorption occurred in the first half of the study (see Table 7.3-3). Finally, the skin preparation is also considered potentially absorbable.

[b] Cells with insufficient recovery (<95%) were corrected by normalization of absorption estimate to 100% recovery.

[c] In accordance with the EFSA Guidance on Dermal Absorption (EFSA Journal 2012;10(4):2665) one standard deviation was added to the mean % dermal penetration in cases where the standard deviation was ≥ 25% of the mean value. This value was then rounded to the required number of significant figures.

n.a.: not applicable

D. ABSORPTION KINETICS

The mean values of the kinetic parameters determined from the linear region of the cumulative absorbed dose curve are presented in Table 7.3-3. Within the exposure period of 8 hours very low amounts of the applied radioactivity penetrated through the human skin membrane into the receptor fluid at all dose levels, i.e. 1.66% of the low dose, 0.25% of the middle dose, and 0.02% of the high dose. For the high dose level most values measured were close to or below the Limit of Quantitation (LOQ), therefore the calculated cumulative values should be considered as worst case and the corresponding standard deviation of the mean values was high. The absorption rate was calculated to be 0.0092 and 0.0070 µg/cm²·h for the low and middle dose levels, respectively. The absorption rate for the high dose level could not be calculated since all values were below the LOQ level.

Table 7.3-3: Cumulative in-vitro dermal penetration of boscalid formulated as BAS 516 07 F through human skin - Penetration kinetics

III. CONCLUSION

The in-vitro dermal absorption of ^{14}C-BAS 510 F formulated as BAS 516 07 F through human skin is very low. The absorption estimates (sum of the absorbed dose and the remaining dose associated to the skin membrane) for boscalid were 0.23 ± 0.30% for the formulation 'concentrate' (1:2 aqueous slurry) and 1.05 ± 1.18% and 3.00 ± 0.91% of the 1:150 and 1:1200 spray dilutions, respectively. According to the EFSA Guidance on Dermal Penetration this translates into absorption estimates to be used for risk assessment of 0.5 and 4.0% for the formulations concentrate and aqueous dilutions, respectively.

Executive Summary

In an in-vitro experiment, the dermal penetration of pyraclostrobin (BAS 500 F) formulated as BAS 516 07 F through human skin was determined. For this a high dose (formulation 'concentrate' – 1:2 aqueous slurry feasible for application; nominal dose 231 µg pyraclostrobin per cm²), a mid dose (1:150 aqueous dilution; 3.8 µg pyraclostrobin per cm²) and a low dose (1:600 aqueous dilution; 0.92 µg pyraclostrobin per cm²) was applied to human dermatomed skin at a volume of 10 µL/cm². The skin membranes were set up in flow through diffusion cells. The exposure of the skin to the test material lasted 8 hours; thereafter the skin was thoroughly washed. Further penetration of the remaining test item after this wash was measured for additional 16 hours. During the experimental period the receptor fluid (water/ethanol 9:1 (v/v) for low and middle doses, and water/ethanol 8:2 (v/v) for the high dose level) was collected in hourly intervals between 0-8 hours and thereafter in 2 hours intervals until the end of the experiments.

In summary, pyraclostrobin, applied as BAS 516 07 F to human skin membrane, penetrated at a very low extent at all concentrations tested. Summing up the absorbed dose with that associated to the skin membrane, dermal absorption estimates for pyraclostrobin of 0.12 ± 0.07% for the formulation concentrate and 2.37 ± 2.78% and 1.65 ± 1.79% for the mid and low dose, respectively, are proposed. The dermal penetration estimates to be used for risk assessment were therefore calculated to be 0.2 and 5% for the formulation concentrate and the aqueous spray dilutions, respectively.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

a) ^{14}C- pyraclostrobin (tolyl-ring-U-C14)
b) BAS 516 CN F (BAS 516 07 F blank formulation without pyraclostrobin, but containing all other ingredients including bocalid)
c) unlabeled pyraclostrobin

Description:
a) Solution in toluene
b) solid, brown
c) solid / melt, red to brown

Lot/Batch #:
a) 566-5101
b) FD-131202-0018
c) COD-001236

Purity:
a) radiochemical purity: 99.9%; specific activity: 6.6 MBq/mg
b) BAS 516 07 F without pyraclostrobin
c) 99.02%

Stability of test compound:
a) The storage stability of the test substance was confirmed by HPLC analysis prior to and after termination of the study
b) no data
c) Stable: Expiry date 01.10.2015

2. Vehicle: water

3. Human skin preparations:

Source: Institute for pathology, Kantonspital Basel, Switzerland

Preparation: Dermatomed (split thickness) human skin membranes with a thickness of about 400 µm were prepared.

Storage of skin samples: Human skin samples were stored at -20°C wrapped until preparation of the split thickness skin membranes and the skin membranes were stored refrigerated (+5°C) until use.

4. Reagents:

Receptor fluid: Water/ethanol (8:2 (v/v); pyraclostrobin solubility 8.2 mg/L) for the high dose formulation
Water/ethanol (9:1 (v/v); pyraclostrobin solubility 0.88 mg/L) for the low and mid dose

Extraction media: none

Washing solution: mild shower gel solution: Nivea douche fitness, Beiersdorf, Germany (1% in tap water)

5. Preparation of the dosing solutions

High dose A3 (formulation 'concentrate', 1:2 aqueous slurry):
The formulation 'concentrate' was diluted in the lowest possible amount of water (1 part formulation + 2 parts water) feasible for dermal application with a pipette. An amount of 66.2 mg unlabeled pyraclostrobin was weighed in a flask and a volume (300 µL) of the stock solution containing 1.1 mg [^{14}C]- pyraclostrobin was added and further diluted with 4.7 mL of dichloromethane. This procedure led to a final specific activity of approximately 112 kBq/mg. An amount (932.8 mg) of BAS 516 CN F blank formulation was added. The organic solvent was removed using a rotary evaporator. The dry formulation was then suspended in 2 ml water. The final formulation was measured prior to administration by LSC and had a concentration of 24 mg [^{14}C]-pyraclostrobin/mL. The concentration of radioactivity was 2698 kBq/mL (measured). A density of 1.16 g/mL was determined in the final formulation.

Mid dose A2 (aqueous 1:150 dilution):
A volume (1950 µL) of the stock solution containing approximately 6.2 mg [^{14}C]-pyraclostrobin was placed in a flask and 93.3 mg of the blank formulation BAS 516 CN F was added. The solvent of the stock solution was removed under a stream of nitrogen. Once dried, this formulation was further diluted with 15 mL water according to a ratio of 1:150. The final formulation was measured prior to administration by LSC and had a concentration of radioactivity of 2728 kBq/mL corresponding to 0.41 mg [^{14}C]-pyraclostrobin/mL.

Low dose A1 (aqueous 1:600 dilution):
A volume of the middle dose formulation A2, i.e. 1.5 mL containing about 0.01 g BAS 516 07 F, was further diluted with 4.5 mL water to a total volume of 6 mL in order to achieve a dilution ratio of 1:600. The final formulation was measured prior to administration by LSC and had a concentration of radioactivity of 698 kBq/mL corresponding to 0.11 mg [^{14}C]- pyraclostrobin/mL.

Analyses:
Liquid scintillation counting and/or HPLC verified the homogeneity and accuracy of the test substance preparations. Taking and analyzing samples at time of application confirmed the stability of the test-substance in the preparation.

The conditions of the HPLC analysis are described in the table below:

Column:	Nucleosil 120-5 C18 (incl. pre-column RP18) 5µm, 250 mm x 4 mm (l x i.d.)
Mobile Phase: Eluent A:	Water/acetonitrile/tetrahydrofuran/acetic acid (450/500/50/1)
Flow:	1 mL/min
Gradient: 0-40 min	100 % A (isocratic)
Wavelength:	275 nm
Detection:	UV-detector (Merck-Hitachi Model L-4000), Radiomatic 500TR radioactivity flow monitor

B. TEST PERFORMANCE

1. Dates of experimental work: 06-Jan-2014 - 20-Jan-2014

2. Study design:

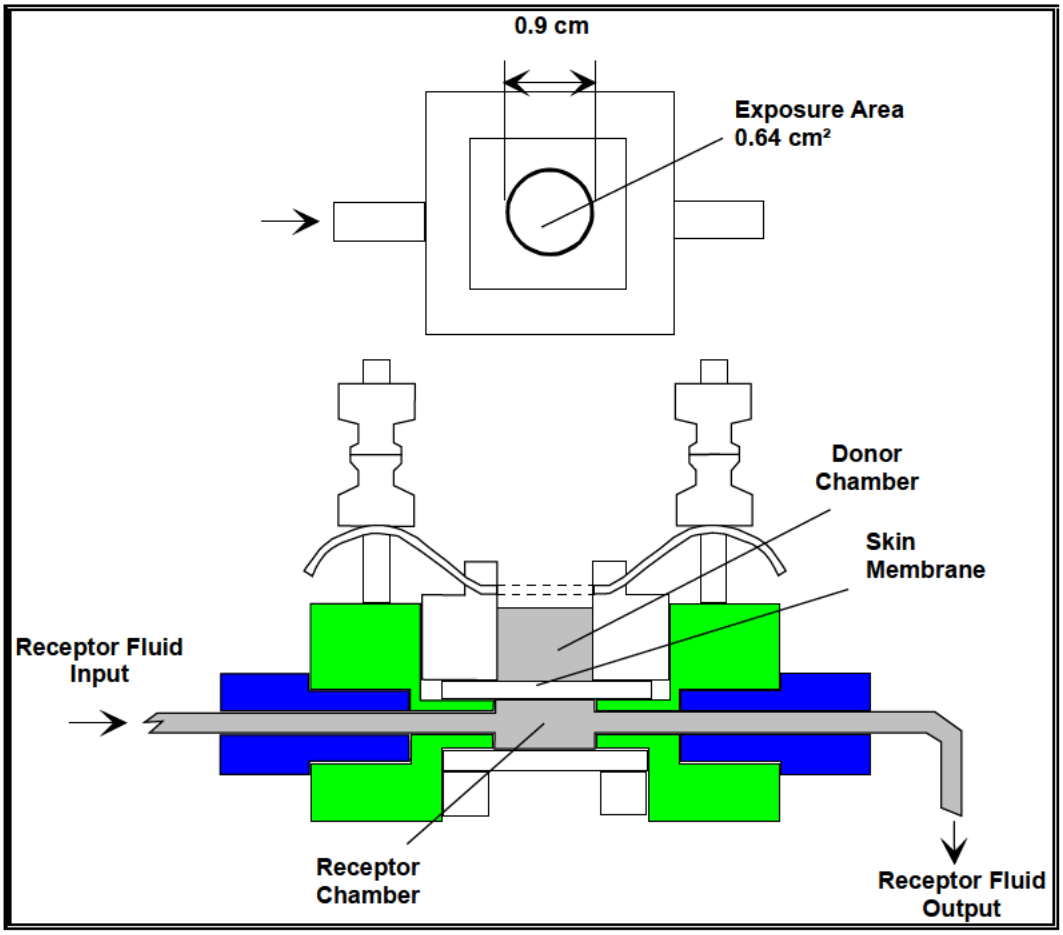
The penetration of pyraclostrobin through human dermatomed skin was determined using an automated flow through cell system (see Figure 7.3-2). Seven flow-through diffusion cells were placed in one aluminium manifold connected to a water bath to maintain the temperature of the skin membranes at 31 ± 1°C. Each diffusion cell consisted of a donor and receptor chamber. The area of skin membrane exposed to the donor chamber was 0.64 cm^2. The receptor chambers were connected to a multi-channel peristaltic pump. The pump speed was adjusted to about 3 mL/h. During the given time intervals, the effluent from the cell was collected directly into vials on a fraction collector.

Pieces of the skin membranes (approximately 1.8 x 1.8 cm) were cut and mounted in the diffusion cells between the donor and receptor chamber, 7 cells per formulation each. The cells were placed in the manifolds and connected to the peristaltic pump. For an equilibration period of 0.5 – 1 hour, saline (0.9% NaCl w/v) was pumped through the receptor chamber at a flow rate of about 3 mL/h.

The integrity of the skin membranes was checked by applying 50 µl tritium water (about 200000 dpm) to the skin membrane surface. The donor chamber was covered with adhesive tape (occluded conditions). The cumulative penetration was determined over 6 hours by collecting hourly fractions. The permeability coefficient (K_p) of each skin membrane was calculated for the 3 - 6 hours interval. Human membranes with $K_p > 3.0 \cdot 10^{-3}$ cm/h were excluded from the subsequent experiment.

After 6 hours, adhesive tape was removed from the donor cell chamber and the cells left open overnight with the saline flowing through the receptor chamber.

Figure 7.3-2: Schematic depiction of a flow-through diffusion cell



Those cells with skin membranes of acceptable K_p values in the integrity test were arranged on the manifold. Skin from a total of 5 donors was used and skin from 4 different donors were used per dose group. Aliquots of 6 µl of the application solution was applied to the surface of the skin membranes. The donor chambers were covered by a permeable tape (non-occluded conditions). The receptor fluid water/ethanol (9:1 v/v for the 1:150 and 1:600 dilutions and 8:2 v/v for the formulation 'concentrate'), was delivered at a flow rate of ca. 3 mL/h. The perfusates were collected at ambient temperature in time intervals as follows:

0 - 8 hours:	1 hour intervals	(8 intervals)
8 - 24 hours:	2 hours intervals	(8 intervals)

At the end of the exposing period, i.e. 8 hours after start of exposure, the surface of the skin membrane was thoroughly rinsed (3 times / 0.5 mL) with a mild shower gel solution (1% in tap water), then the skin membrane was gently brushed with cotton swabs wetted with the mild shower gel solution (2 times). The skin membrane was finally rinsed once with 0.5 mL water and dried with one cotton swab. The skin membrane rinse and the used cotton swabs were combined to one specimen and analyzed for radioactivity (skin membrane wash 8 h). The donor chamber was covered again with a permeable tape (non-occluded conditions) until end of experiment (24 hours).

Twenty-four hours after application the perfusate sampling was terminated. The skin membrane surface was washed again as described after the exposure period. The skin membrane rinse and the used cotton swabs were combined to one specimen and analysed for radioactivity (skin membrane wash 24 h). The skin membranes were removed from the diffusion cell and consecutively stripped with adhesive tape until the stratum corneum/epidermis was removed from the skin membrane, i.e. 15 tape strips were needed. The first five stripping tapes were analysed individually (Tape Strips I-V) and the stripping tape 6 to 10 and 11 to 15 were combined to a specimen pool of five tape strips each, i.e. Tape Strips VI and VII.

Aliquots of each specimen were measured for radioactivity after solubilization with tissue solubilizer (Solvable). The skin membranes remaining after stripping were digested in tissue solubilizer (Solvable) and the radioactivity was determined by LSC.
The donor cell was finally washed with 15 ml ethanol/water (1:1) and the radioactivity in the donor cell wash was determined by LSC.

II. RESULTS AND DISCUSSION

A. STABILITY, HOMOGENEITY AND CONTENT

The stability, homogeneity and content of pyraclostrobin in the application medium were confirmed by analysis. The radiochemical purity was in the range of 98.3 to 99.2%.

B. INTEGRITY TEST OF SKIN SAMPLES

All skin samples passed the integrity test. The mean permeability coefficients for the formulation ‘concentrate’ and the 1:150 and 1:600 aqueous dilutions were 1.84 ± 0.60, 1.95 ± 0.71 and 1.61 ± 0.41, respectively.

C. APPLIED DOSE AND RECOVERY OF DOSE

The measurement of the control doses of formulation A1 (low dose) revealed an amount of radioactivity accounting for 198211 dpm/6 µL (± 4.3%). This concentration was more than 20% lower as measured immediately after preparation of the formulation, i.e. 251152 dpm/6 µL (± 4.7%). Furthermore, the balance results of formulation A1 revealed a mean recovery of 118.25%. Both observations give strong indication for a higher dose level as compared to the measured control doses. All penetration values (% of dose) were therefore normalized to 100% recovery and the applied dose for formulation A1 was adapted regarding to the mean recovery of 118.25%. The applied doses per dose group are given in Table 7.3-4.

Table 7.3-4: Applied doses

Dose group	Actual nominal dose [µg/cm²]	dpm/cell	Concentration [mg/cm³]
A1 Low dose	0.8 0.92*	198211 234386*	0.083 0.099*
A2 Mid dose	3.8	970073	0.408
A3 High dose	231	991739	24.6

* Values adapted to 118.25% recovery

The mean recoveries were 97.9, 102.8 and 100.0% (normalized) for the high, mid and low dose levels, respectively (see Table 7.3-5). As group mean total recovery for all dose groups were > 95% - in agreement with the EFSA Guidance on Dermal Absorption - no adjustment of the dermal penetration values were necessary. The individual recovery for the high, mid and low dose was in the range of 92.4 – 101.5%, 99.1 – 107.9% and 107.8 – 133.7% (before adaption to 100%), respectively.

In all dose groups absorption was not essentially completed. After 12 hours 59.7, 54.2 or 58.2% of the total penetrated radioactivity was recovered in the receptor media at the high, mid and low dose, respectively (see Table 7.3-6). Accordingly, only the first two tape strips were not added to the absorption estimate.

Nearly the entire dose, i.e. 97.78% was recovered from the skin washing, donor chamber and the 1st and 2nd tape strip at the high dose. In case of the cells treated with the mid and low dose, the values were 100.4 and 98.35%, respectively. The amount associated with the skin preparations was 0.08, 1.69 and 0.98% for the high, mid and low dose, respectively.

The absorbed dose, i.e. the sum of perfusates, amounted to < 0.01, 0.68 and 0.67% at the high, mid and low doses, respectively. The total absorption, which corresponds to the amount recovered from skin including the 3rd to 15th tape strip and the absorbed dose, thus, sum up to 0.11, 2.37 and 1.65% for the high, mid and low dose, respectively.

The total amount of pyraclostrobin recovered in the cumulative penetration after 24 hours was 0.055 µg/cm², 0.026 µg/cm² and 0.006 µg/cm² for the high, mid and low dose, respectively. Since the skin membrane area was 0.64 cm² following amounts of pyraclostrobin were found after 24 h: 0.0352 µg, 0.0166 µg and 0.0038 µg for the high, mid and low dose, respectively. When compared to the maximum solubilisation capacity in the total receptor medium volume of 72 mL (3 mL/h for 24 h) of 590.4 µg and 63.4 µg, the solubility in the receptor media was about 16773, 3817 and 16674-fold higher than actually needed for the high, mid and low dose, respectively. These results show that the maximum concentration of the test substance in the receptor chamber does not exceed 10% of the saturation concentration as recommended by EFSA.

1 Applied dose and concentration of group A1 were adapted to 118.25% recovery
2 Recovery data for the low dose were normalized
Values may not calculate exactly due to rounding of figures
a Grouping is different than in the report: In accordance with the EFSA Guidance on Dermal Absorption (EFSA Journal 2012;10(4):2665) the radioactivity in the second tape-strip pool (3rd to 6th tape strip) is considered potentially absorbable if less than 75% of the absorption occurred in the first half of the study (see Table 7.3-6). Finally, the skin preparation is also considered potentially absorbable.
b Cells with insufficient recovery (<95%) were corrected by normalization of absorption estimate to 100% recovery.
c In accordance with the EFSA Guidance on Dermal Absorption (EFSA Journal 2012;10(4):2665) one standard deviation was added to the mean % dermal penetration in cases where the standard deviation was ≥ 25% of the mean value. This value was then rounded to the required number of significant figures.
n.a. not applicable

D. ABSORPTION KINETICS

The mean values of the kinetic parameters determined from the linear region of the cumulative absorbed dose curve are presented in Table 7.3-6. Within the exposure period of 8 hours very low amounts of the applied radioactivity penetrated through the human skin membrane into the receptor fluid at all dose levels, i.e. 0.27% of the low dose, 0.24% of the middle dose, and < 0.01% of the high dose. For all dose levels most values measured were close to or below the LOQ (limit of quantification) level, therefore the calculated cumulative values should be considered as worst case. The absorption rate was calculated to be 0.0004 and 0.0015 µg/cm²·h for the low and middle dose levels, respectively. The absorption rate for the high dose level could not be calculated since all values were below the LOQ level.

Table 7.3-6: Cumulative in-vitro dermal penetration of pyraclostrobin formulated as BAS 516 07 F through human skin - Penetration kinetics

III. CONCLUSION

The in-vitro dermal absorption of ^{14}C-pyraclostrobin formulated as BAS 516 07 F through human skin is very low. The absorption estimates (sum of the absorbed dose and the remaining dose associated to the skin membrane) for pyraclostrobin were 0.12 ± 0.07% for the formulation 'concentrate' and 2.37 ± 2.78% and 1.65 ± 1.79% of the 1:150 and 1:600 spray dilutions, respectively. The dermal penetration estimates to be used for risk assessment were therefore calculated to be 0.2% and 5% for the formulation concentrate and the aqueous spray dilutions, respectively.

Table of Contents

CP 9 FATE AND BEHAVIOUR IN THE ENVIRONMENT

BAS 516 07 F is a new representative formulation, which has not been evaluated during previous Annex I inclusion processes.

CP 9.1 Fate and behaviour in soil

No studies were performed with BAS 516 07 F. The fate and behavior in soil is sufficiently addressed by information given in M-CA 7.1.

CP 9.1.1 Rate of degradation in soil

No studies were performed with BAS 516 07 F. The rate of degradation in soil is sufficiently addressed by information given in M-CA 7.1.2.

CP 9.1.1.1 Laboratory studies

No laboratory studies were performed with BAS 516 07 F. Data for pyraclostrobin and its metabolites are covered by information given in M-CA 7.1.2.1.

CP 9.1.1.2 Field studies

No field studies were performed with BAS 516 07 F. Data for pyraclostrobin and its metabolites are covered by information given in M-CA 7.1.2.2.

CP 9.1.1.2.1 Soil dissipation studies

No soil dissipation studies were performed with BAS 516 07 F. Data for pyraclostrobin and its metabolites are covered by information given in M-CA 7.1.2.2.1.

CP 9.1.1.2.2 Soil accumulation studies

No soil accumulation studies were performed with BAS 516 07 F. Data for pyraclostrobin and its metabolites are covered by information given in M-CA 7.1.2.2.2.

CP 9.1.2 Mobility in the soil

No studies were performed with BAS 516 07 F. The mobility in soil is sufficiently addressed by information given in M-CA 7.1.4.

CP 9.1.2.1 Laboratory studies

No laboratory studies were performed with BAS 516 07 F. Data for pyraclostrobin and its metabolites are covered by information given in M-CA 7.1.4.1.

CP 9.1.2.2 Lysimeter studies

Due to the negligible leaching risk of pyraclostrobin and its metabolites, lysimeter studies are not considered necessary.

CP 9.1.2.3 Field leaching studies

Due to the negligible leaching risk of pyraclostrobin and its metabolites, field leaching studies are not considered necessary.

CP 9.1.3 Estimation of concentrations in soil

Predicted environmental concentrations in soil (PEC_S)

Report: CP 9.1.3/1

GLP: no

Executive Summary

PEC_{soil} were calculated for a fourfold application of pyraclostrobin and its aerobic soil metabolites BF 500-6 and BF 500-7 to potatoes at the nominal application rate and interval. Anaerobic soil metabolites (BF 500-3, BF 500-4 and BF 500-5) are not considered relevant for the assessment in soil, since soil organisms are not viable under these conditions. In addition, the anaerobic soil metabolites are immediately further degraded when aerobic conditions are re-established. Conservative crop interception values were selected in accordance with the guidance of the FOCUS groundwater scenarios workgroup (2012). A crop interception value of 80% was chosen for all four applications to potatoes.

A soil bulk density of 1.5 g cm^{-3} and a soil layer depth of 5 cm were assumed for the calculations.

Maximum PEC_{soil} for pyraclostrobin and its soil metabolites were calculated. No accumulation is triggered for pyraclostrobin (DT_{90} of trigger endpoints < 365 days). However, $PEC_{soil,plateau}$ and $PEC_{soil,accu}$ of the metabolites were also taken into account due to multi-year application of pyraclostrobin to potatoes.

Table 9.1.3-1: PEC_{soil} concentrations of pyraclostrobin and its soil metabolites BF 500-6 and BF 500-7 after application to potatoes

Compound	$PEC_{soil,plateau}$ [mg kg^{-1}] in 0 - 20 cm depth	$PEC_{soil,max}$ [mg kg^{-1}] in 0 - 5 cm depth	$PEC_{soil,accu}$ [mg kg^{-1}] (= $PEC_{soil,plateau}$ + $PEC_{soil,max}$) in 0 - 5 cm depth
Pyraclostrobin	-	0.015	-
BF 500-6	0.004	0.004	0.008
BF 500-7	0.002	0.003	0.005

I. MATERIAL AND METHODS

Application scenario

Calculations were carried out for a worst-case application scenario of pyraclostrobin applied to potatoes. Conservative crop interception values were chosen as recommended by the FOCUS groundwater scenarios workgroup [*FOCUS (2012): Generic guidance for Tier 1 FOCUS Ground Water Assessments, v2.1, 64 pp.*]. The aerobic soil metabolites BF 500-6 and BF 500-7 were additionally considered in the assessment. Anaerobic soil metabolites (BF 500-3, BF 500-4 and BF 500-5) are not considered relevant for the assessment in soil, since soil organisms are not viable under these conditions. In addition, the anaerobic soil metabolites are immediately further degraded when aerobic conditions are re-established.

Table 9.1.3-2 summarizes the worst-case application scenario of pyraclostrobin applied to potatoes. The minimum application interval for the respective crop was considered as conservative scenario.

Table 9.1.3-2: Worst-case application scenario of pyraclostrobin applied to potatoes considered for the PEC_{soil} calculations

Crop	Potatoes
Growth stage at first application [BBCH]	51
Application rate [g a.s. ha^{-1}]	17
No. of applications [-]	4
Interval [d]	10
Interception [%]	80 / 80 / 80 / 80
Amount reaching the soil surface [g a.s. ha^{-1}]	3.4 / 3.4 / 3.4 / 3.4
Total yearly soil load [g a.s. ha^{-1}]	13.6

Environmental fate parameters

Degradation of pyraclostrobin in soil

The aerobic soil degradation of pyraclostrobin under laboratory conditions was investigated in five studies with altogether 10 soils for 120 to 360 days at a temperature of 20°C and a soil moisture of 40 to 53% of maximum water holding capacity (MWHC) (see M-CA 7.1.2.1). The degradation kinetics of these studies were re-evaluated in a separate study [*CA 7.1.2.1.1/3, Eickler B. – BASF DocID 2014/1093424*]. An overview of the non-normalized DT_{50} values is given in the table at the end of M-CA 7.1.2.1.2.

The dissipation behavior of pyraclostrobin was investigated in two different field dissipation studies conducted in Europe between 1997 and 1999 with altogether six trials located in Germany (n=3), Spain (n=2) and Sweden (n=1) (see section 7.1.2.2). The degradation kinetics were evaluated in a separate study [*CA 7.1.2.2.1/1, Eickler B. – BASF DocID 2014/1093423*]. An overview of the DT_{50} values is given in the table at the end of study *CA 7.1.2.2.1/4*.

In addition, four terrestrial field dissipation trials were conducted in Europe between 2011 and 2012 [*CA 7.1.2.2.1/2, Bayer H., Marwitz A. - BASF DocID 2013/1348661*]. These trials were located in Denmark, Germany, Italy and France, and the plots were covered with sand to exclude surface processes according to the requirements of the EFSA guidance for evaluating laboratory and field dissipation studies to obtain $DegT_{50}$ (2010) [*EFSA (2010): Guidance for evaluating laboratory and field dissipation studies to obtain $DegT_{50}$ values of plant protection products in soil. EFSA Journal 2010;8(12):1936, 67 pp.*]. Due to the specific design of the studies, the obtained degradation half-lives in the soil matrix are not appropriate for derivation of trigger endpoints and were therefore not considered for PEC_{soil} calculation.

For the calculations of PEC_{soil} the worst-case DT_{50} from the field studies of 55.8 days (SFO) was used.

Formation and degradation of BF 500-6 and BF 500-7 in soil

Two metabolites of pyraclostrobin, BF 500-6 and BF 500-7, were found in laboratory aerobic soil metabolism and degradation studies with maximum occurrences of 12 to 31% and of 1 to 14% of the applied radioactivity (AR), respectively.

In the older pyraclostrobin field dissipation trials [*old EU Dossier, A II M 7.1.1.2.2/1, Kellner O., Zangmeister W. – BASF DocID 1999/11301; old EU Dossier, A II M 7.1.1.2.2/2, Kellner O., Zangmeister W. – BASF DocID 1999/11292*] BF 500-6 was found only rarely at a single trial site, and BF 500-7 was not detected (limit of quantification 0.01 mg kg^{-1}). In the new field dissipation study [*CA 7.1.2.2.1/2, Bayer H., Marwitz A. – DocID 2013/1348661*], the metabolites BF 500-6 and BF 500-7 were detected at maximum occurrences of 28 and 19% of applied parent amount, respectively.

For PEC_{soil} calculations, the maximum occurrences of 31% observed in the laboratory and 19% observed in the field study were used for BF 500-6 and BF 500-7, respectively.

The $DegT_{50}$ values of the metabolites calculated from laboratory studies with the parent or with the metabolites ranged from 95.9 to 971.2 days and from 81.5 to >1000 days for BF 500-6 and BF 500-7, respectively. As the $DegT_{50}$ values of BF 500-6 and BF 500-7 were close to the worst-case default value of 1000 days this default value was used for PEC_{soil} calculations.

Calculation methods

Maximum, actual and time-weighted average concentrations in soil ($PEC_{soil,max}$, $PEC_{soil,act}$, $PEC_{soil,twa}$) were calculated for the parent substance and its soil metabolites. The calculations were carried out based on the approach given in the guidance of the FOCUS workgroup on degradation kinetics [*FOCUS (2006): "Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration" Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference Sanco/10058/2005 version 1.0 of November 2011, 436 pp.*]. Additionally, the accumulation behaviour of the metabolites BF 500-6 and BF 500-7 in soil was assessed assuming application over many years.

Calculation of maximum concentrations in soil ($PEC_{soil,max}$)

The metabolites BF 500-6 and BF 500-7 are formed by a dimeric reaction, i.e. one metabolite molecule is formed out of two parent molecules. Hence, for the calculation of the respective f_{mol} the molar mass of the parent has to be considered twice (i.e. $f_{mol} = M_{met} / (2 \cdot M_{par})$). The resulting f_{mol} are 0.788 and 0.768 for the metabolites BF 500-6 and BF 500-7, respectively.

The maximum PEC values in soil ($PEC_{soil,max}$) were calculated considering the respective application rate, a soil bulk density of 1.5 g cm^{-3} and a thickness of the soil layer of 5 cm (Equation 9.1.3-1).

Equation 9.1.3-1 Calculation of the maximum PEC_{soil}

$$PEC_{soil,max,n} = \sum_{i=1}^{n} \left[\left(\frac{A_i \cdot (1 - f_{int,i})}{100 \cdot d \cdot bd_{soil}} \cdot f_{max,soil} \cdot f_{mol} \right) \cdot e^{-k \cdot (t_n - t_i)} \right]$$

with:	$PEC_{soil,max}$	maximum concentration in soil after n applications	[mg kg^{-1}]
	n	number of applications	[-]
	A_i	application rate at i-th application	[g a.s. ha^{-1}]
	$f_{int,i}$	fraction intercepted by plant cover at i-th application	[-]
	d	depth of soil layer (5 cm)	[cm]
	bd_{soil}	soil bulk density (1.5 g cm^{-3})	[g cm^{-3}]
	k	degradation rate (= ln (2) / DT_{50})	[d^{-1}]
	t_i	time of i-th application	[d]
	t_n	time of n-th (last) application	[d]
	$f_{max,soil}$	maximum observed formation in soil	[-]
	f_{mol}	correction factor for molar mass difference	[-]

Actual and time-weighted average concentrations ($PEC_{soil,act}$ and $PEC_{soil,twa}$)

The actual concentration in soil ($PEC_{soil,act}$) was calculated for different time points t = 1, 2, 4, 7, 14, 21, 28, 50 and 100 days after the occurrence of the maximum concentration according to Equation 9.1.3-2. First order kinetics (SFO) is assumed, since this type of kinetics was observed in laboratory studies and field trials.

Equation 9.1.3-2 Calculation of the actual PEC_{soil}

$$PEC_{soil,act} = PEC_{soil,max} \cdot e^{-k \cdot t}$$

with:	$PEC_{soil,act}$	actual concentration in soil	[mg kg^{-1}]
	$PEC_{soil,max}$	maximum concentration in soil	[mg kg^{-1}]
	k	degradation rate (= ln (2) / DT_{50})	[d^{-1}]
	t	time after last application	[d]

The maximum time-weighted average concentrations ($PEC_{soil,twa}$) for exposure periods of 1, 2, 4, 7, 14, 21, 28, 50 and 100 days were derived from the time series of PEC values ranging from day of the first application up to 200 DAT (days after first treatment) using a moving time-frame Excel spreadsheet. For a given exposure period t, the spreadsheet calculates the respective set of time-weighted average concentrations from the time series first (moving time-frame) and scans for the highest value in the set afterwards, see Equation 9.1.3-3.

Equation 9.1.3-3 Calculation of the time-weighted average PEC_{soil}

$$PEC_{soil,twa}(\Delta t) = \max\left[\frac{1}{m}\sum_{t=t_j}^{t_j+\Delta t} PEC_{soil}(t)\right] \qquad \text{for } j = 0,\ldots,200$$

with:	$PEC_{soil,twa}$	worst-case time-weighted average concentration in soil for time interval Δt	[mg kg^{-1}]
	PEC_{soil}	concentration in soil at time t	[mg kg^{-1}]
	t	time	[d]
	t_j	start time point for integration	[d]
	Δt	time interval	[d]
	j	running variable for time step	[-]
	m	number of time steps in time interval t	[-]

Maximum PEC_{soil} due to multi-year application ($PEC_{soil,accu}$)

The potential of accumulation in soil was assessed for metabolites BF 500-6 and BF 500-7. For this purpose, the plateau concentration in soil at steady state ($PEC_{soil,plateau}$) and the overall accumulation PEC in soil ($PEC_{soil,accu}$) after application of pyraclostrobin over many years were determined following Equation 9.1.3-4 and Equation 9.1.3-5. The ploughing depth was set to 20 cm to represent the depth of soil cultivation in arable crops. This conservative standard approach with regard to field crops covers also the mixing depth of 30 cm for vegetables which could be considered for potatoes.

Equation 9.1.3-4 Calculation of the plateau PEC_{soil}

$$PEC_{soil,plateau} = \frac{PEC_{soil,max,d}}{1 - e^{-kt}} \cdot e^{-k \cdot (t-i)}$$

with:	$PEC_{soil,plateau}$	plateau concentration at steady state	[mg kg^{-1}]
	$PEC_{soil,max,d}$	maximum soil concentration following last application considering a certain mixing depth	[mg kg^{-1}]
	t	interval between application seasons (365 days)	[d]
	i	interval between first application and last application in the cropping season	[d]
	k	degradation rate (= ln(2) / DT_{50})	[d^{-1}]

The overall accumulation PEC in soil ($PEC_{soil,accu}$) represents the highest potential soil concentration considering the multi-year accumulation load as background concentration ($PEC_{soil,plateau}$) plus the peak concentration ($PEC_{soil,max}$) after application in the top soil layer. For this purpose, the $PEC_{soil,plateau}$ and the $PEC_{soil,max}$ in the top soil layer of 5 cm were added (see Equation 9.1.3-5).

Equation 9.1.3-5 Calculation of the overall accumulation PEC_{soil}

$$PEC_{soil,accu} = PEC_{soil,plateau} + PEC_{soil,max}$$

with:	$PEC_{soil,accu}$	maximum concentration in soil for the accumulation risk assessment	[mg kg^{-1}]
	$PEC_{soil,plateau}$	concentration at steady state (plateau concentration) related to the plough layer depth of 20 cm	[mg kg^{-1}]
	$PEC_{soil,max}$	maximum concentration that gives respect to the soil load after one application period related to a soil layer depth of 5 cm	[mg kg^{-1}]

II. RESULTS AND DISCUSSION

The maximum, actual and time weighted average PEC_{soil} values of pyraclostrobin and its metabolites for a soil layer depth of 5 cm are shown in Table 9.1.3-3.

Table 9.1.3-3: PEC_{soil} of pyraclostrobin, BF 500-6 and BF 500-7 after application to potatoes

III. CONCLUSION

Initial, short-term and long-term actual and time-weighted average PEC_{soil} were calculated for pyraclostrobin, active substance in the formulated product BAS 516 07 F, and its aerobic soil metabolites BF 500-6 and BF 500-7.

The predicted concentrations in soil are appropriate to be used for the subsequent risk assessment for soil organisms.

Report:	CP 9.1.3/2 Kallweit W., 2014b Predicted environmental concentrations of BAS 510 F - Boscalid in soil, groundwater, surface water and sediment following application to potatoes in Europe 2014/1001461

Executive Summary

Predicted environmental concentrations in soil (PEC_{soil}) were calculated for a fourfold application of boscalid to potatoes at the nominal application rate and interval. A conservative crop interception value of 80% for all applications was selected in accordance with the guidance of the FOCUS groundwater scenarios workgroup. This represents a worst-case assumption regarding the soil load of boscalid.

A soil bulk density of 1.5 g cm^{-3} and a soil layer depth of 5 cm were assumed for the calculations. Additionally, the accumulation behavior of boscalid in soil was assessed with the FOCUS standard approach and with two approaches based on accumulation studies with boscalid in the field.

The maximum PEC_{soil}, the actual PEC_{soil} after 100 days, the time-weighted average PEC_{soil} for a period of 100 days and the maximum $PEC_{soil,accu}$ values are summarized in the following table.

Table 9.1.3-6: PEC_{soil} values of boscalid following application to potatoes

I. MATERIAL AND METHODS

Application scenario

Calculations were carried out for a worst-case application scenario of boscalid applied to potatoes as given in Table 9.1.3-7.

Table 9.1.3-7: Worst-case application scenario of boscalid applied to potatoes considered for the PEC_{soil} calculations

Potatoes	
Max. no. of applications [-]	4
Crop growth stage at first application [BBCH]	51
Minimum application interval [d]	10
Application rate [g a.s. ha^{-1}]	67
Interception [%]	80 / 80 / 80 / 80
Amount reaching the soil surface [g a.s. ha^{-1}]	13.4 / 13.4 / 13.4 / 13.4
Total yearly soil load [g a.s. ha^{-1}]	53.6

Environmental fate parameters

Degradation of boscalid in soil

The degradation behavior of boscalid was investigated in five field soils [*Kellner O., Keller W. – BASF DocID 2000/1000123; Bayer H., Grote C. – BASF DocID 2000/10013295*]. Standardization of the field data to 20°C [*Platz K. – BASF DocID 2000/1017044; Platz K. – BASF DocID 2012/1288168*] was only possible for three out of the five studies due to scattering of data and a high uncertainty of degradation rates estimated from the Spanish sites Huelva and Sevilla. The standardized worst-case field half-life (Q_{10} = 2.2) from the three studies was 212 days and the respective geometric mean (Q_{10} = 2.2) was 130 days.

PEC_{soil} were calculated using the worst-case field half-life at 15°C, which was calculated from the respective value of 212 days at 20°C with the Arrhenius Equation. The Q_{10} value was set to 2.58 instead of 2.2 following the opinion of EFSA [*EFSA (2007) "Opinion on a request from EFSA related to the default Q_{10} value used to describe the temperature effect on transformation rates of pesticides in soil. Scientific Opinion of the Panel on Plant Protection Products and their Residues (PPR-Panel). Question No EFSA-Q-2007-048. The EFSA Journal (2007) 622, 1-32*]. The combination of low Q_{10} of 2.2 for normalization of field DT_{50} to 20°C [*BASF DocID 2000/1017044; BASF DocID 2012/1288168*] and high Q_{10} of 2.58 for recalculating DT_{50} to 15°C leads to worse-case degradation conditions for temperatures below 20°C. PEC_{soil} calculations can therefore be considered conservative regarding the use of the Q_{10} value.

The resulting worst-case field DT_{50} of 340.5 days was used for calculating maximum, actual and time-weighted average PEC_{soil}.

Calculation methods

Calculation of maximum concentrations in soil ($PEC_{soil,max}$)

The maximum PEC values in soil ($PEC_{soil,max}$) were calculated considering the respective application rate, a soil bulk density of 1.5 g cm^{-3} and a thickness of the soil layer of 5 cm (Equation 9.1.3-6). This formula has been derived from Equation 9.1.3-1 based on the constant dosage and interception rate of boscalid for the application to potatoes.

Equation 9.1.3-6 Calculation of the maximum PEC_{soil}

$$PEC_{soil,max} = \frac{A \cdot (1 - f_{int})}{100 \cdot d \cdot bd} \cdot \frac{(1 - e^{-n \cdot k \cdot i})}{(1 - e^{-k \cdot i})}$$

with:	$PEC_{soil,max}$	global maximum concentration in soil after multiple applications	[mg kg^{-1}]
	A	application rate of the active substance boscalid	[g a.s. ha^{-1}]
	f_{int}	fraction intercepted by the plant cover	[-]
	d	depth of soil layer (5 cm)	[cm]
	bd	soil bulk density (1.5 g cm^{-3})	[g cm^{-3}]
	k	degradation rate (= ln(2) / DT_{50})	[d^{-1}]
	i	minimum interval between applications	[d]
	n	maximum number of applications	[-]

Actual and time-weighted average concentrations ($PEC_{soil,act}$ and $PEC_{soil,twa}$)

Calculations of actual and time-weighted average concentrations in soil ($PEC_{soil,act}$, $PEC_{soil,twa}$) were calculated for boscalid using the same methods as for pyraclostrobin [described in *CP 9.1.3/1*].

Maximum PEC_{soil} due to multi-year application ($PEC_{soil,accu}$)

The accumulation behavior of the substance boscalid in soil was assessed with the FOCUS standard approach and with two approaches based on accumulation studies with boscalid in the field.

$PEC_{soil,accu}$ based on standard approach according to FOCUS

The plateau concentration in soil at steady state ($PEC_{soil,plateau}$) and the overall accumulation PEC in soil ($PEC_{soil,accu}$) after application over many years were determined for boscalid using the same equations as for pyraclostrobin [described in *CP 9.1.3/1*]. The maximum concentration in soil is derived using Equation 9.1.3-5 considering a 30 cm mixing depth for potatoes.

$PEC_{soil,accu}$ based on accumulation behavior observed in field studies

$PEC_{soil,accu}$ was calculated in two ways that consider the accumulation behavior of boscalid as observed during accumulation studies in grapevine [*Kellner et al. – BASF DocID 2004/1003851*] and vegetable crops [*Penning et al. – BASF DocID 2009/1070939*]. The first approach was based on measured total boscalid residues in soil. The residues were used to derive an accumulation factor, which was then applied to calculate $PEC_{soil,accu}$ in the soil layer of interest (top 5 cm) from the yearly application rate of the use under assessment. The second approach was based on measured concentrations in the top 10 cm soil layer of the accumulation studies that are used to predict concentrations in the soil layer of interest (top 5 cm).

The maximum $PEC_{soil,accu}$ values obtained with these two approaches are considered a conservative and adequate estimate to be used in soil risk assessment.

Approach 1

$PEC_{soil,accu}$ was calculated as the sum of the maximum PEC_{soil} resulting from the annual application pattern ($PEC_{soil,max}$) and the plateau PEC_{soil} ($PEC_{soil,plateau}$) reflecting the background level after multi-year use before the beginning of the annual application period (Equation 9.1.3-7).

Equation 9.1.3-7: Calculation of $PEC_{soil,accu}$ (approach 1)

$$PEC_{soil,accu} = PEC_{soil,max} + PEC_{soil,plateau}$$

with:	$PEC_{soil,accu}$	PEC_{soil} after multi-year application at the end of the annual application period in a soil layer of 5 cm	[mg kg^{-1}]
	$PEC_{soil,max}$	maximum PEC_{soil} due to single-year application in a soil layer of 5 cm	[mg kg^{-1}]
	$PEC_{soil,plateau}$	PEC_{soil} after multi-year application before the beginning of the annual application period	[mg kg^{-1}]

The $PEC_{soil,max}$ for the use under assessment was calculated with the approach described in the relevant section. The respective $PEC_{soil,plateau}$ was calculated considering the accumulation factor (f_{accu}) that was concluded from the ratio of modeled residue plateau to yearly application rate (see Table 9.1.3-8). $PEC_{soil,plateau}$ is the yearly application rate in the GAP multiplied by f_{accu} and then related to a typical soil cultivation layer of defined depth and bulk density, where the residues are distributed evenly due to ploughing (Equation 9.1.3-8). The depth of the soil cultivation layer is 0.1 m for permanent cultures and 0.3 m for vegetables considered for potatoes.

Equation 9.1.3-8: Calculation of $PEC_{soil,plateau}$ (approach 1)

$$PEC_{soil,plateau} = \frac{f_{accu} \cdot A_{GAP} \cdot 1000}{depth \cdot 10000 \cdot bd}$$

with:	$PEC_{soil,plateau}$	PEC_{soil} after multi-year application before the beginning of the annual application period	[mg kg^{-1}]
	f_{accu}	accumulation factor concluded from relevant accumulation study (see Table 9.1.3-8)	[-]
	A_{GAP}	Yearly application rate of use under assessment	[g ha^{-1}]
	depth	depth of soil cultivation layer	[m]
	bd	bulk density of soil cultivation layer (1500 kg m^{-3})	[kg m^{-3}]

Table 9.1.3-8: Accumulated fraction (f_{accu}) of boscalid from field studies in grapevine and vegetables

Accumulation study	Modeled minimum residue plateau [kg ha^{-1}]	Yearly application rate [kg ha^{-1}]	Ratio of residue plateau to application rate (f_{accu}) [-]
Grapevine	2.0	2.10	0.95
Vegetables	1.5	1.27[a]	1.18

[a] Average rate of triennial crop rotation scheme (1st year: 2.1 kg ha^{-1}, 2nd year: 1.7 kg ha^{-1}, 3rd year: 0 kg ha^{-1})

In the present study, $PEC_{soil,accu}$ (approach 1) was calculated using the results of the vegetables accumulation study for potatoes.

Approach 2

$PEC_{soil,accu}$ was calculated based on the maximum PEC_{soil} in the soil layer of interest (top 5 cm) from the relevant accumulation study ($PEC_{soil,study,max}$). The approach is considered to be an advanced version of the estimation approach proposed by the Rapporteur Member State in the 2nd addendum to the Draft Assessment Report.

The $PEC_{soil,accu}$ for the use under assessment was calculated by rescaling the $PEC_{soil,study,max}$ from the relevant accumulation study with the ratio of the yearly application rate in the GAP and the study as described in Equation 9.1.3-9.

Equation 9.1.3-9: Calculation of $PEC_{soil,accu}$ (approach 2)

$$PEC_{soil,accu} = PEC_{soil,study,max} \cdot \frac{A_{GAP}}{A_{study}}$$

with:	$PEC_{soil,accu}$	PEC_{soil} after multi-year application at the end of the annual application period	[mg kg^{-1}]
	$PEC_{soil,study,max}$	maximum PEC_{soil} in soil layer of interest (top 5 cm) in relevant accumulation study at the end of the annual application period	[mg kg^{-1}]
	A_{GAP}	Yearly application rate of use under assessment	[g ha^{-1}]
	A_{study}	Yearly application rate of relevant accumulation study related to $PEC_{soil,study,max}$	[g ha^{-1}]

$PEC_{soil,study,max}$ for the top 5 cm was not measured in the accumulation studies, but can be calculated from the reported concentrations in the upper 10 cm soil layer. Table 9.1.3-9 summarizes $PEC_{soil,study,max}$ values of the two accumulation studies that were calculated for different soil layer depths.

Table 9.1.3-9: Maximum PEC_{soil} of boscalid in two accumulation studies after the annual application period with regard to different top soil layer depths

Accumulation study	A_{study} [g ha^{-1}]	$PEC_{soil,study,max}$ of boscalid [mg kg^{-1}]		
		1 cm	2.5 cm	5 cm
Grapevine	2100	7.024	3.076	2.094
Vegetables	1700[a]	7.214	2.954	1.553

[a] $PEC_{soil,study,max}$ values resulted from those years in the crop rotation scheme of the study, when 1700 g ha^{-1} boscalid were applied

In the present study, $PEC_{soil,accu}$ (approach 2) was calculated using the results of the vegetables accumulation study for potatoes.

II. RESULTS AND DISCUSSION

Maximum, actual and time-weighted average PEC_{soil}

The PEC_{soil} values of boscalid after spray application to potatoes are shown in Table 9.1.3-10.

Table 9.1.3-10: PEC_{soil} values of boscalid following application to potatoes

[a] Time: days after maximum concentration ($PEC_{soil,act}$) or time interval ($PEC_{soil,twa}$)

Maximum PEC_{soil} due to multi-year application ($PEC_{soil,accu}$)

$PEC_{soil,accu}$ calculated with the standard approach according to FOCUS is given in Table 9.1.3-11.

Table 9.1.3-11: $PEC_{soil,plateau}$ and $PEC_{soil,accu}$ of boscalid following multi-year application to potatoes (standard approach)

Crop	Cultivation soil depth [cm]	$PEC_{soil,plateau}$ [mg kg^{-1}]	$PEC_{soil,max}$ in 5 cm depth [mg kg^{-1}]	$PEC_{soil,accu}$ (= $PEC_{soil,plateau}$ + $PEC_{soil,max}$) in 5 cm depth [mg kg^{-1}]
Potatoes	30	0.011	0.069	0.080

$PEC_{soil,accu}$ in a soil layer of 0 - 5 cm calculated with approach 1 together with the relevant values of $PEC_{soil,plateau}$ and $PEC_{soil,max}$ are given in Table 9.1.3-12.

Table 9.1.3-12: $PEC_{soil,accu}$ of boscalid following multi-year application to potatoes (approach 1)

Crop	Cultivation soil depth [cm]	$PEC_{soil,plateau}$ [mg kg^{-1}]	$PEC_{soil,max}$ in 5 cm depth [mg kg^{-1}]	$PEC_{soil,accu}$ (= $PEC_{soil,plateau}$ + $PEC_{soil,max}$) in 5 cm depth [mg kg^{-1}]
Potatoes	30	0.070	0.069	0.140[a]

[a] exact value from Excel data with higher numerical precision

$PEC_{soil,accu}$ in a soil layer of 0 - 5 cm calculated with approach 2 together with the relevant $PEC_{soil,study,max}$ and the ratio of total yearly application rates in the GAP and the study are given in Table 9.1.3-13.

Table 9.1.3-13: $PEC_{soil,accu}$ of boscalid following multi-year application to potatoes (approach 2)

Crop	$PEC_{soil,study,max}$ in 5 cm depth [mg kg^{-1}]	A_{GAP}/A_{Study} [-]	$PEC_{soil,accu}$ ($PEC_{soil,study,max}$ x A_{GAP}/A_{Study}) in 5 cm depth [mg kg^{-1}]
Potatoes	1.553	0.158	0.245[a]

[a] exact value from Excel data with higher numerical precision

A comparison of the $PEC_{soil,accu}$ values obtained with the FOCUS standard approach and the two approaches based on field accumulation studies shows that calculation with approach 2 results in the highest $PEC_{soil,accu}$ values.

III. CONCLUSION

Initial, short-term and long-term actual and time-weighted average PEC_{soil} were calculated for boscalid, active substance in the formulated product BAS 516 07 F.

The predicted concentrations in soil are appropriate to be used for the subsequent risk assessment for soil organisms.

CP 9.2 Fate and behaviour in water and sediment

CP 9.2.1 Aerobic mineralisation in surface water

No studies were performed with BAS 516 07 F. The aerobic mineralisation in surface water is sufficiently addressed by information given in M-CA 7.2.2.2.

CP 9.2.2 Water/sediment study

No water/sediment studies were performed with BAS 516 07 F. Data for pyraclostrobin and its metabolites are covered by information given in M-CA 7.2.2.3.

CP 9.2.3 Irradiated water/sediment study

No irradiated water/sediment studies were performed with BAS 516 07 F. Data for pyraclostrobin and its metabolites are covered by information given in M-CA 7.2.2.4.

CP 9.2.4 Estimation of concentrations in groundwater

CP 9.2.4.1 Calculation of concentrations in groundwater

Predicted environmental concentrations in groundwater (PEC_{GW})

Report: CP 9.2.4/1
Kallweit W., 2014a
Predicted environmental concentrations of BAS 500 F - Pyraclostrobin and its metabolites in soil, groundwater, surface water and sediment following application to cereals, maize and potatoes
2014/1000685

Executive Summary

Predicted environmental concentrations in groundwater (PEC_{gw}) of pyraclostrobin and its aerobic soil metabolites BF 500-6 and BF 500-7, as well as its anaerobic soil metabolites BF 500-3, BF 500-4 and BF 500-5 following application of BAS 516 07 F to potatoes were calculated in accordance with the guidance of the FOCUS groundwater scenarios work group (2000, 2009, 2012). Although these anaerobic soil metabolites are degraded again quickly under aerobic conditions, they were considered (according to Regulation 1107/2009) for an assessment in groundwater.

Tier 1 PEC_{gw} of pyraclostrobin and its soil metabolites were calculated with the models FOCUS-PEARL 4.4.4 and FOCUS-PELMO 5.5.3 for all available FOCUS scenarios of potatoes (fourfold application of 17 g a.s. ha^{-1}, BBCH 51, 10 day interval, 80% interception for all applications) with an annual application pattern (continuous cropping over a period of 26 years).

The maximum PEC_{gw} for pyraclostrobin and its soil metabolites were < 0.001 µg L^{-1} and thus clearly below the 0.1 µg L^{-1} threshold value.

I. MATERIAL AND METHODS

The leaching assessment for pyraclostrobin and its metabolites was conducted at Tier 1 of the tiered assessment scheme proposed by the FOCUS groundwater higher tier working group. The aerobic soil metabolites BF 500-6 and BF 500-7 were considered in the assessment. In addition the anaerobic soil metabolites BF 500-3, BF 500-4 and BF 500-5 were considered even though they are degraded again quickly under aerobic conditions.

The simulations were carried out using FOCUS-PEARL 4.4.4 and FOCUS-PELMO 5.5.3 in combination with the FOCUS standard scenarios.

Applied procedures methods and scenarios follow the recommendations of the following guidelines:

- *FOCUS (2009): Assessing Potential for Movement of Active Substances and their Metabolites to Groundwater in the EU Final Report of the Groundwater Workgroup of FOCUS, amending FOCUS (2000), EC Document Reference Sanco/13144/2010, 604 pp.*
- *FOCUS (2000): "FOCUS groundwater scenarios in the EU plant protection product review process" Report of the FOCUS Groundwater Scenarios Workgroup, EC Document Reference Sanco/321/2000, 197 pp.*
- *FOCUS (2012): Generic guidance for Tier 1 FOCUS Ground Water Assessments, v2.1, 64 pp.*].

Application scenarios

PEC_{gw} values of pyraclostrobin were calculated for the same worst-case application scenario as for the PEC_{soil} assessment (M-CP 9.1.3). PEC_{gw} calculations were performed for all FOCUS groundwater scenarios that are parameterized for potatoes.

Application dates were selected following FOCUS recommendations. The worst-case application scenario and application dates for all relevant FOCUS scenarios are shown in Table 9.2.4.1-1.

Table 9.2.4.1-1: Worst-case application scenario for PEC_{gw} calculations of pyraclostrobin applied to potatoes

Crop	Potatoes			
Growth stage at first application [BBCH]	51			
No. of applications [-]	4			
Interval [days]	10			
Application rate [g a.s. ha^{-1}]	17

Environmental fate parameters

Degradation parameters of the parent

A total of 18 degradation endpoints for environmental fate modeling from different laboratory and field trials were reported (see M-CP 9.1.3) in four studies [*CA 7.1.2.1.1/3, Eickler B. – BASF DocID 2014/1093424; CA 7.1.2.1.1/1, Hassink J., Kuhnke G. – BASF DocID 2013/1337273; CA 7.1.2.2.1/1, Eickler B. – BASF DocID 2014/1093423; CA 7.1.2.2.1/4, Pape L. – BASF DocID 2014/1105764*]. As the endpoint in *Hassink J., Kuhnke G.* [*BASF DocID 2013/1337273*] was calculated for actual study conditions, it was further normalized to reference conditions (20°C, pF2). In all other studies normalized degradation endpoints were reported. In study *CA 7.1.2.2.1/1* [*Eickler B. – BASF DocID 2014/1093423*] the two Spanish field trials (ALO/01/98 and ALO/02/98) were considered to be not appropriate for derivation of modeling endpoints as the extreme climatic conditions during the trials were not representative for the EU.

An overview of individual DT_{50} values considered to select endpoints for PEC_{gw} calculations is given in Table 7.1.2.1.1-26 and/or Table 7.1.2.1.1-27 (laboratory studies) and in Table 7.1.2.2.1-24 (field studies).

For derivation of an appropriate degradation endpoint for PEC_{gw} modeling the EFSA endpoint selector was used [*EFSA $DegT_{50}$ and Sorption Endpoint Selector. Download from: http://www.efsa.europa.eu/en/130725a/docs/130725aax1.xls, date of access: 15.04.2014*]. Accordingly, the bias-corrected geometric mean $DegT_{50}$ value of 28.3 days based on the results of the field studies was used as modeling input.

Sorption of pyraclostrobin to soil

The sorption behavior of pyraclostrobin was investigated in six soils by batch-equilibrium experiments [*old EU Dossier, A II M 7.1.2/1, Ziegler G. - BASF DocID 1998/10650*]. An overview of individual $K_{f,oc}$ and 1/n values considered to select endpoints for PEC_{gw} calculations is given in M-CA 7.1.3.1.1. For the PEC_{gw} calculations of pyraclostrobin, an arithmetic mean $K_{f,oc}$ of 9304 mL g^{-1} (equivalent to a $K_{f,om}$ value of 5397 mL g^{-1}) and an arithmetic mean 1/n of 0.95 were used.

Formation and degradation of the metabolites in soil

BF 500-3
In laboratory experiments under aerobic conditions and in field dissipation trials with pyraclostrobin, the metabolite BF 500-3 was either not detected or formed in amounts far below 5% of the amount of applied parent (see M-CA 7.1.1). Under anaerobic conditions it was formed in high amounts by a very fast de-methoxylation of pyraclostrobin (see M-CA 7.1.1). This reaction is the first step also in the aerobic soil degradation process. However, further reaction to successive metabolites and bound residues is too fast to detect this short-lived transient intermediate.

To account for the rapid formation and degradation of BF 500-3 under aerobic conditions, a conservative default DT_{50} of 1 day and a formation fraction of 1 from pyraclostrobin were considered for PEC_{gw} calculations.

BF 500-4
The metabolite BF 500-4 was never found in soil under aerobic conditions. Under anaerobic conditions it was observed with up to 11.1% TAR *[old EU Dossier, A II M 7.1.1.2.1/5, Kellner O. - BASF DocID 1999/10079; old EU Dossier, A II M 7.1.1.2.1/6, Kellner O. - BASF DocID 1999/11103*]. The aerobic degradation of BF 500-4 under laboratory conditions was investigated in three soils [*CA 7.1.2.1.2/3, Ebert D., Dalkmann P. – BASF DocID 2013/1294779*]. The corresponding DT_{50} values were normalized to reference conditions (20°C, pF2), see Table 7.1.2.1.2-24 at the end of study *CA 7.1.2.1.2/3*. The geometric mean of the normalized DT_{50} values of 2.82 days was used as input parameter for BF 500-4 for PEC_{gw} calculations.

In the kinetic re-evaluation of the anaerobic soil degradation studies of pyraclostrobin formation fractions of BF 500-4 from BF 500-3 of 1 and 0.692 were reported [*CA 7.1.2.1.3/1, Pape L. – BASF DocID 2014/1000701*]. Therefore, a formation fraction of 1 was used as worst-case assumption for PEC_{gw} calculations.

BF 500-5
Under aerobic conditions, the metabolite BF 500-5 occurred only in one soil with 2.8% TAR. Under anaerobic conditions it was found with up to 7.7% TAR [*Kellner O. - BASF DocID 1999/11103*]. The aerobic degradation of BF 500-5 under laboratory conditions was investigated in three soils [*CA 7.1.2.1.2/4, Schoof S., Possienke M. – BASF DocID 2013/1294780*]. The corresponding DT_{50} were normalized to reference conditions (20°C, pF2), see Table 7.1.2.1.2-34 at the end of study *CA 7.1.2.1.2/4*. As all DT_{50} values were below 1 day a default DT_{50} value of 1 day was used for PEC_{gw} calculations as worst-case assumption.

In the kinetic re-evaluation of the anaerobic soil degradation studies of pyraclostrobin a formation fraction of BF 500-5 from BF 500-4 of 0.409 was reported and was considered for PEC_{gw} calculations [*CA 7.1.2.1.3/1, Pape L. – BASF DocID 2014/1000701*].

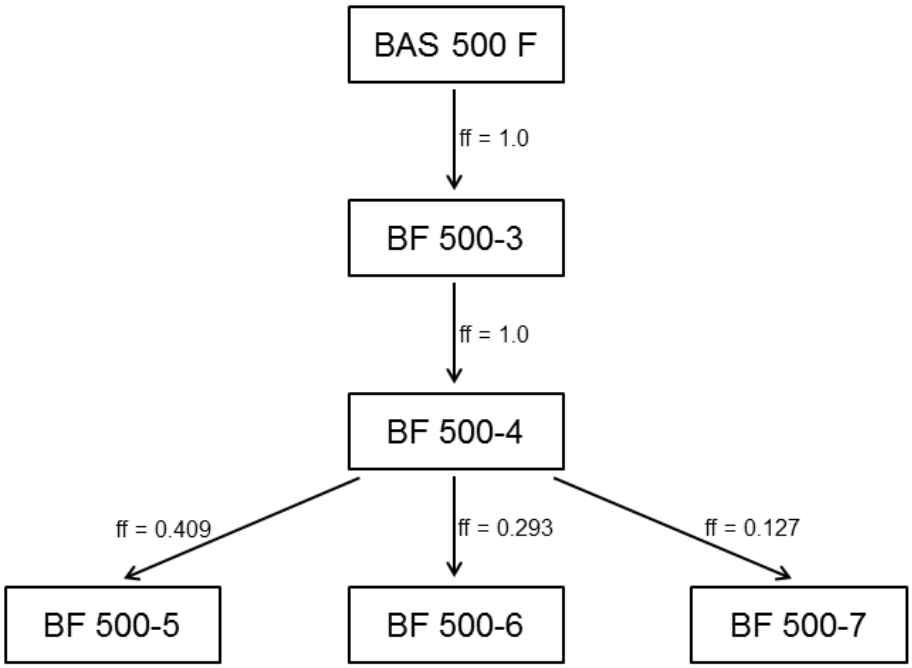
BF 500-6 and BF 500-7
The metabolites BF 500-6 and BF 500-7 were found in aerobic soil degradation studies as well as in field dissipation studies with pyraclostrobin. Degradation endpoints for modeling are available from kinetic evaluations of aerobic laboratory degradation studies with pyraclostrobin and aerobic laboratory degradation studies with the metabolites (see table at the end of study *CA 7.1.2.1.2/4*) as well as with the new field dissipation study with pyraclostrobin (see table at the end of study *CA 7.1.2.2.1/4*) [*Hassink J., Kuhnke G. – BASF DocID 2013/1337273; Eickler B. – BASF DocID 2014/1093424; Pape L. – BASF DocID 2014/1105764; CA 7.1.2.1.2/1, Tornisielo A., Sacchi R.R. – BASF DocID 2011/1142307; CA 7.1.2.1.2/2, Tornisielo A., Sacchi R.R. – BASF DocID 2011/1142308*].

Where necessary, the reported DT_{50} values were normalized to reference conditions (20°C, pF2), see tables at the end of study *CA 7.1.2.1.2/1* (BF 500-6) and at the end of study *CA 7.1.2.1.2/2* (BF 500-7). For derivation of appropriate degradation endpoints for PEC_{gw} modeling the EFSA endpoint selector was used. Accordingly, the bias-corrected geometric mean of pooled laboratory and field DT_{50} values of 321.0 days for BF 500-6 and 312.0 days for BF 500-7 was used for the PEC_{gw} calculations.

Formation fractions of BF 500-6 and BF 500-7 were reported in the kinetic evaluations of laboratory and field studies with pyraclostrobin either directly from the parent or from BF 500-3 (see table at the end of study *CA 7.1.2.1.2/4* and table at the end of study *CA 7.1.2.2.1/4*).

In the aerobic degradation study with BF 500-4 the metabolites occurred as degradates of BF 500-4 [*CA 7.1.2.1.2/3, Ebert D., Dalkmann P. – BASF DocID 2013/1294779*]. Consequently, this pathway was also assumed for PEC_{gw} calculations. For the preceeding metabolites BF 500-3 and 500-4 formation fractions of 1 were considered, respectively (see above). Thus, for BF 500-6 and BF 500-7 the reported formation fractions from pyraclostrobin or from BF 500-3 can be directly considered. As such the arithmetic mean values derived from pooled field and laboratory data (following the EFSA approach for degradation rates) of 0.293 (BF 500-6) and 0.127 (BF 500-7) were used.

The complete transformation scheme considered for the PEC_{gw} calculations is shown in Figure 9.2.4.1-1.



ff formation fraction

Figure 9.2.4.1-1: Transformation scheme of pyraclostrobin in soil used for PEC_{gw} simulations

Sorption of the metabolites to soil

An overview of individual K_{oc} values for the metabolites of pyraclostrobin considered to select endpoints for PEC_{gw} calculations is given in M-CA 7.1.3.1.2 and summarized in the tables below. For BF 500-3 and BF 500-4 arithmetic mean K_{oc} of 9315 mL g^{-1} (n = 6) and 9819 mL g^{-1} (n = 5) as well as a worst-case default 1/n of 1 were used for PEC_{gw} calculations, respectively. For BF 500-5, an arithmetic mean $K_{f,oc}$ of 705 mL g^{-1} (n = 5) and the corresponding arithmetic mean 1/n of 0.85 were considered, while for BF 500-6 and BF 500-7, the median of 11 K_{oc} values of 107301 mL g^{-1} and 149900 mL g^{-1} and a default 1/n of 1 were used.

Input parameters for pyraclostrobin and its metabolites

A summary of the substance parameters used for the Tier 1 PEC_{gw} calculations is given in Table 9.2.4.1-2 to Table 9.2.4.1-7.

II. RESULTS AND DISCUSSION

The 80th percentiles of the predicted annual leachate concentrations in groundwater after application to potatoes were below 0.001 µg L^{-1} for pyraclostrobin and its metabolites BF 500-3, BF 500-4, BF 500-5, BF 500-6 and BF 500-7 for all scenarios. Consequently, the leaching of unacceptable amounts of pyraclostrobin after application to potatoes is highly unlikely.

III. CONCLUSION

Predicted environmental concentrations in groundwater (PEC_{gw}) of pyraclostrobin and its metabolite BF 500-3, BF 500-4, BF 500-5, BF 500-6 and BF 500-7 were calculated following application of BAS 516 07 F to potatoes. A tiered approach was considered to address the risk for groundwater following the guidelines of FOCUS groundwater. No risk was identified for the parent compound, nor for its soil metabolites at Tier 1 (PEC_{gw} < 0.001 µg L^{-1}).

Report: CP 9.2.4/2
Kallweit W., 2014b
Predicted environmental concentrations of BAS 510 F - Boscalid in soil, groundwater, surface water and sediment following application to potatoes in Europe
2014/1001461

Guidelines: SANCO/321/2000, FOCUS Groundwater (2012) Generic guidance for FOCUS groundwater scenarios v 2.1, FOCUS Kinetics (2006) SANCO/10058/2005 version 1.0 of Nov. 2011, SANCO/4802/2001 rev. 2 (FOCUS surface water scenarios) May 2003, FOCUS Surface Water (2012) SANCO/4802/2001 v1.1, FOCUS groundwater (2009): SANCO/13144/2009

GLP: no

Executive Summary

PEC_{gw} values were calculated according to the guidance of the FOCUS groundwater scenarios workgroup using the models FOCUS-PEARL 4.4.4 and FOCUS-PELMO 5.5.3. All scenarios available for the $FOCUS_{gw}$ crop potatoes were considered for the leaching assessment. Continuous cropping over a period of 26 years was assumed and annual application of the active substance was taken into account. Calculations were based on the worst-case scenario considered for calculating PEC_{soil}.

The 80th percentiles of the predicted annual average leachate concentrations of boscalid were below 0.001 µg L^{-1} in all tested scenarios. Therefore, the leaching of unacceptable amounts of boscalid is highly unlikely.

I. MATERIAL AND METHODS

The leaching assessment for boscalid was conducted at Tier 1 of the tiered assessment scheme proposed by the FOCUS groundwater higher tier working group. The simulations were carried out using FOCUS-PEARL 4.4.4 and FOCUS-PELMO 5.5.3 in combination with the FOCUS standard scenarios.

Application scenario

PEC_{gw} values of boscalid were calculated for the same worst-case application scenario as for the PEC_{soil} assessment (M-CP 9.1.3). All FOCUS groundwater scenarios that are parameterized for the $FOCUS_{gw}$ crop potatoes were considered.

Application dates were selected following FOCUS recommendations and are equal to the ones for pyraclostrobin. A summary of the application scenario considered for the PEC_{gw} calculations is given in Table 9.2.4.1-8.

Table 9.2.4.1-8: Worst-case application scenario of boscalid applied to potatoes considered for the PEC_{gw} calculations

Crop	Potatoes
$FOCUS_{gw}$ crop	Potatoes
Max. no. of applications [-]	4
Crop growth stage at first application [BBCH]	51
Minimum application interval [d]	10
Application rate[g a.s. ha^{-1}]	67
Interception [%]	80 / 80 / 80 / 80
Amount reaching the soil surface [g a.s. ha^{-1}]	13.4 / 13.4 / 13.4 / 13.4
Total yearly soil load [g a.s. ha^{-1}]	53.6

Environmental fate parameters

Degradation of boscalid in soil

The degradation behavior of boscalid in soil was described using the geometric mean DT_{50} of 130.0 days that was calculated from field DT_{50} normalized to 20°C (Q_{10} = 2.2) (see M-CP 9.3.1 for details). PEC_{gw} were calculated using a Q_{10} value of 2.58 as recommended by EFSA [*EFSA (2007) "Opinion on a request from EFSA related to the default Q_{10} value used to describe the temperature effect on transformation rates of pesticides in soil. Scientific Opinion of the Panel on Plant Protection Products and their Residues (PPR-Panel). Question No EFSA-Q-2007-048. The EFSA Journal (2007) 622, 1-32*]. The combination of Q_{10} = 2.2 for normalization and Q_{10} = 2.58 for simulation leads to worse-case degradation conditions for temperatures below 20°C, which are predominant in the FOCUS scenarios. The leaching assessment can therefore be considered conservative regarding the use of the Q_{10} value.

Sorption of boscalid to soil

The sorption behavior of boscalid was investigated in batch-equilibrium sorption studies for a variety of soils [*Seher, A. – BASF DocID 1998/10513*]. The $K_{f,oc}$-values ranged from 507 to 1110 mL g^{-1} with corresponding Freundlich exponents 1/n between 0.839 and 0.887. The respective arithmetic mean $K_{f,oc}$ of 771 mL g^{-1} (corresponding to a $K_{f,om}$ value of 447 mL g^{-1}) and Freundlich exponent of 0.864 were used for the PEC_{gw} calculations.

Summary of input parameters

The substance specific input parameters such as DT_{50}, $K_{f,oc}$, molecular mass, vapor pressure and aqueous solubility as well as further parameters, which are set to standard assumptions, are given in Table 9.2.4.1-9.

II. RESULTS AND DISCUSSION

The simulated concentrations of boscalid in groundwater following fourfold application of 67 g a.s. ha^{-1} to potatoes were < 0.001 µg L^{-1} in all tested scenarios using both models. Consequently, the leaching of unacceptable amounts of boscalid after application to potatoes is highly unlikely.

III. CONCLUSION

Predicted environmental concentrations in groundwater (PEC_{gw}) of boscalid were calculated following application of BAS 516 07 F to potatoes. PEC values in groundwater were derived in accordance with the guidance of the FOCUS groundwater scenarios work group. The 80th percentile average annual leachate concentrations of boscalid were below 0.001 µg L^{-1} in all tested scenarios. The leaching of unacceptable amounts of boscalid after application to potatoes is highly unlikely.

CP 9.2.4.2 Additional field tests

No additional field tests were performed with BAS 516 07 F. Data for the active substance and its metabolites are covered by information given in M-CA 7.

GLP: no

Executive Summary

Predicted environmental concentrations in surface water (PEC_{sw}) and sediment (PEC_{sed}) were calculated for pyraclostrobin after single and fourfold spray application of 17 g a.s. ha^{-1} to potatoes considering the entry pathways spray drift, drainage and runoff.

The metabolites of pyraclostrobin which were observed in major amounts in water (BF 500-5, BF 500-11, BF 500-13, BF 500-14) and in sediment (BF 500-3, BF 500-6, BF 500-7) were also considered for the assessment in the respective environmental compartments, taking into account their formation after entry of the parent substance.

Additionally, for the metabolites BF 500-6 and BF 500-7 occurring in major amounts in soil under aerobic conditions the entry pathways runoff and drainage of the metabolites into surface water were taken into account. Since both metabolites have very low water solubilities (2 - 3 µg L^{-1}) and extremely high sorption values (K_{oc}>10^5 mL g^{-1}), they will reach surface water bodies via runoff or drainage in a soil particle-bound form. They then sink to the sediment surface, i.e. they are extremely unlikely to occur freely dissolved in molecular form in the water phase. Consequently BF 500-6 and BF 500-7 were only considered for PEC calculations in the sediment compartment.

For the metabolites BF 500-3 and BF 500-5 runoff and drainage of the metabolites are not relevant as entry pathways into surface water as the metabolites did not occur in relevant amounts in soil under aerobic conditions. The metabolite BF 500-4 was not found either in water/sediment studies or in soil under aerobic conditions and was therefore not considered in the assessment.

The calculations were performed according to the FOCUS surface water guidance documents [*FOCUS (2001, 2012)*].

Calculations for pyraclostrobin were carried out at Step 1 to Step 3. A tiered approach was considered for the parent substance, with endpoints derived from a dark water/sediment study being used at Tier 1 and endpoints from an irradiated water/sediment study being used at Tier 2. PEC values for the metabolites were calculated for FOCUS Step 1 and 2 level. Input parameters for the metabolites were derived from the study in which they occurred, i.e. in dark or irradiated water/sediment systems.

The software packages STEPS1-2 in FOCUS version 2.1, FOCUS-PRZM version 1.5.6, FOCUS-MACRO version 4.4.2 and FOCUS-TOXSWA version 3.3.1 for Step 3 were used for the calculations. At Step 2 of the assessment, the regions ‘North Europe’ and ‘South Europe’ were taken into account. At Step 3, all FOCUS scenarios available for potatoes were considered.

A summary of the maximum PEC_{sw} of pyraclostrobin and its metabolites calculated for each step of the assessment is given in the tables below.

Pyraclostrobin

Tier 1 (parameters from dark water/sediment study)

[2] BF 500-11, BF 500-13 and BF 500-14 did not occur in soil or sediment phase in significant amounts

I. MATERIAL AND METHODS

Predicted environmental concentrations in surface water (PEC_{sw}) and sediment (PEC_{sed}) were calculated for pyraclostrobin after single and fourfold spray application of 17 g a.s. ha^{-1} to potatoes considering the entry pathways spray drift, drainage and runoff.

The metabolites of pyraclostrobin, which were observed in major amounts in water (BF 500-5, BF 500-11, BF 500-13, BF 500-14) and in sediment (BF 500-3, BF 500-6, BF 500-7), were also considered for the assessment in the respective environmental compartments, taking into account their formation after entry of the parent substance. Additionally, for the metabolites occurring in major amounts in soil under aerobic conditions (BF 500-6, BF 500-7) the entry pathways runoff and drainage of the metabolites into surface water were taken into account.

Since both metabolites have very low water solubilities (2 - 3 µg L^{-1}) and extremely high sorption values (K_{oc}>10^5 mL g^{-1}), they will reach surface water bodies via runoff or drainage in a soil particle-bound form. They then sink to the sediment surface, i.e. they are extremely unlikely to occur freely dissolved in molecular form in the water phase. Consequently BF 500-6 and BF 500-7 were only considered for PEC calculations in the sediment compartment.

For the metabolites BF 500-3 and BF 500-5 runoff and drainage of the metabolites are not relevant as entry pathways into surface water as the metabolites did not occur in relevant amounts in soil under aerobic conditions. Metabolite BF 500-4 was neither found in water/sediment studies nor in soil under aerobic conditions and was therefore not considered in the assessment.

The calculations were performed according to the FOCUS surface water guidance documents [*FOCUS (2001): FOCUS Surface Water Scenarios in the EU Evaluation Process under 91/414/EEC Report of the FOCUS Working Group on Surface Water Scenarios. EC Document Reference SANCO/4802/2001-rev.2. final. 238 pp; FOCUS (2012): "FOCUS Surface Water Scenarios in the EU Evaluation Process under 91/414/EEC" Report of the FOCUS Working Group on Surface Water Scenarios. EC Document Reference SANCO/4802/2001 version 1.2. 357 pp.*].

Application scenarios

The worst-case application scenarios of pyraclostrobin considered for PEC_{sw} and PEC_{sed} calculations are given in Table 9.2.5-29.

Table 9.2.5-5: Application scenarios of pyraclostrobin applied to potatoes considered for PEC_{sw} and PEC_{sed} calculations

$FOCUS_{sw}$ crop	Potatoes
Growth stage [BBCH]	51
Application rate [g a.s. ha^{-1}]	17
Max. no. of applications [-]	4
Interval [d]	10
Total yearly application rate [g a.s. ha^{-1}]	80 / 80 / 80 / 80

Environmental fate parameters

Fate and behavior in soil

Degradation and sorption of pyraclostrobin

The degradation behavior of pyraclostrobin in soil has been investigated under both laboratory and field conditions. An overview of individual DT_{50} considered to select endpoints for PEC calculations is given in the tables at the end of study *CA 7.1.2.1.1/3* and study *CA 7.1.2.2.1/4*. The sorption behavior of pyraclostrobin is described in M-CP 9.2.4 (section on PEC_{gw}).

The normalized bias-corrected geometric mean half-life of 28.3 days (at 20°C and pF2) from the eight relevant field trials, an arithmetic mean $K_{f,oc}$ of 9304 mL g^{-1} and the corresponding 1/n of 0.95 were used for the PEC_{sw} calculations.

Degradation and sorption of the metabolites of pyraclostrobin

The degradation behavior of the metabolites of pyraclostrobin in soil has been investigated under laboratory (BF 500-3, BF 500-5, BF 500-6, BF 500-7) and field conditions (BF 500-6, BF 500-7). An overview of individual DT_{50} considered to select endpoints for PEC calculations is given in the tables at the end of study *CA 7.1.2.1.2/4* and study *CA 7.1.2.2.1/4*. The sorption behavior of the metabolites of pyraclostrobin is described in M-CP 9.2.4 (section on PEC_{gw}).

As the metabolites BF 500-3 and BF 500-5 did not occur in relevant amounts in soil under aerobic conditions, a maximum occurrence in soil of 0.01% and a DT_{50} of 1 day were assumed as worst-case default input parameters. The arithmetic mean K_{oc} values of 9315 mL g^{-1} and 705 mL g^{-1} for BF 500-3 and BF 500-5, respectively, were considered for the calculations.

For the metabolite BF 500-6 a maximum occurrence in soil of 31% TAR observed in the laboratory, a bias-corrected geometric mean DT_{50} of 321.0 days and a median K_{oc} value of 107301 mL g^{-1} were used as modeling input.

For the metabolite BF 500-7 a maximum occurrence in soil of 19% TAR observed in field degradation studies, a bias-corrected geometric mean DT_{50} of 312.0 days and a median K_{oc} value of 149900 mL g^{-1} were used as modeling input.

The metabolites BF 500-11, BF 500-13 and BF 500-14 occur only in water. As there are no data on soil degradation and sorption available, a maximum occurrence in soil of 0.01%, a DT_{50} of 1 day and a K_{oc} of 1 x 10^{-10} mL g^{-1} were assumed as worst-case default input parameters.

Fate and behavior in aquatic systems

Pyraclostrobin

Degradation and partitioning of pyraclostrobin in aquatic systems have been investigated in a range of studies with different test designs and an increasing level of environmental relevance: dark and irradiated water/sediment systems and outdoor mesocosm [*old EU Dossier, A II M 7.2.1.3.2/1, Staudenmaier H. - BASF DocID 1999/11241*; *old EU Dossier, A II M 7.2.1.3.2/2, Ebert D. - BASF DocID 1999/11791*; *CA 7.2.2.4/2, Ebert D. – BASF DocID 2011/1101715; old EU Dossier, A III M 10.2.2/1, Dohmen G. P. - BASF DocID 2000/1000011*]. In order to reflect the different test designs in the model calculations a tiered approach was considered.

At **Tier 1** the assessment was based on the results of the water/sediment study conducted under dark laboratory conditions [*Staudenmaier H. - BASF DocID 1999/11241*]. The degradation kinetics were re-evaluated in a separate study [*CA 7.2.2.3/1, Wiedemann G. – BASF DocID 2012/1165029*]. At Level P-I, for System A whole system DT_{50} values of 23.3 and 26.8 days were reported for chlorophenyl- and tolyl-labeled pyraclostrobin, respectively, while for System B no reliable endpoints could be derived. The kinetic evaluation at Level P-II did not result in reliable endpoints. According to FOCUS kinetics a case-by-case decision should be made if reliable endpoints (P-I, System B) cannot be derived with the recommended standard procedures. For System B a $DegT_{90}$ in the whole system of approximately 30 days can be estimated visually, which is considerably shorter than the endpoint calculated for System A. Hence, the results of the kinetic evaluation of System A represent the worst-case of the two w/s systems investigated. Consequently, only the results of the kinetic evaluation of System A are to be considered as worst-case for further usage. In accordance with FOCUS degradation kinetics [*FOCUS (2006)*] the geometric mean DT_{50} in the total system of 25.0 days was considered for the total system at Step 1. Due to the high sorption tendency of pyraclostrobin the total system DT_{50} value of 25.0 days was used at Step 2 and 3 for the sediment phase, while the conservative default value of 1000 days was used for the water phase.

At **Tier 2** the assessment was based on the results of the water/sediment-studies conducted under irradiated laboratory conditions [*Ebert D. - BASF DocID 1999/11791*; *Ebert D. – BASF DocID 2011/1101715*]. While in *Ebert D.* [*BASF DocID 2011/1101715*] degradation endpoints could be derived only at Level P-I, the kinetic re-evaluation of *Ebert D.* [*BASF DocID 1999/11791*] resulted in appropriate degradation endpoints at Level P-I and Level P-II [*CA 7.2.2.4/1, Miles B. - BASF DocID 2012/1021122*]. The reported endpoints (dissipation half-life in water of 4.47 days) are considered as a realistic worst-case scenario compared to the outdoor mesocosm study, where a dissipation half-life in water of 3.5 days was reported. Consequently, the respective Level P-II degradation half-lives of 7.50 days in water and 6.48 days in sediment were used as input for modeling at Step 2 and 3 while for Step 1 calculations a $DegT_{50}$ in the total system calculated at Level P-I of 7.2 days was considered in accordance with FOCUS kinetics [*FOCUS (2006)*].

Metabolites of pyraclostrobin

In the dark water/sediment study the metabolites BF 500-3, BF 500-6 and BF 500-7 occurred as major metabolites [*Staudenmaier H. - BASF DocID 1999/11241*]. Additionally, BF 500-3, BF 500-11, BF 500-13 and BF 500-14 occurred in relevant amounts in the irradiated water/sediment study [*Ebert D. - BASF DocID 1999/11791*], and BF 500-5 was detected as major metabolite in the study on aerobic mineralization in surface water [*CA 7.2.2.2/1, Ebert D., Possienke M. – BASF DocID 2013/1002741*]. An overview of the DT_{50} values for the metabolites of pyraclostrobin in water/sediment systems is shown at the end of M-CA 7.2.2.

BF 500-3 was observed at amounts >5% TAR in the sediment compartment of the water/sediment studies under dark as well as under irradiated conditions, whereas in the water compartment no residues above 5% TAR were detected [*Staudenmaier H. - BASF DocID 1999/11241; Ebert D. - BASF DocID 1999/11791; Ebert D. – BASF DocID 2011/1101715*]. Therefore, PEC_{sed} calculations were conducted considering the results from the dark and the irradiated studies separately. Regarding the calculations representing the dark conditions, the maximum occurrence in the total system (mean of two labels) of 67.7% TAR [*Staudenmaier H. - BASF DocID 1999/11241*] and a conservative default DT_{50} of 1000 days were used, while for irradiated conditions the maximum occurrence in the total system of 21.9% TAR and a DT_{50} in the total system of 92.5 days from the kinetic re-evaluation were considered [*Ebert D. - BASF DocID 1999/11791; Miles B. - BASF DocID 2012/1021122*].

BF 500-5 was observed as major metabolite in the water phase of the study on aerobic mineralization in surface water, whereas it did not occur in relevant amounts in the sediment phase [*Ebert D., Possienke M. – BASF DocID 2013/1002741*]. Therefore, PEC_{sw} calculations were conducted considering the maximum occurrence of 10.9% TAR observed in the pelagic test and a conservative default DT_{50} of 1000 days.

BF 500-6 and BF 500-7 were observed at amounts >5% TAR in the sediment compartment of the water/sediment study under dark conditions, whereas in the water compartment no residues above 5% TAR were detected [*Staudenmaier H. - BASF DocID 1999/11241*]. Therefore, PEC_{sed} calculations were conducted considering the maximum occurrences of 6.5% TAR and 6.3% TAR (mean of two labels) for BF 500-6 and BF 500-7, respectively, and a conservative default DT_{50} of 1000 days.

BF 500-11, BF 500-13 and BF 500-14 were observed as major metabolites under irradiated conditions in the water compartment, whereas they did not occur in relevant amounts in the sediment compartment [*Ebert D. - BASF DocID 1999/11791*]. Therefore, PEC_{sw} calculations were conducted considering the sum of the maximum occurrences in water and sediment of 12.0% TAR, 17.8% TAR and 12.1% TAR for BF 500-11, BF 500-13 and BF 500-14, respectively. For BF 500-11 and BF 500-14 the DT_{50} values in the total system of 22.6 days and 17.3 days from the kinetic re-evaluation were considered, respectively [*Miles B. - BASF DocID 2012/1021122*]. For BF 500-13 a reliable half-life could not be estimated from the data of the irradiated water/sediment study because the maximum occurrence of the metabolite was at the last sampling date [*Ebert D. - BASF DocID 1999/11791*]. However, results of the aqueous photolysis study show a significant degradation of BF 500-13 in water with a calculated half-life of 30.7 days (rounded value) under continuous irradiation [*old EU Dossier, A II M 7.2.1.2/2, Scharf J. - BASF DocID 1999/11286*]. In order to represent a realistic radiation scenario (12 h radiation followed by 12 h darkness) the reported half-life was multiplied with a factor of 2 resulting in a DT_{50} of 61.3 days, which was used as input parameter for PEC_{sed} calculations.

Surface water assessment according to FOCUS

The calculations were performed in a stepwise approach according to the recommendations of the FOCUS working group on surface water scenarios (2001, 2012).

For all calculations, the following model versions were used: STEPS1-2 in FOCUS version 2.1, FOCUS-PRZM version 1.5.6, FOCUS-MACRO version 4.4.2 and FOCUS-TOXSWA version 3.3.1. The modeling runs were set up with SWASH version 3.1.

Setup of FOCUS surface water runs

Pyraclostrobin

FOCUS Step 1 to Step 3 calculations were carried out for PEC_{sw} and PEC_{sed} for pyraclostrobin considering the entry routes spray drift, drainage and runoff for spray application to potatoes.

STEP 1 and Step 2 scenario settings

At Step 1 and 2, appropriate application periods and parameters for crop interception according to the actual GAP for potatoes were considered as shown in Table 9.2.5-6. The regions 'North Europe' and 'South Europe' as implemented in FOCUS STEPS1-2 were considered.

Table 9.2.5-6: Steps 1-2 FOCUS scenarios for the selected FOCUS crops

FOCUS$_{sw}$ crop	Interception class	Application period	Region
Potatoes	Full canopy	Mar – May	North and South Europe

Step 3 scenario settings

At Step 3, all FOCUS scenarios parameterized for potatoes (D3, D4, D6, R1 - R3) were selected for the simulations. In the SWASH shell the application method was set to ‘ground spray’. The chemical application method (CAM) was set to option '2' (application to foliage). The length of the application window that is required for the Pesticide Application Tool (PAT) to determine actual application dates was chosen to cover the whole application window as specified in the GAP. Considering the minimum application interval of 10 days, a minimum length of the application window of 60 days is required for multiple application to potatoes. The actual dates for field application differ according to the crop development in the different European regions and from year to year.

The start date of the application windows was set to coincide with the earliest growth stage defined for application to potatoes in the GAP (BBCH 51). To cover the whole application period according to GAP, the first application was assumed to take place 30 days after emergence and the last application was assumed 3 days prior to harvest (derived from the pre-harvest interval (PHI) provided in the GAP).

The detailed application timing used for the simulations is shown in Table 9.2.5-7.

Table 9.2.5-7: Application timing for pyraclostrobin in potatoes in the relevant scenarios (Step 3)

Scenario	Water body	Application window[a]	Application dates according to PAT[b]
Potatoes			
D3 - Vredepeel	ditch	9th June - 12th September	14th June / 26th June / 8th July / 24th July
D4 - Skousbo	pond	21st June - 20th September	21st June / 4th July / 27th August / 10th September
D4 - Skousbo	stream	21st June - 20th September	21st June / 4th July / 27th August / 10th September
D6 – Thiva (1st)	ditch	10th May - 12th July	17th May / 4th June / 23rd June / 5th July
D6 – Thiva (2nd)	ditch	4th September - 22nd November	4th September / 14th September / 27th September / 7th October
R1 - Weiherbach	pond	4th June - 5th September	9th June / 29th June / 11th July / 28th July
R1 - Weiherbach	stream	4th June - 5th September	9th June / 29th June / 11th July / 28th July
R2 - Porto	stream	13th April - 12th June	22nd April / 7th May / 20th May / 3rd June
R3 - Bologna	stream	10th May - 29th August	18th May / 1st June / 11th June / 21st June

[a] calculations for single and multiple applications were conducted in separate runs
[b] for calculation of single application the first date was considered

Metabolites of pyraclostrobin

For the metabolites of pyraclostrobin, PEC values were calculated at FOCUS Step 1 and 2. The results of the calculations are reported for those compartments where the respective metabolites had been detected as major metabolites. The simulations were carried out according to the approach and application scenarios for the parent compound.

Overview of the FOCUS levels used for the simulations

Table 9.2.5-8 gives an overview of the FOCUS levels, at which the PEC values of the respective compounds were simulated.

Table 9.2.5-8: Summary of the selection of the FOCUS levels for each compound

Compound	PEC_{sw} calculations conducted with FOCUS Step	PEC_{sed} calculations conducted with FOCUS Step	Reported PEC_{sw}	Reported PEC_{sed}
Pyraclostrobin	1, 2, 3, 4	1, 2, 3	max, act, twa	max
BF 500-3	-[1]	1, 2	-[1]	max
BF 500-5	1, 2	-[2]	max	-[2]
BF 500-6	-[3]	1, 2	-[3]	max
BF 500-7	-[3]	1, 2	-[3]	max
BF 500-11	1, 2	-[4]	max	-[4]
BF 500-13	1, 2	-[4]	max	-[4]
BF 500-14	1, 2	-[4]	max	-[4]

[1] BF 500-3 did not occur in soil or water phase in significant amounts
[2] BF 500-5 did not occur in soil or sediment phase in significant amounts
[3] BF 500-6 and BF 500-7 will not occur free in water phase due to low water solubility and high sorption values
[4] BF 500-11, BF 500-13 and BF 500-14 did not occur in soil or sediment phase in significant amounts

Pyraclostrobin

For a summary of the environmental fate parameters of pyraclostrobin used for modeling at Step 1 to Step 3 of the assessment, see Table 9.2.5-9. The input parameters for the metabolites are summarized in Table 9.2.5-10 to Table 9.2.5-16. Some default assumptions were made as the measured data could not cover all required model input, e.g. solubility in water, maximum occurrence in soil, DT_{50} in soil and K_{oc} of the aquatic metabolites BF 500-11, BF 500-13 and BF 500-14.

II. RESULTS AND DISCUSSION

All calculated PEC_{sw} and PEC_{sed} values are available in the study report. For the sake of compactness, only the maximum concentrations of pyraclostrobin and its metabolites in surface water (PEC_{sw}) and in sediment (PEC_{sed}) are reported below. Actual and time-weighted average concentrations of pyraclostrobin in surface water are presented exemplarily for Tier 1 as it provides the worst-case PECs.

SURFACE WATER

Global maximum concentrations – pyraclostrobin

Step 1 and 2

Table 9.2.5-17: Steps 1-2: $PEC_{sw,max}$ of pyraclostrobin following application to potatoes

FOCUS$_{sw}$ crop	Tier	Pyraclostrobin $PEC_{sw,max}$ [µg L^{-1}]					
		Step 1		Step 2			
				North Europe		South Europe	
		Single	Multiple	Single	Multiple	Single	Multiple
Potatoes	Tier 1	0.579	2.316	0.156	0.128	0.156	0.164
	Tier 2	0.579	2.316	0.156	0.112	0.156	0.144

Step 3

Tier 1 (parameters from dark water/sediment study)

Table 9.2.5-18: Step 3: $PEC_{sw,max}$ of pyraclostrobin following application of 17 g a.s. ha^{-1} to potatoes (Tier 1)

Location	Water body		Potatoes	
			Single application	Multiple application
D3	ditch	$PEC_{sw,max}$ [µg L^{-1}] main entry route	0.088 Drift	0.059 Drift

BF 500-7	6.221	24.885	0.423	1.569	0.790	2.989

III. CONCLUSION

Predicted environmental concentrations (PEC) were calculated for pyraclostrobin and its metabolites in surface water (BF 500-5, BF 500-11, BF 500-13, BF 500-14) and in sediment (BF 500-3, BF 500-6, BF 500-7) following application of the formulated product BAS 516 07 F to potatoes under European conditions.

For the parent compound a tiered approach using endpoints from dark (Tier 1) and irradiated (Tier 2) water/sediment studies was considered for the calculations. While this had almost no effect on maximum PEC_{sw}, the maximum PEC_{sed} in Tier 2 decreased slightly (with approximately 17% for, fourfold application, R1–stream). Time weighted average (TWA) values did not differ significantly between the two tiers. Despite the large discrepancy between the degradation rates in the water compartment between the two tiers, the results show that sorption from the water phase to sediment is the dominating process. This is in agreement with the behavior observed in aqueous metabolism studies. Although the selection of endpoints has no major effect on the PEC_{sw} values, it considerably affects the behavior in sediment. Since pyraclostrobin breakdown under irradiated conditions is a relevant pathway and degradation occurs rapidly these Tier 2 endpoints should be considered for further usage.

The predicted concentrations in surface water are appropriate to be used for the subsequent risk assessment for aquatic organisms.

Report: CP 9.2.5/2
Kallweit W., 2014b
Predicted environmental concentrations of BAS 510 F - Boscalid in soil, groundwater, surface water and sediment following application to potatoes in Europe
2014/1001461

Guidelines: SANCO/321/2000, FOCUS Groundwater (2012) Generic guidance for FOCUS groundwater scenarios v 2.1, FOCUS Kinetics (2006) SANCO/10058/2005 version 1.0 of Nov. 2011, SANCO/4802/2001 rev. 2 (FOCUS surface water scenarios) May 2003, FOCUS Surface Water (2012) SANCO/4802/2001 v1.1, FOCUS groundwater (2009): SANCO/13144/2009

GLP: no

Executive Summary

Predicted environmental concentrations in surface water (PEC_{sw}) and sediment (PEC_{sed}) were calculated for boscalid, according to the recommendations of the FOCUS working group on surface water scenarios (2001, 2012) in a stepwise approach considering the entry pathways spray drift, drainage and runoff. Calculations were carried out for single and fourfold application of boscalid to potatoes taking into account the maximum application rate (67 g a.s. ha^{-1}) and the minimum application interval (10 days).

Calculations were carried out at Step 1 to Step 3 level. The software packages STEPS1-2 (version 2.1) for Step 1 and Step 2 and SWASH 3.1 in combination with MACRO 4.4.2, PRZM 1.5.6 and TOXSWA 3.3.1 for Step 3 were used for the calculations. At Step 2 of the assessment, the regions 'North Europe' and 'South Europe' were taken into account. At Step 3 all FOCUS surface water scenarios relevant for potatoes were considered for the calculations.

The maximum concentrations of boscalid in surface water and sediment are summarized in the following table.

Table 9.2.5-28: Summary of highest global PEC_{sw} and PEC_{sed} values of boscalid following application to potatoes

FOCUS level	SURFACE WATER	SEDIMENT
	Max. PEC_{sw} [µg L^{-1}]	Max. PEC_{sed} [µg kg^{-1}]
Step 1	46.515	348.754
Step 2	5.554	41.843
Step 3	2.064 D6 d (2nd), multiple	3.189 R2 s, multiple

d = ditch, s = stream
multiple = multiple application

I. MATERIAL AND METHODS

Application scenarios

According to Good Agricultural Practice (GAP), boscalid is scheduled for up to four applications to potatoes at a maximum application rate equivalent to 67 g a.s. ha^{-1} per treatment and a minimum interval of 10 days. The worst-case application scenarios considered for PEC_{sw} and PEC_{sed} calculations are given in Table 9.2.5-29.

Table 9.2.5-29: Worst-case application scenarios of boscalid applied to potatoes considered for PEC_{sw} and PEC_{sed} calculations

Potatoes		
Max. no. of applications [-]	1	4
Crop growth stage at first application [BBCH]	51	51
Minimum application interval [d]	-	10
Application rate [g a.s. ha^{-1}]	67	67
Total yearly application rate [g a.s. ha^{-1}]	67	268

Environmental fate parameters

Fate and behavior in soil

Details about the degradation behavior of boscalid in soil can be found in M-CP 9.1.3. The geometric mean DT_{50} of 130.0 days that was calculated from field DT_{50} normalized to 20°C (Q_{10} = 2.2) was used for the calculations in surface water. Simulations were carried out using a Q_{10} value of 2.58 as recommended by EFSA [*EFSA (2007)*]. The combination of Q_{10} = 2.2 for normalization and Q_{10} = 2.58 for simulation leads to worse-case degradation conditions for temperatures below 20°C, which are predominant in the FOCUS scenarios. $PEC_{sw,sed}$ calculations can therefore be considered conservative regarding the use of the Q_{10} value.

Details about the sorption behavior of boscalid to soil can be found in M-CP 9.2.4. The arithmetic mean $K_{f,oc}$ of 771 mL g^{-1} and the arithmetic mean Freundlich exponent of 0.864 were used for the $PEC_{sw,sed}$ calculations.

Fate and behavior in aquatic systems

The dissipation behavior of boscalid in water was investigated in two water/sediment studies under different test conditions. The first study was performed under standard conditions in the laboratory in the dark [*Ebert – BASF DocID 2000/1000135*]. To reflect a more realistic environmental scenario, the second water/sediment study was conducted under outdoor conditions with the influence of natural sunlight [*Fent – BASF DocID 2000/1017038*].

The standard water/sediment study [*Ebert – BASF DocID 2000/1000135*] was conducted in the laboratory at 20°C under dark conditions. Two aquatic test systems were investigated representing a pond and a river system. The dissipation of boscalid in the water phase of both systems was mainly based on sorption processes. The highest amount of boscalid in sediment was observed in the river system with 78.8% TAR. The amount of bound residues in the sediment was low; a maximum value of 12.9% was observed the pond system at day 100 after treatment. The best-fit (non single first-order) DT_{50} values describing dissipation from the water phase of both systems were determined graphically; they were estimated to be 9 days and 3 days, respectively. It was not possible to estimate single first-order DT_{50} values describing degradation in water and sediment that are necessary input parameters for FOCUS surface water models.

The outdoor study [*Fent – BASF DocID 2000/1017038*] was accomplished in a pond water/sediment system (location "Kellmetschweiher"). The maximum concentration in sediment was observed at day 103 with 28.2% TAR.

In a kinetic evaluation [*Platz – BASF DocID 2000/1017047*] the observed residues of boscalid in the water and in the sediment phase were fitted with the help of a compartment model that considered the dissipation of boscalid in water and in sediment, and sorption/desorption processes in the sediment phase. Residues up to day 58 with fairly constant temperature conditions of about 20°C were considered. The biotic/abiotic degradation rate in water (separated from partitioning) of 32 days was used in the assessment, which is considered as a realistic worst-case estimate of degradation in the aquatic phase of water/sediment systems.

Degradation in the sediment and the total water/sediment system could not be estimated [*Platz – BASF DocID 2000/1017047*]. Therefore, conservative default values of 1000 days were considered in the calculations for the degradation of boscalid in the total system and in sediment.

Surface water assessment according to FOCUS

The calculations were performed in a stepwise approach according to the recommendations of the FOCUS working group on surface water scenarios (2001, 2012).

For all calculations the following model versions were used: STEPS1-2 in FOCUS version 2.1, FOCUS-PRZM version 1.5.6, FOCUS-MACRO version 4.4.2 and FOCUS-TOXSWA version 3.3.1. The modeling runs were set up with SWASH version 3.1.

Setup of FOCUS surface water runs

Calculations for boscalid were carried out at Step 1 to Step 3, according to the recommendations of the FOCUS working group on surface water scenarios and considering the entry routes spray drift, drainage and runoff. The scenario settings for Step 1 – 3 are equal to the ones for pyraclostrobin.

Summary of input parameters

A summary of the environmental fate parameters of boscalid used for modeling is given in Table 9.2.5-30.

Table 9.2.5-30: Summary of FOCUS input parameters for boscalid for PEC_{sw} and PEC_{sed} calculations

Parameter	Value	Remarks

II. RESULTS AND DISCUSSION

Predicted concentrations in surface water

Global maximum concentrations

Step 1 and 2

Predicted environmental concentrations in surface water of boscalid at Step 1 and 2 are given in Table 9.2.5-31.

Table 9.2.5-31: Steps 1-2: $PEC_{sw,max}$ of boscalid following application of 67 g a.s. ha^{-1} to potatoes

$FOCUS_{sw}$ crop	$PEC_{sw,max}$ [µg L^{-1}]					
	Step 1		Step 2			
			North Europe		South Europe	
	Single	Multiple	Single	Multiple	Single	Multiple
Potatoes	11.629	46.515	0.990	3.162	1.637	5.554

Step 3

Predicted environmental concentrations in surface water of boscalid at Step 3 are given in Table 9.2.5-32.

Table 9.2.5-32: Step 3: $PEC_{sw,max}$ of boscalid following application of 67 g a.s. ha^{-1} to potatoes

III. CONCLUSION

Predicted environmental concentrations in surface water (PEC_{sw}) and sediment (PEC_{sed}) were calculated for boscalid following application of the formulated product BAS 516 07 F to potatoes under European pedo-climatic conditions.

The predicted concentrations in surface water are appropriate to be used for the subsequent risk assessment for aquatic organisms.

CP 9.3 Fate and behaviour in air

CP 9.3.1 Route and rate of degradation in air and transport via air

No studies were performed with BAS 516 07 F. The route and rate of degradation in air as well as transport via air is sufficiently addressed by information given in M-CA 7.3.

Predicted environmental concentrations from airborne transport

No risk assessment needs to be performed, because both active substances in BAS 516 07 F, pyraclostrobin and boscalid, have a very low volatilisation potential and a short DT_{50} in air. Consequently no PECs have been calculated.

CP 9.4 Estimation of concentrations for other routes of exposure

No other routes of exposure are relevant for the use of BAS 516 07 F in potatoes.

Table of Contents

CP 10 ECOTOXICOLOGICAL STUDIES ON PLANT PROTECTION PRODUCT

BAS 516 07 F is a new representative formulation, which has not been evaluated during a previous Annex I inclusion process.

This document reviews the ecotoxicological studies for BAS 516 07 F, a WG formulation containing 67 g/kg pyraclostrobin and 267 g/kg boscalid. In addition, risk assessments are provided, which show that BAS 516 07 F is safe for aquatic and terrestrial non-target organisms.

CP 10.1 Effects on birds and other terrestrial vertebrates

The risk assessment on birds and mammals considers the principles given in the latest guidance document by EFSA (*Anonymous 2009: Guidance Document on risk assessment for Birds & Mammals on request from EFSA. EFSA Journal 2009; 7(12):1438. European Food Safety Authority*), hereafter cited as EFSA/2009/1438. EU agreed endpoints and endpoints from new studies are used for the risk assessments on birds and mammals together with data from new additional studies.

The representative formulation BAS 516 07 F is containing pyraclostrobin and boscalid. No separate risk assessment for boscalid will be presented in the following chapter, as the active substance in focus of the evaluation is pyraclostrobin. Boscalid is solely addressed in the context of the assessment of combined effects of formulations containing more than one active substance (i.e. dietary risk assessment for a virtual compound and the formulation).

In addition, the potential risk to amphibians and reptiles will be addressed following the new requirement under Regulation 1107/2009.

Study conducted for the avian risk assessment

For the avian risk assessment the following new information on formulation toxicity is used (Table 10.1-1). The study summary is given in M-CP 10.1.1.2.

Table 10.1-1: New information used for the avian risk assessment

Data point	Reference (BASF DocID)	Year	Title
M-CP 10.1.1.2/1	2006/1030309	2006	BAS 516 07 F - Acute toxicity in the bobwhite quail (*Colinus virginianus*) after single oral administration (LD_{50})

CP 10.1.1 Effects on birds

In this chapter, data on BAS 516 07 F are evaluated and the risk assessments are presented for the active substance pyraclostrobin and for the evaluation of combined effects of formulations containing more than one active substance based on the already registered use pattern.

Table 10.1.1-1: Endpoints for birds

Test system	Test species	Study endpoints	Endpoints used in present risk assessment [4]
Acute toxicity	*Colinus virginianus*	LD_{50} > 2000 mg a.s./kg b.w. [1]	LD_{50} (geometric mean) = 1701 mg a.s./kg b.w. [5]
	Serinus canaria	LD_{50} > 1446 mg a.s./kg b.w. [2]	
Reproductive toxicity (long-term)	*Colinus virginianus*	NOEL = 105 mg a.s./kg b.w./d [1] [3]	NOEC = 1000 mg a.s./kg diet NOEL = 105 mg a.s./kg b.w./d [2]

1 Endpoints confirmed in the ecotoxicology section of the Review Report for the active substance pyraclostrobin, SANCO/1420/2001-Final. 8. September 2004
2 Based on data from a new study and therefore not evaluated during the previous Annex I process. For the detailed study summary please refer to M-CA 8.1.1.1/1
3 Daily Dose [mg/kg b.w./d] calculated based on study data for food consumption and body weight
4 Endpoints according to EFSA/2009/1438
5 For calculation of LD_{50} (geometric mean) please refer to Table 10.1.1-3

RISK ASSESSMENT

Summary of avian toxicity testing

The avian toxicity studies with pyraclostrobin relevant for the dietary risk assessment for birds are summarized in Table 10.1.1-2. The listed studies have been already evaluated during the previous Annex I listing process except for the acute toxicity study in the canary (BASF DocID 2013/1400375). The two available and already evaluated short term toxicity studies in bobwhite quail and mallard duck are not listed below, because they are no longer part of the core data package according to EFSA/2009/1438.

Table 10.1.1-2: Summary of avian studies on the acute and reproductive toxicity of pyraclostrobin

Test system	Test species	Results	Reference (BASF DocID)
Acute oral toxicity	*Colinus virginianus*	LD_{50} > 2000 mg a.s./kg b.w. [1)]	1997/11136
	Serinus canaria	LD_{50} > 1446 mg a.s./kg b.w.	2013/1400375
Sub-chronic toxicity and reproduction	*Colinus virginianus*	NOEC = 1000 mg a.s./kg diet NOEL = 105 mg a.s./kg b.w./d [1) 2)]	1999/11207
	Anas platyrhynchos	NOEC = 1000 mg a.s./kg diet NOEL = 128 mg a.s./kg b.w./d [2)]	1999/11206

1 Endpoints confirmed in the ecotoxicology section of the Review Report for the active substance pyraclostrobin (SANCO/1420/2001-Final. 8. September 2004).
2 Daily Dose [mg/kg b.w./d] calculated based on study data for food consumption and body weight

Calculated avian toxicity endpoint for use in the acute tier 1 risk assessment

For pyraclostrobin acute oral studies in the bobwhite quail and the canary are available (Table 10.1.1-2). No mortality occurred in any of the two acute oral toxicity bird studies in the highest dose tested. However, in the study with the bobwhite quail treatment related effects were observed at the two highest dose groups (i.e. dose groups of 1000 and 2000 mg a.s./kg b.w.) and therefore no extrapolation of the LD_{50} >2000 mg a.s./kg b.w. for the bobwhite quail is possible according to EFSA/2009/1438 (2.1.2, p.16). In the study with the canary no clear signs of toxicity were seen up to the highest dose tested of 1446 mg a.s./kg b.w.. It would be thus permissible to extrapolate an LD_{50} value upwards. However, for a conservative evaluation an extrapolation of the LD_{50} >1446 mg a.s./kg b.w. for the canary is not conducted.

According EFSA/2009/1438 a geometric mean of the endpoints can be used in the acute dietary risk assessment as two different species were tested and the endpoint of the most sensitive species (i.e. the canary) is not by a factor of 10 below the overall geometric mean. The most sensitive endpoint with an LD_{50} > 1446 mg a.s./kg b.w./d in the canary is clearly higher than the 'assessment factor LD_{50}' of 170.1 mg a.s./kg b.w./d (Table 10.1.1-3). Hence, the geometric mean of both acute toxicity endpoints will be used.

The overall geometric mean LD_{50} value, i.e. the **LD_{50} (geometric mean) = 1701 mg a.s./kg b.w.** is the relevant endpoint to be used for the acute avian risk assessment.

Table 10.1.1-3: Calculation of the relevant avian toxicity endpoint for the acute risk assessment of pyraclostrobin

Characteristic	*Colinus virginianus*	*Serinus canaria*
Experimentally obtained LD_{50} [mg a.s./kg b.w.]	> 2000 [1)]	> 1446 [2)]
Birds tested/group [no.]	10	10
Mortality at highest dose level [%]	0	0
Extrapolation factor [3)]	--	--
LD_{50} (extrapolated) [4)] [mg a.s./kg b.w.]	--	--
LD_{50} (overall geometric mean) [5)] [mg a.s./kg b.w.]	1701	
Assessment factor LD_{50} [6)]: LD_{50} (overall geometric mean) / 10 [mg a.s./kg b.w.]	170.1	

1 BASF DocID 1997/11136
2 BASF DocID 2013/1400375
3 Extrapolation factor can be applied to an LD_{50} value in case 10 birds were tested and no mortalities occurred at the highest dose tested (EFSA GD 2009, 2.1.2, p.16). For a conservative evaluation an extrapolation of the endpoints derived is not conducted.
4 LD_{50} multiplied by the extrapolation factor
5 Determination of the geometric mean out of the LD_{50} values of >2000 and >1446 mg a.s./kg b.w. of the acute oral toxicity studies (EFSA/2009/1438, 2.4.2)
6 'Assessment factor LD_{50}' of all the tested species, geometric mean divided by a factor of 10 (EFSA/2009/1438, 2.4.2)

Calculated avian toxicity endpoint for use in the <u>reproductive</u> tier 1 risk assessment

In order to obtain the relevant toxicity endpoint to be used in the screening and tier 1 reproductive risk assessment, the lowest NOEL from available bird reproduction studies and the 'assessment factor LD_{50}' [LD_{50} (overall geometric mean) / 10] from acute toxicity studies (EFSA/2009/1438, p. 33 and 35) have to be considered.

The lowest toxicity value from the avian reproduction study for pyraclostrobin is NOEL = 105 mg a.s./kg b.w./d derived from the study with bobwhite quail (BASF DocID 1999/11207). The acute toxicity endpoint was calculated to LD_{50} = 1701 mg a.s./kg b.w. (Table 10.1.1-3).

Following EFSA/2009/1438 (p. 33 and 35), either the overall lowest NOEL or the 'assessment factor LD_{50}' is to be selected as relevant reproductive toxicity endpoint. Since the lowest of both is the NOEL, the value of **NOEL = 105 mg a.s./kg b.w./d** will be used in the screening step and the tier 1 reproductive risk assessment for pyraclostrobin.

Results from available toxicity testing with the formulation

The avian toxicity study with BAS 516 07 F (BASF DocID 2006/1030309) relevant for the risk assessment for birds is summarized in Table 10.1.1-4. Please note that the study was erroneously included in the Application submitted in January 2014 in M-CP 10.1.1.1 and is now given in M-CP 10.1.1.2.

Table 10.1.1-4: Summary of avian study on the acute toxicity of BAS 516 07 F

Test system	Test species	Results	Reference (BASF DocID)
Acute oral toxicity	*Colinus virginianus*	LD_{50} > 3200 mg/kg b.w.	2006/1030309

This study was not evaluated during previous Annex I listing processes. Therefore, the study is submitted within this dossier together with a detailed study summary provided in chapter 10.1.1.2. In addition, an acute risk assessment for BAS 516 07 F considering the **LD_{50} > 3200 mg/kg b.w. for BAS 516 07 F** is provided below.

Metabolites of pyraclostrobin

The metabolism of pyraclostrobin in potential food items of wild living birds or mammals (i.e. green plant matter, fruits, or seeds) was investigated in plant metabolism studies in grapes (BASF DocIDs 1998/10988 and 2000/1000201), potatoes (BASF DocIDs 1999/11419 and 2000/1000048) and wheat (BASF DocID 1999/11137). Most metabolites occurred only at trace amounts far below 10% TRR in the potential food items. The only metabolite that occurred at higher levels in potential food items was the desmethyl metabolite (BF 500-3, synonym: 500M07). It was found at levels of up to 15.3% TRR in grapes, 21.4% TRR in green matter of potatoes, 13.1% TRR in wheat forage, and 10.5% TRR in wheat grains. However, this desmethyl metabolite was also detectable in rats (BASF DocID 1999/11781), goats (BASF DocID 2000/1000004) and hens (BASF DocID 1999/11480). Hence, it can be concluded that the mammalian toxicity studies with pyraclostrobin cover this metabolite, and that the dietary risk assessment for pyraclostrobin provided for birds and mammals covers the potential risk from this metabolite.

Water metabolites are of minor importance for the risk assessment for wild living birds and mammals, considering the predominant route of exposure via food items like plants, seeds, or arthropods. Water uptake itself or exposure via the aquatic compartment, however, can play a role in the drinking water and the secondary poisoning risk assessment for fish-eaters. Hence in the following the risk from relevant surface water metabolites to birds and mammals is considered. The metabolites BF 500-5, BF 500-11, BF 500-13, BF 500-14 were found at levels slightly above 10% TAR in surface water (for details see M-CA 7.2). However, the risk from these metabolites to birds and mammals is considered to be covered by the presented risk assessments for the parent compound pyraclostrobin due to the following reasons:

i) PEC values of the metabolites are by a factor of ~30-66 below the one of the parent (highest global PEC_{sw}, max [µg/L] following FOCUS Step1 for the use in potatoes are for the metabolites BF 500-5 = 0.035 µg/L, BF 500-11 = 0.055 µg/L, BF 500-13 = 0.072 µg/L, BF 500-14 = 0.078 µg/L, and for the parent BAS 500 F = 2.316 µg/L; for details see M-CP 9.2)

ii) There are no specific toxicity studies with the metabolites BF 500-5, BF 500-11, BF 500-13, BF 500-14 available in birds or mammals, however, the low toxicity of the metabolites was confirmed in standard acute fish toxicity studies with *O. mykiss*.

Summary of relevant avian toxicity endpoints to be used in the screening and tier 1 risk assessments

The avian toxicity endpoints relevant for the screening and tier 1 risk assessments are given in Table 10.1.1-5.

Table 10.1.1-5: Avian toxicity endpoints for screening and tier 1 risk assessments of pyraclostrobin and BAS 516 07 F

Test substance	Test system	Relevant toxicity endpoint
Pyraclostrobin	Acute oral toxicity	LD_{50} (geometric mean) = 1701 mg a.s./kg b.w.
	Sub-chronic toxicity and reproduction	NOEL = 105 mg a.s./kg b.w./d
BAS 516 07 F	Acute oral toxicity	LD_{50} > 3200 mg a.s./kg b.w.

Relevant exposure scenarios

The relevant scenarios for the intended representative use patterns of the formulation BAS 516 07 F (Table 10.1.1-6) for potatoes are given in Table 10.1.1-7.

Table 10.1.1-6: Critical use pattern for BAS 516 07 F

Crop	EFSA/2009/ 1438 crop group	Application time (BBCH growth stage)	No. of applications	Interval [days]	Maximum application rate per treatment		
					Pyraclostrobin [kg/ha]	Boscalid [1)] [kg/ha]	BAS 516 07 F [kg/ha]
Potatoes	Potatoes	51-89	4	10	0.017	0.067	0.25

1 Not relevant for renewal of approval of pyraclostrobin. Therefore, the a.s. boscalid is not evaluated here.

Table 10.1.1-7: Summary of exposure scenarios to be considered for risk assessments for spray applications of BAS 516 07 F in potatoes at BBCH 51 – 89

Scenario	Generic focal species
Potatoes BBCH ≥ 20	Small insectivorous bird "wagtail"
Potatoes BBCH ≥ 40	Small omnivorous bird "lark"

CP 10.1.1.1 Acute oral toxicity

In this section, the dietary TER acute values for the screening step and tier 1 assessment obtained by means of the EFSA calculator tool (version of 9 July 2010, http://www.efsa.europa.eu/de/efsajournal/pub/1438.htm) are presented in Table 10.1.1.1-1.

Table 10.1.1.1-1: Pyraclostrobin: Acute dietary risk assessment for birds in potatoes - results from EFSA calculator tool

Data from Data_Entry worksheet	**Crop**	**Application rate (kg a.s./ha)**	**Number of applications**	**Application Interval**	**DT_{50}**	**LD_{50}**	
	Potatoes	0.017	4	10	10.0	1701	
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF (90)**	**Daily Dietary Dose (Multiple)**	**TER**	**No refinement step required**
	Small omnivorous bird	158.8	2.7	1.5	4.05	420.1	
First Tier Risk Assessment:							
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**			**Shortcut value**	**TER**	**No refinement required**
	Potatoes BBCH ≥ 20	Small insectivorous bird "wagtail" ground invertebrates with interception 50% ground arthropods, 50% foliar arthropods			25.2	2647.1	
	Potatoes BBCH ≥ 40	Small omnivorous bird "lark" Combination (invertebrates without interception) 25% crop leaves 25% weed seeds 50% ground arthropods			7.2	9264.7	

In conclusion, even under the conservative assumptions of the screening step and the tier 1 acute dietary risk assessment all TER_A values for pyraclostrobin exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low acute risk for birds from the use of BAS 516 07 F in potatoes according to the recommended use pattern.

CP 10.1.1.2 Higher tier data on birds

Please note that this section, albeit suggested by its header, does not only include higher tier data on birds. The calculations presented in Table 10.1.1.2-1 are the dietary TER reproductive values of the screening step and tier 1 assessment obtained by means of the EFSA calculator tool (version of 9 July 2010, http://www.efsa.europa.eu/de/efsajournal/pub/1438.htm) for potatoes.

Table 10.1.1.2-1: Pyraclostrobin: Reproductive dietary risk assessment for birds in potatoes - results from EFSA calculator tool

Data from Data_Entry worksheet	**Crop**	**Application rate (kg a.s./ha)**	**Number of applications**	**Application Interval**	**DT_{50}**	**Repro End Point (mg/kg b.w./d)**	**Time weighted average (TWA)**
	Potatoes	0.017	4	10	10.0	105	0.53
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF (90)**	**Daily Dietary Dose (Multiple)**	**TER**	**No refinement step required**
	Small omnivorous bird	64.8	1.10	1.9	1.11	94.7	
First Tier Risk Assessment:							
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**			**Shortcut value**	**TER**	**No refinement required**
	Potatoes BBCH ≥ 20	Small insectivorous bird "wagtail" ground invertebrates with interception 50% ground arthropods, 50% foliar arthropods			9.7	632.3	
	Potatoes BBCH ≥ 40	Small omnivorous bird "lark" Combination (invertebrates without interception) 25% crop leaves 25% weed seeds 50% ground arthropods			3.3	1858.6	

In conclusion, even under the conservative assumptions of the screening and the tier 1 reproductive risk assessments, all TER_{LT} values for pyraclostrobin exceed the trigger values set by Commission regulation (EU) 546/2011 for acceptability of effects, hence indicating a low reproductive risk for birds from the use of BAS 516 07 F in potatoes according to the recommended use pattern.

Acute toxicity of the formulation

An acute oral toxicity study with the formulation BAS 516 07 F in the bobwhite quail is available available and summarized below. Please note that the study was erroneously included in the Application submitted in January 2014 in chapter M-CP 10.1.1.1.

The results of the study show no increased formulation toxicity as the formulation is practically acutely non-toxic to birds (LD_{50} > 3 200 mg BAS 516 07 F/kg b.w.).

A detailed study summary is presented in the following. Further, an acute risk assessment for BAS 516 07 F considering the LD_{50} from formulation toxicity testing is provided below.

Report:	CP 10.1.1.2/1 [redacted], 2006b BAS 516 07 F - Acute toxicity in the bobwhite quail (Colinus virginianus) after single oral administration (LD50) 2006/1030309
Guidelines:	EPA 71-1, EPA 850.2100, EPA 540/9-85-007
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

A standard guideline study has been carried out to determine the effect of administration of BAS 516 07 F via gavage on the bobwhite quail (*Colinus virginianus*) and to determine the acute median lethal dose (LD_{50}) as well as the no observed effect level (NOEL). The study complies with the data requirements of US EPA FIFRA § 71-1 1982 and OPPTS 850.2100.

Bobwhite quails (*Colinus virginianus*) were approximately 5 months old, and before their first egg-laying season. The dose groups consisted of 5 male and 5 female birds. After fasted for about 22 hours the birds were administered doses of 0 (control), 800, 1 600 and 3 200 mg BAS 516 07 F / kg body weight in 0.5% aqueous carboxymethylcellulose (CMC) suspension by gavage into the crop. Mortalities and signs of toxicity were recorded for 14 days after administration.

No toxic signs were observed in the control and all dose groups. The highest dose causing no mortality was 3 200 mg BAS 516 07 F/kg b.w. No treatment-related impairment of food uptake or of body weights was observed in any of the dose groups. The gross post-mortem examination showed no treatment-related abnormalities in surviving birds after sacrifice. The highest dose tested without toxic signs was 3 200 mg BAS 516 07 F / kg b.w. The "No Observed Effect Level" (NOEL) was ≥ 3200 mg BAS 516 07 F / kg b.w. The acute median lethal dose (LD_{50}) was > 3 200 mg BAS 516 07 F / kg b.w.

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 516 07 F, batch no. 1789; content of a.s.: Boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); Pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).
Test species:	Bobwhite quail (*Colinus virginianus*), indistinguishable from wild birds; age: approx. 5 months: source: Küberich, Wiesentheid/Geesdorf, Germany.

B. STUDY DESIGN

Test design:	Birds were treated once by administering the test item in aqueous CMC-dispersion by gavage (5 males / 5 females per dose group) into the crop. Observation period: 14 days. Assessment for mortality and clinical signs was carried out three times on day of dosing, thereafter daily. Assessment of body weight was carried out on the day of dosing and on days 7 and 14.
Endpoints:	LD_{50}, mortality, clinical signs, feed consumption, body weight (b.w.), gross pathological examinations were conducted on all surviving birds sacrificed at the termination of the definitive test.
Test concentrations:	Control, 800, 1 600 and 3 200 mg BAS 516 07 F / kg body weight (nominal).
Test conditions:	Birds fasted for 22 hours before administration of the test item; temperature 21°C ± 2°C, relative humidity: 35% - 70%, photoperiod 8 hours light : 16 hours dark during the test period, light intensity: 53 lux - 135 lux.
Analytics:	The test item concentrations were analyzed using HPLC with UV-detection.
Statistics:	Descriptive statistics, ANOVA followed by Dunnett-test for weight data ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements:
The results of the analytical verification of the test item concentration were within a range of 94% to 98% for Boscalid and 96% to 100% for pyraclostrobin of the nominal concentrations during the test. The biological results are therefore based on the nominal values.

Biological results:
No toxic signs were observed in the control and all dose groups. The highest dose causing no mortality was 3 200 mg BAS 516 07 F / kg b.w. No treatment-related impairment of feed uptake or of body weights was observed in any of the dose groups. The gross post-mortem examination showed no treatment-related abnormalities in surviving birds after sacrifice.
The highest dose tested without toxic signs was 3 200 mg BAS 516 07 F / kg b.w. The "No Observed Effect Level" (NOEL) was ≥ 3 200 mg BAS 516 07 F / kg b.w. The acute median lethal dose (LD_{50}) was > 3 200 mg BAS 516 07 F / kg b.w. The results are summarized below.

Acute toxicity of BAS 516 07 F to the bobwhite quail (*Colinus virginianus*)

Mortality	Dose [mg BAS 516 07 F/kg b.w.]
Highest dose causing no treatment-related mortality	3 200
LD_{50} (14 d)	> 3 200
NOEL	≥ 3 200

III. CONCLUSION

In an acute toxicity test with the bobwhite quail, the 14 day LD_{50} of BAS 516 07 F was > 3 200 mg BAS 516 07 F / kg b.w. The NOEL was ≥ 3 200 mg BAS 516 07 F / kg b.w.

Acute risk assessment considering the LD_{50} from toxicity testing with BAS 516 07 F

Toxicity endpoint of the formulation for birds

Please note that the use of the endpoint from the acute toxicity study (BASF DocID 2006/1030309) of BAS 516 07 F on bobwhite quails (*i.e.* setting LD_{50} to 3200 mg/kg b.w. in the tier 1 calculations with EFSA calculator tool) will lead to an over-conservative approach as no substance-related mortality occurred throughout the study period, and it can thus be expected that the true LD_{50}, which would be actually relevant, is clearly higher.

A tier 1 acute dietary exposure assessment and TER calculation with the LD_{50} > 3200 mg BAS 516 07 F /kg b.w. from the acute oral bobwhite quail study with the formulation will be carried out (see below). However, due to the points mentioned above, the risk is adequately and more realistically assessed using the LD_{50} mix for a virtual compound in Table 10.1.1.2-10.

Exposure

BAS 516 07 F is intended to be used in potatoes with four applications at a maximum single application rate of 0.25 kg as BAS 516 07 F/ha, taking into account the density of the formulation of 1.04 g/cm^3 (see Table 10.1.1-6 for the critical use pattern). The relevant scenarios for the critical use pattern are given in Table 10.1.1-7.

Calculation of the screening and tier 1 risk assessment for BAS 516 07 F according to EFSA/2009/1438

The screening and tier 1 TER values for the acute dietary risk assessment for birds as obtained by means of the EFSA calculator tool (version of 9 July 2010, http://www.efsa.europa.eu/de/efsajournal/pub/1438.htm) are presented for in Table 10.1.1.2-2.

Table 10.1.1.2-2: BAS 516 07 F: Acute risk assessment for birds in potatoes - results from EFSA calculator tool

Data from Data_Entry worksheet	**Crop**	**Application rate (kg formulation/ ha)**	**Number of applications**	**Application Interval**	**DT_{50}**	**LD_{50}**	
	Potatoes	0.25	4	10	10.0	>3200.0	
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF (90)**	**Daily Dietary Dose (Multiple)**	**TER**	**No refinement step required**
	Small omnivorous bird	158.8	39.7	1.5	59.55	53.7	
First Tier Risk Assessment:							
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**		**Shortcut value**	**TER**	**No refinement required**	
	Potatoes BBCH ≥ 20	Small insectivorous bird “wagtail” ground invertebrates with interception 50% ground arthropods, 50% foliar arthropods		25.2	> 338.6		
	Potatoes BBCH ≥ 40	Small omnivorous bird “lark” Combination (invertebrates without interception) 25% crop leaves 25% weed seeds 50% ground arthropods		7.2	> 1185.2		

In conclusion, even under the conservative assumptions of the screening step and the tier 1 acute dietary risk assessment all TER_A values for the formulation exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low acute risk for birds from the use of BAS 516 07 F in potatoes according to the recommended use pattern.

Effects of secondary poisoning

The log P_{ow} of the active substance pyraclostrobin is 3.99 (SANCO/1420/2001-final), which triggers an assessment for the potential risk through secondary poisoning according to EFSA/2009/1438.

Risk assessment for earthworm-eating birds

The risk assessment for earthworm-eating birds will be based on the worst-case PEC_{soil} (twa, 21 days) derived from M-CP 9.1. The calculations and the resulting TER_{LT} values are summarized in Table 10.1.1.2-3.

Table 10.1.1.2-3: Risk assessment for pyraclostrobin concerning earthworm-eating birds (tier 1) – dry soil approach

Parameter	Pyraclostrobin	Reference
PEC_{soil} (twa, 21 days) [1] [mg/kg soil]	0.013	M-CP 9.1
K_{ow}	9772	SANCO/1420/2001-final
K_{oc} (arithmetic mean)	9304	SANCO/1420/2001-final
f_{oc} (default)	0.02	EFSA/2009/1438
BCF [2]	0.635	--
PEC_{worm} [mg/kg] [3]	0.008	--
Daily dose [mg/kg b.w./d] [4]	0.009	EFSA/2009/1438
NO(A)EL [mg/kg b.w./d]	105.0	Table 10.1.1-1
TER_{LT} [5]	**12119.70**	**--**

1 PEC_{soil} (twa, 21 days) value calculated for four applications of BAS 516 07 F in potatoes. For details see chapter 9.1.
2 Bioconcentration factor (BCF) = $(0.84 + 0.012 \times K_{ow}) / f_{oc} \times K_{oc}$
3 $PEC_{worm} = PEC_{soil} \times BCF$
4 Daily dose = $1.05 \times PEC_{worm}$
5 TER_{LT} = NO(A)EL / Daily dose.

Risk assessment for fish-eating birds

The risk assessment for fish-eating birds will be based on the worst-case PEC_{sw} (twa, 21 days) derived from M-CP 9.2. The calculations and the resulting TER_{LT} values are summarized in Table 10.1.1.2-4.

Table 10.1.1.2-4: Risk assessment for pyraclostrobin concerning fish-eating birds (tier 1)

Parameter	Pyraclostrobin	Reference
$PEC_{sw,}$ (twa, 21 days) [mg/L] [1)]	$0.121 * 10^{-3}$	M-CP 9.2
BCF fish (max. worst case)	736	SANCO/1420/2001-final
PEC_{fish} [mg/kg] [2)]	0.089	--
Daily dose [mg/kg b.w./d] [3)]	0.014	EFSA/2009/1438
NO(A)EL [mg/kg b.w./d]	105.0	Table 10.1.1-1
TER_{LT} [4)]	**7415.30**	--

1 Highest PEC_{sw} (twa, 21 days) from FOCUS Step 2 (South Europe) calculation for a multiple application scenario of BAS 516 07 F in potatoes with parameters from dark water/sediment study as worst-case. For details see chapter M-CP 9.2.
2 PEC_{fish} = PEC_{sw} (twa, 21 days) x BCF
3 Daily dose = 0.159 * PEC_{fish}
4 TER_{LT} = NO(A)EL / Daily dose

In the above risk assessments for earthworm- and fish-eating birds, the TER values exceed the trigger of 5 set by Commission regulation (EU) 546/2011 for acceptability of effects. It can therefore be concluded that the application of BAS 516 07 F in potatoes does not provide reason for concern regarding a potential accumulation of the active substance pyraclostrobin in the food chain or for concern of secondary poisoning.

Biomagnification in terrestrial food chains

No evidence was found for potential of accumulation of pyraclostrobin in animal tissue (Review Report for the active substance pyraclostrobin. Appendix II, endpoints and related information. 1. Toxicology and metabolism. September 2004).

Based on this it can be concluded that the potential for bioaccumulation in animal tissue for pyraclostrobin is low and thus no further assessment on biomagnification is required.

Risk for birds through drinking water

EFSA/2009/1438 proposes an assessment methodology for the risk to birds from active substances in drinking water using small granivorous birds as indicator species in tier 1. Out of the two scenarios, i.e. the leaf and the puddle scenario, the leaf scenario is not relevant for use in potatoes. Consequently, in a drinking water risk assessment for birds only the 'puddle scenario' would need to be considered for the application of BAS 516 07 F in potatoes.

According to EFSA/2009/1438 no specific calculations of exposure and TER values are necessary when the ratio of effective application rate (in g/ha) to relevant endpoint (in mg/kg b.w./d) does not exceed 50 in the case of less sorptive substances (Koc < 500 L/kg) or 3000 in the case of more sorptive substances (Koc ≥ 500 L/kg). The ratio calculations for effective application rate to relevant endpoint are detailed in a screening step in Table 10.1.1.2-5. The ratio for acute and reproductive endpoints for pyraclostrobin (0.02 and 0.4, respectively) do not exceed the threshold value of 3000 as given by EFSA/2009/1438 for more sorptive substances (Koc > 500 L/kg), thus no specific calculations of exposure for birds through drinking water for the puddle scenario are necessary (Table 10.1.1.2-5).

In conclusion, the risk through drinking water from the use of BAS 516 07 F in potatoes is acceptable.

Table 10.1.1.2-5: Screening step for drinking water risk assessment - ratio of effective application rate to relevant endpoint for birds

Parameter	Pyraclostrobin	Reference
K_{oc} [L/kg]	9304	SANCO/1420/2001-final
DT_{50} (soil) [d]	18	M-CP 9.2
Number of applications	4	Table 10.1.1-6
Interval [d]	10	Table 10.1.1-6
MAF_m 1)	2.46	--
Max use rate [g/ha]	17	Table 10.1.1-6
AR_{eff} [g/ha] 2)	41.82	--
LD_{50} [mg/kg b.w.]	1701	Table 10.1.1-1
Ratio (acute) 3)	0.02	--
Reproductive endpoint [mg/kg b.w./d]	105	Table 10.1.1-1
Ratio (repro) 3)	0.4	--
Trigger 4)	3000	--
Drinking water assessment required [Yes/No] 5)	No	--

1 $MAFm = (1-e^{-nki}) / (1-e^{-ki})$ with $k = ln(2)/DT_{50}$ (rate constant), n = number of applications and i = application interval [d]
2 AR_{eff} = Application rate (g/ha) x MAF_m
3 Ratio of AR_{eff} and relevant toxicity endpoint
4 Trigger according to EFSA/2009/1438
5 Drinking water risk assessment is not necessary when trigger value is not exceeded.

A quantitative drinking water risk assessment is not triggered for the recommended use pattern of BAS 516 07 F in potatoes according to EFSA/2009/1438 criteria. Therefore, the risk to birds via drinking water is acceptable.

Exposure to several active substances

In the following the risk of birds being exposed to a formulated product containing more than one active substance is addressed using the **EFSA/2009/1438 approach on "Combined effects of simultaneous exposure to several active substances"**. The simultaneous exposure of animals to residues of two potential toxicants of BAS 516 07 F, i.e. pyraclostrobin and boscalid, was estimated according to information given in Appendix B of EFSA/2009/1438.

Acute risk assessment for a virtual compound with surrogate LD_{50} (=LD_{50} mix)

Calculation of surrogate LD_{50} values for acute effects (mortality)

The following equation has been used for deriving a surrogate LD_{50} (mix) for a mixture of active substances based on the assumption of dose additivity.

Equation 1:

$$LD_{50(mix)} = \left(\sum_i \frac{X(a.s._i)}{LD_{50}(a.s._i)} \right)^{-1}$$

With:

$X(a.s._i)$ = fraction of active substance [i] in the mixture; ($\Sigma X(a.s._i) = 1$)
$LD_{50}(a.s._i)$ = acute toxicity value for active substance [i]
LD_{50}(mix) is also called 'surrogate LD_{50}'

The acute risk assessment for a virtual compound is assessed for the formulation BAS 516 07 F.

According to the label, BAS 516 07 F contains 67 g/kg pyraclostrobin and 267 g/kg boscalid. The relative amounts of pyraclostrobin and boscalid for the formulated product are given in Table 10.1.1.2-6.

Table 10.1.1.2-6: Relative amounts of pyraclostrobin and boscalid in BAS 516 07 F

Formulation	BAS 516 07 F	
Active substance	**Amount a.s. in product [g/kg]**	**Fraction of active substance in product**
Boscalid	267	0.80
Pyraclostrobin	67	0.20
Sum	334	1

Avian acute oral toxicity studies have been carried out with the active substances pyraclostrobin (Table 10.1.1-1) and boscalid (Table 10.1.1.2-7). Equation 1 has been used for deriving a surrogate LD50 for a mixture of active substances as presented in Table 10.1.1.2-8.

Table 10.1.1.2-7: EU agreed acute endpoint of boscalid for birds

Study type	Test species	EU agreed endpoints	Endpoints used in risk assessment
Boscalid			
Acute toxicity to birds	*Colinus virginianus*	LD_{50} > 2000 mg a.s. / kg b.w.[1)]	LD_{50} > 2000 mg a.s. / kg b.w.[1)]

1 Endpoint from Review Report given under '3 Ecotoxicology' for the active substance boscalid, SANCO/3919/2007-rev. 5, 17.01.08

Table 10.1.1.2-8: Calculation of surrogate LD_{50} values for acute dietary risk assessment calculated from acute endpoints of active substances

Active substance	Acute LD_{50} [mg a.s./kg b.w.]	Fraction of a.s. in product: X ($a.s._i$)	X ($a.s._i$)/$LD_{50\ i}$	Sum [1)]	Surrogate LD_{50} [2)] [mg virtual compound/kg b.w.]
Boscalid	>2000	0.8	0.00040	0.00052	1931.9
Pyraclostrobin	1701	0.2	0.00012		

1 $\sum$ (X ($a.s._i$) / extrapolated $LD_{50\ i}$)
2 Surrogate LD_{50} = 1/($\sum$ X ($a.s._i$) / extrapolated $LD_{50\ of\ a\ s}$)

The surrogate LD_{50}, or LD_{50} (mix), for the mixture of active substances in BAS 516 07 F is 1931.9 mg virtual compound/kg b.w.

According to EFSA/2009/1438 the calculated LD_{50} (mix) can be used in the risk assessment if the deviation between the 'tox per fraction' of the active substance to the tox per fraction of the mixture are greater than 10% for each active substance. This is the case for the tox per fraction of pyraclostrobin and boscalid as detailed in Table 10.1.1.2-9. The tox per fraction for boscalid deviates by 30% to the tox per fraction of the mixture and for pyraclostrobin it deviates by 339% to the tox per fraction of the mixture. Therefore, the calculated LD_{50} (mix) can be used in the risk assessment using the combination toxicity approach.

Table 10.1.1.2-9: Deviation of the tox per fraction comparing pyraclostrobin and boscalid to the tox per fraction of the mixture

Active substance	Tox per fraction (a.s.) [1)] [mg a.s./kg b.w.]	LD_{50} (mix) [2)] [mg virtual compound/kg b.w.]	Deviation [3)] [%]
Boscalid	2501.9	1931.9	30
Pyraclostrobin	8479.6		339

1 Extrapolated LD_{50} ($a.s._i$) /X ($a.s._i$)
2 LD50 (mix) is the "tox per fraction (mix)" and calculated with LD_{50} (mix) = surrogate LD_{50}) /Σ X($a.s._i$). This means that the LD_{50} (mix) is equal to the surrogate LD_{50}, since the sum of the fractions of a.s. in the product must equal 1.
3 (100/Tox per fraction (mix) x Tox per fraction ($a.s._i$))-100

In conclusion, the acute ecotoxicological endpoint, estimating mixture toxicity of pyraclostrobin and boscalid as contained in the formulation BAS 516 07 F is LD_{50} (mix) = 1931.9 mg virtual compound/kg b.w.

Exposure

BAS 516 07 F (containing the active substances pyraclostrobin and boscalid) is intended to be used in potatoes from BBCH 51-89 (Table 10.1.1-6). The potential exposure of birds to pyraclostrobin and boscalid was estimated following four applications of BAS 516 07 F at the maximum use rate of 0.25 kg product/ha, corresponding to 0.017 kg/ha pyraclostrobin and 0.067 kg/ha boscalid. For details please refer to the use pattern in Table 10.1.1-6.

According to the EFSA/2009/1438 an endpoint for a mixture of active substances calculated assuming dose additivity should be conceived as an endpoint of a single virtual compound. Therefore, the exposure calculation for the risk assessment is based as well on this assumption. Content in the formulation and application rate per hectare should thus be expressed in terms of this virtual compound. Therefore, the overall application rate for active substances combined of 0.084 kg virtual compound/ha is considered for the acute risk assessment. The relevant scenarios are given in Table 10.1.1-7.

Calculation of the screening and tier 1 risk assessment for a virtual compound according to EFSA/2009/1438

The avian screening and tier 1 TER values for the acute dietary risk assessment of the virtual compound as obtained by means of the EFSA calculator tool (version of 9 July 2010, http:// www.efsa. europa.eu /de /efsajournal/pub/1438.htm) are presented in Table 10.1.1.2-10.

Table 10.1.1.2-10: Virtual compound: Acute risk assessment for birds in potatoes - results from EFSA calculator tool

Data from Data_Entry worksheet	**Crop**	**Application rate (Kg/ha)**	**Number of applications**	**Application Interval**	**DT_{50}**	**LD_{50}**	
	Potatoes	0.084	4	10	10.0	1931.9	
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF (90)**	**Daily Dietary Dose (Multiple)**	**TER**	**No refinement step required**
	Small omnivorous bird	158.8	13.34	1.5	20.01	96.6	
First Tier Risk Assessment:							
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**			**Shortcut value**	**TER**	**No refinement required**
	Potatoes BBCH ≥ 20	Small insectivorous bird "wagtail" ground invertebrates with interception 50% ground arthropods, 50% foliar arthropods			25.2	608.4	
	Potatoes BBCH ≥ 40	Small omnivorous bird "lark" Combination (invertebrates without interception) 25% crop leaves 25% weed seeds 50% ground arthropods			7.2	2129.5	

In conclusion, even under the conservative assumptions of the screening step and the tier 1 acute dietary risk assessment all TER values for the virtual compound exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low acute risk for birds from the use of BAS 516 07 F in potatoes.

Consideration of mixture toxicity for sublethal effects and effects on reproduction

Please note that it is currently not recommended to consider the use of predicted toxicity values as surrogates in the reproductive risk assessment. For a detailed discussion please refer to Appendix B (p.4) of EFSA/2009/1438.

Conclusion

In conclusion, even under the conservative assumptions of the screening step and the tier 1 acute dietary risk assessments for the virtual compound and the formulation, all TER_A values, from the risk assessment addressing the combined effects of simultaneous exposure to two active substances, exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low acute risk for birds from the use of BAS 516 07 F in potatoes according to the recommended use pattern.

CP 10.1.2 Effects on terrestrial vertebrates other than birds

Data on BAS 516 07 F are evaluated and the risk assessments are presented for the active substance pyraclostrobin and for the evaluation of combined effects of formulations containing more than one active substance based on the already registered use pattern.

Table 10.1.2-1: Endpoints for mammals

Test system	Test species	EU agreed endpoints	Endpoints used in present risk assessment
Acute toxicity	Rat	LD_{50} > 5000 mg a.s./kg b.w. [1)]	LD_{50} > 5000 mg a.s./kg b.w.
Reproductive toxicity (long-term)	Rat	--	NOEL = 3 mg a.s./kg b.w./d [2)]

1 Endpoints confirmed in the Ecotoxicology section of the Review report for the active substance pyraclostrobin, September 2004.

2 Daily Dose [mg/kg b.w./d] calculated based on study data for food consumption and body weight.

RISK ASSESSMENT

Summary of mammalian toxicity testing

The mammalian toxicity studies with pyraclostrobin relevant for a tier 1 dietary risk assessment for wild mammals are summarized in Table 10.1.2-2.

Table 10.1.2-2: Summary of studies relevant for the mammalian risk assessment for pyraclostrobin

Test system	Test species	Results	Reference (BASF DocID)
Acute oral toxicity	Rat	LD_{50} > 5000 mg a.s./kg b.w. [1)]	1998/10965
Reproductive toxicity	Rat	$NOEL_{Reproduction}$ = 32.6 mg a.s./kg b.w./d [2)] $NOEL_{Offspring}$ = 8.2 mg a.s./kg b.w./d [2)] $NOEL_{Parents}$ = 8.2 mg a.s./kg b.w./d [2)]	1999/11869
Developmental toxicity	Rat	$NOEL_{Rel\ Maternal}$ = 10 mg a.s./kg b.w./d [2)] $NOEL_{Rel\ Developmental}$ = 50 mg a.s./kg b.w./d [2)]	1999/11511
	Rabbit	$NOEL_{Rel\ Maternal}$ = 3 mg a.s./kg b.w./d [2)] $NOEL_{Rel\ Developmental}$ = 5 mg a.s./kg b.w./d [2)]	2001/1003803 and 1999/11512

1 Endpoints confirmed in the Ecotoxicology section of the Review report for the active substance pyraclostrobin, September 2004.

2 Daily Dose [mg/kg b.w./d] calculated based on study data for food consumption and body weight.

Mammalian toxicity endpoint for use in the acute tier 1 risk assessment

There is one acute oral toxicity test with pyraclostrobin available in rats (BASF DocID 1998/10965). This study resulted in an **LD_{50} > 5000 mg a.s./kg b.w.**, which is the relevant endpoint to be used in the acute risk assessment.

Mammalian toxicity endpoint for use in the reproductive tier 1 risk assessment

In order to obtain the relevant toxicity endpoint for the tier 1 reproductive risk assessment, the lowest NOAEL from the two-generation rat study and the lowest relevant endpoint from the developmental studies have to be considered.

For pyraclostrobin, the lowest toxicity endpoint from these studies (Table 10.1.2-2) is the **NOEL = 3 mg a.s./kg b.w./d**, derived from the developmental rabbit study. This value is the endpoint used for the screening and tier 1 reproductive risk assessment.

Results from available toxicity testing with the formulation

The mammalian toxicity study with BAS 516 07 F relevant for the risk assessment for mammals is summarized in Table 10.1.2-3.

Table 10.1.2-3: Summary of mammalian study on the acute toxicity of BAS 516 07 F

Test system	Test species	Results	Reference (BASF DocID)
Acute oral toxicity	Rat	LD_{50} > 2000 mg/kg b.w.	2008/1004838 [1)]

1 For detailed study summary please refer to M-CP 7.1.1.

A full summary of this study is given in M-CP 7.1.1. An acute risk assessment for BAS 516 07 F considering the **LD_{50} > 2000 mg/kg b.w. for BAS 516 07 F** is provided further below.

Metabolites of pyraclostrobin

A full assessment of the relevance of pyraclostrobin metabolites for the birds and mammals risk assessment is given in M-CP 10.1.1. Please refer to M-CP 10.1.1 for details.

Summary of relevant mammalian toxicity endpoints to be used in the screening and tier 1 risk assessments

The mammalian endpoints relevant for the screening step and for the tier 1 risk assessments are given in Table 10.1.2-4.

Table 10.1.2-4: Mammalian toxicity endpoints for screening and tier 1 risk assessments of pyraclostrobin and BAS 516 07 F

Test substance	Test system	Relevant toxicity endpoint
Pyraclostrobin	Acute oral toxicity	LD_{50} > 5 000 mg a.s./kg b.w.
	Sub-chronic toxicity and reproduction	NOEL = 3 mg a.s./kg b.w./d
BAS 516 07 F	Acute oral toxicity	LD_{50} > 2000 mg a.s./kg b.w.

Relevant exposure scenarios

The relevant scenarios for the already registered use pattern (Table 10.1.2-5) are given in Table 10.1.2-6.

Table 10.1.2-5: Critical use pattern for BAS 516 07 F

Crop	Crop group according to EFSA/2009/ 1438	Application time (BBCH growth stage)	Number of applications	Interval [days]	Maximum application rate per treatment		
					Pyraclostrobin [kg/ha]	Boscalid[1)] [kg/ha]	BAS 516 07 F [L/ha]
Potatoes	Potatoes	51-89	4	10	0.017	0.067	0.25

1 Not relevant for the renewing the approval of pyraclostrobin. Therefore, the a.s. boscalid is not evaluated here.

Table 10.1.2-6: Summary of exposure scenarios to be considered for risk assessments for spray applications of BAS 516 07 F in potatoes

Scenario	Generic focal species
Potatoes BBCH ≥ 20	Small insectivorous mammal “shrew”
Potatoes BBCH ≥ 40	Large herbivorous mammal “lagomorph”
Potatoes BBCH ≥ 40	Small herbivorous mammal "vole"
Potatoes BBCH ≥ 40	Small omnivorous mammal “mouse”

CP 10.1.2.1 Acute oral toxicity to mammals

In this section, the dietary TER acute values for the screening step and tier 1 assessment obtained by means of the EFSA calculator tool (version of 9 July 2010, http://www.efsa.europa.eu/de/efsajournal/pub/1438.htm) are presented for pyraclostrobin in Table 10.1.2.1-1.

Table 10.1.2.1-1: Pyraclostrobin: Acute dietary risk assessment for mammals in potatoes - results from EFSA calculator tool

Data from Data_Entry worksheet	**Crop**	**Application rate (kg a.s./ha)**	**Number of applications**	**Application Interval**	**DT_{50}**	**LD_{50}**	
	Potatoes	0.017	4	10	10.0	>5000	
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF (90)**	**Daily Dietary Dose (Multiple)**	**TER**	**No refinement step required**
	Small herbivorous mammal	118.4	2.01	1.5	3.02	1656.1	
First Tier Risk Assessment:							
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**		**Shortcut value**	**TER**	**No refinement required**	
	Potatoes BBCH ≥ 20	Small insectivorous mammal “shrew” ground dwelling invertebrates with interception 100% ground arthropods		5.4	>36310.8		
	Potatoes BBCH ≥ 40	Large herbivorous mammal “lagomorph” Non-grass herbs 100% Non-grass herbs		10.5	>18674.1		
	Potatoes BBCH ≥ 40	Small herbivorous mammal "vole Grass + cereals 100% grass		40.9	>4794.1		
	Potatoes BBCH ≥ 40	Small omnivorous mammal “mouse” Combination (invertebrates without interception) 25% weeds 50% weed seeds 25% ground arthropods		5.2	>37707.4		

In conclusion, even under the conservative assumptions of the screening and tier 1 acute dietary risk assessment all TER_A values for pyraclostrobin exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low acute risk for mammals from the use of BAS 516 07 F in potatoes according to the recommended use pattern.

CP 10.1.2.2 Higher tier data on mammals

Please note that this section, albeit suggested by its header, does not only include higher tier data on mammals. The calculations presented for potatoes in Table 10.1.2.2-1 are the **dietary TER reproductive values for the screening step and tier 1 assessment** obtained by means of the EFSA calculator tool (version of 9 July 2010, http://www.efsa.europa.eu /de/efsajournal/pub/1438.htm).

Table 10.1.2.2-1: Pyraclostrobin: Reproductive risk assessment for mammals in potatoes - results from EFSA calculator tool

Data from Data_Entry worksheet	**Crop**	**Application rate (Kg a.s./ha)**	**Number of applications**	**Application Interval**	**DT_{50}**	**Repro End Point (mg/kg bw/d)**	**Time weighted average (TWA)**
	Potatoes	0.017	4	10	10	3	0.53
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF mean**	**Daily Dietary Dose (Multiple)**	**TER**	**No refinement step required**
	Small herbivorous mammal	48.3	0.82	.19	0.83	3.63	
First Tier Risk Assessment:							
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**			**Shortcut value**	**TER**	**No refinement required**
	Potatoes BBCH ≥ 20	Small insectivorous mammal “shrew” ground dwelling invertebrates with interception 100% ground arthropods			1.9	92.2	
	Potatoes BBCH ≥ 40	Large herbivorous mammal “lagomorph” Non-grass herbs 100% Non-grass herbs			4.3	40.8	
	Potatoes BBCH ≥ 40	Small herbivorous mammal "vole Grass + cereals 100% grass			21.7	8.1	
	Potatoes BBCH ≥ 40	Small omnivorous mammal “mouse” Combination (invertebrates without interception) 25% weeds 50% weed seeds 25% ground arthropods			2.3	76.2	

In conclusion, even under the conservative assumptions of the tier 1 reproductive dietary assessments, all TER_{LT} values for pyraclostrobin exceed the trigger values set by Commission regulation (EU) 546/2011 for acceptability of effect. This indicates a low reproductive risk for mammals from the use of BAS 516 07 F in potatoes according to the recommended use pattern.

Acute oral toxicity of the preparation

An acute oral toxicity study is available for the formulation BAS 516 07 F. The results of the study show no increased formulation toxicity as the formulation is practically acutely non-toxic to mammals (LD_{50} > 2000 mg BAS 516 07 F/kg b.w.). A detailed summary of this study is given in M-CP 7.1.1.

Please note, an acute risk assessment for BAS 516 07 F with LD_{50} from formulation toxicity testing is provided further below.

Acute risk assessment considering the LD_{50} from toxicity testing with BAS 516 07 F

Toxicity endpoint of the formulation for mammals

Acute oral toxicity studies of formulations are not specifically designed for use in wild mammal risk assessments but are conducted for the purpose of classification and labelling and include testing of rates with single doses of the intact formulation administered by oral gavage. The type and pattern of exposure of wild mammals following a foliar spray in the field is very different than the exposure pattern tested in acute oral gavage tests.

Hence, the results of such acute oral toxicity tests are of limited relevance for the acute wild mammal risk assessment. Nevertheless, for a conservative estimate, the endpoint of the acute oral toxicity study with BAS 516 07 F on rats (i.e. LD_{50} > 2000 mg/kg b.w.) will be used for a tier 1 acute risk assessment of the formulation. The results of the tier 1 acute dietary exposure assessment and TER calculation will be presented below.

However, note that the risk of the formulation is considered to be adequately and more realistically assessed using the LD_{50} mix for a virtual compound in Table 10.1.2.2-10.

Exposure

BAS 516 07 F is intended to be used in potatoes with four applications at a maximum single application rate of 0.25 kg as BAS 516 07 F/ha (see Table 10.1.1-6 for the critical use pattern). The relevant scenarios for the critical use pattern are given in Table 10.1.1-7.

Calculation of the screening and tier 1 risk assessment for BAS 516 07 F according to EFSA/2009/1438

The screening and tier 1 TER values for the acute dietary risk assessment for mammals as obtained by means of the EFSA calculator tool (version of 9 July 2010, http://www.efsa.europa.eu/de/efsajournal/pub/1438.htm) are presented in Table 10.1.2.2-2.

Table 10.1.2.2-2: BAS 516 07 F: Acute risk assessment for mammals - results from EFSA calculator tool

Data from Data_Entry worksheet	**Crop**	**Application rate (kg formulation/ha)**	**Number of applications**	**Application Interval**	**DT_{50}**	**LD_{50}**	
	Potatoes	0.25	4	10	10	>2000	
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF (90)**	**Daily Dietary Dose (Multiple)**	**TER**	**No refinement required**
	Small herbivorous mammal	118.4	29.60	1.5	44.40	>45.0	

Tier 1 Risk Assessment:					
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**	**Shortcut value**	**TER**	**No refinement required**
	Potatoes BBCH ≥ 20	Small insectivorous mammal “shrew” ground dwelling invertebrates with interception 100% ground arthropods	5.4	>987.7	
	Potatoes BBCH ≥ 40	Large herbivorous mammal “lagomorph” Non-grass herbs 100% Non-grass herbs	10.5	>507.9	
	Potatoes BBCH ≥ 40	Small herbivorous mammal "vole Grass + cereals 100% grass	40.9	>130.4	
	Potatoes BBCH ≥ 40	Small omnivorous mammal “mouse” Combination (invertebrates without interception) 25% weeds 50% weed seeds 25% ground arthropods	5.2	>1025.6	

In conclusion, even under the conservative assumptions of the screening step and the tier 1 acute dietary risk assessment all TER values for the formulation exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low acute risk for mammals from the use of BAS 516 07 F in potatoes according to the recommended use pattern.

Effects of secondary poisoning

The log P_{ow} of the active substance pyraclostrobin was determined to be 3.99 (SANCO/1420/2001-final) which triggers an assessment for the potential risk through secondary poisoning according to EFSA/2009/1438.

Risk assessment for earthworm-eating mammals

The risk assessment for earthworm-eating mammals will be based on the worst-case PEC_{soil} (twa, 21 days) derived from M-CP 9.1. The calculations and the resulting TER_{LT} values are summarized in Table 10.1.2.2-3.

Table 10.1.2.2-3: Risk assessment for pyraclostrobin concerning earthworm-eating mammals – dry soil approach

Parameter	Pyraclostrobin	Reference
PEC_{soil} (twa, 21 days) [1] [mg/kg soil]	0.013	M-CP 9.1
K_{ow}	9772	SANCO/1420/2001-final;
K_{oc} (arithmetic mean)	9304	SANCO/1420/2001-final;
f_{oc} (default)	0.02	EFSA/2009/1438
BCF [2]	0.635	--
PEC_{worm} [mg/kg] [3]	0.008	--
Daily dose [mg/kg b.w./d] [4]	0.011	EFSA/2009/1438
NO(A)EL [mg/kg b.w./d]	3	Table 10.1.2-1
TER_{LT} [5]	284.06	--

1 PECsoil (twa, 21 days) value calculated for four applications of BAS 516 07 F in potatoes. For details see chapter 9.1.
2 Bioconcentration factor (BCF) = $(0.84 + 0.012 \times K_{ow}) / f_{oc} \times K_{oc}$
3 $PEC_{worm} = PEC_{soil} \times BCF$
4 Daily dose = $1.28 \times PEC_{worm}$
5 TER_{LT} = NO(A)EL / Daily dose.

The risk assessment for fish-eating mammals will be based on the worst-case PEC_{sw} (twa, 21 days) derived from M-CP 9.2. The calculations and the resulting TER_{LT} values are summarized in Table 10.1.2.2-4.

Table 10.1.2.2-4: Risk assessment for pyraclostrobin concerning fish-eating birds (tier 1)

Parameter	Pyraclostrobin	Reference
$PEC_{sw,}$ (twa, 21 days) [mg/L] 1)	$0.121 * 10^{-3}$	M-CP 9.2
BCF fish (max. worst case)	736	SANCO/1420/2001-final
PEC_{fish} [mg/kg] 2)	0.089	--
Daily dose [mg/kg b.w./d] 3)	0.013	EFSA/2009/1438
NO(A)EL [mg/kg b.w./d]	3.0	Table 10.1.2-1
TER_{LT} 4)	237.23	--

1 Highest PECsw (twa, 21 days) from FOCUS Step 2 (South Europe) calculation for a multiple application scenario of BAS 516 07 F in potatoes with parameters from dark water/sediment study as worst-case.
2 $PEC_{fish} = PEC_{sw}$ x BCF
3 Daily dose = 0.142 x PEC_{fish}
4 TER_{LT} = NO(A)EL / Daily dose

In the above risk assessments for earthworm- and fish-eating mammals, the TER values exceed the trigger of 5 set by Commission regulation (EU) 546/2011 for acceptability of effects. **It can therefore be concluded that the application of BAS 516 07 F in potatoes does not provide reason for concern regarding a potential accumulation of the active substance pyraclostrobin in the food chain or for concern of secondary poisoning.**

Biomagnification in terrestrial food chains

No evidence was found for potential of accumulation of pyraclostrobin in animal tissue (Review report for the active substance pyraclostrobin. Appendix II, endpoints and related information. September, 2004).

Based on this it can be concluded that the potential for bioaccumulation in animal tissue for pyraclostrobin is low and thus no further assessment on biomagnification is required**.**

Risk for mammals through drinking water

EFSA/2009/1438 proposes an assessment methodology for the risk to mammals from active substances in drinking water using small granivorous mammals as indicator species in tier 1. Out of the two scenarios, i.e. the leaf and the puddle scenario, the leaf scenario is not relevant for small mammals. Consequently, in the following drinking water risk assessment for mammals only the ‘puddle scenario’ will be considered for the application of BAS 516 07 F in potatoes.

According to EFSA/2009/1438 no specific calculations of exposure and TER values are necessary when the ratio of effective application rate (in g/ha) to relevant endpoint (in mg/kg b.w./d) does not exceed 50 in the case of less sorptive substances (Koc < 500 L/kg) or 3000 in the case of more sorptive substances (Koc ≥ 500 L/kg). The ratio calculations for effective application rate to relevant endpoint are detailed in a screening step in Table 10.1.2.2-5. The ratio for acute and reproductive endpoints for pyraclostrobin (<0.01 and 13.9, respectively) and do not exceed the threshold value of 3000, as given by EFSA/2009/1438 for more sorptive substances (Koc < 500 L/kg). Thus no specific calculations of exposure and TER for mammals through drinking water for the puddle scenario are necessary**. In conclusion, the risk through drinking water from the intended use of BAS 516 07 F in potatoes is acceptable.**

Table 10.1.2.2-5: Screening step for drinking water risk assessment - ratio of effective application rate to relevant endpoint for mammals

Parameter	Pyraclostrobin	Reference
Koc [L/kg] (arithmetic mean)	9304	SANCO/1420/2001-final
DT_{50} (soil) [days]	18	M-CP 9.2
Number of applications	4	Table 10.1.2-5
Interval [days]	10	Table 10.1.2-5
MAF_m 1)	2.46	--
Max use rate [g/ha]	17	Table 10.1.2-5
AR_{eff} [g/ha] 2)	41.82	--
LD_{50} [mg/kg b.w.]	> 5 000	Table 10.1.2-1
Ratio (acute) 3)	<0.01	--
NO(A)EL [mg/kg b.w./d]	3	Table 10.1.2-1
Ratio (repro) 3)	13.9	--

Drinking water assessment required [Yes/No] 5)	No	--

1 $MAFm = (1-e^{-nki}) / (1-e^{-ki})$ with $k = ln(2)/ DT_{50}$ (rate constant), n = number of applications and i = application interval [d]
2 AR_{eff} = Application rate (g/ha) x MAF_m
3 Ratio of AR_{eff} and relevant toxicity endpoint
4 Trigger according to EFSA/2009/1438
5 Drinking water risk assessment is not necessary when trigger value is not exceeded

Exposure to several active substances

In the following the risk of mammals being exposed to a formulated product containing more than one active substance is addressed using the **EFSA/2009/1438 approach on "Combined effects of simultaneous exposure to several active substances"**. The simultaneous exposure of animals to residues of two potential toxicants of BAS 516 07 F, i.e. pyraclostrobin and boscalid, was estimated according to information given in Appendix B of EFSA/2009/1438.

Acute risk assessment for a virtual compound with surrogate LD_{50} (=LD_{50} mix)

Calculation of surrogate LD_{50} values for acute effects (mortality)

The following equation has been used for deriving a surrogate LD_{50} (mix) for a mixture of active substances based on the assumption of dose additivity.

Equation 1:

$$LD_{50(mix)} = \left(\sum_i \frac{X(a.s._i)}{LD_{50}(a.s._i)} \right)^{-1}$$

With:

$X(a.s._i)$ = fraction of active substance [i] in the mixture; ($\Sigma X(a.s._i) = 1$)
$LD_{50}(a.s._i)$ = acute toxicity value for active substance [i]
LD_{50} (mix) is a synonym for 'surrogate LD_{50}'

The acute risk assessment for a virtual compound is assessed for the formulation BAS 516 07 F.

According to the label, BAS 516 07 F contains 67 g/kg pyraclostrobin and 267 g/kg boscalid. The relative amounts of pyraclostrobin and boscalid for the formulated product are given in Table 10.1.2.2-6.

Table 10.1.2.2-6: Relative amounts of pyraclostrobin and boscalid in BAS 516 07 F

Formulation	**BAS 516 07 F**	
Active substance	**Amount in product [g/kg]**	**Fraction of active substance in product**
Boscalid	267	0.80
Pyraclostrobin	67	0.20
Sum	334	1

Mammalian acute oral toxicity studies have been carried out with the active substances pyraclostrobin (s. Table 10.1.2-1) and boscalid (s. Table 10.1.2.2-7). Equation 1 has been used for deriving a surrogate LD50 for a mixture of active substances as presented in Table 10.1.2.2-8.

Table 10.1.2.2-7: EU agreed acute endpoint of boscalid for mammals

Study type	Test species	EU agreed endpoints	Endpoints used in risk assessment
Boscalid			
Acute toxicity to mammals	Rat	LD_{50} > 5000 mg. a.s. / kg b.w.[1)]	LD_{50} > 5000 mg. a.s. / kg b.w.[1)]

1 Endpoint from Review Report given under '3 Ecotoxicology' for the active substance boscalid, SANCO/3919/2007-rev. 5, 17.01.08

Table 10.1.2.2-8: Calculation of surrogate LD_{50} values for acute dietary risk assessment based on acute endpoints of active substances

Active substance	LD_{50} [mg a.s./kg b.w.]	Fraction of a.s. in product: X ($a.s._i$)	X ($a.s._i$)/$LD_{50\ i}$	Sum[1)]	Surrogate LD_{50} [2)] [mg a.s./kg b.w.]
Boscalid	>5000	0.80	0.00016	0.0002	5000
Pyraclostrobin	>5000	0.20	0.00004		

1 $\sum$ (X (a.s.i)/LD50 i)
2 LD_{50} (mix) (= surrogate LD_{50}) = $1/(\sum X\ (a.s._i)/LD_{50\ of\ a\ s})$

The surrogate LD_{50}, or LD_{50} (mix), for the mixture of active substances in BAS 516 07 F is 5000mg a.s./kg b.w.

According to EFSA/2009/1438 the calculated LD_{50} (mix) can be used in the risk assessment if the deviation between the 'tox per fraction' of the active substance to the tox per fraction of the mixture are greater than 10% for each active substance. This is the case for the tox per fraction of pyraclostrobin and boscalid as detailed in Table 10.1.2.2-9. The tox per fraction values for pyraclostrobin and boscalid deviate by 25% and 399% from the tox per fraction value of the mixture, respectively. Therefore, the calculated LD_{50} (mix) can be used in the risk assessment using the combination toxicity approach.

Table 10.1.2.2-9: Deviation of the tox per fraction comparing pyraclostrobin and boscalid to the tox per fraction of the mixture

Active substance	Tox per fraction (a.s.) [1)] [mg a.s./kg b.w.]	Tox per fraction (mix) [2)] [mg a.s./kg b.w.]	Deviation [3)] [%]
Boscalid	6254.7	5000	25
Pyraclostrobin	24925.4		399

1 $LD_{50}\ (a.s._i)/X\ (a.s._i)$
2 LD_{50} (mix) (= surrogate LD_{50})/Σ X($a.s._i$). This means that acute tox per fraction (mix) = LD_{50} (mix) (= surrogate LD_{50}), since the sum of the fractions must be equal to 1.
3 (100/Tox per fraction (mix) x Tox per fraction ($a.s._i$))-100

In conclusion, the acute ecotoxicological endpoint, estimating mixture toxicity of pyraclostrobin and boscalid is LD_{50} mix = 5000.0 mg virtual compound/kg b.w.

Exposure

BAS 516 07 F (containing the active substances pyraclostrobin and boscalid) is intended to be used in potatoes from BBCH 51-89 (Table 10.1.1-6). The potential exposure of birds to pyraclostrobin and boscalid was estimated following four applications of BAS 516 07 F at the maximum use rate of 0.25 kg product/ha, corresponding to 0.017 kg/ha pyraclostrobin and 0.067 kg/ha boscalid. For details please refer to the use pattern in Table 10.1.1-6. The relevant scenarios are given in Table 10.1.1-7.

According to the EFSA/2009/1438 an endpoint for a mixture of active substances calculated assuming dose additivity should be conceived as an endpoint of a single virtual compound. Therefore, the exposure calculation for the risk assessment is based as well on this assumption. Content in the formulation and application rate per hectare should thus be expressed in terms of this virtual compound. Therefore, the overall application rate for active substances combined of 0.084 kg virtual compound/ha is considered for the acute risk assessment.

Calculation of the screening and tier 1 risk assessment for a virtual compound according to EFSA/2009/1438

The screening and tier 1 TER values for the acute dietary risk assessment for mammals as obtained by means of the EFSA calculator tool (version of 9 July 2010, http://www.efsa.europa.eu/de/efsajournal/pub/1438.htm) are presented in Table 10.1.2.2-10.

Table 10.1.2.2-10: Virtual compound: Acute dietary risk assessment for mammals - results from EFSA calculator tool

Data from Data_Entry worksheet	**Crop**	**Application rate (kg/ha)**	**Number of applications**	**Application Interval**	**DT_{50}**	**LD_{50}**	
	Potatoes	0.084	4	10	10.0	5000	
Screening step:							
Acute risk assessment screening step	**Indicator species**	**Shortcut value**	**Daily Dietary Dose (single)**	**MAF (90)**	**Daily Dietary Dose (Multiple)**	**TER**	**No refinement step required**
	Small herbivorous mammal	118.4	9.95	1.5	14.92	335.2	
First Tier Risk Assessment:							
Calculate TER for each generic focal species selected	**Crop**	**Generic focal species**		**Shortcut value**	**TER**	**No refinement required**	
	Potatoes BBCH ≥ 20	Small insectivorous mammal "shrew" ground dwelling invertebrates with interception 100% ground arthropods		5.4	7348.6		
	Potatoes BBCH ≥ 40	Large herbivorous mammal "lagomorph" Non-grass herbs 100% Non-grass herbs		10.5	3779.3		
	Potatoes BBCH ≥ 40	Small herbivorous mammal "vole Grass + cereals 100% grass		40.9	970.2		
	Potatoes BBCH ≥ 40	Small omnivorous mammal "mouse" Combination (invertebrates without interception) 25% weeds 50% weed seeds 25% ground arthropods		5.2	7631.3		

In conclusion, even under the conservative assumptions of the screening step and the tier 1 acute dietary risk assessment all TER values for a virtual compound exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects. This indicates a low acute risk for mammals from the use of BAS 516 07 F in potatoes according to the recommended use pattern.

Consideration of mixture toxicity for sublethal effects and effects on reproduction

Note that it is currently not recommended to consider the use of predicted toxicity values as surrogates in the risk assessment. For a detailed discussion please refer to Appendix B (p.4) of EFSA/2009/1438.

Conclusion

In conclusion, even under the conservative assumptions of the screening step and the tier 1 acute dietary risk assessment for the virtual compound and the formulation, all TER_A values, from the risk assessment addressing the combined effects of simultaneous exposure to two active substances, exceed the trigger set by Commission regulation (EU) 546/2011 for acceptability of effects for BAS 516 07 F. This indicates a low acute risk for mammals from the use of BAS 516 07 F in potatoes according to the recommended use pattern.

CP 10.1.3 Effects on other terrestrial vertebrate wildlife (reptiles and amphibians)

In a literature review a few references on amphibian studies with pyraclostrobin, respectively pyraclostrobin-containing formulations were identified. Summaries of these publications are provided in M-CA.8.1.4. Please refer to this part of the dossier for details. There are no specific investigations or findings indicating impacts on reptiles.

Specific targeted GLP investigations have been conducted with amphibians using the solo formulation BAS 500 06 F (for details please see M-CP 10.1.3 of BAS 500 06 F).

Risk assessment - other terrestrial vertebrate wildlife: reptiles and amphibians

The laboratory studies conducted under worst-case conditions, using sensitive life stages (metamorphs) and maximizing exposure via direct overspray over animals and bare soil (Belden et al. 2010; Bruehl et al. 2013; BASF DocID 2013/1375098), indicate inherent toxicity of pyraclostrobin, respectively pyraclostrobin containing formulations to amphibians. The results from the two investigations by Belden et al. (2010) and Bruehl et al. (2013) (non-GLP studies, for more details see M-CA 8.1.4) on *Rana temporaria* and *Bufo cognatus* show no impact of the test substance at 22 g a.s./ha, whereas 220 g a.s./ha (reflecting the field rate) caused high mortality (100 and 70% at 220 g a.s./ha for *Rana temporaria* and Bufo cognatus, respectively). The BASF laboratory study with *Rana temporaria* provides comparable results while narrowing down the toxicity range. Results are shown in Table 10.1.3-1.

The above-mentioned laboratory studies show that young, juvenile frogs and toads can be sensitive if oversprayed directly with EC formulated pyraclostrobin (containing organic solvents). BASF conducted additionally a study (BASF DocID 2014/1221859) investigating the impact of the same product when not overspraying the toads directly, but exposing them to bare soil that has been oversprayed before. The toxicity to animals exposed to the soil residues shortly after spraying was significantly reduced as compared to direct overspray, and following a time interval of about four hours between spraying and animals moving onto the contaminated soil, no effects on the toads were observed even at elevated rates of 310 g a.s./ha.

Table 10.1.3-1: List of endpoints obtained in studies with amphibians

Study	Test species	Test substance	Formulation type	Appl. rate [g a.s./ha]	Effect (% mortality)
Belden et al. (2010)	*Bufo cognatus*	BAS 500 00 F (Headline®)	EC (emulsifiable concentrate)	22	0
				220	70
				2200	100
Brühl et al. (2013)	*Rana temporaria*	BAS 500 00 F (Headline®)	EC	22	0
				220	100
		BAS 500 18 F	CS (capsule suspension)	2200	no significant effect
BASF DocID 2013/1375098	*Rana temporaria*	BAS 500 06 F	EC	40	0
				63	0 sublethal symptoms
				99	70
BASF DocID 2014/1375098	*Bufo bufo*	BAS 500 06 F	EC	155 / 15 min 219 / 15 min 310 / 15 min 310 / 60 min 310 / 4 h[1)]	0 0 (20% sublethal) 20 (60% sublethal) 20 (40% sublethal) (20)[2)] (0% sublethal)

[1)] Animals were exposed to the respective rates either shortly (within 15 minutes) or 1 h or 4 h after spraying.
[2)] The observed toxicity in this case is not considered treatment-related.

BAS 516 07 F is a WG-formulation containing no organic solvents. It is assumed that the toxicity of this product is lower than the toxicity of the solo EC-formulation BAS 500 06 F. However, additional studies with BAS 516 07 F have not been conducted as the risk assessment shown later on indicates low risk of BAS 516 07 F applications to amphibians even when using the data from the EC-formulation.

In previous chapters it has been demonstrated that there is a low risk of pyraclostrobin to bird and mammal species. Yet, pyraclostrobin and certain pyraclostrobin containing formulations can be toxic to amphibians. The particular sensitivity of amphibians is most likely due to their specific skin morphological and physiological differences (dermal toxicity). The amphibian skin not only constitutes a much lesser barrier as compared to the skin of mammals and birds (Quaranta et al., 2009), however, it is itself a sensitive organ relevant for respiration and uptake of water and regulation of minerals in amphibians (see Wells, 2007 for a review). It seems likely that pyraclostrobin, in case sufficiently large surfaces of the skin are exposed, impacts mitochondrial respiration in the skin and thus disturbs a vital process for respiration and function of the skin. However, if the vital function is not sufficiently (largely) disturbed, the substance being rapidly metabolized and excreted (compare M-CA 5.1 and M-CA 6.2) will not cause any further sub-lethal or chronic latency effects. This is in agreement with the observed finding: effects are observed rather rapidly and if there are no rapid effects or once recovery from initial effects occurs, then there is no delayed or long-term toxicity.

The laboratory studies indicate the potential intrinsic toxicity of pyraclostrobin. However, conditions as simulated in these worst-case laboratory studies bear little relevance to field situations.

In general, amphibians need both terrestrial and aquatic habitats. In Europe, most amphibian species depend on aquatic breeding sites and use the terrestrial habitat within 300 - 1000 m of the surrounding area (e.g. Semlitsch and Bodie 2003, Schabetsberger et al. 2004, Sinsch et al. 2012, Berger et al. 2011). Agricultural landscapes, too, may constitute habitats used by amphibians, if these are in the range of the aquatic breeding sites (summary in Berger et al. 2011).
However, agricultural landscapes are generally perceived as low quality environments for most amphibian species for several reasons, posing high resistance to movement for aquatic breeding amphibians, which is corroborated by studies showing lower abundance and association of amphibians with arable land (Pagetti et al. 2006, e.g. *Bufo bufo*: Kyek et al. 1997, Piha et al. 2007; *Epidalea calamita*: Miaud and Sanuy 2005; *Triturus carnifex, T. marmoratus*: Jehle and Arntzen 2000). In particular, agricultural fields with no or low plant cover are avoided since amphibians have to face high water losses in anthropogenically disturbed areas without sufficient plant cover (Rothermel and Semlitsch 2002, Mazerolle and Desrochers 2005, Cosentino et al. 2011). The risk of desiccation and the lack of cover against predators are likely the major factors leading to avoidance of amphibians of such areas. Mazerolle and Vos (2006) observed that *Rana esculenta* opted to take migration routes with higher cover rather than taking shortcuts through bare field. Similar behaviour was reported by Berger et al. (2011) during telemetry and mark-and recapture studies with *Bufo bufo, Triturus cristatus* and *Pelobates fuscus* in agricultural fields in Germany: individuals migrated either fast through the field taking the shortest route, and subsequently stayed in off-crop habitats, which offer more plant cover and structure; or they returned into cover offered by the pond's surrounding. Individuals of *B. bufo* continued to stay in the arable field when favourable conditions, i.e. burrows, stubble field with clods and sufficient plant material, were found (see also Kneitz 1998).

Thus, habitat use and behaviour of amphibians in agricultural landscapes highly depend on availability of cover in the respective area (Berger et al. 2011).

The dependence on a moist and the preference for a structured environment with high plant cover is especially crucial for juvenile amphibians. Due to their smaller size and volume to surface ratio, juvenile amphibians are more sensitive to environmental influences, especially desiccation, than adult life stages (Rittenhouse et al. 2008). Accordingly, Vos et al. (2007) found an even more pronounced preference for meadows in contrast to arable land in *Rana temporaria* juveniles than in adults (individuals found in meadows: arable land; 9.6:1 (juveniles), 4.3:1 (adults)). Crop fields might therefore be used by these sensitive stages only if they offer sufficient plant cover and therefore a favourable microclimate and protection against predators.

Habitat use, of course, depends on biology and ecology of the respective species. A few amphibian species, which are physiologically and behaviourally adapted to arid conditions, may also use agricultural fields with low plant cover as habitats (e.g. *P. fuscus, Epidalea calamita*). However, also for these species availability of shelter and cover are of crucial importance (Seebacher and Alford 2002). By their fossorial behaviour and staying in moist shelters (e.g. stone embankments, burrows) during the day, postponing search for food to the night and using short rainy events for rehydration (Nöllert and Nöllert 1992, Miaud et al. 2000, Eggert 2002) they avoid dehydration and extreme temperatures (Seebacher and Alford 2002).

This predominantly nocturnal activity (and hiding behaviour during the day) can be found in many European amphibian species (e.g. *Rana temporaria*, *B. bufo, Lissotriton vulgaris*, see Günther 1996). Furthermore, nocturnal activity, the use of shelter and plant cover also limits visual encounter by predators, a strong selective force shaping behaviour in organisms (Lima and Dill 1990). At the same time this behaviour reduces significantly potential exposure to pesticide applications generally.

In summary, a number of aspects will significantly reduce potential exposure and thus the risk to pesticides under realistic field conditions:

- avoidance of agricultural sites, particularly those with low plant cover
- behavioral aspects: burrowing, hiding, nocturnal activity
- more sensitive juveniles will migrate into or through agricultural fields later in the year, when there is either dense plant cover and/or no pesticide use.

The risk assessment has to consider the likely exposure next to the toxicity data. In order to do this appropriately it is essential to consider behavioural aspects in addition to simple interception calculations. Therefore, semi-field studies with *Rana temporaria* and *Bufo bufo* were designed and conducted. These studies cover realistic (worst-case) exposure and behavior. In addition, they cover all routes of exposure: direct spraying, contact to treated surfaces and uptake of contaminated feed.

Higher tier semi-field study with juvenile Rana temporaria under realistic worst-case conditions

Test item	Application rate	affected (%)
BAS 500 06 F	0.75 x max field rate (0.94 L/ha) 1.0 x max field rate (1.25 L/ha) 1.25 x max field rate (1.56 L/ha)	0 0 0[#]

[#] One single individual (out of 16) showed a short term, transient behavioural impact

Higher tier semi-field study with juvenile Bufo bufo under realistic worst-case conditions

Test item	Application rate	affected (%)
BAS 500 06 F	1.0 x max field rate (1.25 L/ha) 1.5 x max field rate (1.875 L/ha) 10 x max field rate (12.5 L/ha)	0 0 50 (75)[#]

[#] One animal was moribund (if counted as dead mortality results in 75%)

The semi-field studies demonstrate that applications of BAS 500 06 F under realistic conditions will be of low risk to amphibians. Even elevated rates of 1.56 L/ha (study with *Rana temporaria*) and 1.875 L/ha (study with *Bufo bufo*), corresponding to over 313 and 375 g a.s./ha did not cause any mortality under realistic worst-case conditions in the field.

Considering in the first tier just the results from the laboratory studies it is demonstrated that application rates of less than 40 to 60 g pyraclostrobin/ha are of low risk to amphibians even under absolute worst-case conditions. The rate of pyraclostrobin applied in the formulated product BAS 516 07 F is only 17 g/ha. The second active substance in this product (boscalid) is generally of significantly lower toxicity to all groups of non-target organisms (e.g. compare fish endpoints of LC_{50} = 0.0062 mg/L for pyraclostrobin and LC_{50} =2.7 mg/L for boscalid). There is neither any information that boscalid or related compounds would cause significant toxicity to amphibians.
Considering the results from the worst-case laboratory studies, i.e. no mortality at 63 g pyraclostrobin/ha and comparing this to the application rate of 17 g pyraclostrobin/ha it can be concluded that applications of BAS 516 07 F to potatoes will be of low risk to amphibians. Furthermore, under realistic conditions exposure will be significantly reduced and accordingly toxicity will be much less as also demonstrated in the semi-field studies, which showed no mortality even at application rates of 313 and 375 g pyraclostrobin/ha, which is about 20-fold higher than the highest application rate of pyraclostrobin by the use of BAS 516 07 F in potatoes.

In conclusion, there will be very low risk to amphibians from BAS 516 07 F applications in potatoes according to label recommendations and good agricultural practice.

In the case of reptiles there is even less information available than for amphibians (see the revision by Fryday and Thompson, 2009). The risk from dietary exposure can be assumed to be lower for reptiles than for birds and mammals (Fryday and Thompson 2009). This is because reptiles are poikilotherm (i.e., do not maintain a constant body temperature) and as a result feeding activity will peak at warm days and will be zero during hibernation or at cold days. In contrast, birds and mammals will have to maintain a constant body temperature and, hence, will need to feed every day (Fryday and Thompson 2009). Uncertainties remain on the contribution of dermal exposure to the overall exposure to reptiles. However, in contrast to amphibians the skin of reptiles is much less permeable; it functions in general as protection and barrier and it is not an organ used for respiration or water/mineral exchange with the environment. Thus, reptiles are considered less vulnerable to dermal exposure as compared to amphibians. Nevertheless, some uncertainty with respect to the risk to reptiles, i.e. whether they are sufficiently covered by other (more standard) ecotoxicological data will remain and further research is needed.

However, pyraclostrobin containing products have been used for many years in many countries worldwide and usually at much higher rates compared to the use of BAS 516 07 F in potatoes. So far, there are no publications indicating a potential risk of this compound to reptiles and despite the long term use worldwide the applicant is not aware of findings or (incidence) reports that amphibians or reptiles were harmfully affected by correct applications of pyraclostrobin containing fungicides.

CP 10.2 Effects on aquatic organisms

The EU agreed endpoints for the active substance pyraclostrobin (BAS 500 F) and its major metabolites plus endpoints from new studies and revised endpoints from EU agreed studies, respectively, are used for the risk assessment on aquatic organisms (see Table 10.2-1). The new representative formulation BAS 516 07 F was neither evaluated as part of the previous Annex I inclusion process of pyraclostrobin nor the one of boscalid. The respective data are presented within this chapter. A comprehensive risk assessment for the active substance, its metabolites and the formulation based on the already registered use pattern is provided below. The risk assessment is based on the "Guidance on tiered risk assessment for plant protection products for aquatic organisms in edge-of-field surface waters", EFSA Journal 2013; 11(7):3290.

For the evaluation of potential effects of boscalid (BAS 510 F), the second active substance in the formulation, the considered EU agreed endpoints can be found in: Monograph (Vol. 3, Annex B.9, 2002), Addendum 2 to DAR (Vol. 3, Annex B.9, 2006) and EU Review Report (SANCO/3919 /2007-rev.5, 2008). The relevant endpoints used in the risk assessments for boscalid are included in Table 10.2-1.

In general, different code numbers of different numbering systems are assigned to the metabolites of pyraclostrobin. In this chapter all metabolites are identified by the BF-code and synonym metabolite codes are given in brackets only where deemed to be helpful.

Table 10.2-1: EU agreed and new /revised endpoints for aquatic species

Test substance	Test species	EU agreed endpoints	Endpoints used in standard and refined risk assessment
Acute toxicity to fish			
Pyraclostrobin	*Oncorhynchus mykiss*	96 h LC_{50} = 0.00616 mg/L	96 h LC_{50} = 0.00616 mg/L
Pyraclostrobin	*O. mykiss* [1)]	--	96 h LC_{50} = 0.0062 mg/L
Pyraclostrobin	*Cyprinodon variegatus* [1), 2)]	--	96 h LC_{50} = 0.0769 mg/L
Pyraclostrobin	*Cyprinus carpio*	96 h LC_{50} = 0.0177 mg/L	96 h LC_{50} = 0.0177 mg/L
Pyraclostrobin	*Danio rerio* [3)]	96 h LC_{50} = 0.0619 mg/L	96 h LC_{50} = 0.0619 mg/L
Pyraclostrobin	*Lepomis macrochirus*	96 h LC_{50} = 0.0254 mg/L	96 h LC_{50} = 0.0254 mg/L
Pyraclostrobin	*L. macrochirus* [3)]	--	96 h LC_{50} = 0.0114 mg/L
Pyraclostrobin	*Leuciscus idus melanotus* [4)]	96 h LC_{50} = 0.0191 mg/L	96 h LC_{50} = 0.0191 mg/L
Pyraclostrobin	*Oryzias latipes* [3)]	96 h LC_{50} = 0.0533 mg/L	96 h LC_{50} = 0.0533 mg/L
Pyraclostrobin	*Pimephales promela* [3)]	96 h LC_{50} = 0.0161 mg/L	96 h LC_{50} = 0.0161 mg/L
BF 500-3	*O. mykiss* [1)]	--	96 h LC_{50} > 0.0948 mg/L
BF 500-5	*O. mykiss* [1)]	--	96 h LC_{50} =11.3 mg/L
BF 500-11	*O. mykiss*	96 h LC_{50} > 100 mg/L	96 h LC_{50} > 100 mg/L
BF 500-13	*O. mykiss*	96 h LC_{50} > 50 < 100 mg/L	96 h LC_{50} > 50 < 100 mg/L
BF 500-14	*O. mykiss*	96 h LC_{50} > 39.4 < 82.6 mg/L	96 h LC_{50} > 39.4 < 82.6 mg/L

Test substance	Test species	EU agreed endpoints	Endpoints used in standard and refined risk assessment
Boscalid	*O. mykiss*	96 h $LC_{50} \cong 2.7$ mg/L	96 h $LC_{50} \cong 2.7$ mg/L
BAS 516 07 F *	*O. mykiss*	--	96 h $LC_{50} = 0.088$ mg/L
Chronic toxicity to fish			
Pyraclostrobin	*O. mykiss* (ELS study)	98 d NOEC = 0.00235 mg/L	98 d NOEC = 0.00235 mg/L
Pyraclostrobin	*C. variegatus* [1), 2)] (ELS study)	36 d NOEC = 0.0108	36 d NOEC = 0.0108
Pyraclostrobin	*P. promelas* [1)] (ELS study)	36 d NOEC = 0.00414	36 d NOEC = 0.00414
Boscalid	*O. mykiss* (ELS)	97 d NOEC = 0.125 mg/L	97 d NOEC = 0.125 mg/L
Acute toxicity to aquatic invertebrates			
Pyraclostrobin	*Daphnia magna*	48 h $EC_{50} = 0.0157$ mg/L	48 h $EC_{50} = 0.0157$ mg/L
BF 500-3	*D. magna* [1)]	--	48 h $EC_{50} > 0.100$ mg/L
BF 500-5	*D. magna* [1)]	--	48 h $EC_{50} > 10.0$ mg/L
BF 500-11	*D. magna*	48 h $EC_{50} > 100$ mg/L	48 h $EC_{50} > 100$ mg/L
BF 500-13	*D. magna*	48 h $EC_{50} > 100$ mg/L	48 h $EC_{50} > 100$ mg/L
BF 500-14	*D. magna*	48 h $EC_{50} > 60.9$ mg/L	48 h $EC_{50} > 60.9$ mg/L
Boscalid	*D. magna*	48 h $EC_{50} = 5.33$ mg/L	48 h $EC_{50} = 5.33$ mg/L
BAS 516 07 F	*D. magna*	--	48 h $EC_{50} = 0.210$ mg/L
Chronic toxicity to aquatic invertebrates			
Pyraclostrobin	*D. magna*	21 d NOEC = 0.004 mg/L	21 d NOEC = 0.004 mg/L
Boscalid	*D. magna*	21 d NOEC = 1.31 mg/L	--
		--	21 d NOEC = 0.80 mg/L [1)]
Sub-lethal toxicity to sediment dwelling aquatic invertebrates			
Pyraclostrobin	*Leptocheirus plumulosus* [1), 2)] (spiked sediment)	--	10 d $LC_{50} = 4.41$ mg/kg dry sediment
Chronic toxicity to sediment dwelling aquatic invertebrates			
Pyraclostrobin	*Chironomus riparius* (spiked water)	28 d NOEC = 0.040 mg/L	28 d NOEC = 0.040 mg/L
Pyraclostrobin	*C. riparius* [1)] (spiked sediment)	--	28 d NOEC = 1.37 mg/kg dry sediment
BF 500-3	*C. riparius* [1)] (spiked sediment)	--	28 d NOEC $\geq$ 16.0 mg/kg dry sediment
BF 500-6	*C. riparius* [1)] (spiked sediment)	--	28 d NOEC 1.2 mg/kg dry sediment
BF 500-7	*C. riparius* [1)] (spiked sediment)	--	28 d NOEC $\geq$ 123.5 mg/kg dry sediment
Boscalid	*C. riparius* (spiked water)	28 d NOEC = 1.0 mg/L	28 d NOEC = 1.0 mg/L
Boscalid	*C. riparius* (spiked sediment)	28 d NOEC = 23.26 mg/kg dry sediment	28 d NOEC = 23.26 mg/kg dry sediment

Test substance	Test species	EU agreed endpoints	Endpoints used in standard and refined risk assessment
Toxicity to algae			
Pyraclostrobin	*Pseudokirchneriella subcapitata*	96 h E_rC_{50} > 0.843 mg/L	72 h E_rC_{50} > 0.843 mg/L [4]
		96 h E_bC_{50} = 0.152 mg/L	--
BF 500-3	*P. subcapitata* [1]	--	72 h E_rC_{50} > 1.17 mg/L [5]
BF 500-5	*P. subcapitata* [1]	--	72 h E_rC_{50} = 5.33 mg/L
BF 500-11	*Scenedesmus subspicatus*	72 h E_rC_{50} > 100 mg/L	72 h E_rC_{50} > 100 mg/L
		72 h E_bC_{50} > 100 mg/L	--
BF 500-13	*S. subspicatus*	72 h E_rC_{50} > 100 mg/L	72 h E_rC_{50} > 100 mg/L
		72 h E_bC_{50} = 66 mg/L	--
BF 500-14	*S. subspicatus*	72 h E_rC_{50} > 100 mg/L	72 h E_rC_{50} > 100 mg/L
		72 h E_bC_{50} = 46.6 mg/L	--
Boscalid	*P. subcapitata*	96 h E_rC_{50} = 3.75 mg/L	96 h E_rC_{50} = 3.75 mg/L
		96 h E_yC_{50} = 1.34 mg/L	--
BAS 516 07 F	*P. subcapitata*	--	72 h E_rC_{50} = 10.8 mg/L
Toxicity to aquatic macrophytes			
Pyraclostrobin	*Lemna gibba* [1]	--	14 d E_bC_{50} = 1.72 mg/L
Higher tier studies / calculations			
Pyraclostrobin	*O. mykiss* (TTE study; different exposure durations [1]	--	96 h LC_{50} > 0.027 mg/L (0.5 h peak exposure) [6]
		--	96 h LC_{50} = 0.022 mg/L (2 h) [6]
		--	96 h LC_{50} = 0.015 mg/L (8 h) [6]
Pyraclostrobin	SSD (based on 96 h NOECs for 8 fish species)	--	HC_5 = 0.00338 mg/L
Pyraclostrobin	*O. mykiss* (ELS study with multiple exposure)	97 d NOEC = 0.005 mg/L	97 d NOEC = 0.005 mg/L
Pyraclostrobin	outdoor mesocosm (multiple spray application) [3]	6 mo NOEC = 0.008 mg/L	6 mo NOEC = 0.008 mg/L
		6 mo NOEAEC > 0.0080 < 0.0240 mg/L	6 mo NOEAEC > 0.008 < 0.024 mg/L

ELS = early life stage; NO(E)AEC = No observed (ecologically) adverse effect concentration; LC = life cycle; TTE = Time-To-Effect/Event; SSD = Species Sensitivity Distribution; HC_5 = 5% hazardous concentration

* Study was conducted with the minor change formulation BAS 516 00 F (reference is made to Document JCP 1.4.1 of the BAS 516 07 F dossier).

[1] Study not submitted during the previous Annex I inclusion process of pyraclostrobin.

[2] marine / saltwater species

[3] Study was performed with the previous representative solo-formulation BAS 500 00 F; however, results are given in mg a.s./L.

[4] In accordance to recent guidelines (EFSA, 2013; OECD, 2011), the 72 h endpoints of the EU agreed study on the green alga have been (re-)calculated from original data. The re-calculated values are presented here and are used in the aquatic risk assessment; for details on these calculations please refer to the respective supplement. A summary of this study and the re-calculations is provided in M-CA 8.2.

[5] In accordance to recent guidelines (EFSA, 2013; OECD, 2011), the 72 h endpoints obtained in the 96 h / 120 h alga studies are considered as relevant endpoint and are presented here.

[6] Endpoint obtained in the TTE study after exposure over respective duration, i.e. the value in brackets (0.5, 2 or 8 hours exposure time).

Risk assessment for aquatic organisms

Toxicity

An overview on all available toxicity data for all aquatic organisms is provided in Table 10.2-2 for the active substance and the formulated product and in Table 10.2-3 for the metabolites of pyraclostrobin.

Studies with the formulated product BAS 516 07 F are summarized in this chapter, while summaries of the new studies with the active substance and its major metabolites are provided in M-CA 8.2. For completeness this includes some older studies that had not been submitted during the previous Annex I inclusion process (e.g. because there is no respective data requirement in the EU) and also EU agreed studies that have been amended in the meantime (e.g. due to recalculations of endpoints or a new evaluation according to current guidelines). Further information on the EU agreed studies, which have been already evaluated within the previous Annex I inclusion process of pyraclostrobin, can be found in the Monograph (Vol. 3, Annex B.9, August 2001) and the EU Review Report (SANCO/1420/2001-final, September 2004). Furthermore, the reports of these studies will be provided to RMS, co-RMS and EFSA and are available upon request for other member states.

Active substance pyraclostrobin and formulated product

Table 10.2-2: List of studies and endpoints for aquatic organisms and the active substance pyraclostrobin (BAS 500 F) and the formulated product BAS 516 07 F

Organism	Endpoint	Value [mg/L]	Reference (BASF DocID)

	72 h E_yC_{50}	3.0	

Bold figures: Where several endpoints are available for the same group or where several endpoints are available for one study based on different effect parameters (e.g. for algae and macrophytes), the relevant endpoint is used in the standard TER calculations.

ELS = early life stage; NO(E)AEC = No observed (ecologically) adverse effect concentration; LC = life cycle; TTE = Time-To-Effect/Event; SSD = Species Sensitivity Distribution; HC_5 = 5% hazardous concentration

[#] At tier I level, only the endpoints for the standard aquatic test species are considered even though studies on additional invertebrate/alga species are available partly resulting in lower endpoints. This is considered appropriate as a mesocosm study is available covering the risk to a great number of different aquatic invertebrate and alga species (for detailed justifications see below).

[+] Spearman-Karber estimate of LC_{50} with confidence limits

[*] Geometric mean with corresponding LC_0 (>) and LC_{100} (<) values

[1)] Study has not been submitted during the previous Annex I inclusion process of pyraclostrobin (summaries for the studies with pyraclostrobin and its metabolites are provided in M-CA 8.2; summaries for the studies with the formulation are provided below).

[2)] Marine / saltwater species

[3)] Study was performed with the solo-formulation BAS 500 00 F (containing 250 g pyraclostrobin/L, nominally)

[4)] The 48-h LC_{50} obtained in the 96 h study is used in the risk assessment according to EU Regulation 283/2013 (European Commission, 2013) on the data requirements for active substances and the EFSA Aquatic Guidance Document (EFSA, 2013).

[5)] In accordance to recent guidelines (EFSA, 2013; OECD, 2011), the 72 h endpoints of the EU agreed study on the green alga have been (re-)calculated from original data. The re-calculated values are presented here and are used in the aquatic risk assessment; for details on these calculations please refer to the supplement. A summary of this study and the re-calculations is provided below.

[6)] In accordance to recent guidelines (EFSA, 2013; OECD, 2011), the 72 h endpoints obtained in the 96 h / 120 h alga studies are considered as relevant endpoint and are presented here

7) In this study the 24, 48, and 72 hour effective concentrations were not calculated because sufficient growth had not yet occurred in any of the test groups to allow for these calculations; thus the 96 h endpoints obtained in the 120 h alga studies are presented here.
8) Due to the reasoning given below, the study on this alga species is considered to be not valid.
9) Based on frond numbers 10) Based on dry weight
11) Endpoint obtained in the TTE study after peak exposure over respective duration, i.e. the value in brackets (0.5, 2 or 8 h exposure time).
12) For details on SSD / geometric mean calculations and derivation of respective RAC values please refer to the refined risk assessment presented below.
13) During the peer review this substance had been considered to be not valid; however, this was done apparently based on a misunderstanding of the data; more explanation in the respective text on the fish RA.
14) A statistically significant impact based on a small reduction in male weight was given at 0.676 µg/L; however, a biologically relevant impact (based on female weight reduction and a corresponding reduced reproduction level) was observed at the highest test concentration only (but which had no impact on the F1 generation). Accordingly, the NOEC is 1.28 µg/L.
15) Study was conducted with the minor change formulation BAS 516 00 F (reference is made to Document JCP 1.4.1 of the BAS 516 07 F dossier).
16) Two acute studies on *D. magna* were performed with BAS 516 07 F. The first study showed some shortcomings (i.e. measured concentrations of boscalid were > 120% of nominal concentrations at test initiation and test end indicating an overdose over the whole study period). Therefore, and as the study results could not be based on mean measured concentrations (formulation contains two active substances) the study was repeated and the results of the second study are considered as relevant endpoints for the aquatic risk assessment.

Metabolites of pyraclostrobin (BAS 500 F)

The results from toxicity tests on representative freshwater species with the major aquatic metabolites are summarized in Table 10.2-3.

In the dark water/sediment study the metabolites BF 500-3, BF 500-6 and BF 500-7 occurred as major metabolites (see M-CP 9.1 - 9.2). Additionally, BF 500-3, BF 500-11, BF 500-13 and BF 500-14 occurred in relevant amounts in the irradiated water/sediment study and BF 500-5 was detected as major metabolite in the study on aerobic mineralization in surface water.

The pyraclostrobin metabolite BF 500-3 was not observed in standard aerobic soil metabolism studies, but only in soil under anaerobic conditions (see M-CP 9.1 - 9.2), however, aerobic conditions are predominant in soil. The sorption behavior of BF 500-3 was investigated in the context of the EU review of pyraclostrobin showing a mean K_{oc} of 9315 mL/g (see M-CP 9.2). Due to its non-occurrence under more relevant aerobic conditions and its high K_{oc}, this metabolite will not be relevant for drainage or runoff entry into surface water. BF 500-3 was observed in sediment with a maximum occurrence of 16.9% TAR in an irradiated water/sediment study. The highest amount of BF 500-3 in the water phase never exceeded 5.0% TAR and thus, this metabolite is only relevant in the sediment phase. Nevertheless, toxicity studies were performed for BF 500-3 on fish, daphnids and algae (on the request of Canadian authorities) that were not included in the previous pyraclostrobin EU review; summaries for these studies are provided in M-CA 8.2. These studies (see Table 10.2-3) showed no toxicity up to the solubility level of this metabolite. The evaluation above shows that both theoretical considerations and also the evidence from toxicity studies demonstrate a very low risk to aquatic organisms resulting from water exposure to metabolite BF 500-3. Therefore, the results from these studies are not considered further in the risk assessment. However, as a major sediment metabolite it has also been tested in a 28 d spiked sediment study with *Chironomus riparius* and the results are used in the respective TER calculations (see below).

The aerobic soil metabolites BF 500-6 and BF 500-7 show very high sorption indicating that they are non-mobile in soil (BF 500-6: median K_{oc} of 107301 mL/g; BF 500-7: median K_{oc} of 149900 mL/g; see M-CP 9.2). Considering the high sorption, the low mobility in soil and the very low water solubility, it can be concluded that BF 500-6 and BF 500-7 will not enter surface water to any ecotoxicologically relevant amount. Furthermore, studies with these metabolites and soil organisms indicate very low toxicity and overall low ecotoxicological potential. To assess the risk to sediment dwelling organisms, 28 d spiked sediment studies on *C. riparius* have been conducted with both metabolites. Study summaries are provided in M-CA 8.2 and the results are considered for the risk assessment below.

The metabolite BF 500-5 was found in relevant amounts in the OECD 309 study (dark) in water and was not detected in the sediment phase of the suspended solid test. This metabolite was therefore considered not to be relevant for the sediment.

The metabolites BF 500-11, BF 500-13 and BF 500-14 were observed in the water phase of irradiated water/sediment systems. The highest amount of the metabolites BF 500-11, BF 500-13 and BF 500-14 in the sediment phase of water/sediment systems never exceeded 0.6, 2.1 and 0.7% TAR, respectively; these metabolites were therefore considered not to be relevant for the sediment.

Further information on the metabolites of pyraclostrobin can be found in document N3.

Table 10.2-3: Summary of toxicity values for aquatic organisms of the major metabolites of pyraclostrobin

Organism	Endpoint	Value [mg/L]	Reference (BASF DocID)
Metabolite: BF 500-3 (Reg. No. 340266; 500M07)

1) Study has not been submitted during the previous Annex I inclusion process of pyraclostrobin (study summaries are provided in M-CA 8.2).

2) In accordance to recent guidelines (EFSA, 2013; OECD, 2011), the 72 h endpoints obtained in the 96 h alga study are considered as relevant endpoint and are presented here.

3) The pyraclostrobin metabolites BF 500-6 and BF 500-7 do not occur to any significant extent in water; they are thus considered to be only of relevance in sediment.

Exposure

The critical use pattern of BAS 516 07 F considered in the risk assessment below is presented in Table 10.2-4.

Table 10.2-4: Critical use pattern

Crop	Application time (BBCH growth stage)	Number of applications	Minimum interval [days]	Application rate per treatment		
				boscalid [kg a.s./ha]	pyraclostrobin [kg a.s./ha]	BAS 516 07 F [kg/ha]
potatoes	51 - 89	4	10	0.067	0.017	0.25

Aquatic organisms may be exposed to BAS 516 07 F through spray drift and to the active substances and their metabolites through spray drift, run-off and drainage from the application site into adjacent water bodies. Exposure of aquatic organisms from these routes was estimated by calculating Predicted Environmental Concentrations in surface water (PEC_{sw}) and sediment (PEC_{sed}) for the active substance and its major metabolites using the FOCUS surface water models. The PEC values were calculated for single and fourfold application of BAS 516 07 F in potatoes at a use rate of 0.25 kg/ha (equivalent to 17 g pyraclostrobin/ha). A stepwise approach has been followed, starting with simple worst-case assumptions in the first two steps and proceeding to more realistic worst-case conditions in the third step of the exposure assessment. PEC values were calculated with endpoints derived from a dark water/sediment study (Tier 1) and additionally with parameters derived from an irradiated water/sediment study (Tier 2).

However, only tier 1 PEC values were considered for the following aquatic risk assessment, except for the metabolites BF 500-11, BF 500-13 und BF 500-14 that were mainly observed in irradiated water/sediment studies. Accordingly, only PEC values derived from irradiated water/sediment studies are reported for these metabolites.

The resulting PEC_{sw} and PEC_{sed} values for pyraclostrobin and its major metabolites are presented in Table 10.2.3-1 and Table 10.2.3-2. Only the worst-case PEC values are presented, either resulting from calculations for single or multiple applications. The pyraclostrobin metabolites BF 500-3, BF 500-6 and BF 500-7 do not occur to any significant extent in water. They are thus considered to be of relevance only in sediment and only PEC_{sed} values have been calculated for these metabolites. The highest amount of the metabolites BF 500-11, BF 500-13 and BF 500-14 in the sediment phase of water/sediment systems never exceeded 0.6, 2.1 and 0.7% TAR, respectively; the metabolite BF 500-5 was not detected in the sediment phase of the suspended solid test. These metabolites were therefore considered to be not relevant for the sediment and no PEC_{sed} values were calculated.

A summary of the FOCUS $PEC_{sw, max}$ values for pyraclostrobin and its major metabolites used for the aquatic risk assessment are provided in the Appendix at the end of this chapter. For full details of the assumptions used in the exposure calculations, please see M-CP 9.2.5.

Toxicity exposure ratios

The following TER calculations were conducted based on application of BAS 516 07 F according to the already registered use in potatoes. The initial risk assessments were carried out by comparing the $PEC_{sw, max}$ and $PEC_{sed, max}$ values with the acute and long-term toxicity endpoints.

According to the EFSA Aquatic Guidance Document (EFSA Journal 2013;11(7):3290) measured and calculated mixture toxicity should be compared to determine synergistic, additive or antagonistic effects of the formulation. In the following the concentration addition (CA) model is used as proposed by EFSA (see table below).
To determine the respective formulation effect, EFSA proposed to calculate the model deviation ratio (MDR), which divides the calculated mixture toxicity ($LC_{50}/EC_{50\ mix\text{-}CA}$) by the measured mixture toxicity ($LC_{50}/EC_{50\ PPP}$). Ecotoxicity studies are biological test systems which underlie a certain natural biological variability when repeating a study. Hence, a threshold has to be defined, when an increased/ decreased mixture toxicity effect cannot be seen as only additive any longer. EFSA proposes a factor of 5, i.e. if the MDR is between 0.2 and 5 the observed and calculated mixture toxicities are considered in agreement.

The calculated MDR values are between 0.51 and 1.10 for all organisms (see Table 10.2-5), indicating that the formulation does not cause an (unexpected) increased toxicity compared to the active substances. For example, the measured and calculated toxicity for the most sensitive group, i.e. fish is nearly identical with the LC_{50} values of 0.088 and 0.091 mg/L. Accordingly, the formulation causes no synergisms or additional toxicity.

Table 10.2-5: Comparison of the measured toxicity of the formulated product BAS 516 07 F and the calculated mixture toxicity of the active substances

Test species	Endpoint & Test system	Measured toxicity of BAS 516 07 F (EC_{XPPP}) [mg/L]	Calculated mixture toxicity ($EC_{Xmix\text{-}CA}$) § [mg/L]	MDR ($EC_{Xmix\text{-}CA}$ / EC_{XPPP})
O. mykiss	LC_{50}, acute, 96 h	0.088	0.091	1.03
D. magna	EC_{50}, acute, 48 h	0.210	0.232	1.10
P. subcapitata #	E_rC_{50}, static, 72 h	10.8	> 6.64	0.61
	E_yC_{50}, static, 72 h	3.0	1.53	0.51

PPP = Plant Protection Product; CA = concentration addition; MDR = model deviation ratio

§ The mixture toxicity of the formulation was re-calculated assuming concentration addition based on the measured toxicity data of pyraclostrobin and boscalid and their nominal contents within the formulation (i.e. 67 g pyraclostrobin/kg and 267 g boscalid/kg).

As no clear growth rate endpoint was obtained in the study with pyraclostrobin on green algae (i.e. E_rC_{50} > 0.843 mg/L), also the endpoint yield was used for comparison of the toxicity data; for boscalid the 96 h endpoints are used as no 72 h endpoints are available for green algae.

With regard to the mixture risk assessment EFSA further states that if the toxicity of the mixture is largely explained by the toxicity of a single active substance, a sufficient protection level might be achieved by simply basing the RA on the toxicity data for that single 'driver'.

Regarding BAS 516 07 F, the active substance pyraclostrobin is clearly driving the risk for the most sensitive organism groups fish and *Daphnia.* In acute studies, boscalid was two orders of magnitude less toxic to fish and daphnia as compared to pyraclostrobin (2.7 mg/L / 0.0062mg/L ~factor 440 for fish and 5.33 mg/L / 0.0157 mg/L for daphnids ~factor 340). Similarly, in chronic studies pyraclostrobin provides 53 and 200 times lower endpoints for fish and *Daphnia,* respectively, as compared to boscalid. Thus, despite the about 4 times higher content of boscalid in the formulated product, the toxicity is clearly driven by the active substance pyraclostrobin.
This is reflected in calculations of fish toxicity to the product based on pyraclostrobin alone (0.092 mg/L) as compared to the mixture calculation (0.091 mg/L) in relation to the actually measured value of 0.088 mg/L (see also above). These values are nearly identical and well within the limit of experimental variation. This is also stated by the new EFSA guidance document on aquatics: "*it is assumed that a difference in toxicity is relevant to RA, if the relevant NOEC or ECx values differ by a factor of more than three in studies with the same species conducted under comparable test conditions*" (EFSA 2013, p. 83).

Furthermore, chronic exposure to the product is highly unlikely (pyraclostrobin has a dissipation half-life in water of 4.47 days).

In conclusion, boscalid has no significant contribution to the observed toxicity of the product to the most sensitive aquatic species and there is no indication of combined or unexpected toxicity. Therefore, the aquatic risk assessment presented for the active substance pyraclostrobin also cover the risk to aquatic organisms following the proposed uses of BAS 516 07 F and no additional TER calculations were performed for the formulated product.

TER_A for fish

Two acute toxicity endpoints for *O. mykiss* are available for the active substance; a study performed under static conditions and an additional study performed for the US under flow-through conditions. Both studies provide nearly identical endpoints based on mean measured concentrations, i.e. of 6.16 and 6.2 µg/L, respectively. In the following risk assessment of pyraclostrobin the rounded value of 6.2 µg/L is used. TER_A values were calculated using worst-case FOCUS Step 1 and 2 $PEC_{sw, max}$ values. The results are presented in Table 10.2-6. The acute risk to fish from the product BAS 516 07 F is addressed by the risk assessment for the active substance pyraclostrobin (see reasoning above).

Table 10.2-6: Fish acute TER values for pyraclostrobin and its major metabolites using worst-case FOCUS Step 1 and 2 $PEC_{sw, max}$ values

Test organism	Test substance	96 h LC_{50} [µg/L]	FOCUS Step	$PEC_{sw, max}$ [µg/L]	TER_A	Trigger value
O. mykiss	pyraclostrobin	6.2	2	0.164	**38**	100
O. mykiss	BF 500-5	11300	1	0.035	322857	100
O. mykiss	BF 500-11	> 100000	1	0.055	> 1818182	100
O. mykiss	BF 500-13	> 50000 < 100000	1	0.072	> 694444 < 1388889	100
O. mykiss	BF 500-14	> 39400 < 82600	1	0.078	> 505128 < 1058974	100

TERs shown in **bold** fall below the relevant trigger.

The calculated TER_A value for pyraclostrobin is below the trigger value of 100 based on FOCUS Step 2 calculation following application of BAS 516 07 F in potatoes. Therefore, additional TER calculations considering Step 3 $PEC_{sw, max}$ values are presented in Table 10.2-7.

The TER_A values for the metabolites BF 500-5, BF 500-11, BF 500-13 and BF 500-14 exceed the trigger value of 100 by far based on worst-case FOCUS Step 1 calculations, indicating low ecotoxicological relevance of the metabolites.

Table 10.2-7: Fish acute TER values for pyraclostrobin using worst-case FOCUS Step 3 $PEC_{sw, max}$ values

FOCUS Scenarios		96 h LC_{50} [µg/L]	FOCUS Step 3	
			$PEC_{sw, max}$ [µg/L]	TER_A
D3	ditch	6.2	0.088	**70**
D4	pond	6.2	0.005	1240
	stream	6.2	0.069	**90**
D6 (1st)	ditch	6.2	0.088	**70**
D6 (2nd)	ditch	6.2	0.087	**71**
R1	pond	6.2	0.010	620
	stream	6.2	0.061	102
R2	stream	6.2	0.081	**77**
R3	stream	6.2	0.086	**72**

TERs shown in **bold** fall below the relevant trigger

Based on FOCUS Step 3 calculations the TER_A values for pyraclostrobin are below the standard trigger of 100 for some scenarios following application of BAS 516 07 F in potatoes.

For a more thorough assessment of the risk to fish additional studies and a refined risk assessment have been conducted. Besides the standard fish species *O. mykiss,* seven other fish species were tested in acute 96 h laboratory studies with pyraclostrobin (see Table 10.2-2). To ease test item application, some of the additional tests were conducted using pyraclostrobin in the form of the previous representative solo-formulation BAS 500 00 F (due to the low water solubility of pyraclostrobin) the addition of solvents is appropriate anyway). A comparison of acute toxicity data with trout tested with the solo-formulation and the active substance provided a slightly lower endpoint for the solo-formulation (4 µg/L as compared to 6.2 µg/L for the a.s.). These data were considered in the previous Annex I inclusion process. Therefore, the use of data from tests with this formulation is considered a conservative surrogate for active substance testing.
Pyraclostrobin shows a very steep concentration response relationship. Therefore, in several cases no effect was observed at the first concentration whereas 100% mortality was found at the next higher concentration. In other studies, only one mortality measurement could be made between 0 and 100% mortality. To obtain relevant figures for the following calculations, in the first case the LC_{50} was determined as geometric mean between the two concentrations, while in the latter case a Spearman-Karber estimate of the LC_{50} was calculated using the mortality and analytical data for the relevant concentrations from the original study reports. Thereby the results may deviate slightly from those given in some of the reports, where no statistical analysis of the LC_{50} had been performed. The respective results were corrected for analytically determined concentrations. These studies and the respective endpoint re-calculations have already been evaluated during the previous Annex I inclusion process.

Additional species testing reduces uncertainty in the risk assessment by addressing better capturing of inter-species variations in sensitivity. According to the proposals of the EFSA Panel on Plant Protection Products and their Residues (PPR) given in the Aquatic Guidance Document (EFSA, 2013), it is recommended to preferably apply a species sensitivity distribution (SSD) approach for refined risk assessment if data on a sufficient number of species is available for the respective group of aquatic organisms. For fish, the SSD approach should be applied if toxicity data is available for at least 5 different species (for pyraclostrobin data on 8 species are available). The PPR Panel further recommends to use acute NOEC/LC_{10} values to construct the SSD for fish, since a higher protection level is desired for vertebrates than for invertebrates and plants.

Therefore, an SSD analysis based on the 96 h NOEC values for 8 fish species was conducted and the results of these calculations are presented below. The data used for SSD calculations are summarized in Table 10.2-8. For fish species were more than one study was performed (i.e. *O. mykiss* and *L. macrochirus*), the arithmetic mean of the endpoints of these studies was considered for SSD calculations.

Table 10.2-8: Pyraclostrobin endpoints selected for calculation of the Hazardous Concentrations based on Species Sensitivity Distribution (SSD) Analysis

Test species	LC_{50} [µg a.s./L]	NOEC / LC_{10} [µg a.s./L]	Ratio (LC_{50}/NOEC)	Reference (BASF DocID)
O. mykiss Salmonidae	6.16 #	4.5	1.4	1999/11414
	6.2	3.6	1.7	2000/5034
	6.2 *	**4.1 ***	1.5	--
C. carpio Cyprinidae	17.7 +	**12.1**	1.5	1998/11580
C. variegatus Cyprinodontidae	76.9	**53.5**	1.4	2000/5032
D. rerio Cyprinidae	61.9 #	**23.4**	2.6	1999/11834
L. idus melanotus Cyprinidae	19.1 +	**13.5**	1.4	1999/11835
L. macrochirus Centrarchidae	25.4 #	10.9	2.3	1998/10951
	11.4	6.1	1.9	2000/5033
	18.4 *	**8.5 ***	2.2	--
O. latipes Adrianichthyidae	53.3 #	**16.5**	3.2	1999/11821
P. promelas Cyprinidae	16.1 #	**7.0**	2.3	1999/11833

Bold values were used for SSD calculations.
* Arithmetic mean value of two studies conducted with the same species.
\# Spearman-Karber estimate of LC_{50} (for confidence limits see endpoint tables above; Table 10.2-2).
\+ Geometric mean (for corresponding LC_0 (>) and LC_{100} (<) values see endpoint tables above).

The SSD calculations have been performed using the software tool ETX 2.0 (RIVM, 2004). The results (graphs and statistical results) are shown below. In the first step, the toxicity data (NOEC) were subjected to three different goodness of fit tests (Anderson-Darling, Kolmogorov-Smirnov and the Cramer von Mises), where the normality was checked at different significance levels. The respective analysis of the NOEC values confirms normal distribution of the data (see below).

Analysis of normality

Parameters of the normal distribution

Name	Value	Description
mean	1.114	mean of the log toxicity values
s.d.	0.341	sample standard deviation
n	8	sample size

Goodness of fit tests

Sign. level	Tests for normality n=8					
	Anderson-Darling		Kolmogorov-Smirnov		Cramer von Mises	
0.1	0.631	Accepted	0.819	Accepted	0.104	Accepted
0.05	0.752	Accepted	0.895	Accepted	0.126	Accepted
0.025	0.873	Accepted	0.995	Accepted	0.148	Accepted
0.01	1.035	Accepted	1.035	Accepted	0.179	Accepted
Statistic	0.1757		0.4090		0.0114	

Figure 10.2-1: SSD Histogram (based on 96 h NOEC values for 8 fish species)

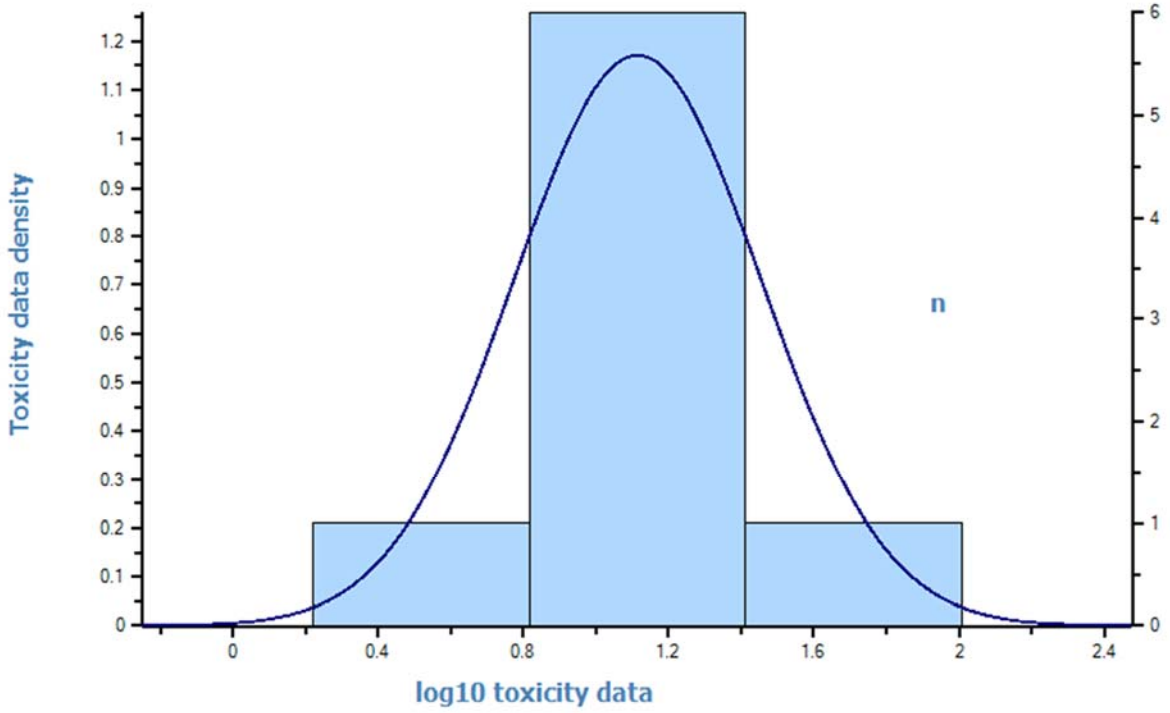

Figure 10.2-2: Species sensitivity distribution (based on 96 h NOEC values for 8 fish species)

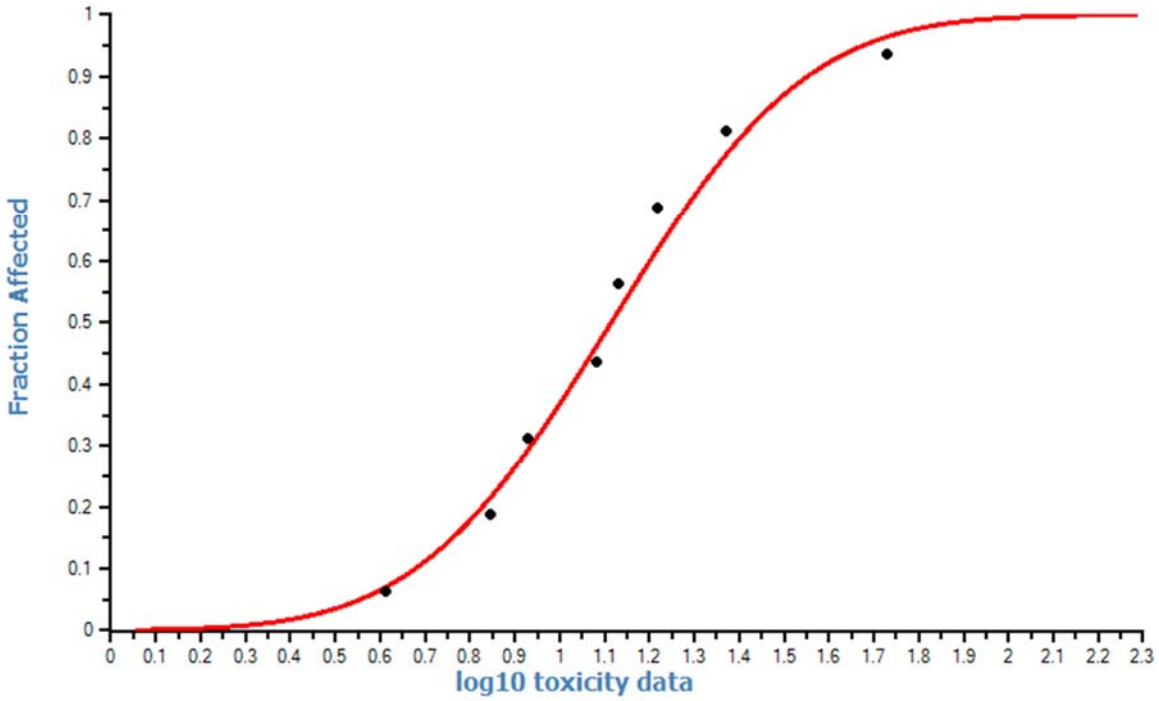

The median HC_5 (hazardous concentration to 5% of the tested species that is predicted with 50% certainty) and also the lower limit HC_5 values ($LLHC_5$; hazardous concentration to 5% of the tested species that is predicted with 95% certainty) can be derived from the SSD curves (see table below).

HC_5 results based on acute (96 h) NOEC data for 8 fish species

Name	Value	log10(Value)	Description
LL HC_5	1.069	0.029	lower estimate of the HC_5
HC_5	**3.381**	0.529	median estimate of the HC_5
UL HC_5	6.139	0.788	upper estimate of the HC_5
sprHC_5	5.745	0.759	spread of the HC_5 estimate

The **median HC_5** for fish can thus be determined to be **3.381 µg a.s./**L.

According to the recommendation given in the EFSA Aquatic GD (2013), an assessment factor of 3 should be applied on the median HC_5 from an SSD constructed with acute NOEC values for fish for derivation of an SSD-RAC (Regulatory Acceptable Concentration), when latency of effects is not to be expected, which is clearly the case for pyraclostrobin (compare chronic risk assessment for fish below). In this case, the use of an AF of 3 is considered warranted also taking into account the various aspects mentioned in the aquatic GD:

- The quality of the acute toxicity data used to construct the SSD is high. All data are based on endpoints from GLP studies meeting all the listed criteria and including analytical support. A wide taxonomical range has been covered with eight species from five different fish families.
- The lower limit value of the HC_5 is about one third of the median HC_5, the fit of the curve is good and the relevant statistical parameters are met well.
- The SSD-RAC is not higher than the tier 3 RAC derived from effect class 1 of the mesocosm study. In fact, it is about three times lower (might indicate the appropriateness of a lower assessment factor).
- The position of the toxicity data in the lower tail of the SSD are either on the SSD curve or are positioned on the right side of the SSD curve (might indicate the appropriateness of a lower assessment factor).
- The steepness of the SSD curve is less than a factor of 100 between the lowest and the highest NOEC, however, it has to be considered that this is an SSD approach for fish only, where in general the difference between species sensitivities is much less than for the taxonomically more diverse group of invertebrates. In fact, a wide range of sensitivities has been covered in this investigation.
- Since sufficient information is available for the substance, read-across information for compounds with a similar mode of action is not needed.
- The acute to chronic ratio is significantly smaller than 10 (might indicate the appropriateness of a lower assessment factor).

Accordingly, an assessment factor of three is well justified and still conservative.

The endpoint obtained with the marine fish species (*Cyprinodon variegatus)* is twice higher than the next least sensitive species. It might be considered to omit this endpoint from the freshwater fish risk assessment as it may not be representative for freshwater species. However, omitting this higher NOEC value, the resulting median and lower limit HC_5 would be slightly higher (3.89 µg/L, respectively 1.48 µg/L as compared to 3.38 and 1.07 µg/L). As a conservative assumption the lower HC_5 value (i.e. including the higher toxicity endpoint) will be used.

Following this approach and applying the recommended assessment factor an **SSD-RAC_{acute} of 1.13 µg a.s./L** can be derived. This concentration is considered unlikely to cause unacceptable toxicity to fish, the most sensitive group of aquatic organisms.

TER_A calculations based on the HC_5 value and worst-case FOCUS Step 3 $PEC_{sw, max}$ values are shown in Table 10.2-9.

Table 10.2-9: Fish acute TER values for pyraclostrobin based on the median HC_5 and worst-case FOCUS Step 3 $PEC_{sw, max}$ values

FOCUS Scenarios		HC_5 (8 species) [µg/L]	FOCUS Step 3	
			$PEC_{sw, max}$ [µg/L]	TER_A*
D3	ditch	3.38	0.088	38
D4	pond	3.38	0.005	676
	stream	3.38	0.069	49
D6 (1st)	ditch	3.38	0.088	38
D6 (2nd)	ditch	3.38	0.087	39
R1	pond	3.38	0.010	338
	stream	3.38	0.061	55
R2	stream	3.38	0.081	42
R3	stream	3.38	0.086	39

* A TER trigger of 3 is considered appropriate for comparison to the median HC_5 (for justification see above).

Based on the SSD approach the TER_A values for pyraclostrobin indicate low acute risk to fish following application of BAS 516 07 F in potatoes with no need for any additional mitigation measures.

In addition, a time-to-effect study has been performed with pyraclostrobin on rainbow trout as the most sensitive fish species (see M-CA 8.2.1, BASF DocID 2000/1014919). The study was conducted to assess the impact of short exposure pulses typical for moving water bodies such as streams by employing different exposure durations (i.e. 0.5, 2 and 8 hours). The results of this study demonstrate that short term exposure, which might be encountered in plumes of moving water bodies, will be tolerated at much higher levels.

For short exposure times (i.e. 0.5 h), simulating average flow velocities in moving water bodies such as creeks and streams, LC_{50} values of > 27 µg/L were found. In a slower moving stream, generating exposure times of about 2 hours, concentrations of up to 18 µg/L are tolerated by the most sensitive species, and even more long-term pulses (8 hours) resulted in 2 - 3 times lower toxicity as compared to the standard 96 hour exposure period.

We propose to base the overall RAC for edge of field surface waters on the hazardous concentrations (HC_5) derived from species sensitivity distributions with fish as recommended in Table 6 of the Aquatic Guidance Document (EFSA, 2013) considering that:

- There is a large dataset from acute and chronic fish studies
- Toxicity is driven by the acute toxicity
- There are no sub-lethal effects at concentrations without mortality even in long-term chronic studies
- Latency of effects is clearly not given
- Pyraclostrobin dissipates quite rapidly from water (short exposure periods only)

Nevertheless, for completeness the chronic risk will be addressed below and TER_{LT} will be provided as well.

TER_{LT} for fish

The TER_{LT} value for pyraclostrobin and fish was calculated using the NOEC obtained in the chronic 98 day early life stage study on *O. mykiss* and the worst-case FOCUS Step 2 PEC_{sw} value. The result is shown in Table 10.2-10.

Table 10.2-10: Fish long-term TER value for pyraclostrobin using the worst-case FOCUS Step 2 $PEC_{sw, max}$ value

Test organism	98 d NOEC [µg/L]	FOCUS Step	$PEC_{sw, max}$ [µg/L]	TER_{LT}	Trigger value
O. mykiss	2.35	2	2.316	**1.0**	10

TERs shown in **bold** fall below the required trigger.

The TER_{LT} value for pyraclostrobin is below the long-term trigger value of 10 based on FOCUS Step 2 calculation for application of BAS 516 07 F in potatoes. Therefore, additional TER calculations considering Step 3 PEC values are presented in Table 10.2-11.

Table 10.2-11: Fish long-term TER values for pyraclostrobin using worst-case FOCUS Step 3 $PEC_{sw, max}$ values and the lowest chronic fish endpoint

FOCUS Scenarios		98 d NOEC [µg/L]	FOCUS Step 3	
			$PEC_{sw, max}$ [µg/L]	TER_{LT}
D3	ditch	2.35	0.088	27
D4	pond	2.35	0.005	470
	stream	2.35	0.069	34
D6 (1st)	ditch	2.35	0.088	27
D6 (2nd)	ditch	2.35	0.087	27
R1	pond	2.35	0.010	235
	stream	2.35	0.061	39
R2	stream	2.35	0.081	29
R3	stream	2.35	0.086	27

Based on FOCUS Step 3 calculations, all TER values exceed the standard long-term trigger of 10, indicating low chronic risk to fish following applications of BAS 516 07 F in potatoes with no need for additional mitigation measures.

In addition to the ELS study on *O. mykiss,* ELS studies on two other fish species have been performed (i.e. *C. variegatus* and *P. promelas,* see Table 10.2-2). The results for the three tested fish species can be used to calculate the **geometric mean of 4.72 µg a.s./L.** Considering the standard chronic assessment factor of 10 this results in a **geomean-$RAC_{chronic}$ of 0.472 µg a.s./L**. Considering the geomean of 4.72 µg/L in the above TER_{LT} calculations instead of only the lowest endpoint of the chronic studies, provide even higher TER_{LT} values (by factor of two) clearly showing low risk to fish from the use of BAS 516 07 F in potatoes.

Amphibian tadpoles

There is some limited information from literature on amphibian tadpoles, another aquatic vertebrate group. Hooser et al. (2012) (see CA 8.2.8/6) observed tadpole toxicity to the active substance pyraclostrobin (LC_{50} = 10 µg/L), which is in the range of fish data. The spacing of concentrations was rather rough (factor of three). Therefore, a more precise derivation of the LC_{50} is difficult. They observed higher toxicity for a pyraclostrobin formulated product (LC_{50} = 3.7 µg/L) with apparently slight mortality at 1.7 µg/L already. In another study of the same research group (Hartman et al. 2014, see CA 8.1.4/3) tadpoles of the same species were used again and exposed over a long term period at 1.7 µg/L. In this study they did not find any mortality at all; in contrast they found that tadpoles within this treatment group performed actually better than the control showing a shorter development time, without negative impact at all on biomass development. The slightly positive impact of the fungicide treatment is difficult to evaluate as the overall and particularly the control performance of the tadpoles (i.e. the development time) was rather poor.

Several literature evaluations compare the aquatic toxicity of amphibians to other aquatic organisms and fish in particular (Aldrich, 2009; Fryday and Thompson, 2012). The most comprehensive one was published recently (Weltje et al., 2013). A common conclusion of these data evaluations is that other aquatic endpoints (generally available for pesticides) cover the potential toxicity to amphibians in water.
The literature data shown above is not fully conclusive, however, seems to confirm in general the same trend. Accordingly, we consider that the risk assessment performed for fish as the most sensitive group of aquatic organisms should also cover the risk to amphibians.
It has to be borne in mind though that amphibian tadpoles may inhabit shallower water bodies than fish. If such sensitive water bodies are close to treated fields and if tadpoles inhabit such systems during time of application, there might be a higher risk to this group of organisms. The exact level would need to be determined by a proper and robust test on tadpoles. If for example we assume a twice lower water level, but if toxicity to tadpoles would also be twice lower as compared to the most sensitive fish species (which is roughly the case here considering the a.s. data for tadpoles (Hooser E.A. et al., 2012, see CA 8.2.8/6) and the lowest fish endpoint), then the resulting risk would be the same.

TER_A for *Daphnia magna*

TER_A values for *Daphnia magna* were calculated for pyraclostrobin and its major metabolites using worst-case FOCUS Step 1 and 2 $PEC_{sw, max}$ values and are given in Table 10.2-12.

Table 10.2-12: Acute TER values for *D. magna* exposed to pyraclostrobin and its major metabolites using worst-case FOCUS Step 1 and 2 $PEC_{sw, max}$ values

Test organism	Test substance	48 h EC_{50} [µg/L]	FOCUS Step	$PEC_{sw, max}$ [µg/L]	TER_A	Trigger value
D. magna	Pyraclostrobin	15.7	2	0.164	**96**	100
D. magna	BF 500-5	> 10000	1	0.035	> 285714	100
D. magna	BF 500-11	> 100000	1	0.055	> 1818182	100
D. magna	BF 500-13	> 100000	1	0.072	> 1388889	100
D. magna	BF 500-14	> 60900	1	0.078	> 780769	100

TERs shown in **bold** fall below the relevant trigger.

The TER_A value for pyraclostrobin is (slightly) below the trigger of 100 based on FOCUS Step 2 calculation for application in potatoes. Therefore, additional TER calculations based on FOCUS Step 3 PEC values are presented in Table 10.2-13.

The TER_A values for the metabolites BF 500-5, BF 500-11, BF 500-13 and BF 500-14 exceed the trigger value of 100 based on worst-case FOCUS Step 1 calculations, indicating low ecotoxicological relevance of the metabolites.

Table 10.2-13: Acute TER values for *D. magna* exposed to pyraclostrobin using FOCUS Step 3 $PEC_{sw, max}$ values

FOCUS Scenarios		48 h EC_{50} [µg/L]	FOCUS Step 3	
			$PEC_{sw, max}$ [µg/L]	TER_A
D3	ditch	15.7	0.088	178
D4	pond	15.7	0.005	3140
	stream	15.7	0.069	228
D6	ditch	15.7	0.088	178
D6	ditch	15.7	0.087	180
R1	pond	15.7	0.010	1570
	stream	15.7	0.061	257
R2	stream	15.7	0.081	194
R3	stream	15.7	0.086	183

The TER_A values for pyraclostrobin exceed the standard acute trigger value of 100 based on FOCUS Step 3 calculations, indicating low acute risk to aquatic invertebrates following applications of BAS 516 07 F in potatoes with no need for any additional mitigation measures.

Furthermore, a mesocosm study is available indicating low risk to aquatic invertebrates at concentrations of 8 µg a.s./L or less (for more details see also the following chapter on *Daphnia* long term risk assessment).

Comparison of the respective worst-case FOCUS Step 1 $PEC_{sw, max}$ value for the active substance pyraclostrobin (= 2.316 µg a.s./L for potatoes) to the proposed $RAC_{mesocosm}$ demonstrates low risk to aquatic invertebrates following the use of BAS 516 07 F in potatoes.

Additional studies have been conducted with the marine invertebrate species *A. bahia* and *C. virginica,* partly resulting in lower endpoints compared to EC_{50} for *D. magna* (see M-CA 8.2). However, the mesocosm study includes a great number of different and more relevant freshwater invertebrate species (for more details see below and chapter M-CA 8.2). Thus, the higher tier assessment based on the mesocosm study is most appropriate to address the risk to aquatic invertebrates.

TER_{LT} for *Daphnia magna*

The TER_{LT} value for *Daphnia magna* was calculated for pyraclostrobin using the worst-case FOCUS Step 2 $PEC_{sw, max}$ value and is given in Table 10.2-14.

Table 10.2-14: Long-term TER value for *D. magna* exposed to pyraclostrobin using the worst-case FOCUS Step 2 $PEC_{sw, max}$ value

Test organism	21 d NOEC [µg/L]	FOCUS Step	$PEC_{sw, max}$ [µg/L]	TER_{LT}	Trigger value
D. magna	4.0	2	0.164	24	10

The TER_{LT} value for pyraclostrobin exceeds the long-term trigger value of 10 based on FOCUS Step 2 calculation, indicating low chronic risk to aquatic invertebrates following the proposed use of BAS 516 07 F in potatoes with no need for any additional mitigation measures.

Furthermore, a mesocosm study is available (BASF DocID 2000/1000011 + supplement 2012/1357084) and a refined risk assessment has been performed providing more realistic information about the potential risk to aquatic invertebrates. A mesocosm study provides a complex and compelling impression of the potential effects of a test substance under realistic conditions. Thus, mesocosm data allows for a general conclusion on aquatic ecosystems since major direct effects will be quite comparable within different systems (Leeuwangh, 1994).

The Dutch Platform for Assessment of Higher-Tier Studies has produced a Guidance Document on how micro-/mesocosm data should be presented and evaluated in a uniform and transparent manner (RIVM Guidance Document; de Jong et al., 2008;). The EFSA Aquatic GD (EFSA, 2013) proposes to largely use this document to present and evaluate micro-/mesocosm studies for regulatory purposes when placing plant protection products on the European market. Consequently, the mesocosm study has been evaluated following the RIVM Guidance document; for details please refer to the supplement to this study (BASF DocID 2012/1357084). Executive summaries of the originally submitted study and the evaluation according to RIVM are provided in M-CA 8.2. The mesocosm evaluation according to this new procedure results basically in the same conclusion as previously given during the Annex I listing process, i.e. a high quality study covering a wide range of sensitive species and measurements providing robust endpoints.

The results of the extensive and complex mesocosm study using a worst-case exposure scenario (i.e. 8 applications of the test substance applied as the solo-formulation BAS 500 00 F) showed that pyraclostrobin can have effects on a few species at concentrations of 24 µg a.s./L. For all plankton species the effects were found to be reversible. These transient effects are thus not considered to pose a significant (ecologically unacceptable) risk to planktonic communities in aquatic ecosystems. However, fish and molluscs may also be affected at this concentration. No effects on any species or endpoint were observed at the second highest test concentration of 8 µg a.s./L, constituting the ecosystem NOEC. The multitude of endpoints and species and environmental conditions in this mesocosm study show clearly that at this (and lower) concentration no adverse effects on aquatic communities can be expected even after multiple applications. The ecologically acceptable concentration (NOEAEC) of pyraclostrobin is thus between 8 µg a.s./L and 24 µg a.s./L.

In addition, this study still encompassed unrealistic worst case conditions (8 applications of the test substance). The number of applications will be much less under practical conditions (1-4). It is highly unlikely, that eight times a 95% worst case situation with respect to drift will be encountered.

Considering the multitude of endpoints covered, the inclusion of sensitive and relevant species, the worst-case character of the mesocosm study related to exposure and the realistic worst-case test system applied, it can be concluded that no assessment factor to the **NOEC of 8 µg a.s./L** is warranted (which is also in line with previous recommendations, guidances). However, the new Aquatic Guidance Document (EFSA 2013) recommends using an assessment factor of two in this case for the ETO-RAC derivation. Following this approach, this results in an **$RAC_{mesocosm}$ of 4 µg a.s./L.**

A comparison of the respective worst-case FOCUS Step 1 $PEC_{sw, max}$ value for the active substance pyraclostrobin (= 2.316 µg a.s./L for potatoes) to the proposed $RAC_{mesocosm}$ demonstrates low risk to aquatic invertebrates following the proposed use of BAS 516 07 F in potatoes.

TER_A for aquatic insect

Acute tests were not conducted with an aquatic insect species. Instead, chronic studies were performed with the active substance pyraclostrobin and its soil metabolites BF 500-3, BF 500-6 and BF 500-7 on *Chironomus riparius*, which address the potential long-term risk of the active substance to aquatic insects (see below). Furthermore, a mesocosm study is available for pyraclostrobin covering various aquatic invertebrate species including aquatic insects.

TER_{LT} for aquatic insect

TER_{LT} values for *Chironomus riparius* were calculated for water and sediment exposure.

The resulting TER_{LT} value for pyraclostrobin following water exposure using the worst-case FOCUS Step 1 PEC_{sw} value is given in Table 10.2-15.

Table 10.2-15: Long-term TER value for *C. riparius* exposed to pyraclostrobin using the worst-case FOCUS Step 1 $PEC_{sw, max}$ value (water exposure)

Test organism	28 d NOEC [µg/L]	FOCUS Step	$PEC_{sw, max}$ [µg/L]	TER_{LT}	Trigger value
C. riparius (spiked water)	40	1	2.316	17	10

The TER_{LT} value for pyraclostrobin exceeds the long-term trigger of 10 based on FOCUS Step 1 calculation, indicating low chronic risk to aquatic insects resulting from water exposure following application of BAS 516 07 F in potatoes.

In order to assess similarly the risk arising from sediment exposure, TER values were calculated using the 28 d NOECs from chronic spiked-sediment studies with *C. riparius*. The resulting TER_{LT} values for pyraclostrobin and its soil sediment metabolites BF 500-3, BF 500-6 and BF 500-7 using FOCUS Step 1 and 2 $PEC_{sed, max}$ values are given in Table 10.2-16.

Table 10.2-16: Long-term TER values for *C. riparius* exposed to pyraclostrobin and its major soil metabolites using the worst-case FOCUS Step 1 and 2 $PEC_{sed, max}$ values (sediment exposure)

Test substance	Test organism	28 d NOEC [µg/kg dry sediment]	FOCUS Step	$PEC_{sed, max}$ [µg/kg dry sediment]	TER_{LT}	Trigger value
pyraclostrobin	*C. riparius* (spiked sediment)	1370	2	14.142	97	10
BF 500-3	*C. riparius* (spiked sediment)	≥ 16000	1	2.724	≥ 5874	10
BF 500-6	*C. riparius* (spiked sediment)	1200	1	41.471	29	10
BF 500-7	*C. riparius* (spiked sediment)	≥ 123500	1	24.885	≥ 4963	10

The TER_{LT} value for pyraclostrobin and its soil metabolites BF 500-3, BF 500-6 and BF 500-7 exceed the standard long-term trigger of 10 based on FOCUS Step 1 and 2 calculations, indicating low chronic risk to aquatic insects resulting from sediment exposure following application of BAS 516 07 F in potatoes.

Furthermore, a mesocosm study is available for pyraclostrobin covering various aquatic invertebrate species including aquatic insects. Based on the mesocosm results a $RAC_{mesocosm}$ of 4 µg a.s./L could be received (see text above), demonstrating low risk to aquatic organisms (at FOCUS Step 1 level; water exposure) following the proposed uses of BAS 516 07 F.

TER_A for aquatic crustacean

An acute spiked sediment study has been conducted with the estuarine amphipod *Leptocheirus plumulosus.* The sensitivity of this marine crustacean species seems to be within the range of freshwater species (NOEC = 2.74 mg/kg as compared to 1.37 mg/kg for *Chironomus* in the chronic test). Although this study is not required for registration in the EU, TER calculations based on the resulting 10-day LC_{50} value and worst-case FOCUS Step 2 $PEC_{sed, max}$ are presented in Table 10.2-17.

Table 10.2-17: Acute TER value for *L. plumulosus* exposed to pyraclostrobin using the worst-case FOCUS Step 2 $PEC_{sed, max}$ value (sediment exposure)

Test organism	10 d LC_{50} [µg/kg dry sediment]	FOCUS Step	$PEC_{sed, max}$ [µg/kg dry sediment]	TER_A	Trigger value
L. plumulosus	4410	2	14.142	312	100

The TER_A value for pyraclostrobin exceeds the standard trigger of 100 based on FOCUS Step 2 calculation, indicating low acute risk to aquatic (sediment dwelling) crustacean following application of BAS 516 07 F in potatoes. Furthermore, a mesocosm study is available for pyraclostrobin covering various aquatic invertebrate species including aquatic crustacean species (see above).

TER_{LT} for aquatic crustacean

TER_{LT} calculations for the freshwater crustacean *Daphnia magna* are presented above.

An additional chronic study has been conducted with the marine species *A. bahia* showing lower endpoints compared to the NOEC *for D. magna*. However, the mesocosm study (see above) includes a great number of different and relevant freshwater invertebrate species providing strong evidence that the mysid data are not representative for freshwater organisms. Thus, the higher tier assessment based on the mesocosm study provides the more relevant and more comprehensive data base for the assessment of the risk to freshwater invertebrates.

TER_A for aquatic gastropod mollusc

TER_A values for aquatic gastropod molluscs are not required since BAS 516 07 F is not foreseen for direct application to surface water.
An additional chronic study has been conducted for the US with the marine species *C. virginica* showing endpoints in the range of *D. magna* endpoints. However, the mesocosm study (see above) includes a great number of different and relevant freshwater invertebrate species including aquatic gastropod molluscs. Thus, the higher tier assessment based on the mesocosm study provides the more relevant and more comprehensive data base for the assessment of the risk to freshwater invertebrates.

TER_{LT} for aquatic gastropod mollusc

TER_{LT} values for aquatic gastropod molluscs are not required since BAS 516 07 F is not foreseen for direct application to surface water. Therefore, no investigations have been performed with aquatic gastropod molluscs. Furthermore, mesocosm data are available for the active substance pyraclostrobin and thus information on gastropod mollusc species.

TER for algae

Besides the study on the standard green alga *P. subcapitata*, studies on three further alga species have been conducted, partly resulting in lower endpoints compared to the endpoints for the green alga. However, following the recommendations and validity criteria defined in the current OECD guideline 201 for alga testing (OECD, 2011) the 120 h studies the blue-green alga *Anabaena flos-aquae* and marine diatom *Skeletonema costatum* are considered to be not valid because in both studies, at least one validity criterion is not met (for details please refer to chapter M-CA 8.2).
The study with the freshwater diatom *Navicula pelliculosa* showed some shortcomings, too, i.e. no clear dose-response relationship could be shown, because effects at the four highest tested concentrations are in a similar range (i.e. growth rate after 120 h at the four highest tested concentrations is between 68 and 72% of control). Moreover, a mesocosm study is available including a great number of different algae species (including *Navicula* species). Thus, the higher tier assessment based on the mesocosm study provided above also covers the risk to algae. At tier 1 level, TER calculations are thus only performed based on the re-calculated 72 hour growth rate endpoint from the 96 hour study with the standard green alga *P. subcapitata.*
The resulting TER values for pyraclostrobin and its major metabolites using FOCUS Step 1 $PEC_{sw,\ max}$ values are given in Table 10.2-18.
The risk of the product BAS 516 07 F to algae is sufficiently addressed by the risk assessment for the active substance pyraclostrobin (see reasoning given above).

Table 10.2-18: TER values for algae exposed to pyraclostrobin and its major metabolites using FOCUS Step 1 $PEC_{sw,\ max}$ values

Test organism	Test substance	72 h E_rC_{50} [µg/L]	FOCUS Step	$PEC_{sw,\ max}$ [µg/L]	TER	Trigger value
P. subcapitata	pyraclostrobin	> 843	1	2.316	> 364	10
P. subcapitata	BF 500-5	5330	1	0.035	152286	10
S. subspicatus	BF 500-11	> 100000	1	0.055	> 1818182	10
S. subspicatus	BF 500-13	> 100000	1	0.072	> 1388889	10
S. subspicatus	BF 500-14	> 100000	1	0.078	> 1282051	10

The TER values for pyraclostrobin and its metabolites BF 500-5, BF 500-11, BF 500-13 and BF 500-14 exceed the trigger of 10 based on worst-case FOCUS Step 1 calculations, indicating low risk to algae following application of BAS 516 07 F in potatoes.

TER_{LT} for aquatic plants

Additional aquatic plant testing would not be required for this fungicide, however, for registration purposes in the USA a Lemna study is available. The respective TER_{LT} values for aquatic plants (given in Table 10.2-19) were calculated for pyraclostrobin using the growth rate endpoint of the 14 day study with *Lemna gibba* and FOCUS Step 1 $PEC_{sw, max}$ values.

Table 10.2-19: TER_{LT} values for *Lemna gibba* exposed to pyraclostrobin using the worst-case FOCUS Step 1 $PEC_{sw, max}$ value

Test organism	14 d E_rC_{50} [µg/L]	FOCUS Step	$PEC_{sw, max}$ [µg/L]	TER_{LT}	Trigger value
L. gibba	1720	1	2.316	743	10

The TER_{LT} value for pyraclostrobin exceeds the trigger of 10 based on worst-case FOCUS Step 1 calculation, indicating low risk to aquatic plants following application of BAS 516 07 F in potatoes with no need for additional mitigation measures.

Summary of the Refined Risk Assessment

Pyraclostrobin is toxic to aquatic organisms. Based on standard precautionary assumptions, some risk to aquatic organisms is indicated following applications of a product containing this active substance very close to sensitive aquatic systems. In order to refine the risk a number of additional and higher tier studies were performed. These include additional species testing, tests using more realistic exposure scenarios, a time-to-effect study and a mesocosm investigation.

The mesocosm study, which covers a wide range of relevant and sensitive aquatic organisms (but only one fish species), results in a clear NOEC of 8 µg/L, even though it simulates a worst-case exposure situation. Accordingly, an ETO-RAC of 4 µg/L can be derived.
In order to further refine the risk assessment for fish besides the standard fish species *O. mykiss,* seven additional fish species were tested in acute 96 h laboratory studies with pyraclostrobin. In line with the recommendations of the Aquatic Guidance document (EFSA, 2013) an SSD analysis was conducted based on the 96 h NOEC values. The median HC_5 for fish was determined to be 3.381 µg a.s./L. An assessment factor of 3 was shown to be warranted to be applied on the median HC_5. Following this approach an overall **RAC** for edge-of-field surface waters **of 1.13 µg a.s./L** can be derived.

Overall Conclusion

The fungicidal product BAS 516 07 F and the active substance pyraclostrobin, respectively, show toxicity to aquatic organisms and contamination of aquatic ecosystems must be avoided. However, the standard and refined risk assessment provided for pyraclostrobin and its major metabolites demonstrate that application of BAS 516 07 F in potatoes according to good agricultural practice is of low risk to aquatic ecosystems with no need for additional mitigation measures.

CP 10.2.1 Acute toxicity to fish, aquatic invertebrates, or effects on aquatic algae and macrophytes

The following fish acute toxicity study performed with the new representative formulation BAS 516 07 F (tested with the minor change formulation BAS 516 00 F) is provided in support of the assessment and has not been previously evaluated on the EU-level. The very similar composition of both products (BAS 516 07 F and BAS 516 00 F) is shown in Doc JCP 1.4.1.

Report:	CP 10.2.1/1 [redacted] 2000a BAS 516 00 F - Acute toxicity study on the rainbow trout (Oncorhynchus mykiss WALBAUM 1792) in a static system (96 hours) 2000/1018726
Guidelines:	EPA 72-1, OECD 203, EEC 92/69 A V C 1
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In a static acute toxicity laboratory study, juvenile rainbow trout were exposed to BAS 516 00 F nominal concentrations of 0.040, 0.063, 0.100, 0.160 and 0.250 mg BAS 516 00 F/L and a water control in groups of 10 animals in glass aquaria containing 50 L water. Fish were observed for survival and symptoms of toxicity within 1 h after start of exposure and 4, 24, 48, 72 and 96 hours after start of exposure.

The biological results are based on the nominal concentrations. After 96 hours of exposure no mortality was observed in the control and at concentrations of up to and including 0.063 mg BAS 516 00 F/L, whereas 80% mortality was observed at 0.100 mg/L. At the two highest tested concentrations of 0.160 and 0.250 mg/L, 100% mortality was observed within the first day of the test.

In a static acute toxicity study with rainbow trout the LC_{50} (96 h) of BAS 516 00 F was 0.088 mg/L based on nominal concentrations. The NOEC (96 h) was determined to be 0.063 mg/L (nominal).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 00 F, batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal: 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal: 6.7%).

B. STUDY DESIGN

Test species: Rainbow trout (*Oncorhynchus mykiss* WALBAUM 1972), age: about 4 months, mean body length 5.4 cm (4.5 - 6.4 cm); mean body weight 1.4 g (0.8 - 2.1 g); raised in house from fertilized eggs supplied by "Trout Breeding, Erber Soehne", Eusserthal, Germany.

Test design: Static system (96 hours); 10 fish per aquarium (loading: about 0.3 g fish/L) and per concentration; assessment of mortality and symptoms of toxicity within 1 hour after start of exposure and 4, 24, 48, 72 and 96 hours after start of exposure.

Test concentrations: Control, 0.040, 0.063, 0.100, 0.160 and 0.250 mg/L (nominal).

Test conditions: Glass aquaria with stainless steel frame (60 x 35 x 40 cm), test volume: 50 L, dechlorinated, filtered tap water; temperature: 12°C; pH 8.1 - 8.4; oxygen content: 8.0 mg/L - 10.5 mg/L; total hardness: about 2.5 mmol; acid capacity: about 5.5 mmol/L; photoperiod 16 h light : 8 h dark; no aeration; no feeding.

Analytics: Analytical verification of test item concentrations was conducted using a RP-HPLC with UV-detection.

Statistics: Descriptive statistics; calculation of approximate LC_{50} as geometric mean of LC_0 and LC_{100}.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentration was conducted in each concentration at the beginning and, except for the highest concentration tested, at the end of the test. The analyzed contents of boscalid ranged from 93.6 to 99.7% of nominal at test initiation and from 93.1 to 94.7% of nominal at test termination. Measured concentrations of pyraclostrobin were between 87.8 and 104.8% of nominal in samples taken at test initiation and decreased to values between 32.1 and 76.2% of nominal at test termination. As initial measured concentrations confirmed correct application of the test substances, the following biological results are based on nominal concentrations.

Biological results: After 96 hours of exposure no mortality was observed in the control and at concentrations of up to and including 0.063 mg BAS 516 00 F/L, whereas 80% mortality was observed at 0.100 mg/L. At the two highest tested concentrations of 0.160 and 0.250 mg/L, 100% mortality was observed within the first day of the test. Sub-lethal effects (i.e. swimming near the bottom) were found at 0.100 mg BAS 516 00 F/L after 96 hours. The results are summarized in Table 10.2.1-1.

Table 10.2.1-1: Acute toxicity (96 h) of BAS 516 00 F on rainbow trout (*O. mykiss*)

Concentration [mg/L] (nominal)	**Control**	0.040	0.063	0.100	0.160	0.250
Mortality [%]	0	0	0	80	100	100
Symptoms [1)]	None	none	none	D	--	--
Endpoints [mg BAS 516 00 F/L] (nominal)						
LC_{50} (96 h)	0.088					
NOEC (96 h)	0.063					

[1)] Symptoms: D = swimming near the bottom
-- not observed / all animals dead

III. CONCLUSION

In a static acute toxicity study with rainbow trout the LC_{50} (96 h) of BAS 516 00 F was 0.088 mg/L based on nominal concentrations. The NOEC (96 h) was determined to be 0.063 mg/L (nominal).

The following *Daphnia* acute toxicity studies performed on BAS 516 07 F are provided in support of the assessment and have not been previously evaluated on the EU-level. The first study showed some shortcomings (i.e. measured concentrations of boscalid were > 120% of nominal concentrations at test initiation and test end, indicating an overdose over the whole study period). Therefore, and as the study results could not be based on mean measured concentrations (formulation contains two active substances with different recoveries) the study was repeated and the results of the second study are considered as relevant endpoints for the aquatic risk assessment. Nevertheless, the summary of the first study is provided below for completeness.

Report:	CP 10.2.1/2 Janson G.-M., 2007a Acute toxicity of BAS 516 07 F to Daphnia magna STRAUS in a 48 hour static test 2007/1008605
Guidelines:	OECD 202, EPA 850.1010
GLP:	yes (certified by Landesamt fuer Umweltschutz und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a 48-hour static acute toxicity laboratory study, water flea neonates were exposed to BAS 516 07 F at nominal concentrations of 0 (control), 0.030, 0.054, 0.097, 0.175, 0.315 and 0.567 mg BAS 516 07 F/L in 4 replicates per concentration, containing 5 daphnids each. Daphnids were observed for immobility 24 hours and 48 hours after start of exposure.

The biological results are based on nominal concentrations. After 48 hours of exposure, no immobility was observed in the control and at the test item concentration of 0.054 mg/L, whereas 5, 50 and 80% immobility occurred at 0.030, 0.097 and 0.175 mg/L. At the two highest tested concentrations all daphnids were immobile after 48 hours of exposure. The effects after 48 hours observed at the four highest tested concentrations of exposure were statistically significantly different compared to the control. No other sublethal effects were observed during the test.

In a 48-hour static acute toxicity study with *Daphnia magna*, the EC_{50} (48 h) of BAS 516 07 F was 0.120 mg/L based on nominal concentrations. The NOEC was determined to be 0.054 mg/L (nominal).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 07 F, batch no. 1789, content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 26.7% (nominal: 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.8% (nominal: 6.7%).

B. STUDY DESIGN

Test species: Water flea (*Daphnia magna* STRAUS), neonates collected from in house culture (originally obtained from Institute National de Recherché Chimique Appliquée, France), >2 <24 hours old at test initiation.

Test design: Static system (48 hours), 6 test concentrations plus control, 4 replicates with 5 daphnids in each; assessment of immobility after 24 and 48 hours.

Endpoints: NOEC and EC_{50} based on immobility of daphnids.

Test concentrations: Control, 0.030, 0.054, 0.097, 0.175, 0.315 and 0.567 mg BAS 516 07 F/L (nominal).

Test conditions: Glass vessels, test volume 50 mL, dilution water "M4" (Elendt medium); pH 7.92 - 8.12; oxygen content: 8.5 mg/L - 9.3 mg/L; total hardness: 2.42 mmol/L at test initiation; conductivity: 654µS/cm at test initiation; temperature: 19.9°C - 20.9°C; light intensity: 290 lux - 465 lux; photoperiod: 16 h light : 8 h dark; no feeding, no aeration.

Analytics: Analytical verification of test item concentrations was conducted using a HPLC-method with MS detection.

Statistics: Descriptive statistics; Fisher's Exact Test for determination of the NOEC ($\alpha = 0.05$), probit analysis for determination of the EC_{50} value.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification was conducted in each concentration at the beginning and at the end of the test. The analyzed contents of boscalid ranged from 107.9 to 124.3% of nominal concentrations at test initiation and further increased to 111.9 to 129.1% of nominal at test termination. Measured concentrations of pyraclostrobin were between 102.2 and 112.1% of nominal in samples taken at test initiation and between 100.4 and 112.5% at test termination. The measured concentrations did not confirm the correct application of the test substance. However, since two compounds were measured with different recoveries a simple conversion to mean measured concentrations was not meaningful. Therefore, the following biological results are based on nominal concentrations.

Biological results: After 48 hours of exposure, no immobility was observed in the control and at the test item concentration of 0.054 mg/L, whereas 5, 50 and 80% immobility occurred at 0.030, 0.097 and 0.175 mg/L. At the two highest tested concentrations all daphnids were immobile after 48 hours of exposure. The effects after 48 hours observed at the four highest tested concentrations of exposure were statistically significantly different compared to the control (Fisher's exact test, $\alpha = 0.05$). No other sublethal effects were observed during the test. For results see Table 10.2.1-2.

Table 10.2.1-2: Effects of BAS 516 07 F on *Daphnia magna* immobility

Concentration [mg/L] (nominal)	**Control**	**0.030**	**0.054**	**0.097**	**0.175**	**0.315**	**0.567**
Immobility (24 h) [%]	0	5	0	10	20	90 *	100 *
Immobility (48 h) [%]	0	5	0	50 *	80 *	100 *	100 *
Endpoints [mg BAS 516 07 F/L] (nominal)							
EC_{50} (48 h)	0.120 (95% confidence limits: 0.102 - 0.139)						
NOEC (48 h)	0.054						

* Statistically significantly different compared to the control (Fisher's exact test, $\alpha = 0.05$)

III. CONCLUSION

In a 48-hour static acute toxicity study with *Daphnia magna*, the EC_{50} (48 h) of BAS 516 07 F was 0.120 mg/L based on nominal concentrations. The NOEC was determined to be 0.054 mg/L (nominal).

Report:	CP 10.2.1/3 Janson G.-M., 2009a Acute toxicity of BAS 516 07 F to Daphnia magna STRAUS in a 48 hour static test 2009/1117877
Guidelines:	OECD 202, EPA 850.1010
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a static acute toxicity laboratory study, water flea neonates were exposed to BAS 516 07 F at nominal concentrations of 0 (control), 0.060, 0.096, 0.154, 0.246 and 0.393 mg BAS 516 07 F/L in 4 replicates per concentration, containing 5 daphnids each. Daphnids were observed for immobility 24 hours and 48 hours after start of exposure.

The biological results are based on nominal concentrations. After 48 hours of exposure, no immobility was observed in the control, whereas 5, 10, 10 and 55% immobility occurred at 0.060, 0.096, 0.154 and 0.246 mg/L. At the highest tested concentration of 0.393 mg BAS 516 07 F/L all daphnids were immobile after 48 hours of exposure. After 48 hours of exposure statistically significant effects on mobility of daphnids was observed at the two highest concentrations of 0.246 and 0.393 mg BAS 516 07 F/L. No other sublethal effects were observed during the test.

In a 48-hour static acute toxicity study with *Daphnia magna* the EC_{50} of BAS 516 07 F was 0.210 mg/L based on nominal concentrations. The NOEC was determined to be 0.154 mg/L (nominal).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 07 F, batch no. 11041, content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 26.9% (nominal: 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.5% (nominal: 6.7%).

B. STUDY DESIGN

Test species: Water flea (*Daphnia magna* STRAUS), neonates collected from in house culture (originally obtained from Institute National de Recherché Chimique Appliquée, France), >2 <24 hours old at test initiation.

Test design: Static system (48 hours), 5 test concentrations plus control, 4 replicates with 5 daphnids in each; assessment of immobility after 24 and 48 hours.

Endpoints: NOEC and EC_{50} based on immobility of daphnids.

Test concentrations: Control, 0.060, 0.096, 0.154, 0.246 and 0.393 mg BAS 516 07 F/L (nominal).

Test conditions: Glass vessels, test volume 50 mL, dilution water "M4" (Elendt medium); pH 7.98 - 8.04; oxygen content: 8.7 mg/L - 8.9 mg/L; total hardness: 2.37 mmol/L at test initiation; conductivity: 659µS/cm at test initiation; temperature: 21.6°C - 21.7°C; light intensity: 426 lux - 721 lux; photoperiod: 16 h light : 8 h dark; no feeding, no aeration.

Analytics: Analytical verification of test item concentrations was conducted using a HPLC-method with MS detection.

Statistics: Descriptive statistics; Fisher's Exact Test for determination of the NOEC, probit analysis for determination of the EC_{50} value.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification was conducted in each concentration at the beginning and at the end of the test. The analyzed contents of boscalid ranged from 98.0 to 110.0% of nominal at test initiation and from 95.8 to 105.1% of nominal at test termination. Measured concentrations of pyraclostrobin were between 94.6 and 104.3% of nominal in samples taken at test initiation and between 89.6 and 99.8% at test termination. As measured concentrations confirmed correct application of the test substance, the following biological results are based on nominal concentrations.

Biological results: After 48 hours of exposure, no immobility was observed in the control, whereas 5, 10, 10 and 55% immobility occurred at 0.060, 0.096, 0.154 and 0.246 mg/L. At the highest tested concentration of 0.393 mg BAS 516 07 F/L all daphnids were immobile after 48 hours of exposure. After 48 hours of exposure statistically significant effects on mobility of daphnids was observed at the two highest concentrations of 0.246 and 0.393 mg BAS 516 07 F/L (Fisher's exact test, $\alpha = 0.05$). No other sublethal effects were observed during the test. For results see Table 10.2.1-3.

Table 10.2.1-3: Effects of BAS 516 07 F on *Daphnia magna* immobility

Concentration [mg/L] nominal	**Control**	**0.060**	**0.096**	**0.154**	**0.246**	**0.393**
Immobility (24 h) [%]	0	5	10	10	25	70 *
Immobility (48 h) [%]	0	5	10	10	55 *	100 *
Endpoints [mg BAS 516 07 F/L] nominal						
EC_{50} (48 h)	0.210					
NOEC (48 h)	0.154					

* Statistically significantly different compared to the control (Fisher's exact test, $\alpha = 0.05$)

III. CONCLUSION

In a 48-hour static acute toxicity study with *Daphnia magna* the EC_{50} of BAS 516 07 F was 0.210 mg/L based on nominal concentrations. The NOEC was determined to be 0.154 mg/L (nominal).

The following algae toxicity study performed with BAS 516 07 F is provided in support of the assessment and has not been previously evaluated on the EU-level.

Report:	CP 10.2.1/4 Hoffmann F., 2007a Effect of BAS 516 07 F on the growth of the green alga Pseudokirchneriella subcapitata 2007/1005074
Guidelines:	OECD 201
GLP:	yes (certified by Landesamt fuer Umweltschutz und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a 72-hour static acute toxicity laboratory study, the effect of BAS 516 07 F on the growth of the green alga *Pseudokirchneriella subcapitata* was investigated. The following nominal concentrations were applied: 0 (control), 1, 2, 4, 8, 16 and 32 mg BAS 516 07 F/L. Assessment of growth was conducted 0, 24, 48 and 72 h after test initiation. The percentage growth inhibition, relative to the control, was calculated for each test concentration from mean growth rates and yield based on number of cells.

The biological results are based on nominal concentrations. No morphological effects on algae were observed in the control and all test item concentrations.

In a 72-hour algae test with *Pseudokirchneriella subcapitata* the E_rC_{50} for BAS 516 07 F was determined to be 10.8 mg/L based on nominal concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 07 F, batch no. 1789, content of a.s. boscalid (BAS 510 F, Reg. No. 300 355): 26.7% (nominal: 26.7%), pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.8% (nominal: 6.7%).

B. STUDY DESIGN

Test species: Unicellular fresh water green alga, *Pseudokirchneriella subcapitata* (Reinsch) Korshikov (syn. *Selenastrum capricornutum* Prinz), SAG 61.81; stock obtained from the "Sammlung von Algenkulturen" Göttingen, Germany.

Test design: Static system; test duration 72 hours; 6 test concentrations, each with 5 replicates per treatment plus a control with 10 replicates; daily assessment of growth.

Endpoints: EC_{10} and EC_{50} with respect to growth rate and yield after exposure over 72 hours.

Test concentrations: Control, 1, 2, 4, 8, 16 and 32 mg BAS 516 06 F/L (nominal).

Test conditions: Erlenmeyer dimple flasks; test volume 60 mL; nutrient solution according to OECD 201; pH 8.1 at test initiation and pH 7.78 - 7.91 at test termination; temperature: 22°C ± 1°C; initial cell densities: 1 x 10^4 cells/mL; continuous light at about 8000 lux; continuous shaking.

Analytics: Analytical verification of test item concentrations was conducted using an HPLC-method with MS detection.

Statistics: Descriptive statistics; probit analysis and logit analysis for determination of EC_x values for growth rate and yield, respectively.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentration was conducted in each concentration at the beginning and at the end of the test. The analyzed contents of boscalid ranged from 100.3 to 117.5% of nominal at test initiation and from 100.2 to 105.1% of nominal at test termination. Measured concentrations of pyraclostrobin were between 100.0 and 110.4% of nominal at test initiation and between 89.8 and 93.4% of nominal at test termination. As measured concentrations confirmed correct application of the test substance, the following biological results are based on nominal concentrations.

Biological results: No morphological effects on algae were observed in the control and all test item concentrations. The effects on algal growth rate and yield are summarized in Table 10.2.1-4.

Table 10.2.1-4: Effect of BAS 516 07 F on the growth of green alga *P. subcapitata*

Concentration [mg/L] nominal	**Control**	**1**	**2**	**4**	**8**	**16**	**32**
Inhibition in 72 h (growth rate) [%]	--	0.7	12.6	28.2	46.6	59.8	74.4
Inhibition in 72 h (yield) [%]	--	2.9	40.5	69.3	86.4	92.8	96.8
Endpoints [mg BAS 516 07 F/L] nominal							
E_rC_{50} (72 h)	**10.8** (95% confidence limits: 10.2 - 11.4)						
E_rC_{10} (72 h)	1.8 (95% confidence limits: 1.6 - 1.9)						
E_yC_{50} (72 h)	3.0 (95% confidence limits: 2.8 - 3.1)						
E_yC_{10} (72 h)	0.9 (95% confidence limits: 0.8 - 1.0)						

III. CONCLUSION

In a 72-hour algae test with *Pseudokirchneriella subcapitata* the E_rC_{50} for BAS 516 07 F was determined to be 10.8 mg/L based on nominal concentrations.

CP 10.2.2 Additional long-term and chronic toxicity studies on fish, aquatic invertebrates and sediment dwelling organisms

Chronic toxicity to fish and aquatic invertebrates

The results obtained in the acute study on *O. mykiss* and *D. magna* with the formulated product BAS 516 07 F (partly tested with the minor change formulation BAS 516 00 F) are in good agreement with the results expected from the data with the active substances (see reasoning given above). Furthermore, the results obtained with the formulated product are in good agreement with the results expected from the data with the active substance pyraclostrobin, which basically determines the toxicity of the product to aquatic organisms whereas boscalid contributes only minor to the overall toxicity of the product. The data demonstrate that the formulation does not cause significant unexpected (additional) toxicity to fish and daphnids. Accordingly, there are no indications of synergism or additional toxicity from the formulation. Therefore, the studies conducted with the active substances can be used to assess the chronic risk resulting from BAS 516 07 F application. No further testing with the product is indicated.

CP 10.2.3 Further testing on aquatic organisms

Marine or estuarine organisms

Studies on marine or estuarine species are not required according to the relevant EU documents and no studies have been conducted with the formulation BAS 5160 07 F on marine or estuarine organisms. The contamination of estuarine and marine environments is considered to be minimal compared to freshwater habitats adjacent to agricultural land according to the use pattern, the potential route of contamination and the dissipation of the active substance. Thus, the risk to those habitats is covered by the risk assessment for freshwater ecosystems.

Microcosm or mesocosm study

No microcosm or mesocosm study has been performed with the formulated product BAS 516 07 F, however, a mesocosm study has been performed with pyraclostrobin (using the previous representative solo formulation BAS 500 00 F, which is of the same formulation type). The mesocosm study has been evaluated following the RIVM Guidance document (de Jong et al., 2008). Executive summaries of the originally submitted study and the evaluation according to RIVM are provided in M-CA 8.2.

The mesocosm study provided a clear NOEC of 8 µg a.s./L. The ecologically acceptable concentration (NOEAEC) of pyraclostrobin was determined to be between 8 µg a.s./L and 24 µg a.s./L. Based on the results of this study a **$RAC_{mesocosm}$ of 4 µg a.s./L** could be derived (by applying an assessment factor of 2 on NOEC), which was considered for a refined risk assessment (as described above).

Residue data in fish
A respective evaluation has been performed during the previous Annex I inclusion process. No new data are provided. The following gives a brief summary of the previous evaluation:
The log P_{ow} of the active substance pyraclostrobin was determined to be 3.99 (EU Review Report, SANCO/1420/2001-final, September 2004). Hence, a bioaccumulation study in fish has been performed with pyraclostrobin, which is (together with a new fish metabolism study, CA 6.2.5/2) discussed in detail in M-CA 6.2.5 (please refer to CA 6.2.5/1). An apparent steady state was reached after 2 - 4 days of exposure. The bioconcentration factors for whole fish were 379 - 507 (two labels). The half-life for elimination was 0.9 days. The time for elimination of 90% of the activity varied between 2.8 and 3.0 days. The nature of radioactivity in fish tissues after 28 days of exposure consisted of the parent substance (39 - 74%) and 4 metabolites (2 - 9%). Due to the limited bioaccumulation and the rapid metabolization and excretion of the active substance (and its metabolites), there is no risk of bioaccumulation. In addition, pyraclostrobin dissipates rapidly in water prohibiting continuous exposure.

Residues of pyraclostrobin in fish are of no concern and no accumulation in the food chain is to be expected.

Accumulation in aquatic non-target organisms
A respective evaluation has been performed during the previous Annex I inclusion process. No new data are provided. Bioaccumulation of the active substance pyraclostrobin under natural conditions is not expected to occur (see "Residue data in fish" above). Additional studies are not required or necessary to determine bioaccumulation in aquatic non-target organisms.

Appendix

The Predicted Environmental Concentrations (PEC) of pyraclostrobin and its major metabolites in surface water and sediment used for the aquatic risk assessment are summarized in the tables below. No additional PEC values have been calculated for the formulated product, as there is no indication for any unexpected (higher) toxicity compared to the active substance - see the reasoning given below.

Table 10.2.3-1: Worst-case FOCUS Step 1 and 2 $PEC_{sw,\ max}$ and $PEC_{sed,\ max}$ values for pyraclostrobin and its major metabolites following application of BAS 516 07 F in potatoes

Test substance	$PEC_{sw,\ max}$ [µg/L]			$PEC_{sed,\ max}$ [µg/kg dry sediment]		
	Step 1	Step 2		Step 1	Step 2	
		EU North	EU South		EU North	EU South

CP 10.3 Effects on arthropods

The new representative formulation BAS 516 07 F was not evaluated within a previous Annex I inclusion process. It is a water dispersible granule (WG) containing 67 g/kg pyraclostrobin and 267 g/kg boscalid.

CP 10.3.1 Effects on bees

The EU agreed endpoints for the active substance pyraclostrobin as described in the EU Review Report (SANCO/1420/2001-final, September 2004) plus endpoints from new studies with the active substance and the new representative formulation BAS 516 07 F are used for the risk assessment on honeybees (see Table 10.3.1-1).

Table 10.3.1-1: Ecotoxicological endpoints for honeybees and bumblebees

Test substance	EU agreed endpoints	Endpoints used in risk assessment
Studies on adult honeybees		
Pyraclostrobin	oral (48 h) LD_{50} > 73.1 µg a.s./bee contact (48 h) LD_{50} > 100.0 µg a.s./bee	oral (48 h) LD_{50} > 73.1 µg a.s./bee contact (48 h) LD_{50} > 100.0 µg a.s./bee
Pyraclostrobin [1)]	--	oral (48 h) LD_{50} > 110.0 µg a.s./bee contact (48 h) LD_{50} > 100.0 µg a.s./bee
BAS 516 07 F [2)]	--	oral (48 h) LD_{50} > 258.7 µg/bee contact (48 h) LD_{50} > 299.4 µg/bee
Studies on honeybee queens		
Pyraclostrobin (tested as Pristine) [3)]	--	No unacceptable effects in queen development, queen survival and adult worker bee health using 400 ppm Pristine treated pollen (measured concentration: 22 ppm pyraclostrobin)
Studies on adult bumblebees		
Pyraclostrobin	--	Oral (96 h) LD_{50} > 97.2 µg a.s./bumblebee Contact (96 h) LD_{50} > 100 µg a.s./bumblebee
Studies on residues		
Pyraclostrobin [4)]	--	Applied rate: 143 g pyraclostrobin/ha Highest residue: 16.6 mg pyraclostrobin/kg (90^{th} percentile, found in sunflower pollen)
Pyraclostrobin [4)]	--	Applied rate: 143 g pyraclostrobin/ha Highest residue: 6.7 mg pyraclostrobin/kg (90^{th} percentile, found in oilseed rape pollen)

1) New acute study has been conducted since the results for the reference substance were out of range in the original study; the results of the new study will be used in the risk assessments below.

2) Tests were carried out with BAS 516 00 F, which is a minor change formulation of BAS 516 07 F (the detailed composition of both products is given in Document JCP 1.4.1).

3) Peer-reviewed scientific study was carried out with Pristine, a formulation similar to BAS 516 07 and containing 25.2% boscalid and 12.8% pyraclostrobin (for details see study summary in M-CP 10.3.1.3 below). The study is presented as additional information.

4) Study was carried out with BAS 556 03 F as a surrogate for pyraclostrobin. BAS 556 03 F contains 130 g pyraclostrobin/L and 80 g metconazole/L. The study is presented as additional information.

Overall summary

Data on BAS 516 07 F and its potential effects on honeybees are evaluated and appropriate risk assessments are provided for the active substance and the formulation based on the already registered use pattern in potatoes (critical GAP: maximum 4 x 17 g pyraclostrobin per ha).

The endpoints and calculated HQs for acute oral and acute contact exposure of honeybees to pyraclostrobin and BAS 516 07 F (see Table 10.3.1-2) are below the trigger value of 50 demonstrating low acute risk to honeybees.

Tests with the formulation have been partly carried out with BAS 516 00 F, which is a minor change formulation of BAS 516 07 F (the detailed composition of both products is given in Document JCP 1.4.1).

Table 10.3.1-2: Toxicity data, maximum single application rates and HQ values for honeybees

Test substance	Use pattern	Exposure route	Endpoint [µg/bee]	Maximum single application rate	Hazard quotient (HQ)	HQ assessment trigger
Risk assessment on adult honeybees						
Pyraclostrobin	potatoes	acute oral	$LD_{50} > 110$	17 g a.s./ha	< 0.15	50
		acute contact	$LD_{50} > 100$		< 0.17	
BAS 516 07 F [1)]		acute oral	$LD_{50} > 258.7$	250 g/ha	< 0.97	
		acute contact	$LD_{50} > 299.4$		< 0.84	

1) Tests were carried out with BAS 516 00 F, which is a minor change formulation of BAS 516 07 F (the detailed composition of both products is given in Document JCP 1.4.1).

Two studies were conducted with pyraclostrobin containing products in two different crops, sunflower and oilseed rape (OSR) to determine the residues in the bee relevant matrices pollen and nectar. The highest exposure (90th percentile) was found in pollen, i.e. 16.6 mg/kg (sunflower) and 6.7 mg/kg (OSR).

Additionally, no unacceptable effects in queen development, queen survival and adult worker bee health were observed using pollen treated with the product Pristine (measured concentration: 22 ppm pyraclostrobin). As currently no risk assessment scheme exists, these results are presented as additional information.

Also for non-*Apis* bees currently no risk assessment scheme exists under Regulation (EC) No 1107/2009. Nevertheless, the potential acute toxicity (oral and contact) of pyraclostrobin to adult bumblebees was addressed in a laboratory study (BASF DocID 2016/1000530), which is described in M-CA 8.3.1.1).

Overall conclusion:
The proposed use of BAS 516 07 F in potatoes present a low risk to honeybees and will not adversely affect honeybees or honeybee colonies.

Toxicity

Table 10.3.1-3 presents the results of honeybee and bumblebee toxicity studies. For a summary of the studies with pyraclostrobin, please refer to M-CA 8.3. Further details regarding the tests with the formulation are provided in M-CP 10.3.1.1.

Table 10.3.1-3: Summary of endpoints of pyraclostrobin and BAS 516 07 F to honeybees and bumblebees

Substance	Endpoint	LD_{50} [µg/bee]	Reference (BASF DocID)
Studies on adult honeybees			
Pyraclostrobin	48 h oral LD_{50}	> 73.1	1999/11457
	48 h contact LD_{50}	> 100	
Pyraclostrobin [1)]	48 h oral LD_{50}	> 110	2013/1003210
	48 h contact LD_{50}	> 100	
BAS 516 07 F [2)]	48 h oral LD_{50}	> 258.7	2001/1000868
	48 h contact LD_{50}	> 299.4	
Studies on honeybee queens			
Pyraclostrobin (tested as Pristine) [3)]	No unacceptable effects in queen development, queen survival and adult worker bee health using 400 ppm Pristine treated (measured concentration: 22 ppm pyraclostrobin)		2013/1416303
Studies on adult bumblebees			
Pyraclostrobin	96 h oral LD_{50}	> 97.2 µg a.s./bee	2016/1000530
	96 h contact LD_{50}	> 100 µg a.s./bee	
Residue studies			
Pyraclostrobin [4)]	Applied rate: 143 g pyraclostrobin/ha Highest residue: 16.6 mg pyraclostrobin/kg (90th percentile, found in sunflower pollen)		2014/1000204
Pyraclostrobin [4)]	Applied rate: 143 g pyraclostrobin/ha Highest residue: 6.7 mg pyraclostrobin/kg (90th percentile, found in oilseed rape pollen)		2014/1000182

1) New acute study has been conducted since the results for the reference substance were out of range in the original study; the results of the new study will be used in the risk assessments below.
2) Tests were carried out with BAS 516 00 F, which is a minor change formulation of BAS 516 07 F (the detailed composition of both products is given in Document JCP 1.4.1).
3) Peer-reviewed scientific study was carried out with Pristine, a formulation similar to BAS 516 07 and containing 25.2% boscalid and 12.8% pyraclostrobin (for details see study summary in M-CP 10.3.1.3 below). The study is presented as additional information.
4) Study was carried out with BAS 556 03 F as a surrogate for pyraclostrobin. BAS 556 03 F contains 130 g pyraclostrobin/L and 80 g metconazole/L. The study is presented as additional information.

Exposure

Applications of pesticides can potentially result in exposure of honeybees either through direct over-spray, or by contact with residues on plants while bees are foraging for food. Potatoes might be of attractiveness to foraging bees during the time of application. In order to consider a worst-case scenario, the maximum application rate for pyraclostrobin as applied with the maximum recommended rate of BAS 516 07 F is used for the risk assessment.

Table 10.3.1-4: Proposed use pattern of BAS 516 07 F

Crop	Application time (BBCH code)	Number of applications	Interval [d]	Application rate per treatment		
				Boscalid [g a.s./ha]	Pyraclostrobin [g a.s./ha]	BAS 516 07 F [g/ha]
potatoes	51 – 89	4	10	67	17	250

Risk assessment for bees

The acute risk to honeybees from the use of BAS 516 07 F in potatoes was assessed using the maximum single application rate and the LD_{50} values to calculate hazard quotients [*EPPO/OEPP, 2003: Environmental risk assessment scheme for plant protection products, Chapter 10: Honeybees (PP 3/10(2)). Bulletin OEPP/EPPO Bulletin 33: 141-145*] as follows:

$$\text{Hazard Quotient (HQ)} = \frac{\text{Maximum application rate [g formulation/ha]}}{\text{Acute } LD_{50} \text{ [µg formulation/bee]}}$$

HQs for honeybees were calculated for oral exposure and contact exposure to BAS 516 07 F. A HQ < 50 indicates low risk to honeybees in the field.

Table 10.3.1-5: Risk to honeybees from exposure to pyraclostrobin and BAS 516 07 F considering the worst-case application rate

Test substance	Application rate [g/ha]	Endpoint	LD_{50} [µg/bee]	Hazard quotient HQ	Trigger
Risk assessment on adult honeybees					
Pyraclostrobin	17	48 h oral	> 110	< 0.15	50
		48 h contact	> 100	< 0.17	
BAS 516 07 F [1)]	250	48 h oral	> 258.7	< 0.97	
		48 h contact	> 299.4	< 0.84	

1) Tests were carried out with BAS 516 00 F, which is a minor change formulation of BAS 516 07 F (the detailed composition of both products is given in Document JCP 1.4.1).

The calculated HQs for acute oral and acute contact exposure of honeybees to pyraclostrobin and BAS 516 07 F are clearly below the trigger value of 50. Therefore, low risk to honeybees is expected from the application of BAS 516 07 F in potatoes.

Additionally, no unacceptable effects in queen development, queen survival and adult worker bee health were observed using 400 ppm Pristine treated pollen (which is according to analysis equivalent to 22 ± 2 ppm pyraclostrobin treated pollen). Pristine is a formulation similar to BAS 516 07 F (both WG formulations containing pyraclostrobin and boscalid). The study summary is shown in M-CP 10.3.1.3 below. As currently no risk assessment scheme exists, these results are presented as additional information.

In an acute toxicity study on adult bumblebees with pyraclostrobin, the oral LD_{50} after 96 h was ≥ 97.2 µg a.s./bumblebee, while the contact LD_{50} after 96 h was > 100 µg a.s./bumblebee. As currently no risk assessment scheme exists, these results are presented as additional information.

CP 10.3.1.1 Acute toxicity to bees

CP 10.3.1.1.1 Acute oral toxicity to bees

Report:	CP 10.3.1.1.1/1 Kling A., 2001a Assessment of side effects of BAS 516 00 F to the honey bee, Apis mellifera L. in the laboratory 2001/1000868
Guidelines:	OECD 213, OECD 214
GLP:	yes (certified by Ministerium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Executive Summary

In a limit test, young adult worker bees (*Apis mellifera* L.) were exposed to BAS 516 00 F. The toxicity of the test product was determined in an oral test at a nominal concentration of 100 µg a.s./bee (based upon the sum of the active substances, this corresponds to a dose of 299.4 µg product/bee). Additionally, honeybees were treated with dimethoate as reference item at concentrations ranging from 0.08 to 0.25 µg a.s./bee or with aqueous syrup solution as a control. The test was conducted with 5 replicates per test concentration, each of the test cages contained 10 bees. Assessment of mortality was done after 4, 24 and 48 hours.

In the oral toxicity test the maximum test concentration (299.4 µg/bee) corresponded to an actual intake of 258.7 µg/per bee. At this concentration a corrected mortality of 22.0% was observed after 48 hours. No abnormal behavior like discoordinated movements and apathy were observed over the entire time of the experiment.

Toxicity of BAS 516 00 F was tested in an acute oral toxicity test on honeybees. The LD_{50} (48 h) was > 258.7 µg BAS 516 00 F/bee.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).

Test species: Honeybee (*Apis mellifera* L.); working bees; age: approx. 22 - 32 days, deriving from a healthy colony which descended from a breeding line of a beekeeper in Rheinland-Pfalz, Germany.

B. STUDY DESIGN

Test design: Limit test; acute oral toxicity test; duration 48 h; 5 replicates per test concentration, each consisting of 10 bees in one cage; assessment of mortality after 4, 24 and 48 hours.

Endpoint: LD_{50}.

Reference item: BAS 152 11 I (dimethoate 400 g/L).

Test concentrations: Control, 100 µg a.s./bee (based upon the sum of the active substances on the nominal contents, this corresponds to a dose of 299.4 µg product/bee); 4 concentrations of the reference item

Test conditions: Temperature: 24.0°C - 26.0°C; relative humidity: 50% - 66%; photoperiod: 24 h darkness.

Statistics: Descriptive statistics.

II. RESULTS AND DISCUSSION

In the oral toxicity test the maximum test concentration (299.4 µg/bee) corresponded to an actual intake of 258.7 µg/per bee. At this concentration a corrected mortality of 22.0% was observed after 48 hours. The results are summarized in Table 10.3.1.1.1-1.

Table 10.3.1.1.1-1: Toxicity of BAS 516 00 F to honeybees (*Apis mellifera*) in an oral toxicity test

Treatment [µg /bee]	Uptake of test item [µg /bee]	Corrected mortality [1] [%]	
		24 h	48 h
299.4 [2]	258.7	20	22
		Endpoints [µg/bee]	
LD_{50} (48 h)		> 258.7	

1) According to Schneider-Orelli (1947).
2) Equivalent to 100 µg a.s./bee (sum of both active substances).

III. CONCLUSION

Toxicity of BAS 516 00 F was tested in an acute contact toxicity test on honeybees. The LD_{50} (48 h) was > 258.7 µg BAS 516 00 F/bee.

CP 10.3.1.1.2 Acute contact toxicity to bees

Report:	CP 10.3.1.1.2/1 Kling A., 2001a Assessment of side effects of BAS 516 00 F to the honey bee, Apis mellifera L. in the laboratory 2001/1000868
Guidelines:	OECD 213, OECD 214
GLP:	yes (certified by Ministerium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Executive Summary

In a limit test, young adult worker bees (*Apis mellifera* L.) were exposed to BAS 516 00 F. The toxicity of the test product was determined in a contact test at a concentration of 100 µg a.s./bee (based upon the sum of the active substances, this corresponds to a dose of 299.4 µg product/bee). Additionally, honeybees were treated with dimethoate as reference item at concentrations ranging from 0.11 to 0.27 µg a.s./bee or with tap water as a control. The test was conducted with 5 replicates per test concentration, each of the test cages contained 10 bees. Assessment of mortality was done after 4, 24 and 48 hours.

In the contact toxicity test no corrected mortality was observed at the concentration of 299.4 µg/bee after 48 hours. No abnormal behavior like discoordinated movements and apathy were observed over the entire time of the experiment.

Toxicity of BAS 516 00 F was tested in an acute contact toxicity test on honeybees. The LD_{50} (48 h) was > 299.4 µg BAS 516 00 F/bee.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).

Test species: Honeybee (*Apis mellifera* L.); working bees; age: approx. 22 - 32 days, deriving from a healthy colony which descended from a breeding line of a beekeeper in Rheinland-Pfalz, Germany.

B. STUDY DESIGN

Test design: Limit test; acute contact toxicity test; duration 48 h; 5 replicates per test concentration, each consisting of 10 bees in one cage; assessment of mortality after 4, 24 and 48 hours.

Endpoint: LD_{50}.

Reference item: BAS 152 11 I (dimethoate 400 g/L).

Test concentrations: Control, 100 µg a.s./bee (based upon the sum of the active substances on the nominal contents, this corresponds to a dose of 299.4 µg product/bee);4 concentrations of the reference item.

Test conditions: Temperature: 24.0°C - 26.0°C; relative humidity: 50% - 66%; photoperiod: 24 h darkness.

Statistics: Descriptive statistics.

II. RESULTS AND DISCUSSION

In the contact toxicity test no corrected mortality was observed at the concentration of 299.4 µg/bee after 48 hours. The results are summarized in Table 10.3.1.1.2-1.

Table 10.3.1.1.2-1: Toxicity of BAS 516 00 F to honeybees (*Apis mellifera*) in a contact toxicity test

Treatment [µg /bee]	Corrected mortality [1] [%]	
	24 h	48 h
299.4 [2]	0	0
Endpoints [µg/bee]		
LD_{50} (48 h)	> 299.4	

[1] According to Schneider-Orelli (1947).
[2] Equivalent to 100 µg a.s./bee (sum of both active substances).

III. CONCLUSION

Toxicity of BAS 516 00 F was tested in an acute contact toxicity test on honeybees. The LD_{50} (48 h) was > 299.4 µg BAS 516 00 F/bee.

CP 10.3.1.2 Chronic toxicity to bees

According to SANCO/10606/2014 (May 16th, 2014) a study on chronic toxicity on honeybees is not required for AIR 3 substances submitted before January 1st, 2015. In addition, this data point is covered by M-CA 8.3.1.3

CP 10.3.1.3 Effects on honey bee development and other honey bee life stages

From the performed literature search, the following peer-reviewed scientific study on queen-rearing success in honeybees (*Apis mellifera* L.) was considered relevant and reliable (with restrictions; RI 2) for the terrestrial risk assessment of pyraclostrobin. Thus, it is presented as additional information for the terrestrial risk assessment and has not been evaluated previously.

Report:	CP 10.3.1.3/1 Johnson R.M., Percel E.G., 2013a Effect of a fungicide and spray adjuvant on queen-rearing success in honey bees (Hymenoptera: Apidae) 2013/1416303
Guidelines:	<none>
GLP:	no

Executive Summary

The aim of this study was to test the effects of the fungicide Pristine (12.8% pyraclostrobin and 25.2% boscalid) and adjuvant on honeybee (*Apis mellifera*) queen development and survival. A new bioassay was developed, in which queens are reared in closed swarm boxes for 4 d, until capping, with nurse bees fed exclusively on artificially contaminated pollen. Pollen was treated with four concentrations of formulated Pristine (0.4, 4, 40, and 400 ppm). Additionally, the bees were treated with diflubenzuron (100 ppm) as reference item and with water as control.

No effect of the test item treatment was observed in relation to changes in the weight of the pollen frame. Pesticide treatment appeared to have no effect on syrup removal.
No changes in nurse bee activity or behavior were noted in any of the treatments. Considering queen development, there was no statistically significant difference between the survival rates in the Pristine treatments compared to the control. The capping rate of grafted larvae was also not statistically significantly different between the test item treatments compared to the control. The mean thoracic width of the control was 4.54 mm compared to 4.47, 4.52, 4.49 and 4.54 mm in the test item treatments with concentrations of 0.4, 4, 40 and 400 ppm, respectively. No statistically significant differences were observed up to and including the highest concentration tested.
Chemical analysis of four pollen samples treated with 400 ppm Pristine taken from pollen frames after 4 d in the swarm box contained 22 ± 2 ppm pyraclostrobin and 47 ± 5 ppm boscalid.

In a toxicity laboratory study with pyraclostrobin (tested as Pristine containing 12.8% pyraclostrobin and 25.2% boscalid and being similar to BAS 516 07 F) on honeybees, no unacceptable effects in queen development, queen survival and adult worker bee health were observed up to and including 400 ppm Pristine treated pollen, the highest concentration tested (according to analysis equivalent to 22 ± 2 ppm pyraclostrobin treated pollen).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Formulated Pristine (25.2% boscalid and 12.8% pyraclostrobin; BASF, Florham Park, NJ). Some information on the fungicide (batch no.; density, etc.) is missing in the study report.

Adjuvant: Break-Thru (100% Polyether-Polymethylsiloxane-Copolymer; Evonik Goldschmidt, Hopewell, VA).

B. STUDY DESIGN

Test species: Honeybee (*Apis mellifera*), young worker larvae (<24 h) were grafted from a mix of Italian and Carniolan breeder colonies and checked for queen emergence. No detailed information is given on the source of the bees.

Test design: To determine the potential effects that the fungicide Pristine has on immature queen development and survival, queens of *Apis mellifera* were reared inside closed swarm boxes provisioned with treated pollen. In total, 1320 larvae were grafted into swarm boxes containing pollen treated with the following: Water control, 4 concentrations of the test item Pristine, one concentration of the adjuvant, one concentration of the adjuvant + Pristine and one concentration of the reference item. Approximately 2.27 kg of nurse bees, measured by equivalent volume, were placed in the prepared swarm boxes. Young worker larvae (<24 h) were grafted into wax queen cups affixed to wooden bars and fitted into special grafting frames holding a total of 60 larvae. Grafting frames were quickly transferred to the middle frame position in prepared swarm boxes. As many as 360 grafts were completed within 1 h by three expert grafters working side by side. After 4 d in the closed swarm boxes, grafting frames were carefully removed and nurse bees were brushed off. Capped queen cells were counted, and frames with queen cells were transferred to an incubator. Three queen cells from each frame were opened, and the royal jelly was removed for chemical analysis. Pollen and syrup consumption in each swarm box was determined by comparing the starting and ending weight of the pollen frame and division board feeder. Dead bees remaining in the swarm box were collected and weighed. After 7 d in the incubator, queen cells were cut from the grafting bars and placed inside individually labeled plastic hair roller queen cages. Caged queen cells were returned to the incubator and checked for queen emergence 4 d later. Emerged queens were counted, and examined for abnormalities. Unemerged queen cells were dissected, and the age at which the unemerged queen died was estimated based on morphological characteristics. Queen quality was assessed by measuring the width of the thorax with a digital caliper. Fresh royal jelly and treated pollen were both collected for chemical-residue testing on the day capped queen cells were removed from swarm boxes.

Quantification of pyraclostrobin and boscalid concentrations in samples exposed to Pristine was accomplished at the USDA-AMS-NSL and a modified version of the QuEChERS method was used to extract the pesticide residues.

Endpoints: Queen development and survival, adult worker bee health.

Reference item: Pond Care Dimilin (0.10% diflubenzuron; Aquarium Pharmaceuticals, Inc., Chalfont, PA).

Test concentrations: Water control; test item: 0.4, 4.0, 40 and 400 ppm Pristine in pollen; reference item: 100 ppm diflubenzuron; adjuvant in combination with test item: 200 ppm Break-Thru and 400 ppm Pristine.

Test conditions: Nurse bees: placed in a dark well-ventilated area in prepared swarm boxes.
Capped and caged queen cells: placed in an incubator (temperature: 34°C; relative humidity: 80%).
Royal jelly and treated pollen storage: temperature: -20°C in a glass vial for chemical analysis.

Statistics: Descriptive statistics; A x^2 goodness-of-fit test was used to determine treatment effects on the survival of queen larvae to capping and adult emergence. One-way analysis of variance (ANOVA) was used to determine treatment differences in food consumption, dead bee accumulation, and queen thoracic width. Tukey's honestly significant difference (HSD) test was used for pairwise comparisons between treatments.

II. RESULTS AND DISCUSSION

In this subsection the focus is on the effects of Pristine on *A. mellifera* larvae, queens and adults. The results of the adjuvant and Pristine in combination with the adjuvant are not summarized here.

Pollen and syrup consumption
No effect of the test item treatment was observed in relation to changes in the weight of the pollen frame. Pesticide treatment appeared to have no effect on syrup removal.

Adult worker bee health
No changes in nurse bee activity or behavior were noted in any of the treatments.

Queen development
There was no statistically significant difference between the survival rates in the Pristine treatments compared to the control. The capping rate of grafted larvae was also not statistically significantly different between the test item treatments compared to the control.

The mean thoracic width of the control was 4.54 mm compared to 4.47, 4.52, 4.49 and 4.54 mm in the test item treatments at concentrations of 0.4, 4, 40 and 400 ppm, respectively. No statistically significant differences were observed up to and including the highest concentration tested. The results are summarized in Table 10.3.1.3-1.

Chemical analysis
Based on the ratio of active substances in pollen treated with this formulated fungicide at the 400 ppm level would be expected to contain 101 ppm boscalid and 51 ppm pyraclostrobin. Chemical analysis of four pollen samples treated with 400 ppm Pristine taken from pollen frames after 4 d in the swarm box contained 47 ± 5 ppm boscalid and 22 ± 2 ppm pyraclostrobin, approximately half the expected concentration. Three of four royal jelly samples taken from 400 ppm Pristine treatments contained detectable levels of pyraclostrobin (47-52 ppb), but boscalid was not detected in any royal jelly sample.

Table 10.3.1.3-1: Comparisons of thoracic width of queens reared with Pristine treated pollen

Treatment	Concentration (ppm)	n	Thoracic width (mm)
Water control	--	159	4.54
Pristine	0.4	76	4.47
Pristine	4.0	71	4.52
Pristine	40	65	4.49
Pristine	400	168	4.54

The reference item diflubenzuron showed statistically significant differences in queen development and survival. No diflubenzuron-treated queens survived to emergence; on dissection, all were putrefied black larvae that appeared to have died soon after capping.

III. CONCLUSION

In a toxicity laboratory study with pyraclostrobin (tested as Pristine containing 25.2% boscalid and 12.8% pyraclostrobin and being similar to BAS 516 07 F) on honeybees, no unacceptable effects in queen development, queen survival and adult worker bee health were observed up to and including 400 ppm Pristine treated pollen, the highest concentration tested (according to analysis equivalent to 22 ± 2 ppm pyraclostrobin treated pollen).

CP 10.3.1.4 Sub-lethal effects

As BAS 516 07 F does not pose an unacceptable risk to honeybees, further tests are not necessary.

CP 10.3.1.5 Cage and tunnel tests

As BAS 516 07 F does not pose an unacceptable risk to honeybees, further tests are not necessary.

CP 10.3.1.6 Field tests with honeybees

As BAS 516 07 F does not pose an unacceptable risk to honeybees, further tests are not necessary.

CP 10.3.2 Effects on non-target arthropods other than bees

The new representative formulation was not evaluated within a previous Annex I inclusion process. Consequently, no EU agreed endpoints are available for non-target arthropods. Endpoints from new studies with the new representative formulation BAS 516 07 F are used for the risk assessments (see Table 10.3.2-1).

Table 10.3.2-1: Ecotoxicological endpoints for non-target arthropods

Test substance	Test species	EU agreed endpoints	Endpoints used in risk assessment
Tier I			
BAS 516 07 F [1)]	*Typhlodromus pyri*	--	LR_{50} > 5.4 kg/ha
	Aphidius rhopalosiphi	--	LR_{50} > 5.4 kg/ha
Tier II			
BAS 516 07 F [1)]	*Chrysoperla carnea* laboratory test	--	LR_{50} > 3.6 kg/ha No unacceptable effects on reproduction up to 3.6 kg/ha

Higher Tier			
BAS 516 07 F [1)]	*Typhlodromus pyri* field studies	--	No unacceptable effects up to 5 x 0.75 kg/ha

[1)] The toxicity tests on non-target arthropods were carried out with BAS 516 00 F, which is a minor change formulation of BAS 516 07 F (the detailed composition of both products is given in Document JCP 1.4.1).

Overall summary

Data on BAS 516 07 F and its potential effects on non-target arthropods are evaluated and appropriate risk assessments are provided based on the already registered use pattern in potatoes (critical GAP: maximum 4 x 17 g pyraclostrobin per ha). Tests with the formulation have been carried out with BAS 516 00 F, which is a minor change formulation of BAS 516 07 F (the detailed composition of both products is given in Document JCP 1.4.1).

The endpoints of non-target arthropods to BAS 516 07 F are shown in Table 10.3.2-2.

Table 10.3.2-2: Effects on other arthropod species

Test substance [1)]	Worst-case use pattern	Species / Life stage	Test type	Endpoint [kg/ha]	PER in-field [kg/ha]	PER off-field [kg/ha]	HQ in-field	HQ off-field

Higher Tier								
BAS 516 07 F	4 x 0.25 kg/ha	Predatory mites all live stages	Field tests, orchards, 3D (3 studies)	No unacceptable effects up to 5 x 0.75 kg/ha	Max. intended use = 4 x 0.25 kg/ha		Endpoint ≥ intended application rate → acceptable risk	

PER = predicted environmental rate, HQ = Hazard Quotient

1) The toxicity tests on non-target arthropods were carried out with BAS 516 00 F, which is a minor change formulation of BAS 516 07 F (the detailed composition of both products is given in Document JCP 1.4.1).

2) Standard 5-fold uncertainty (correction) factor should be included in the calculation to cover the inter-species variability in sensitivity of off-field non-target arthropod species. However, as additional species are tested, the uncertainty is reduced and no additional safety factor was applied.

The calculated hazard quotient of the first tier risk assessment indicated no in-field and no off-field risk for both tested species. However, in order to have additional information for the risk assessment, Tier II tests were carried out with *C. carnea*, *A. bilineata*, *P. cupreus* and *Pardosa* spec. For these species the Tier II risk assessment indicated no in-field and no off-field risk, too. Additionally, three field studies were carried out to observe effects on natural occurring populations of predatory mites. No unacceptable effects on population development of predatory mites were observed up to 5 x 0.75 kg/ha. Therefore, a potential in-field and off-field risk can be excluded for BAS 516 07 F applied to potatoes at 4 x 0.25 kg/ha.

Overall conclusion
Taking into account all available data, it can be concluded that low risk for non-target arthropods is expected from the use of BAS 516 07 F in potatoes at application rates of up to 4 x 0.25 kg/ha. No unacceptable effects on non-target arthropods are expected in in-field and off-field habitats.

Toxicity

The toxicity of BAS 516 07 F to non-target arthropods has been investigated. The testing and risk assessment strategy used follow the approach recommended in the ESCORT 2 guidance document [*Candolfi et al. (2000) 'Guidance Document on regulatory testing procedures for plant protection products with non-target arthropods' From the workshop, European Standard Characteristics of Non-target Arthropod Regulatory Testing (ESCORT 2) 21-23 March 2000*], ESCORT 3 [*Alix, et al. (2012) 'Linking non-target arthropod testing and risk assessment with protection goals'*] and the EC Guidance Document on Terrestrial Ecotoxicology (SANCO/10329, 17 October 2002).

The toxicity of BAS 516 07 F (tested as the minor change formulation BAS 516 00 F; the detailed composition of both products is given in Document JCP 1.4.1) to non-target arthropods has been investigated by carrying out Tier I tests on *Aphidius rhopalosiphi* and *Typhlodromus pyri* and Tier II tests on *Chrysoperla carnea*, *Poecilus cupreus*, *Aleochara bilineata* and *Pardosa* spec. These species are tested, in accordance with ESCORT 2 and 3, as representative non-target arthropods since they have been found to be particularly sensitive species, and therefore can be considered as indicators of potential effects to the most sensitive arthropods in the field. Furthermore, overall three field studies with predatory mites have been carried out with BAS 516 07 F (tested as the minor change formulation BAS 516 00 F; the detailed composition of both products is given in Document JCP 1.4.1). For convenience, the results of these studies are summarized in Table 10.3.2-3. Study summaries are provided below (see M-CP 10.3.2.1, M-CP 10.3.2.2 and M-CP 10.3.2.4).

Table 10.3.2-3: Summary of endpoints for BAS 516 07 F to non-target arthropods [1)]

Species	Exposed life stage	Study type	Application rate [kg/ha]	Corrected mortality [2)] [%]	Sublethal effects [%]	Reference (BASF DocID)

n.d. = not determined

1) The toxicity tests on non-target arthropods were carried out with BAS 516 00 F, which is a minor change formulation of BAS 516 07 F (the detailed composition of both products is given in Document JCP 1.4.1).

2) Negative values indicate an increase, positive a decrease relative to the control.

Table 10.3.2-4: BAS 516 07 F – effects on terrestrial arthropods in field tests

Species	Crop	Application rate [1] [kg BAS 516 07 F/ha]	Sampling time [2]	Effects [3] [%]	Reference (BASF DocID)
predatory mites, natural field population	stone fruit orchard in Germany	5 x 0.75	8 days after 3rd application 7 days before 4th application 9 days after 5th application 29 days after 5th application	15 20 19 -87	2001/1000905
predatory mites, natural field population	apple orchard in Germany	5 x 0.75	5 days after 1st application 6 days after 3rd application 2 days before 4th application 6 days after 5th application 4 weeks after 5th application	25.3 47.2 -12.5 32.6 -28.5	2001/1001866
predatory mites	stone fruit orchard in Switzerland	5 x 0.75	6 days after 5th application 26 days after 5th application	6.9 1.8	2001/1001870

1) The toxicity tests on non-target arthropods were carried out with BAS 516 00 F, which is a minor change formulation of BAS 516 07 F (the detailed composition of both products is given in Document JCP 1.4.1).
2) The effect on mite population according to Abbott (1925) was only calculated for dates in which mite density was higher than 0.1 mites / leaf in the control.
3) Effects calculated according to Abbott (1925). Negative values indicate a higher population development compared to the control.

Exposure

Table 10.3.2-5: Critical use pattern of BAS 516 07 F

Crop	Application time (BBCH code)	Number of applications	Interval [d]	Application rate per treatment		
				Boscalid [g a.s./ha]	Pyraclostrobin [g a.s./ha]	BAS 516 07 F [g/ha]
potatoes	51 - 89	4	10	67	17	250

In-field exposure

Non-target arthropods inhabiting the crop can be exposed to residues of BAS 516 07 F by direct contact, either as a result of overspray or through contact with residues on plants and soil or in food items. BAS 516 07 F is applied at a maximum rate of 4 x 0.25 kg/ha in potatoes.

The in-field exposure (predicted environmental rate, PER) is calculated according to ESCORT 2 using the following equation:

$PER_{in\text{-}field}$ = Application rate [kg/ha] x MAF

The MAF is a generic multiple application factor, which is used to take into account the potential build-up of applied substances between applications based on the application interval, DT_{50} value and number of applications. Default foliar and soil MAF values following multiple applications are given in the ESCORT 2 Guidance Document. For 4 applications, the default MAF of 2.7 (foliar) and 3.4 (soil) is considered, respectively. However, as a pre-emergence or early post-emergence application is not foreseen according to the proposed use pattern, the PER (soil) will not be used in the following risk assessment.

The maximum predicted environmental rate (PER) occurring within the field after application of BAS 516 07 F at the maximum application rate are presented in Table 10.3.2-6.

Table 10.3.2-6: In-field PER values for application of BAS 516 07 F

Substance	Worst-case application rate	$PER_{in\text{-}field}$ (foliar) [kg/ha]
BAS 516 07 F	4 x 0.25 kg/ha	0.675

Off-field exposure

Risk assessment of areas immediately surrounding the crop is considered important since these areas represent a natural reservoir for immigration, emigration and reproduction of arthropod populations and provide increased species diversity. Exposure of non-target arthropods living in off-field areas to BAS 516 07 F will mainly be due to spray drift from field applications. Off-field areas are assumed to be densely vegetated and thus spray drift is unlikely to reach bare ground. Therefore, evaluation of exposure *via* soil residues in off-field areas was not considered. Off-field foliar PER values were calculated from in-field foliar PERs in conjunction with drift values published by the BBA [*90th percentile drift according to BBA (2000): Bundesanzeiger Jg. 52 (Official Gazette), Nr 100, S. 9879-9880 (25.05.2000) Bekanntmachung über die Abtrifteckwerte, die bei der Prüfung und Zulassung von Pflanzenschutzmitteln herangezogen werden*] as shown in the following equation:

$$PER_{off\text{-}field} = \frac{\text{maximum } PER_{in\text{-}field} \times (\%\ \text{drift}/100)}{\text{vegetation distribution factor}}$$

The model used to estimate spray drift was developed for drift onto a two-dimensional water surface and, as such, does not account for interception and dilution by three-dimensional vegetation in off-crop areas. Therefore, a vegetation distribution or dilution factor is incorporated into the equation when calculating PERs to be used in conjunction with toxicity endpoints derived from two-dimensional (glass plate or leaf disc) studies. A dilution factor of 10 is recommended by ESCORT 2. For 3-dimensional studies, i.e. where spray treatment is applied onto whole plants, the dilution factor of 10 is not used, as any dilution over the 3-dimensional vegetation surface is accounted for in the study design. The correction factor from the ESCORT 2 formula for off-field exposure calculation is considered for in the respective risk assessment.

The drift value for four applications at 1 m distance in field crops (i.e. potatoes) is 1.85% of the application rate (74^{h} percentile drift). The drift factor (% drift/100) is therefore 1.85/100 = 0.0185. The resulting PER off-field values are shown in Table 10.3.2-7.

Table 10.3.2-7: Off-field Predicted Environmental Rates (PER)

Study type	Maximum $PER_{in\text{-}field}$ [kg/ha]	drift factor [% drift/100]	Vegetation distribution factor	$PER_{off\text{-}field}$ [kg/ha]
2D exposure scenario	0.675	0.0185	10	0.0012
3D exposure scenario	0.675	0.0185	--	0.012

Risk assessment for other non-target arthropods

The risk to non-target arthropods is assessed using the approach recommended in the published ESCORT 2 document [*Candolfi et al. 2001*] and the EC Guidance Document on Terrestrial Ecotoxicology (SANCO/10329, 17 October 2002).

In-field risk assessment (Tier I)

The potential risk of BAS 516 07 F to in-field non-target arthropods was assessed by calculation of the hazard quotient (HQ) using the $PER_{in\text{-}field}$ and the lowest lethal rate (LR_{50}) values according to the following equation:

$$HQ_{in\text{-}field} = \frac{PER_{in\text{-}field}\ [kg/ha]}{LR_{50}\ [kg/ha]}$$

The HQ trigger for Tier I laboratory studies is 2. The resulting $HQ_{in\text{-}field}$ values are presented in Table 10.3.2-8.

Table 10.3.2-8: In-field HQs for non-target arthropods

Species	LR_{50} [kg/ha]	In-field		Trigger value
		PER [kg/ha]	HQ	
T. pyri Tier I, 2D exposure scenario	> 5.4	0.675	< 0.13	2
A. rhopasoliphi Tier I, 2D exposure scenario	> 5.4	0.675	< 0.13	

The in-field HQ values for the representative test species *T. pyri* and *A. rhopalosiphi* are below the ESCORT 2 trigger value of 2. Thus, the potential in-field risk to non-target arthropods exposed to BAS 516 07 F is considered to be low at this level of testing.

In-field risk assessment (Tier II)

Both $HQ_{in\text{-}field}$ for *T. pyri* and *A. rhopalosiphi* were below the trigger value of 2, therefore no further assessment is necessary. However, a summary of a Tier II in-field evaluation is presented in Table 10.3.2-9.

Table 10.3.2-9: In-field Tier II and higher tier risk assessment for non-target arthropods

Species	Endpoints [kg/ha]	$PER_{in\text{-}field}$ [kg/ha]	Trigger
Tier II			
C. carnea, laboratory test, artificial substrate, 2D exposure scenario	LR_{50} > 3.6	0.675	Endpoint ≥ PER → acceptable risk
C. carnea, extended laboratory test, natural substrate, 2D exposure scenario	LR_{50} > 2 x 1.8 ER_{50} > 2 x 1.8	0.675	Endpoint ≥ PER → acceptable risk
P. cupreus, laboratory test, artificial substrate, 2D exposure scenario	LR_{50} > 3.6 ER_{50} > 3.6	0.675	Endpoint ≥ PER → acceptable risk
A. bilineata, laboratory test, artificial substrate, 2D exposure scenario	ER_{50} > 3.6	0.675	Endpoint ≥ PER → acceptable risk
Pardosa spec., extended laboratory test, natural substrate, 2D exposure scenario	LR_{50} > 3.6 ER_{50} > 3.6	0.675	Endpoint ≥ PER → acceptable risk
Higher Tier			
Predatory mites, 3D exposure scenario, overall 3 field studies	No unacceptable effects up to 5 x 0.75 kg/ha	Max. intended use = 4 x 0.25 kg/ha	Endpoint ≥ intended application rate → acceptable risk

Chrysoperla carnea:
The rate of 3.6 kg BAS 516 00 F/ha, at which no unacceptable effects on survival were observed in a worst-case laboratory, exceeded the in-field predicted environmental rate (PER) of 0.675 kg/ha. Additionally, the rate of 2 x 1.8 kg/ha, at which no unacceptable effects on survival and reproduction were observed in an extended laboratory test, exceeded the in-field predicted environmental rate (PER) of 0.675 kg/ha, too. Therefore, no risk or unacceptable effects are expected for *Chrysoperla carnea* resulting from the intended use of BAS 516 07 F considering in-field habitats.

Poecilus cupreus:
The rate of 3.6 kg BAS 516 00 F/ha, at which no unacceptable effects on survival and feeding capacity were observed, exceeded the in-field predicted environmental rate (PER) of 0.675 kg/ha. Therefore, no risk or unacceptable effects are expected for *Poecilus cupreus* resulting from the intended use of BAS 516 07 F considering in-field habitats.

Aleochara bilineata:
The rate of 3.6 kg BAS 516 00 F/ha, at which no unacceptable effects on reproduction were observed, exceeded the in-field predicted environmental rate (PER) of 0.675 kg/ha. Therefore, no risk or unacceptable effects are expected for *A. bilineata* resulting from the intended use of BAS 516 07 F considering in-field habitats.

Pardosa spec.:
The rate of 3.6 kg BAS 516 00 F/ha, at which no unacceptable effects on survival and feeding capacity were observed, exceeded the in-field predicted environmental rate (PER) of 0.675 kg/ha. Therefore, no risk or unacceptable effects are expected for *Pardosa* spec. resulting from the intended use of BAS 516 07 F considering in-field habitats.

Predatory mites:
To investigate short- and long-term effects of BAS 516 07 F under normal agricultural conditions, three field studies were carried out with the minor change formulation BAS 516 00 F in order to observe effects on natural occurring populations of predatory mites under field conditions.

The field studies were conducted in orchards at different locations in Germany and in Switzerland. BAS 516 00 F was applied at 5 x 0.75 kg/ha, resulting in a total amount of 3.75 kg/ha BAS 516 07 F.

The population density of predatory mites was determined by counting the total number of mites on leaf or flower bud samples. No unacceptable effects on predatory mite populations occurred during the studies and 4 weeks after the last application. This clearly indicates that no unacceptable effects on natural populations occurred at a rate up to and including 5 x 0.75 kg/ha BAS 516 00 F. This rate exceeds the maximum intended application rate of 4 x 0.25 kg/ha BAS 516 07 F. Therefore, no risk or unacceptable effects are expected for predatory mites resulting from the intended use of BAS 516 07 F considering in-field habitats, too.

Off-field risk assessment (Tier I)

In order to assess the potential risk of BAS 516 07 F to off-field non-target arthropods, the predicted environmental rate (Table 10.3.2-7) is compared with the toxicity endpoints according to the following formula:

$$HQ_{off\text{-}field} = \frac{PER_{off\text{-}field}\ [kg/ha]}{LR_{50}\ [kg/ha]} \times \text{Correction factor}$$

The HQ trigger value for Tier I laboratory studies is 2. A correction factor of 10 for Tier I data is recommended by ESCORT 2 to account for extrapolation from testing of only 2 representative species to the expected higher species diversity in off-crop areas. The results are presented in Table 10.3.2-10.

Table 10.3.2-10: Off-field HQ values for non-target arthropods

Species	LR_{50} [kg/ha]	Off-field PER [kg/ha]	Correction factor	Off-field HQ	Trigger value
T. pyri Tier I, 2D exposure scenario	> 5.4	0.0012	10	< 0.002	2
A. rhopasoliphi Tier I, 2D exposure scenario	> 5.4	0.0012		< 0.002	

The off-field HQ values for *T. pyri* and *A. rhopalosiphi* are considerably below the trigger value of 2, indicating that BAS 516 07 F does not pose an unacceptable risk to non-target arthropods in off-field areas.

Off-field risk assessment (Tier II)

Both $HQ_{off\text{-}field}$ for the standard indicator species *T. pyri* and *A. rhopalosiphi* were clearly below the trigger value of 2. In addition, all endpoint from extended lab testing provide sufficient margin of safety to the anticipated off-field PER-values. Therefore, no further assessment is considered necessary.

CP 10.3.2.1 Standard laboratory testing for non-target arthropods

Report:	CP 10.3.2.1/1 Buehler A., 2000a Effect of BAS 516 00 F on the ground dwelling predator Poecilus cupreus (Coleoptera, Carabidae) in a laboratory trial 2000/1012478
Guidelines:	BBA VI 23-2.1.8, Heimbach U. (1991) Auswirkungen von Pflanzenschutzmitteln auf Imagines von Poecilus cupreus L. als Vertreter der Familie Carabidae (= Laufkaefer) im Laboratorium
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In a worst-case laboratory study, adults of *Poecilus cupreus* L (carabid beetle) were exposed to direct application of BAS 516 00 F at a rate of 3600 g/ha on quartz sand. Mortality and behavior were assessed 1 hour, 1, 2, 4, 7, 10 and 14 days after application. Food consumption was recorded 1, 2, 4, 7, 10 and 14 days after application.

BAS 516 00 F caused a mortality of 3.3% after 14 days of exposure. The mean mortality in the water control was 3.3%. So a corrected mortality of 0% was calculated for the test item treatment.

The mean number of consumed pupae per beetle from day 0 - 14 reached 5.67 in the test item and 5.83 in the control, respectively. This results in 97.3% food consumption in the test item relative to the control (effect on food consumption: 2.7%). No statistically significant differences between control and test item concerning food consumption could be shown.

Under worst-case laboratory conditions, no unacceptable effects on survival or feeding rate of *Poecilus cupreus* occurred at an application rate of 3600 g/ha BAS 516 00 F in 400 L water/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).
Test species:	*Poecilus cupreus* L. (carabid beetle), age: 7 weeks old; source: Bio Test Labor GmbH, Sagerheide, Germany.

B. STUDY DESIGN

Test design:	The beetles were exposed to direct application on moist quartz sand. Three treatments (test item, water treated control, reference item) were set up, with 5 test units each and 6 individuals (3 males and 3 females) per test unit. Assessment of mortality and behavior 1 hour, 1, 2, 4, 7, 10 and 14 days after application. Food consumption was recorded 1, 2, 4, 7, 10 and 14 days after application.
Endpoints:	Mortality, behavior and feeding rate of exposed beetles.
Reference item:	BAS 152 11 I (dimethoate, 400 g/L).
Test rates:	3600 g/ha BAS 516 00 F. The reference item was applied equivalent to 1.0 L/ha. The substances were applied in 400 L water/ha. The substances were sprayed upon the substrate and the beetles via laboratory spray applicator.
Test conditions:	Temperature: 18.5°C – 21.5°C; relative humidity: 67% – 85%; photoperiod: 16 h light : 8 h dark; light intensity: 660 lux – 1020 lux; food: fly pupae (*Delia antiqua*).
Statistics:	Descriptive statistics, Wilcoxon's Rank Sum Test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

BAS 516 00 F caused a mortality of 3.3% after 14 days of exposure. The mean mortality in the water control was 3.3%. So a corrected mortality of 0% was calculated for the test item treatment.

The mean number of consumed pupae per beetle from day 0 - 14 reached 5.67 in the test item and 5.83 in the control, respectively. This results in 97.3% food consumption in the test item relative to the control (effect on food consumption: 2.7%). No statistically significant differences between control and test item concerning food consumption could be shown (Wilcoxon's Rank Sum Test; $\alpha = 0.05$) (see Table 10.3.2.1-1).

Table 10.3.2.1-1: Effects on the carabid beetle (Poecilus cupreus) exposed to BAS 516 00 F in a laboratory trial

Treatment	Rate [1] [g/ha]	Mortality [2] [%]	Corrected mortality [3] [%]	Pupae consumed per beetle [4]	Effect on feeding behavior [%]
Control	--	3.3	--	5.83	--
BAS 516 00 F	3600	3.3	0	5.67 n s	2.7
Endpoint [g/ha]					
LR_{50}	> 3600				
Effects on feeding rate	> 3600				

1) Application rate in 400 L water/ha.
2) Mortality: mean of 5 replicates and 6 beetles/replicate, i.e. 30 beetles in total.
3) Corrected mortality according to Schneider-Orelli (1947)
4) mean number of eaten pupae over the entire observation period.
n.s.: not statistically significant compared to the control (Wilcoxon's Rank Sum Test; $\alpha = 0.05$).

The mean mortality in the reference item was 96.7%. This results in a corrected mortality of 96.6%. In the reference item 0.51 pupae per beetle were consumed. The food uptake was reduced by 91.3% when compared to the control.

III. CONCLUSION

Under worst-case laboratory conditions, no unacceptable effects on survival or feeding rate of *Poecilus cupreus* occurred at an application rate of 3600 g/ha BAS 516 00 F in 400 L water/ha.

Report:	CP 10.3.2.1/2 Adelberger I., 2001a BAS 516 00 F: Toxicity to the predatory mite, Typhlodromus pyri SCHEUTEN (Acari, Phytoseiidae) in the laboratory 2001/1000880
Guidelines:	Louis F. Ufer A. (1995) Methodical improvements of standard laboratory tests for determining the side-effects of agrochemicals in predatory mites (Acari: Phytoseiidae) Anz. Schaedlingskde. Pflanzenschutz Umweltschutz 68 pp. 154-154, Overmeer W.P.J. (1988) Laboratory method for testing side-effects of pesticides on the predacious mites Typhlodromus pyri and Amblyseius potentillae (Acari: Phytoseiidae), Bluemel et al. (2000)
GLP:	yes (certified by Ministerium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Executive Summary

In a worst-case laboratory study, *Typhlodromus pyri* Scheuten (Acarina: Phytoseiidae) was exposed to dried residues of BAS 516 00 F on glass plates. Mortality was assessed 3 and 7 days after treatment. For the reproduction assessment, surviving mites from the control and from any treatment group displaying less than 50% corrected mortality were sexed and the number of eggs per females was recorded on day 10, 13 and 14.

The corrected mortality in the different treatment groups ranged between -7.8 and 5.6%. Therefore, the LR_{50} was determined to be > 5400 g/ha. The mean cumulative number of offspring per female was 7.5 in the control and ranged between 7.1 and 8.7 in the test item treatments. The differences between control and test item treatments were not statistically different. No significant effects on the survival and reproduction of *T. pyri* were observed in any of the BAS 516 00 F treatments.

The LR50 obtained under worst-case laboratory conditions on *Typhlodromus pyri* was determined to be > 5400 g/ha BAS 516 00 F in 200 L water/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).

Test species: *Typhlodromus pyri* (predatory mite), protonymphs approximately 1 day old; source: GAB Biotechnologie GmbH, Germany.

B. STUDY DESIGN

Test design: Exposure of the predatory mites was reached via air-dried residues on treated glass plates. Initial evaluation of the test item was done in a range finding test. Based on these results, a main test was designed. Seven treatments (five rates of test item, water control, reference item) were set up with 5 replicates each and each replicate containing 20 mites. The mortality was assessed 3 and 7 days after treatment. For the reproduction assessment, surviving mites from the control and from any treatment group displaying less than 50% corrected mortality were sexed and the number of eggs per females was recorded on day 10, 13 and 14.

Endpoints: LR_{50} (50% mortality of mites after exposure over 7 days), additionally reproduction capacity for three treatment groups displaying less than 50% corrected mortality.

Reference item: BAS 152 11 I (Dimethoate, 400 g/L).

Test rates:

Treatment	BAS 516 00 F [g/ha]
1	66.7
2	200
3	600
4	1800
5	5400

The reference item was applied at an application rate of 45 mL/ha. All substances were applied in 200 L water/ha. The substances were sprayed onto glass plates via laboratory spraying equipment and air dried afterwards.

Test conditions: Exposure: temperature: 23°C - 27°C; relative humidity: 55% - 88%; photoperiod: 16 h light : 8 h dark; light intensity: 3000 - 6000 lux; food: pollen of birch (*Betula pendula*) and bean (*Vicia faba*), mixture of tap water and deionized water (1:2).

Statistics: Descriptive statistics; ANOVA followed by Dunnett's test for mortality and reproduction ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

The LR_{50}-value was determined to be > 5 400 g/ha BAS 516 00 F, the highest rate tested.
The mean cumulative number of offspring per female was 7.5 in the control and ranged between 7.1 and 8.7 in the test item treatments. The differences between control and test item treatments were not statistically different. No significant effects on the survival and reproduction of *T. pyri* were observed in any of the BAS 516 00 F treatments (Dunnett's test, $\alpha = 0.05$) (see Table 10.3.2.1-2).

Table 10.3.2.1-2: Effects on predatory mites (*Typhlodromus pyri*) exposed to BAS 516 00 F in a laboratory trial

Treatment	Rate[1)] [g/ha]	Mortality[2)] [%]	Corrected mortality[3)] [%]	Reproduction[4)] [eggs/female]	Effects on reproduction[5)] [%]
Control	--	10.0	--	7.5	--
BAS 516 00 F	66.7	11.0 n s	1.1	8.0 n s	-8
BAS 516 00 F	200.0	5.0 n s	-5.6	7.3 n s	3
BAS 516 00 F	600.0	11.0 n s	1.1	8.0 n s	-7
BAS 516 00 F	1800.0	3.0 n s	-7.8	7.1 n s	4
BAS 516 00 F	5400.0	15.0 n s	5.6	8.7 n s	-16
Endpoint [g/ha]					
LR_{50}	> 5400				

1) Application rate in 200 L water/ha
2) Mortality: dead and missing mites after 7 days of exposure to BAS 516 00 F on glass surface.
3) Corrected mortality according to Abbott.
4) Reproduction: mean cumulative number of offspring per female.
5) Negative values indicate an increase compared to the control.
n.s. = not statistically significant when compared to the control (Dunnett's test, $\alpha = 0.05$).

The reference item produced 89% mortality of exposed mites after 7 days.

III. CONCLUSION

The LR_{50} obtained under worst-case laboratory conditions on *Typhlodromus pyri* was determined to be > 5400 g/ha BAS 516 00 F in 200 L water/ha.

Report:	CP 10.3.2.1/3 Ufer A., 2001a Effect of BAS 516 00 F on the green lacewing Chrysoperla carnea (Neuroptera: Chrysopidae) in a laboratory trial 2001/1001860
Guidelines:	Hassan S.A. Standard methods to test the side-effects of pesticides on natural enemies of insects and mites. Bull. OEPP 15 pp. 214-255 (1985), Vogt H. et al. (Draft version 02/2000) Laboratory method to test effects of plant protection products on larvae of Chrysoperla carnea (Neuroptera: Chrysopidae)
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In a worst-case laboratory study, larvae of *Chrysoperla carnea* (green lacewing) were exposed to dried residues of BAS 516 00 F on glass plates. Test organisms were exposed until pupae were transferred to preserving jars for development of adults. Mortality checks were carried out regularly until hatching of adult lacewings. In addition, for the control and the test item treatment, the reproduction, i.e. egg deposition and hatching rate, was determined over a 7 days period (2 assessments, 24 hours period each).

24 out of 50 juveniles (48%) died in the 3600 g/ha BAS 516 00 F treatment, compared to a mortality of 18% in the control. This resulted in a corrected mortality of 36.6%. A significant difference in mortality compared to the control was calculated for the test item group. In the 3600 g/ha BAS 516 00 F treatment, 37.4 eggs/female and day were produced and a hatching rate of 84.5% was observed. Slightly less eggs (i.e. 32.7 eggs/female and day) were produced in the water control, where a hatching rate of 93.2% was observed. As all values exceeded the mean number of 15 eggs/female, no treatment related effects on reproduction did occur. No effects on the hatching rate of the F1-generation could be observed, as all hatching rates were well above a mean value of 70%.

Under worst-case laboratory conditions, the LR_{50} for the foliage-dwelling predator *Chrysoperla carnea* can be estimated to be LR_{50} > 3600 g/ha BAS 516 00 F in 200 L water/ha. BAS 516 00 F caused no unacceptable effects on reproduction at an application rate of 3600 g/ha BAS 516 00 F in 200 L water/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).

Test species: *Chrysoperla carnea* (green lacewing), larvae (2-3 days old); source: BASF Agricultural Centre, Limburgerhof, Germany.

B. STUDY DESIGN

Test design: Exposure of the larvae was reached via air-dried residues on treated glass plates. Three treatments (test item, water control, reference item) were set up; each treatment including 50 individuals (= replicates). Test organisms were exposed until pupae were transferred to preserving jars for development of adults. Mortality checks were carried out regularly until hatching of adult lacewings. In addition, for the control and the test item treatment, the reproduction, i.e. egg deposition and hatching rate, was determined over a 7 days period (2 assessments, 24 hours period each).

Endpoints: Pre-imaginal mortality, number of produced eggs/female/day and hatching rate.

Reference item: BAS 152 11 I (dimethoate, 400 g/L).

Test rates: 3600 g/ha BAS 516 00 F. The reference item was applied at a rate of 40 mL/ha. All substances were applied in 200 L water/ha. The substances were sprayed via laboratory spray applicator on glass plates and air dried afterwards.

Test conditions: Temperature: 23.3°C - 26.6°C; relative humidity: 56.0% - 94.2%; photoperiod: 16 h light : 8 h dark; light intensity: larvae: 2100 lux - 4500 lux, pupae: 2100 lux – 6600 lux; food: larvae: fresh *Sitotroga cerealella* eggs, adults: artificial diet.

Statistics: Descriptive statistics; Fisher's Exact test for mortality($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

24 out of 50 juveniles (48%) died during their development to adults in the 3600 g/ha BAS 516 00 F treatment, compared to a mortality of 18% in the control. This resulted in a corrected mortality of 36.6%. A significant difference in mortality compared to the control was calculated for the test item group (Fisher's Exact test; $\alpha = 0.05$).
In the 3600 g/ha BAS 516 00 F treatment, 37.4 eggs/female and day were produced and a hatching rate of 84.5% was observed. Slightly less eggs (i.e. 32.7 eggs/female and day) were produced in the water control, where a hatching rate of 93.2% was observed. As all values exceeded the mean number of 15 eggs/female, no treatment related effects on reproduction did occur. No effects on the hatching rate of the F1-generation could be observed, as all hatching rates were well above a mean value of 70% (see Table 10.3.2.1-3).

Table 10.3.2.1-3: Effects on green lacewing (*Chrysoperla carnea*) exposed to BAS 516 00 F in a laboratory trial

Treatment	Rate[1)] [g/ha]	Mortality[2)] [%]	Corrected mortality[3)] [%]	Reproduction [eggs/female/day]	Hatching rate [%]
Control	--	18	--	32.7	93.2
BAS 516 00 F	3600	48 *	36.6	37.4	84.5
Endpoint [g/ha]					
LR_{50}	> 3600				

1) Application rate in 200 L deionized water/ha.
2) Mortality: percentage of individuals, which did not reach maturity.
3) Corrected mortality according to Schneider-Orelli (1947).
* Statistically significant differences compared to the control (Fisher`s Exact test, $\alpha = 0.05$).

The reference item BAS 152 11 I produced 72% mortality of exposed lacewings. This results in a corrected mortality of 65.9%.

III. CONCLUSION

Under worst-case laboratory conditions, the LR_{50} for the foliage-dwelling predator *Chrysoperla carnea* can be estimated to be LR_{50} > 3600 g/ha BAS 516 00 F in 200 L water/ha. BAS 516 00 F caused no unacceptable effects on reproduction at an application rate of 3600 g/ha BAS 516 00 F in 200 L water/ha.

Report:	CP 10.3.2.1/4 Schuld M., 2001a BAS 516 00 F: Toxicity to the aphid parasitoid, Aphidius rhopalosiphi (Hymenoptera, Braconidae) DESTEFANI-PEREZ in the laboratory 2001/1001864
Guidelines:	Polgar L. (1988) Guideline for testing the effect of pesticides on Aphidius rhopalosiphi Hal. Hym. Aphidiidae. IOBC/WPRS Bulletin XI/4. Meeting Working Group Pesticides and Beneficial Organisms pp. 29-34, Mead-Briggs M. (1992) A laboratory method for evaluating the side-effects of pesticides on the cereal aphid parasitoid Aphidius rhopalosiphi (Destefani-Perez). Aspects of Applied Biology 31 pp. 179-189, Mead-Briggs M. (2000) Draft guideline of the ring testing group
GLP:	yes (certified by Ministerium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Executive Summary

In a worst-case laboratory study, adults of *Aphidius rhopalosiphi* (Hymenoptera: Braconidae) were exposed to dried residues of BAS 516 00 F on glass plates. Assessment of mortality was done approximately 30 min, 2, 24 and 48 hours after test initiation. For the reproduction assessment, 15 females from the control and from any treatment group displaying less than 50% corrected mortality (at maximum 3 rates) were individually confined over pots of untreated, aphid-infested barley plants for 24 h and then removed. The number of parasitized aphid mummies was recorded after 10 days.

The corrected mortality in the different treatment groups ranged between -5.57 and 7.62%. Therefore, the LR_{50} was determined to be > 5400 g/ha. Reproduction of *A. rhopalosiphi* was assessed in the 3 highest test item rates and in the control group. The mean number of mummies was 14.93 in the group treated with 1800 g/ha, 13.07 in the group treated with 3600 g/ha and 10.67 in the group treated with 5400 g/ha, compared to 20.67 in the control group, resulting in effects of 27.8, 36.8 and 48.4%, respectively.

The LR_{50} obtained under worst-case laboratory conditions on the parasitic wasp *Aphidius rhopalosiphi* was determined to be > 5400 g/ha BAS 516 00 F in 200 L water/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).

Test species: *Aphidius rhopalosiphi* (parasitoid), adults less than two days old; source: PK Nützlingszuchten, Welzheim, Germany.

B. STUDY DESIGN

Test design: Exposure of the parasitoids was reached via air-dried residues on treated glass plates. Initial evaluation of the test item was done in a range finding test. Based on these results, a main test was designed. Seven treatments (five rates of the test item, water control, reference item) were set up, with 4 replicates per treatment and each replicate containing 10 wasps. Assessment of mortality was done approximately 30 min, 2, 24 and 48 hours after test initiation. For the reproduction assessment, 15 females from the control and from any treatment group displaying less than 50% corrected mortality (at maximum 3 rates) were individually confined over pots of untreated, aphid-infested barley plants for 24 h and then removed. The number of parasitized aphid mummies was recorded after 10 days. Host: cereal aphids (*Rhopalosiphum padi*).

Endpoints: LR_{50} (50% mortality of wasps after exposure over 48 h), additionally reproduction capacity.

Reference item: BAS 152 11 I (dimethoate, 400 g/L).

Test rates:

Treatment	BAS 516 00 F [g/ha]
1	450
2	900
3	1800
4	3600
5	5400

The reference item was applied at an application rate of 0.85 mL/ha. All substances were applied in 200 L water/ha. The substances were sprayed onto glass plates via laboratory spraying equipment and air dried afterwards.

Test conditions: Exposure: temperature: 20.5°C – 23.5°C, relative humidity: 60% - 77%; continuous light; light intensity: approximately 1400 lux.

Reproduction: temperature: 19.0°C - 22.0°C, relative humidity: 61% - 70.5%; photoperiod: 16 hours light : 8 hours dark; light intensity: 2000 lux - 6000 lux.

Statistics: Descriptive statistics; ANOVA followed by Dunnett's test for mortality; Kruskal-Wallis Test followed by Dunn Test for reproduction ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

The LR_{50}-value was determined to be > 5400 g BAS 516 00 F/ha, the highest rate tested.
Reproduction of *Aphidius rhopalosiphi* was assessed in the 3 highest test item rates and in the control group. The mean number of mummies was 14.93 in the group treated with 1800 g/ha, 13.07 in the group treated with 3600 g/ha and 10.67 in the group treated with 5400 g/ha, compared to 20.67 in the control group, resulting in effects of 27.8, 36.8 and 48.4%, respectively (see Table 10.3.2.1-4).

Table 10.3.2.1-4: Effects on parasitoids (*Aphidius rhopalosiphi)* exposed to BAS 516 00 F in a laboratory trial

Treatment	Rate[1)] [g/ha]	Mortality[2)] [%]	Corrected mortality[3)] [%]	Reproduction[4)] [mummies/female]	Effects on reproduction [%]
Control	--	5.28	--	20.67	--
BAS 516 00 F	450	5.00	-0.30	n. a.	n. a.
BAS 516 00 F	900	0.00	-5.57	n. a.	n. a.

BAS 516 00 F	3600	7.50	2.34	13.07	36.8
BAS 516 00 F	5400	12.50	7.62	10.67 *	48.4
Endpoint [g/ha]					
LR_{50}	> 5400				

1) Application rate in 200 L water/ha.
2) Mortality: after 48 hours of exposure to BAS 516 00 F.
3) Corrected mortality according to Schneider-Orelli (1947).
4) Reproduction: mean number of parasitized aphids/female.
* Statistically significant differences compared to the control (Dunnett's test for mortality; Kruskal-Wallis Test for reproduction, $\alpha = 0.05$).

The reference item caused 100% mortality of exposed wasps after 48 hours.

III. CONCLUSION

The LR_{50} obtained under worst-case laboratory conditions on the parasitic wasp *Aphidius rhopalosiphi* was determined to be > 5400 g/ha BAS 516 00 F in 200 L water/ha.

Report:	CP 10.3.2.1/5 Hermann P., 2001a BAS 516 00 F: Toxicity to the staphylinid beetle, Aleochara bilineata GYLL. (Coleoptera, Staphylinidae) in the laboratory 2001/1001863
Guidelines:	Moreth L. Naton E. (1992) Richtlinie zur Pruefung der Nebenwirkung von Pflanzenschutzmitteln auf Aleochara bilineata Gyll. (Col. - Staphylinidae) (erweiterter Laborversuch) IOBC/WPRS Bulletin 1992
GLP:	yes (certified by Ministerium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Executive Summary

In a worst-case laboratory study, adults of *Aleochara bilineata* (rove beetle) were exposed to quartz sand treated at a rate of 3600 g BAS 516 00 F/ha. Assessment of reproduction was carried out by counting the number of beetles emerged from the parasitized fly pupae starting approximately 4 weeks after application.

The mean number of emerged beetles in the test item treatment was 741. In the water control a mean of 808 beetles emerged. This difference proved to be statistically not significant

BAS 516 00 F caused no effects on the reproduction of the rove beetle *Aleochara bilineata* if applied at a rate of 3600 g/ha BAS 516 00 F in 400 L water /ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).

Test species: *Aleochara bilineata* (rove beetle), adults 2-5 days old; source: De groene Vlieg; NL- 3244 LG - Nieuwe Tonge.

B. STUDY DESIGN

Test design: Exposure of the beetles was reached via treated quartz sand; beetles were introduced into the test units immediately after treatment. Three treatments (test item, water control, and reference item) were set up with 4 replicates per treatment and 10 pairs (male + female) of beetles per replicate. Assessment of reproduction was carried out by counting the number of beetles emerged from the parasitized fly pupae starting approximately 4 weeks after application.

Endpoints: Reproduction of *Aleochara bilineata*.

Reference item: Dursban 480 (chlorpyrifos, 480 g/L).

Test rates: Control, 3600 g/ha BAS 516 00 F. The reference item was applied at a rate of 1.0 L/ha. The substances were applied in 400 L water/ha. The substances were sprayed via laboratory spray applicator on the sand surface.

Test conditions: Temperature: exposure: 18°C - 22°C, emergence of adults: 17.5°C - 22°C; photoperiod: 16 h light : 8 h dark; host organism: onion fly pupae (*Delia antiqua*).

Statistics: Descriptive statistics; ANOVA followed by Dunnett's test for mortality and reproduction ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

The mean number of emerged beetles in the test item treatment was 741. In the water control in the mean 808 beetles emerged. This difference proved to be statistically not significant (Dunnett's test, $\alpha = 0.05$) (see Table 10.3.2.1-5).

Table 10.3.2.1-5: Effects on reproduction efficiency of rove beetles (*Aleochara bilineata*) exposed to BAS 516 00 F in a laboratory trial

Treatment	Rate[1)] [g/ha]	Reproduction [mean number of emerged beetles ± SD]	Effect on reproduction [%]
Control	--	808 ± 77.5	--
BAS 516 00 F	3600	741 ± 37.5	8.3
	Endpoint [g/ha]		
Effects on reproduction	> 3600		

1) Application rate in 400 L water/ha.

The reference item produced a reduction of reproduction of 99.9% compared to the control.

III. CONCLUSION

Under worst-case laboratory conditions BAS 516 00 F caused no unacceptable effects on the reproduction of the ground dwelling predator *Aleochara bilineata* at a rate of 3600 g/ha BAS 516 00 F in 400 L water /ha.

Report:	CP 10.3.2.1/6 Schmitzer S., 2001a Effects of BAS 516 00 F on the wolf spider Pardosa spec. in the laboratory 2001/1005964
Guidelines:	BBA draft guideline 1994, Heimbach U. et al. (2000 Draft) Method for testing effects of plant protection agents on spiders of the genus Pardosa (Araneae Lycosidae) under laboratory conditions
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Landwirtschaft und Forsten, Wiesbaden)

Executive Summary

In a worst-case laboratory study spiders of the genus *Pardosa* (wolf spiders: *Pardosa amentata* 93%, *P. proximata* 3%) were exposed to direct application of BAS 516 00 F at 3600 g/ha on quartz sand. After 2 hours and on day 1, 2, 3, 4, 7, 8, 10, 11 and 14 the number of dead or damaged individuals was assessed. The food consumption was assessed on day 1, 2, 3, 4, 8 and 11.
BAS 516 00 F had no effect on survival and food consumption of *Pardosa sp.* No test item related behavioral abnormalities were observed.

Under worst-case laboratory conditions, no unacceptable effects on survival or feeding rate of *Pardosa* spp. occurred at an application rate of 3600 g/ha BAS 516 00 F in 400 L water/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).
Test species:	Spider of the genus *Pardosa* (wolf spiders: *Pardosa amentata* 93%, *P. proximata* 3%), source: outdoor collected near Münster, Westfalen, Germany.

B. STUDY DESIGN

Test design:	The spiders were exposed to direct application on inert quartz sand. Three treatments (test item, water treated control, reference item) were set up with 34 replicates per treatment with 17 replicates containing 1 adult male and 17 replicates containing 1 adult female. After 2 hours and on day 1, 2, 3, 4, 7, 8, 10, 11 and 14 the number of dead or damaged individuals was assessed. The food consumption was assessed on day 1, 2, 3, 4, 8 and 11.
Endpoints:	Mortality, behavior and feeding rate of exposed spiders.
Reference item:	Perfekthion EC (dimethoate, 400 g/L).
Test rates:	Control, 3600 g/ha BAS 516 00 F. The reference item was applied equivalent to 600 g a.s./ha. The substances were applied in 400 L water/ha. The substances were sprayed on the substrate and the spiders via laboratory spray applicator.
Test conditions:	Temperature: 20°C - 22°C; relative humidity: 60% - 90%; photoperiod: 16 h light : 8 h dark, light intensity: 686 lux - 1326 lux; food: *Drosophila spec.*
Statistics:	Descriptive statistics; Fisher's Exact test for mortality, ANOVA followed by Dunnett's test for food consumption ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

BAS 516 00 F had no effect on survival and food consumption of *Pardosa sp.* No test item related behavioral abnormalities were observed (see Table 10.3.2.1-6).

Table 10.3.2.1-6: Effects on wolf spiders (*Pardosa spec.*) exposed to BAS 516 00 F in a laboratory trial

Treatment	Rate [1] [g/ha]	Mortality [2] [%]	Corrected mortality[3] [%]	Flies consumed [per spider/day]	Effect on feeding capacity [%]
Control	--	0.0	--	3.4	--
BAS 516 00 F	3600	2.9 n s	2.9	3.3 n s	3
	Endpoint [g/ha]				
LR_{50}	> 3600				
Effects on feeding rate	> 3600				

1) Application rate in 400 L water/ha.
2) Mortality: mean of 17 replicates per gender and treatment, i.e. 34 spiders/treatment.
3) Corrected according to Abbott (1925).
n.s. = No statistically significant differences compared to the control (Fisher's Exact test for mortality, Dunnett's test for food consumption, ($\alpha = 0.05$).

The reference item caused a corrected mortality of 79.4%.

III. CONCLUSION

Under worst-case laboratory conditions, no unacceptable effects on survival or feeding rate of *Pardosa* spp. occurred at an application rate of 3600 g/ha BAS 516 00 F in 400 L water/ha.

CP 10.3.2.2 Extended laboratory testing, aged residue studies with non-target arthropods

Report:	CP 10.3.2.2/1 Ufer A., 2001b Effect of BAS 516 00 F on the green lacewing Chrysoperla carnea (Neuroptera: Chrysopidae) in an extended laboratory trial 2001/1001874
Guidelines:	Hassan S.A. Standard methods to test the side-effects of pesticides on natural enemies of insects and mites. Bull. OEPP 15 pp. 214-255 (1985), Vogt H. et al. (Draft version 02/2000) Laboratory method to test effects of plant protection products on larvae of Chrysoperla carnea (Neuroptera: Chrysopidae)
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In an extended laboratory study, larvae of *Chrysoperla carnea* (green lacewing) were exposed to dried residues of BAS 516 00 F on detached bean leaves. The mortality of exposed individuals was assessed regularly until hatching of adult lacewings. For the reproduction assessment in the control and the test item treatment groups the reproduction performance, i.e. egg deposition and hatching rate, was determined over a 7 days period (2 assessments, 24 hours period each).

9 out of 50 juveniles (18%) died in the 2 x 360 g/ha BAS 516 00 F treatment and 14 out of 50 juveniles (28%) died in the 2 x 1800 g/ha BAS 516 00 F treatment. In the control, 6 out of 50 individuals (12%) did not reach maturity. This results in a corrected mortality of 6.8% in the 2 x 360 g/ha treatment and 18.2% in the 2 x 1800 g/ha treatment. The difference between the control and the 2 x 1800 g/ha treatment was statistically significant.
39.8 eggs/female and day were produced in the 2 x 360 g/ha treatment and 36.0 eggs/female and day were counted in the 2 x 1800 g/ha BAS 516 00 F treatment. 41.1 eggs/female and day were produced in the water treated control. As all treatments exceeded the mean number of 15 eggs/female/day, no treatment related effects on reproduction could be shown. No effects on the hatching rate of the F1-generation could be observed, as all hatching rates are well above a mean value of 70%.

Under extended laboratory conditions, the LR_{50} of the foliage-dwelling predator *Chrysoperla carnea* was > 2 x 1800 g/ha BAS 516 00 F. No unacceptable effects on reproduction were observed up to an application rate of 2 x 1800 g/ha BAS 516 00 F in 400 L water/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).

Test species: *Chrysoperla carnea* (green lacewing), larvae (2-3 days old); source: BASF Agricultural Centre, Limburgerhof, Germany.

B. STUDY DESIGN

Test design: Exposure of the larvae was reached via air-dried residues on detached bean leaves (*Phaseolus vulgaris*, variety: St. Andreas). Four treatments were set up (two rates of the test item, water control, reference item) with 50 individuals (replicates)/treatment. Each test item treatment was applied two times with a spray interval of 5 days; for the second application the newly grown leaves were cut. After the test substances had dried, leaves were detached and placed in a plexiglass tray on a wet layer of cotton. The mortality of exposed individuals was assessed regularly until hatching of adult lacewings. For the reproduction assessment in the control and the test item treatment groups the reproduction performance, i.e. egg deposition and hatching rate, was determined over a 7 days period (2 assessments, 24 hours period each).

Endpoints: Preimaginal mortality, additionally reproduction capacity.

Reference item: BAS 152 11 I (dimethoate, 400 g/L).

Test rates: Control, 2 x 360 g/ha BAS 516 00 F and 2 x 1800 g/ha BAS 516 00 F. The reference item was applied corresponding to 1 x 0.1 L/ha. All substances were applied in 400 L water/ha. The substances were sprayed on bean plants via laboratory spray track and air dried afterwards.

Test conditions: Temperature: 23.1°C - 26.7°C; relative humidity: 48.7% - 85.7%; photoperiod: 16 h light : 8 h dark; light intensity: larvae: 1800 lux - 4200 lux, pupae 3100 lux - 6300 lux; food: larvae: fresh *Sitotroga cerealella* eggs, adults: artificial diet.

Statistics: Descriptive statistics, Fisher's Exact test for mortality ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

9 out of 50 juveniles (18%) died during their development to adults in the 2 x 360 g/ha BAS 516 00 F treatment and 14 out of 50 juveniles (28%) died in the 2 x 1800 g/ha BAS 516 00 F treatment. In the control, 6 out of 50 individuals (12%) did not reach maturity. This results in a corrected mortality of 6.8% in the 2 x 360 g/ha treatment and 18.2% in the 2 x 1800 g/ha treatment. The difference between the control and the 2 x 1800 g/ha treatment was statistically significant (Fischer's Exact test; $\alpha = 0.05$).
39.8 eggs/female and day were produced in the 2 x 360 g/ha treatment and 36.0 eggs/female and day were counted in the 2 x 1800 g/ha BAS 516 00 F treatment. 41.1 eggs/female and day were produced in the water control. As all treatments exceeded the mean number of 15 eggs/female/day, no treatment related effects on reproduction could be shown. No effects on the hatching rate of the F1-generation could be observed, as all hatching rates are well above a mean value of 70% (see Table 10.3.2.2-1).

Table 10.3.2.2-1: Effects on green lacewing (*Chrysoperla carnea*), exposed to BAS 516 00 F in an extended laboratory trial

Treatment	Rate[1)] [g/ha]	Mortality[2)] [%]	Corrected mortality[3)] [%]	Reproduction [eggs/female/day]	Hatching rate [%]
Control	--	12	--	41.1	87.8
BAS 516 00 F	2 x 360	18	6.8	39.8	82.6
BAS 516 00 F	2 x 1800	28 *	18.2	36.0	87.9
	Endpoint [g/ha]				
LR_{50}	> 2 x 1800				
Effects on reproduction	> 2 x 1800				

1) Application rate in 400 L water/ha.
2) Mortality: after 7 days of exposure to BAS 516 00 F on bean leaves.
3) Corrected mortality according to Schneider Orelli (1947).
* Statistically significant difference compared to the control (Fischer's Exact test, $\alpha = 0.05$).

The reference item BAS 152 11 I produced a mortality of 80% of exposed green lacewings. This resulted in a corrected mortality of 77.3%.

III. CONCLUSION

Under extended laboratory conditions, the LR_{50} of the foliage-dwelling predator *Chrysoperla carnea* was > 2 x 1800 g/ha BAS 516 00 F. No unacceptable effects on reproduction were observed up to an application rate of 2 x 1800 g/ha BAS 516 00 F in 400 L water/ha.

CP 10.3.2.3 Semi-field studies with non-target arthropods

As BAS 516 07 F does not pose an unacceptable risk to other non-target arthropods, further tests are not necessary.

CP 10.3.2.4 Field studies with non-target arthropods

Report:	CP 10.3.2.4/1 Muether J., 2001a A field study to evaluate the effects of BAS 516 00 F against predatory mites in damson plum 2001/1000905
Guidelines:	BBA VI 23-2.3.4, Bluemel et al. (2000)
GLP:	yes (certified by Ministerium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Executive Summary

A field trial in damson plum was carried out to determine the effects of the fungicide BAS 516 00 F on the population development of predatory mites (Acari: Phytoseiidae). The trial included four treatment groups, two test item treatments with BAS 516 00 F, a water treated control and a reference item treatment. BAS 516 00 F was applied 5 times between mid of April and end of June at a rate of 750 g/ha (treatment T1) in 1500 L water/ha and at a rate of 150 g/ha (treatment T2) in 1500 L water/ha, both calculated for a crown height of 3 m. Three applications were done early in the season during flowering with an spray interval of 6 to 8 days, two applications were done later in the season at BBCH 77 and BBCH 78. The reference item (Antracol WG) was applied 7 times in regularly intervals over the whole season. The population development of predatory mites was assessed in all treatment groups by determining the number of mites on samples consisting of short shoots with flower buds and flowers (early season) and Ieaf samples (Iate season), using the washing method (BOLLER, 1984).

The mean number of mites per short shoots and flower buds was between 3.0 and 15.4 in the control treatment, between 4.2 and 9.8 in the test item treatment (T1), between 2.4 and 14.2 in the test item treatment (T2) and between 3.0 and 12.0 in the reference item treatment. The mean number of mites per leaf was between 0.37 and 3.02 in the control treatment, between 0.31 and 3.66 in the test item treatment (T1), between 0.28 and 2.11 in the test item treatment (T2) and between 0.24 and 0.80 in the reference item treatment. The effect of the test item BAS 516 00 F on the predatory mite populations ranged between -87 and 20% according to ABBOTT (1925) in treatment T1 and ranged between -8 and 32% in the treatment T2. An effect >50% in the reference item treatment was achieved after the 3rd application and the toxic reference produced a maximum effect on mite density of 86%.

BAS 516 00 F caused no unacceptable effects on population development of predatory mites under field conditions in stone fruit (damson plum) if used as tested, with 5 applications and up to an application rate of 750 g/ha in 1500 L water/ha, calculated for a crown height of 3 m.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).

Test species: Predatory mites (52% *Typhlodromus pyri;* 45% *Euseius stipulatus)*, naturally established field population, all stages.

B. STUDY DESIGN

Test plots: The field study was carried out in Freinsheim, south-west Germany. The test site was located in a region typical for stone fruit production. The agricultural practices and stone fruit varieties (damson plum, variety: St. Hubertus) were in accordance with the local farming practices. Height of the trees: 3 m; 500 trees per ha; age of the trees: 11 years.

Test design: Damson plum harboring populations of predatory mites were exposed to spray treatment of two rates of the test item, water for a control, group and a reference item with 5 replicates per treatment and 3 trees per replicate (unsampled margin of 2 meters at both ends of each plot). Test plots were treated with 5 applications, starting with 3 applications in the early season during flowering (target: blossom blight) using a spray interval of 6 - 8 days and two applications in the later season at BBCH 77 - 78 (target: brown rot). The reference item was applied 7 times in regular intervals over the whole season according to the normal use of this product. Applications were carried out using a motorized knapsack atomizer (model SOLO type 423). Assessments: from every plot samples were taken consisting of 75 short shoots with flower buds and flowers (early season) and of at least 40 leaves (late season) to determine mite densities using the washing technique at 1 day before treatment, 6 days after the 1st application, 8 days after the 3rd application, 7 days before the 4th application and 9 days as well as 1 month after the last (5th) application. Because of the very low mite number at the sampling during the period of flowering (75 short shoots with flower buds and flowers), these numbers have not been used for the calculation of effect values.

Endpoints: Population development compared to the control

Reference item: Antracol WG (propineb, 705 g/kg).

Test rates: Control, 5 x 750 g/ha BAS 516 00 F and 5 x 150 g/ha BAS 516 00 F in 1500 L water/ha, both calculated for a crown height of 3 m (500 L water/ha per m crown height). The reference item was applied corresponding to 2250 g/ha in 1500 L water/ha, also calculated for a crown height of 3 m.

Statistics: Descriptive statistics, ANOVA followed by Dunnett's test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

The predatory mite numbers reached a level of 3 mites per leaf in the control plots, demonstrating the suitability of the test site. The predatory mite populations in the plots treated with BAS 516 00 F applied at 750 g/ha rate did not show a statistically significant reduction compared to the control during the whole study. The predatory mite numbers in the plots treated with BAS 516 00 F at the 150 g/ha rate showed a significant reduction of 32%. The statistically significant effect of 32% in the 150 g/ha treatment is considered to be due to natural variability, because this trend was not confirmed by the high rate of 750 g/ha. Besides of that the statistically significant difference of -87% in the 750 g/ha treatment gives additional indication for the variability in natural populations of predatory mites, if only single assessments are considered. Thus, no unacceptable effect on predatory mites was observed in both test item treatments (see Table 10.3.2.4-1 and Table 10.3.2.4-2).

Table 10.3.2.4-1: Mean number of predatory mites exposed to BAS 516 00 F in a field trial

Assessment	Date	Mean number of mites per 75 short shoots with 5-6 flower buds each [1)]			
		Control	BAS 516 00 F 750 g/ha	BAS 516 00 F 150 g/ha	Antracol WG 2250 g/ha / no. of applications performed
Pre-assessment	03.04.00	3.00	4.20	2.40	3.00
6 days after 1st application	10.04.00	15.40	9.80	14.20	12.00 / 1
		Mean number of mites per leaf [1, 2)]			
8 days after 3rd application	26.04.00	0.37	0.31	0.28	0.24 / 3
7 days before 4th application (50 days after 3rd application)	07.06.00	1.60	1.28	1.08	0.60 * / 5
9 days after 5th application	06.07.00	3.02	2.46	2.06*	0.42 * / 7
29 days after 5th application	26.07.00	1.96	3.66 *	2.11	0.80 / 7

1) Including all mobile stages
2) Assessing at least 40 leaves per plot
* Statistically significant different compared to the control (Dunnett's test, $\alpha = 0.05$)

Table 10.3.2.4-2: Effects of BAS 516 00 F and the reference item on populations of predatory mites in a field trial

Assessment	Date	Effects [%] [1]		
		BAS 516 00 F [2] 750 g/ha	BAS 516 00 F [2] 150 g/ha	Antracol WG 2250 g/ha / no. of applications performed
8 days after 3rd application	26.04.00	15	24	34 / 3
7 days before 4th application (50 days after 3rd application)	07.06.00	20	32	62 * / 5
9 days after 5th application	06.07.00	19	32 *	86 * / 7
29 days after 5th application	26.07.00	-87 *	-8	59 / 7

[1] Effects = % reduction compared to the control; calculated according to Abbott (1925).
[2] - = increase compared to the control.
* Statistically significant different compared to the control (Dunnett's test, $\alpha = 0.05$)

For the reference item Antracol WG a maximum reduction of 86% compared to the control at the assessment 9 days after the last application (7 applications of Antracol WG) was observed.

III. CONCLUSION

BAS 516 00 F caused no unacceptable effects on population development of predatory mites under field conditions in stone fruit (damson plum) if used as tested, with 5 applications and up to an application rate of 750 g/ha in 1500 L water/ha, calculated for a crown height of 3 m.

Report:	CP 10.3.2.4/2 Gossmann A., 2001a Effects of BAS 516 00 F on predatory mites Typhlodromus pyri SCHEUTEN (Acari, Phytoseiidae) in apple orchards (field experiments) 2001/1001866
Guidelines:	BBA VI 23-2.3.4, Bluemel et al. (1999) Current improvements by the ring-test group
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Landwirtschaft und Forsten, Wiesbaden)

Executive Summary

A field trial in an apple orchard was carried out to determine the effects of the fungicide BAS 516 00 F on the population development of predatory mites (Acari: Phytoseiidae). The trial included four treatment groups, two test item treatments with BAS 516 00 F, a water treated control and a reference item treatment. BAS 516 00 F was applied 5 times between end of April and begin of July at a rate of 750 g/ha (treatment T1) in 1500 L water/ha and at a rate of 150 g/ha (treatment T2) in 1500 L water/ha, both calculated for a crown height of 3 m. Three applications were done early in the season during flowering with an spray interval of 6 to 8 days, two applications were done later in the season at BBCH 75. The reference item (Antracol WG) was applied 5 times at the same dates. The population development of predatory mites was assessed in all treatment groups by determining the number of mites on Ieaf samples, using the washing method (BOLLER, 1984).

The mean number of mites per leaf was between 0.23 and 1.35 in the control treatment, between 0.21 and 1.39 in the test item treatment (T1), between 0.23 and 1.17 in the test item treatment (T2) and between 0.10 and 0.82 in the reference item treatment. The effect of the test item BAS 516 00 F on the predatory mite populations ranged between -28.5 and 47.2% according to ABBOTT (1925) in treatment T1 and ranged between -8 and 39.9% in the treatment T2. An effect >50% in the reference item treatment was achieved after the 3rd application and the toxic reference produced a maximum effect on mite density of 88.4%.

BAS 516 00 F caused no unacceptable effects on population development of predatory mites under field conditions in apple trees if used as tested, with 5 applications and up to an application rate of 750 g/ha in 1500 L water/ha calculated for a crown height of 3 m.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).

Test species: Predatory mites (98.6% *Typhlodromus pyri)*, naturally established field population, all stages.

B. STUDY DESIGN

Test plots: The field study was carried out in Modautal, south Hessen Germany. The test site was a commercially managed orchard (apple, variety: Jona Gold) with a size of 5 ha. Height of the trees: 2.2 m; 1200 trees per ha; age of the trees: 23 years.

Test design: Apple orchards harboring populations of predatory mites were exposed to spray treatment of two rates of the test item, water for a control group and a reference item; each treatment consisted of 5 replicates with 8 apple trees / replicate; samples were taken from 4 trees in the middle of each plot. The test item was applied 5 times: early in the season with a spray interval of 6 - 8 days (target: blossom blight) and a set of 2 applications later in the season with a 2 weeks interval (target: brown rot). Applications were carried out at approximately BBCH stage 62-63 (start of flowering), 65-66 (full flowering), 67-68 (end of flowering), 6 weeks after 3rd application (BBCH 75) and 2 weeks after 4th application (BBCH 75). Applications were carried out using a back pack air blast sprayer (model Stihl SR 400 II). Assessments: from every plot samples of 100 leaves were taken to determine mite densities using the washing technique 1 day before treatment. Further samplings were performed 5 days after 1st application, 6 days after 3rd application, 2 days before the 4th application, 6 days after 5th application and 4 weeks after 5th application.

Endpoints: Population development compared to the control.

Reference item: Antracol WG (propineb, 705 g/kg).

Test rates: Control, 5 x 750 g/ha BAS 516 00 F and 5 x 150 g/ha BAS 516 00 F in 1500 L water/ha, both calculated for a crown height of 3 m (500 L water/ha per m crown height). The reference item was applied corresponding to 2250 g/ha in 1500 L water/ha, also calculated for a crown height of 3 m.

Statistics: Descriptive statistics, ANOVA followed by Dunnett's test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Very low numbers of mites were found in the early season, because population development just started. Values were far below 1 mite per leaf, therefore care has to be taken with the interpretation of the early assessments. Five days after the 1st application of BAS 516 00 F, no statistically significant effect in mite abundance was observed in either the low rate or the high rate tested in this experiment (Dunnett's test, two sided, $\alpha = 0.05$). Six days after 3rd application, a significant reduction (Dunnett's test, two sided, $\alpha = 0.05$) of mite abundance was observed in the higher rate. The effect on mite abundance was calculated to be 47.2%. Two days before the 4th application (39 days after 3rd application) the mite abundance in the high rate was fully recovered.
Four weeks after the 5th and the last application the mite abundance in both test item treatment groups was comparable to those in the control (see Table 10.3.2.4-3 and Table 10.3.2.4-4).

Table 10.3.2.4-3: Mean number of predatory mites exposed to BAS 516 00 F in a field trial

Assessment	Date	Mean number of mites per leaf [1, 2)]			
		Control	BAS 516 00 F 750 g/ha	BAS 516 00 F 150 g/ha	Antracol WG 2250 g/ha
Pre-assessment	24.04.00	0.23	0.21	0.23	0.25
5 days after 1st application	02.05.00	0.34	0.26	0.26	0.20
6 days after 3rd application	17.05.00	0.88	0.46 *	0.69	0.10 *
2 days before 4th application	19.06.00	1.05	1.18	0.73	0.56 *
6 days after 5th application	12.07.00	1.35	0.91	0.81	0.68
4 weeks after 5th application	03.08.00	1.08	1.39	1.17	0.82

1) Including all mobile stages, mean from 5 replicates.
2) Assessing about 100 leaves per sample.
* Statistically significant different compared to the control (Dunnett's test, $\alpha = 0.05$).

Table 10.3.2.4-4: Effects of BAS 516 00 F and the reference item on predatory mites in a field trial

Assessment	Date	Effects[1] [%]		
		BAS 516 00 F [2] 750 g/ha	BAS 516 00 F [2] 150 g/ha	Antracol WG 2250 g/ha
Pre-assessment	24.04.00	--	--	--
5 days after 1st application	02.05.00	25.3	22.9	41.2
6 days after 3rd application	17.05.00	47.2	21.2	88.4
2 days before 4th application	19.06.00	-12.5	30.4	46.4
6 days after 5th application	12.07.00	32.6	39.9	49.9
4 weeks after 5th application	03.08.00	-28.5	-8.0	23.9

1) Effects = % reduction compared to the control; calculated according to Abbott (1925)
2) - = increase compared to the control
* Statistically significant different compared to the control (Dunnett's test, $\alpha = 0.05$)

The reference item showed effects from more than 40% after the first application until 6 days after the 5th application. Six days after the 3rd application, the effect was by 88.4% and statistically significant. Two days before the 4th application the effect (46.4%) was also statistically significant. Four weeks after the 5th application no effect in the toxic standard group was observable any more.

III. CONCLUSION

BAS 516 00 F caused no unacceptable effects on population development of predatory mites under field conditions in apple trees if used as tested, with 5 applications and up to an application rate of 750 g/ha in 1500 L water/ha calculated for a crown height of 3 m.

Report:	CP 10.3.2.4/3 Nienstedt K.M., 2001a A field test to determine the effect of BAS 516 00 F on predatory mite populations (Acari: Phytoseiidae) on stone fruit trees (cherry, Prunus avium) 2001/1001870
Guidelines:	BBA VI 23-2.3.4, Bluemel et al. (2000)
GLP:	yes (certified by Eidgenoessisches Departement fuer Umwelt, Verkehr, Energie und Kommunikation, Bern, Schweiz)

Executive Summary

A field trial in stone fruit trees (cherry) was carried out to determine the effects of the fungicide BAS 516 00 F on the population development of predatory mites (Acari: Phytoseiidae). The trial included four treatment groups, two test item treatments with BAS 516 00 F, a water treated control and a reference item treatment. BAS 516 00 F was applied 5 times between Mid-April and end of June at a rate of 750 g/ha (treatment T1) in 1500 L water/ha and at a rate of 150 g/ha (treatment T2) in 1500 L water/ha, both calculated for a crown height of 3 m. Three applications were done early in the season during flowering with an spray interval of 6-7 days, two applications were done later in the season at BBCH 75 to BBCH 85 with an spray interval of 8 days. The reference item (Antracol WG) was applied 7 times in regularly intervals over the whole season. The population development of predatory mites was assessed in all treatment groups by determining the number of mites on vegetal material (buds and leaves), using the washing method (BOLLER, 1984).

The mean number of mites per leaf was between 0.01 and 0.54 in the control treatment, between 0.02 and 0.53 in the test item treatment (T1), between 0.02 and 0.63 in the test item treatment (T2) and between 0.0 and 0.01 in the reference item treatment. The effect of the test item BAS 516 00 F on the predatory mite (only calculated for dates on which mite density was higher than 0.1 mites/leaf in the control) populations ranged between 1.8 and 6.9% according to ABBOTT (1925) in treatment T1 and ranged between -18.0 and -6.4% in the treatment T2. The toxic reference produced a maximum effect on mite density of 99.6%.

BAS 516 00 F caused no unacceptable effects on population development of predatory mites under field conditions in stone fruit (cherry orchards) if used as tested, with 5 applications and up to an application rate of 750 g/ha in 1500 L water/ha calculated for a crown height of 3 m.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).

Test species: Predatory mites (100% *Euseius finlandicus)*, naturally established field population, all stages.

B. STUDY DESIGN

Test plots: The field study was carried out in Bischoffszell, Switzerland. The test site was a homogeneous cherry orchard (*Prunus avium*, variety: Oktavia). Height of the trees: 2.8 m; age of the trees: 3rd vegetative year after planting.

Test design: Stone fruit harboring populations of predatory mites were exposed to spray treatment of two rates of the test item, water for a control group and a reference item; 5 replicates / treatment and 8 trees / replicate. 2 trees left untreated between replicates. Test plots were treated with 5 applications, starting with 3 applications in the early season (BBCH 60-67) using a spray interval of 6 - 7 days (target: blossom blight) and two applications in the later season at BBCH 75 – 85 (target: brown rot) with an interval of 8 days. The reference item was applied 7 times in regular intervals over the whole season according to the normal use of this product. Applications were carried out using a back-pack sprayer (Birchmeier M125). Assessments: from every plot samples were taken consisting of about 100 short shoots with flower buds and flowers (early season) and of about 100 leaf samples (late season) to determine mite densities using the washing technique at 6 days before treatment, 5 days after the 1st application, 6 after the 3rd application, 30 days after the 3rd application (6 days before the 4th application) and 6 and 26 days after the last application. Because of the very low mite number at the sampling during the period of flowering (about 100 flower buds), these numbers have not been used for the calculation of effect values.

Endpoints: Population development compared to the control.

Reference item: Antracol WG (propineb, 705 g/kg).

Test rates: Control, 5 x 750 g /ha BAS 516 00 F and 5 x 150 g/ha BAS 516 00 F in 1500 L water/ha, both calculated for a crown height of 3 m (500 L water/ha per m crown height). The reference item was applied corresponding to 3000 g/ha in 1500 L water/ha (0.2%) also calculated for a crown height of 3 m.

Statistics: Descriptive statistics, Repeated Measurement ANOVA.

II. RESULTS AND DISCUSSION

Very low numbers of mites were found in the early season because population development just started. Values were far below 1 mite per leaf; therefore, care has to be taken with the interpretation of the early assessments. At the first sampling date (14.04.00), predatory mite density was 0.01 to 0.02 mites/bud in all treatments. The mite populations increased slowly during the next 2 sampling dates. Although remaining at levels of the same magnitude, which makes an interpretation of the data difficult. However, from the 4th sampling onwards, mite density was above 0.1 in the control and the test item treatments, increasing continuously during the remaining sampling period until a maximum level of 0.5 to 0.6 mites/leaf on the last sampling date (18.07.00). The mite population development was similar in the control and the test item treatments. No statistically significant differences were observed between the control and the test item treatments during the testing period (Repeated measurement ANOVA: α = 0.05).

Effects on mite population according to Abbott (1925) were calculated for the 2 last sampling dates, i.e. 6 and 26 days after the last test item application, since only on this dates the mite density was above 0.1 mites/leaf. For the 150 g/ha test item treatment, no effects on mite population were observed, since negative Abbott values were calculated for the 2 last sampling dates. For the 750 g/ha test item treatment the effects observed were 6.9% and 1.8%, 6 and 26 days after the last application, respectively (see Table 10.3.2.4-5 and Table 10.3.2.4-6).

Table 10.3.2.4-5: Mean number of predatory mites exposed to BAS 516 00 F in a field trial

Assessment	Date	Mean number of mites per flower bud or per leaf [1, 2)]			
		Control	BAS 516 00 F 750 g/ha	BAS 516 00 F 150 g/ha	Antracol WG 3000 g/ha / no. of applications performed
Pre-assessment	14.04.00	0.01	0.02	0.02	0.01
5 days after 1st application	25.04.00	0.04	0.04	0.04	0.01 * / 1
6 days after 3rd application	09.05.00	0.05	0.03	0.04	0 * / 3
6 days before 4th application (30 days after 3rd application)	08.06.00	0.12	0.10	0.16	0 * / 5
6 days after 5th application	28.06.00	0.43	0.40	0.46	0.004 * / 7
26 days after 5th application	18.07.00	0.54	0.53	0.63	0.002 * / 7

1) Including all mobile stages.
2) Assessing at least 100 flower buds or leaves per plot.
* Statistically significant different compared to the control (Repeated Measurement ANOVA, $\alpha = 0.05$).

Table 10.3.2.4-6: Effects of BAS 516 00 F and the reference item on predatory mites in a field trial

Assessment	Date	Effects [1) [%]]		
		BAS 516 00 F 750 g/ha	BAS 516 00 F 150 g/ha [2)]	Antracol WG 3000 g/ha
6 days after 5th application	28.06.00	6.9	-6.4	99.1 [3)]
26 days after 5th application	18.07.00	1.8	-18.0	99.6 [3)]

1) The effect on mite population according to Abbott (1925) was only calculated for dates in which mite density was higher than 0.1 mites / leaf in the control.
2) - = increase compared to the control
3) 7 applications performed.

For the reference item Antracol WG a maximum reduction of 99.6% compared to the control at the assessment 26 days after the last application (7 applications of Antracol WG) was observed.

III. CONCLUSION

BAS 516 00 F caused no unacceptable effects on population development of predatory mites under field conditions in stone fruit (cherry orchards) if used as tested, with 5 applications and up to an application rate of 750 g/ha in 1500 L water/ha calculated for a crown height of 3 m.

CP 10.3.2.5 Other routes of exposure for non-target arthropods

As BAS 516 07 F does not pose an unacceptable risk to other non-target arthropods, further tests are not necessary.

CP 10.4 Effects on non-target soil meso- and macrofauna

The new representative formulation BAS 516 07 F was not evaluated within a previous Annex I inclusion process. It is a water dispersible granule (WG) containing 67 g/kg pyraclostrobin and 267 g/kg boscalid.

Endpoints from new studies with the active substance, its metabolites and the new representative formulation BAS 516 07 F are used for the risk assessment on earthworms and other non-target soil meso- and macrofauna (see Table 10.4-1).

Table 10.4-1: Ecotoxicological endpoints for earthworms and other non-target soil meso- and macrofauna

Test substance	Test species	EU agreed endpoints	Endpoints used in risk assessment
Acute			
Pyraclostrobin	*Eisenia fetida*	LC_{50} = 567 mg a.s./kg dry soil LC_{50} = 283 mg a.s./kg dry soil [1)]	--
BF 500-6		LC_{50} > 1000 mg/kg dry soil LC_{50} > 500 mg/kg dry soil [1)]	--

Field studies			
BAS 516 07 F	earthworm field population	--	No unacceptable effects up to 4.5 kg product/ha (corresponding to 302 g pyraclostrobin/ha and 1504 g total a.s./ha)

1) Toxicity endpoint is re-adjusted using a soil factor of 2 to address the organic content of the soil (peat 10%), and the log P_{ow} of the substance is > 2.

* Study summary is presented in M-CA 8.4.

Overall summary

Data on BAS 516 07 F are evaluated and appropriate risk assessments are provided for the active substance pyraclostrobin, the relevant metabolites and the formulation BAS 516 07 F for the already registered use pattern in potatoes (critical GAP: maximum 4 x 17 g pyraclostrobin per ha).

The endpoints and calculated toxicity/exposure ratios are shown in Table 10.4-2.

Table 10.4-2: Toxicity/exposure ratios for earthworms and other soil non-target macro-organisms

Test substance	Use pattern [g/ha]	Species	Test type	Endpoint [mg/kg dry soil]	PEC [mg/kg dry soil]	TER	Trigger
Pyraclostrobin	4 x 17	*Eisenia fetida*	56-d reproduction test	NOEC $_{CORR}$ = 11.6	0.015	773	5
BF 500-6	--	*Eisenia fetida*	56-d reproduction test	NOEC $_{CORR}$ ≥ 160	0.008	≥ 20000	
BF 500-7	--	*Eisenia fetida*	56-d reproduction test	NOEC $_{CORR}$ ≥ 160	0.005	≥ 32000	
BAS 516 07 F	pyraclostrobin: 4 x 17	*Eisenia fetida*	56-d reproduction test	NOEC = 2.7	0.015	180	
	total a.s.: 4 x 84			NOEC = 13.4	0.260	52	
BAS 516 07 F	pyraclostrobin: 4 x 17	*Folsomia candida*	28-d reproduction test	NOEC = 16.8	0.015	1117	
	total a.s.: 4 x 84			NOEC = 83.8	0.260	322	
BF 500-6	--	*Folsomia candida*	28-d reproduction test	NOEC ≥ 1000	0.008	≥ 125000	
BF 500-7	--	*Folsomia candida*	28-d reproduction test	NOEC ≥ 800	0.005	≥ 160000	
BAS 516 07 F	pyraclostrobin: 4 x 17	*Hypoaspis aculeifer*	14-d reproduction test	NOEC ≥ 33.5	0.015	≥ 2233	
	total a.s.: 4 x 84			NOEC ≥ 167	0.260	≥ 642	

Acute studies on earthworms were performed with pyraclostrobin, the metabolites BF 500-6 and BF 500-7 (see SANCO/1420/2001-final, Monograph 12945/ECCO/BBA/01) and with the formulation BAS 516 07 F. According to Regulation 1107/2009 the tier 1 data requirement for acute toxicity on earthworms has been replaced by a requirement for chronic toxicity (i.e. reproduction) on earthworms. However, from previous submissions according to the former Directive EC 91/414 data on the acute toxicity of BAS 516 07 F to earthworms is available, which is for completeness presented as additional information, although acute endpoints are not used anymore in the current risk assessment (see below for respective chronic studies).

Chronic studies on earthworms were carried out with pyraclostrobin, the metabolites BF 500-6 and BF 500-7 (see M-CA 8.4) as well as with the formulation BAS 516 07 F.

Furthermore, chronic studies on collembolans were carried out with BAS 516 07 F and with the metabolites BF 500-6 and BF 500-7 (for metabolites see M-CA 8.4). Moreover, a chronic study on soil mites and in addition a field study on earthworms has been carried out with BAS 516 07 F.

In the risk assessment, all TER values exceeded the trigger value of 5 for chronic exposure.

Overall conclusion:

It is concluded that the use of BAS 516 07 F in potatoes will not pose unacceptable risks to populations of earthworms or other soil macro-organisms.

CP 10.4.1 Earthworms

Toxicity

Acute and chronic earthworm toxicity studies have been carried out with pyraclostrobin, its metabolites BF 500-6 and BF 500-7, as well as with the formulation BAS 516 07 F. Furthermore, an earthworm field study has been carried out with BAS 516 07 F. Further details on the studies with the formulation are given below (M-CP 10.4.1, M-CP 10.4.1.1 and M-CP 10.4.1.2) and on the studies with the active substance and metabolites in M-CA 8.4. The acute endpoints of the study with BAS 516 07 F are presented as additional information. The earthworm endpoints are summarized in Table 10.4.1-1.

For substances with log P_{ow} values > 2 and a high content of organic material in the artificial soil (i.e. 10% peat), the resulting endpoints have to be corrected by a soil factor of 2 (f_{oc}) in the risk assessment in order to address lower contents of organic material in soil.

The log P_{ow} for the active substance is > 2 (i.e. 3.99). Therefore, the correction was done for the endpoints obtained from the studies where the artificial soil contained more than 5% peat.

Table 10.4.1-1: Summary of earthworm endpoints for BAS 516 07 F, pyraclostrobin and metabolites

Test substance	Endpoint	Value [mg/kg dry soil]	Reference (BASF DocID)
Acute toxicity			
Pyraclostrobin	$LC_{50\ CORR}$	283	1999/10708
BF 500-6	$LC_{50\ CORR}$	> 500	1999/11308
BF 500-7	$LC_{50\ CORR}$	> 500	1999/11309
Pyraclostrobin in BAS 516 07 F [1)]	$LC_{50\ CORR}$	> 34 [2)]	2001/1001837
total a.s. in BAS 516 07 F [1)]		> 168 [2)]	
Chronic toxicity			
Pyraclostrobin	$NOEC_{CORR}$	11.6	2014/1000461
BF 500-6	$NOEC_{CORR}$	≥ 160	2013/1003174

[1)] Study summary is presented below as additional information.
[2)] Endpoint recalculated based on the nominal content of 6.7% pyraclostrobin and 26.7% boscalid in BAS 516 07 F.

Exposure

Table 10.4.1-2: Critical use pattern of BAS 516 07 F

Crop	Application time (BBCH code)	Number of applications	Interval [d]	Application rate per treatment		
				Boscalid [g a.s./ha]	Pyraclostrobin [g a.s./ha]	BAS 516 07 F [g/ha]
potatoes	51 - 89	4	10	67	17	250

The exposure to soil organisms was estimated by calculating the maximum predicted environmental concentrations in soil (PEC_{soil}). For multiple applications, the worst-case maximum PEC_{soil} will be the one immediately after the final application. The worst-case use pattern of BAS 516 07 F foresees four applications to potatoes with a maximum dose rate of 250 g/ha, corresponding to 17 g pyraclostrobin/ha and 67 g boscalid/ha.

For details see M-CP 9.1. The resulting maximum PEC_{soil} values are presented in Table 10.4.1-3.

Table 10.4.1-3: PEC_{soil} values for pyraclostrobin, boscalid and relevant metabolites

Test substance	$PEC_{soil, max}$ [mg/kg dry soil]	$PEC_{soil, plateau}$ [mg/kg dry soil]	$PEC_{soil, accu}$ [mg/kg dry soil]
Pyraclostrobin	0.015	--	--
BF 500-6	0.004	0.004	0.008
BF 500-7	0.003	0.002	0.005
Boscalid	0.069	--	0.245

Risk assessment for earthworms

The potential long-term risk of BAS 516 07 F to earthworms was assessed by calculating long-term TER (TER_{LT}) values by comparing the NOEC values and the maximum instantaneous PEC_{soil} using the following equation:

$$TER_{LT} = \frac{NOEC\,[mg/kg\ dry\ soil]}{PEC_{soil}\,[mg/kg\ dry\ soil]}$$

The resulting TER_{LT} values are presented below:

Table 10.4.1-4: Long-term TER values for earthworms

Test substance	NOEC [mg/kg dry soil]	PEC_{soil} [mg/kg dry soil]	TER_{LT}	TER trigger
Pyraclostrobin	11.6	0.015	773	5
BF 500-6	≥ 160	0.008	≥ 20000	
BF 500-7	≥ 160	0.005	≥ 32000	
Pyraclostrobin in BAS 516 07 F	2.7	0.015	180	
total a.s. in BAS 516 07 F	13.4	0.260	52	

The long-term TER values for BAS 516 07 F, pyraclostrobin and relevant soil metabolites are above the trigger value of 5. Therefore, chronic risk for earthworms arising from long-term use of BAS 516 07 F is negligible. However, for additional information, an earthworm field study was carried out with BAS 516 07 F.

The test site in this study was an arable field. At an application rate of up to 4.5 kg BAS 516 07 F/ha (equivalent to 302 g pyraclostrobin/ha and 1504 g total a.s./ha), no unacceptable effects to earthworm populations were observed (for details see M-CP 10.4.1.2). The intended maximum use of BAS 516 07 F, i.e. 4 x 250g/ha (equivalent to 4 x 17 g pyraclostrobin/ha and 4 x 84 g total a.s./ha) in potatoes is therefore covered by the tested field rate. Thus, it can be concluded that the use of BAS 516 07 F will be of low risk to natural earthworm communities.

Based on the standard risk assessment and on data from the field study, it is concluded that earthworm communities will be at low risk following the use of BAS 516 07 F when applied to potatoes according to the recommended use pattern.

Earthworms – acute toxicity

This study was a former requirement under Council Directive 91/414/EEC and SANCO/10329/2002 rev 2. However, under Regulation (EC) 1107/2009 it is not required anymore. Therefore, the study is considered as additional information.

Report:	CP 10.4.1/1 Wachter S., 2001b Acute toxicity of BAS 516 00 F on earthworms, Eisenia foetida using an artificial soil test 2001/1001837
Guidelines:	OECD 207, ISO 11268-1
GLP:	yes (certified by Ministerium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Executive Summary

Adult earthworms of the species *Eisenia fetida*, were exposed to BAS 516 00 F. The test item was mixed into artificial soil containing 10% peat at rates of 198, 296, 444, 667 and 1000 mg BAS 516 00 F/kg dry soil. For the control treatment, the soil was left untreated.

The worms were placed on the surface of the soil. Four replicates were prepared for each treatment group and the control, each containing 10 worms. Assessment of mortality and behavioral effects were made 7 and 14 days after treatment. Assessment of worm weight was made after 14 days.

After 14 days of exposure, no mortality was observed in the control group. Up to 1000 mg BAS 516 00 F/kg dry soil, a maximum of 20% mortality was observed. The biomass development was statistically significantly inhibited at the tested concentrations of 667 and 1000 mg BAS 516 00 F/kg dry soil. No particular behavioral abnormalities could be observed.

In a 14-d toxicity study with BAS 516 00 F to earthworms (*Eisenia fetida*) the LC_{50} was determined to be > 1000 mg/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).
Test species:	Earthworm (*Eisenia fetida*), adult worms (with clitellum and weight > 300 mg) less than one year old; source GAB Biotechnologie GmbH & IFU Umweltanalytik GmbH, Niefern-Oeschelbronn, Germany.

B. STUDY DESIGN

Test design:	14 d exposure in treated artificial soil; different concentrations of the test item are mixed homogeneously into the soil which is filled in glass vessels before the earthworms are introduced on top of the soil; 5 concentrations; 4 replicates/concentration with 10 worms each. Assessment of worm mortality and behavioral effects after 7 and 14 d, measurement of weight change as sub-lethal parameter after 14 d.
Endpoints:	LC_{50} (50% mortality of earthworms after exposure over 14 days), behavioral effects, weight change.
Test concentrations:	Control, 198, 296, 444, 667 and 1000 mg BAS 516 00 F/kg dry soil.
Test conditions:	Artificial soil according to OECD 207 (10% peat); pH 5.6 - 5.7; water content at test initiation 32.6% - 35.9% (of dry soil); 31.2% - 35.0% at test termination; temperature: 18°C – 22°C.
Statistics:	Descriptive statistics, ANOVA followed by Dunnett-test (α = 0.05) for weight change.

II. RESULTS AND DISCUSSION

After 14 days of exposure, no mortality was observed in the control group. Up to 1000 mg BAS 516 00 F/kg dry soil, a maximum of 20% mortality was observed. The biomass development was statistically significant inhibited at the tested concentrations of 667 and 1000 mg BAS 516 00 F/kg dry soil (Dunnett-test, $\alpha = 0.05$). The results are summarized in Table 10.4.1-5.

Table 10.4.1-5: Effects of BAS 516 00 F on earthworm (*Eisenia fetida*) mortality and biomass (14 d)

BAS 516 00 F [mg/kg dry soil]	Control	198	296	444	667	1000
Mortality [%]	0	0	0	2.5	2.5	20
Weight change [%]	-10.3	-12.7	-12.9	-16.3	-20.1 *	-21.7 *
Endpoints [mg/kg dry soil]						
LC_{50}	> 1000					

* Statistically significant differences compared to the control (Dunnett-test, $\alpha = 0.05$).

III. CONCLUSION

In a 14-d toxicity study with BAS 516 00 F to earthworms (*Eisenia fetida*) the LC_{50} was determined to be > 1000 mg/kg dry soil.

CP 10.4.1.1 Earthworms – sub-lethal effects

Report:	CP 10.4.1.1/1 Friedrich S., 2006a Sublethal toxicity of BAS 516 07 F to the earthworm Eisenia fetida in artificial soil with 5% peat 2006/1015860
Guidelines:	OECD 222
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

The effects of BAS 516 07 F on mortality, biomass development and reproduction of the earthworm *Eisenia fetida* were investigated in a 56-days extended laboratory study. Six application rates (2.5, 5, 10, 20, 40 and 60 mg BAS 516 07 F/kg dry soil) were incorporated into the soil (5% peat) with four replicates per treatment (each containing 10 worms). An untreated control with 8 replicates was included. Assessment of adult worm mortality and biomass development was carried out after 28 days, assessment of behavior, pathological symptoms and reproduction rate (number of juveniles) was carried out after 56 days.

No mortality was observed in any of the treatment groups. Body weights of the earthworms exposed to BAS 516 07 F were not statistically significantly different compared to the control. No statistically significant effects on reproduction were observed up to and including the concentration of 40 mg test item/kg dry soil. In the highest test item concentration of 60 mg test item/kg dry soil the number of juveniles was statistically significantly reduced compared to the control group. Neither behavioral abnormalities nor effects on feeding activity were observed in any of the treatment groups.

In a 56-day earthworm reproduction study with BAS 516 07 F on earthworms, the NOEC was determined to be 40 mg BAS 516 07 F/kg dry soil and the EC_{50} was > 60 mg BAS 516 07 F/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 516 07 F, batch 1789, content of a.s.: pyraclostrobin (BAS 500 F): 6.8% (nominal 6.7%); boscalid (BAS 510 F; Reg. no.:300 355): 26.7% (nominal 26.7%).
Test species:	Earthworm (*Eisenia fetida andrei*), adult worms (with clitellum and weight of 300 mg – 454 mg), approximately 3 months old; source: in-house culture.

B. STUDY DESIGN

Test design:	56-day test in treated artificial soil according to OECD 222 (5% peat only); different concentrations of the test item were incorporated into the soil; 7 treatment groups (6 test item concentrations, control); 4 replicates for the test item treatments, 8 replicates for the control, 10 worms each. Assessment of worm mortality and biomass development after 28 days. Behavior, pathological symptoms and reproduction rate were determined after another 28 days (assessed 56 days after application).
Endpoints:	Mortality, weight change, reproduction rate, feeding activity and behavioral effects
Reference item:	Benlate (Benomyl WP, 500 g/kg). The effects of the reference item were investigated in a separate study.
Test rates:	Control, 2.5, 5, 10, 20, 40 and 60 mg BAS 516 07 F/kg dry soil (nominal).
Test conditions:	Artificial soil according to OECD 222 (with reduced content of peat: 5%); pH 6.3 at test initiation, 6.2 - 6.4 at test termination; water content 24.7% - 24.9% at test initiation and 24.7% - 25.4% at test termination; temperature: 17C - 21C; photoperiod: 16 h light : 8 h dark, light intensity: 570 lux, food: horse manure.
Statistics:	Descriptive statistics, Dunnett-test for weight change and reproduction data ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

No mortality was observed in any of the treatment groups. Body weights of the earthworms exposed to BAS 516 07 F were not statistically significantly different compared to the control (Dunnett-test, $\alpha = 0.05$). No statistically significant effects on reproduction were observed up to and including the concentration of 40 mg test item/kg dry soil. In the test item concentration of 60 mg test item/kg dry soil the reproduction was statistically significantly reduced compared to the control group (Dunnett-test, $\alpha = 0.05$). Neither behavioral abnormalities nor effects on feeding activity were observed in any of the treatment groups. The results are summarized in Table 10.4.1.1-1.

Table 10.4.1.1-1: Effects of BAS 516 07 F on earthworms (*Eisenia fetida andrei)* in a 56-day reproduction study

BAS 516 07 F [mg/kg dry soil]	**Control**	**2.5**	**5**	**10**	**20**	**40**	**60**
Mortality (day 28) [%]	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Weight change (day 28) [%]	65.7	63.6	60.5	61.9	64.0	61.9	58.4
No. of juveniles (day 56)	113	118.3	107.3	112.3	112.8	98.5	78.8 *
Reproduction in [%] of control (day 56)	100	104.6	94.9	99.3	99.8	87.2	69.7
Endpoints [mg/kg dry soil]							
EC_{50}	> 60						
NOEC (day 56)	40						

* Statistically significant different compared to the control (Dunnett-test; $\alpha = 0.05$).

III. CONCLUSION

In a 56 day earthworm reproduction study with BAS 516 07 F on earthworms, the NOEC was determined to be 40 mg BAS 516 07 F/kg dry soil and the EC_{50} was > 60 mg BAS 516 07 F/kg dry soil.

CP 10.4.1.2 Earthworms – field studies

Report:	CP 10.4.1.2/1 Hamberger A., 2011a Field study to evaluate the effects of BAS 516 07 F on earthworms in Southern Germany 2011/1043488
Guidelines:	ISO 11268-3 (1999)
GLP:	yes (certified by Landesanstalt fuer Umwelt, Messungen und Naturschutz Baden-Wuerttemberg, Karlsruhe, Germany)

Executive Summary

An arable land site was chosen as a natural habitat of earthworms. The treatments with 1.5, 3.0 and 4.5 kg BAS 516 07 F/ha were assigned randomly to the plots within each replicate. Over the experimental period from March 2009 until April 2010 four earthworm samplings were evaluated. Earthworm extraction was achieved by hand sorting combined with formalin extraction.
Prior to the treatment, the test site yielded sufficiently high numbers of earthworms of 199.2 individuals per m^2 representing various common earthworm species such as *Lumbricus terrestris* and *Aporrectodea longa* (anecic species) and *Aporrectodea caliginosa* and *A. rosea* (endogeic species).
No statistically significant differences between BAS 516 07 F treatments and the untreated control could be detected in terms of population density or biomass 1, 6 and 12 months after application.

The results of this field study on natural earthworm biocoenosis showed that after application of BAS 516 07 F at 1.5, 3.0 and 4.5 kg/ha no significant long-term effects on natural earthworm populations in terms of abundance and total biomass occurred. No obvious effects on the composition of earthworm population could be observed.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 07 F; batch no. 11041; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 26.7% (nominal 26.9%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.7% (nominal 6.5%).

Test species: Naturally occurring field population of earthworms comprising all mobile stages (juvenile and adult earthworms) including endogeic species such as *Aporrectodea caliginosa* and *A. rosea* as well as anecic species such as *Lumbricus terrestris* and *Aporrectodea longa*.

B. STUDY DESIGN

Test site: Arable field, in Bodelshausen, Southern Germany. The last crop planted was mustard sown in September 2008. The site had received chemical applications in previous years prior to the study but none were applied during the study apart from the test item and toxic standard.

Test design: Randomized block design with 5 treatment groups (control, 3 test item rates and toxic standard) each with four replicates. A number of 20 plots, each 12 m x 13 m, were arranged. The test item was applied using a boom sprayer (Schachtner).

Endpoints: Total abundance and biomass of earthworms.

Reference item: Nociolex (50.0% carbendazim; nominal).

Test rates: Untreated control; Treatment groups: BAS 516 07 F applied at 1.5 kg/ha; 3.0 kg/ha; 4.5 kg/ha; the reference item was applied at 20.0 kg/ha.

Application date: 16.04.2009.

Sampling dates: Pre-sampling: 23-16 days before application (24.03. to 31.03.2009); 1st sampling: 39-43 days after application (25.05. to 29.05.2009); 2nd sampling: 179-182 days after application (12.10. to 15.10.2009); 3rd sampling: 355-358 days after application (06.04. to 09.04.2010).

Extraction method: Hand sorting combined with formalin extraction in the excavated hole; 4 samples per plot were taken at each sampling date.

Test conditions:	Natural field conditions; soil texture: clay 5.3 – 14.9%, silt 48.5 – 69.5%, sand 17.8 – 46.3%, pH 7.6 - 7.7, 48.9 – 64.6% of the maximum water holding capacity; C_{org}: 2.63 – 3.47%; mean air temperature during the trial period: 8.8C.
Statistics:	Descriptive statistics; differences between test item treatments and control: ANOVA followed by Dunnett's t-test, Kruskal-Wallis, Wilcoxon-test or Bonferroni U-test ($\alpha = 0.05$), differences between toxic standard and control: Student or Satterthwaite t-test or U-test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Prior to the treatment, the test site yielded sufficiently high numbers of earthworms of 199.2 individuals per m^2 representing various common earthworm species such as *Lumbricus terrestris* and *Aporrectodea longa* (anecic species) and *Aporrectodea caliginosa* and *A. rosea* (endogeic species).
Surface monitoring on days 1-3 after application showed that there was no acute primary effect on earthworms by the test item. No alive, moribund and dead earthworms were found on the soil surface in any of the plots treated with BAS 516 07 F and in the control plots.
No statistically significant differences between BAS 516 07 F treatments and the untreated control could be detected in terms of population density or biomass 1, 6 and 12 months after application. Dominant adult earthworm species found in the field site were the endogeic species *Aporrectodea caliginosa* and the anecic species *Lumbricus terrestris*. No statistically significant reductions in the abundance and biomass of these earthworm species could be observed in the test item treatments compared to the control. Twelve months after application, the biomass of *Aporrectodea longa* at 3.0 kg BAS 516 07 F/ha was statistically significantly reduced. However, no significant reduction in biomass could be found for *A. longa* at the highest application rate at all sampling dates. Therefore, the significant reduction in biomass for 3.0 kg BAS 516 07 F/ha for *A. longa* cannot be considered to be due to the treatment with BAS 516 07 F. Moreover, there was no significant reduction in abundance found for *A. longa* in all test item treatments at all sampling dates. The results are summarized in Table 10.4.1.2-1.

Table 10.4.1.2-1: Summary of total earthworm abundance and biomass in a field study with BAS 516 07 F

Treatment	Pre sampling 24. - 31.03.2009	First sampling 25. - 29.05.2009	Second sampling 12. - 15.10.2009	Third sampling 06. - 09.04.2010
Total earthworm abundance [Ind./m²]				
Control	202.0	233.5	379.0	352.8
1.5 kg/ha BAS 516 07 F	201.0	269.8	411.3	373.8
% of control	**99.5**	**115.5**	**108.5**	**106.0**
3.0 kg/ha BAS 516 07 F	196.3	232.3	326.8	316.8
% of control	**97.2**	**99.5**	**86.2**	**89.8**
4.5 kg/ha BAS 516 07 F	198.3	237.3	332.0	344.5
% of control	**98.1**	**101.6**	**87.6**	**97.7**
reference item	--	15.1% of control *	49.5% of control *	63.0% of control
Total earthworm biomass [g/m²]				
Control	148.6	150.4	139.7	177.3
1.5 kg/ha BAS 516 07 F	155.2	163.9	135.4	145.2
% of control	**104.4**	**108.9**	**96.9**	**81.9**
3.0 kg/ha BAS 516 07 F	143.6	132.6	109.9	169.7
% of control	**96.6**	**88.1**	**78.7**	**95.7**
4.5 kg/ha BAS 516 07 F	149.7	136.3	130.0	138.5
% of control	**100.8**	**90.6**	**93.0**	**78.1**
reference item	--	9.3% of control *	49.0% of control	72.4% of control *

* Statistically significantly different compared to the control (Student or Satterthwaite t-test or U-test, $\alpha = 0.05$).

Validity of the reference item was proved by clear statistically significant differences in earthworm numbers at the first and second sampling (Student or Satterthwaite t-test or U-test, $\alpha = 0.05$).

III. CONCLUSION

The results of this field study on natural earthworm biocoenosis showed that after application of BAS 516 07 F at 1.5, 3.0 and 4.5 kg/ha no significant long-term effects on natural earthworm populations in terms of abundance and total biomass occurred. No obvious effects on the composition of earthworm population could be observed.

CP 10.4.2 Effects on non-target soil meso- and macrofauna (other than earthworms)

According to SANCO/10329/2002 rev2 final the test on 'sub-lethal effects on collembola or soil mites' is required if *(a)* the $DT_{90,\ field}$ is between 100 and 365 days and *(b)* the standard HQ for arthropods (*T. pyri* and *A. rhopalosiphi*) is above 2.

Toxicity and Exposure

The worst-case $DT_{90,\ field}$ values of pyraclostrobin and the metabolites BF 500-6 and BF 500-7 exceed 100 days. Although the standard HQ value for *T. pyri* and *A. rhopalosiphi* indicated no in-field and no off-field risk (please refer to M-CP 10.3), tests with other soil macro-organisms than earthworms were performed to gain additional information for the risk assessment. Reproduction studies with BAS 516 07 F were carried out with *Folsomia candida* and additionally with *Hypoaspis aculeifer*. The chronic endpoints are summarized in Table 10.4.2-1.

Table 10.4.2-1: Summary of chronic endpoints on *Folsomia candida* and *Hypoaspis aculeifer* for BAS 516 07 F

Test substance	Test species	Endpoint	Value [mg/kg dry soil]	Reference (BASF DocID)
BF 500-6 [1)]	*Folsomia candida*	NOEC	≥ 1000	2013/1068054
BF 500-7 [1)]	*Folsomia candida*	NOEC	≥ 800	2013/1224030
Pyraclostrobin in BAS 516 07 F [1)]	*Folsomia candida*	NOEC	16.8 [2)]	2006/1015861
total a.s. in BAS 516 07 F [1)]			83.8 [2)]	
Pyraclostrobin in BAS 516 07 F [1)]	*Hypoaspis aculeifer*	NOEC	≥ 33.5 [2)]	2014/1010834
total a.s. in BAS 516 07 F [1)]			≥ 167 [2)]	

[1)] Test was conducted with only 5% peat in the test substrate.
[2)] Endpoint recalculated based on the nominal content of 6.7% pyraclostrobin and 26.7% boscalid in BAS 516 07 F.

Risk assessment for other non-target soil meso- and macrofauna (other than earthworms)

For the risk assessment, the chronic toxicity data (NOEC for reproduction) are compared to the predicted environmental concentration considering long-term exposure following multi-year use of BAS 516 07 F. The results are presented in Table 10.4.2-2.

Table 10.4.2-2: Long-term TER values for *Folsomia candida* and *Hypoaspis aculeifer*

Test substance	Test species	NOEC [mg/kg dry soil]	PEC_{soil} [mg/kg dry soil]	TER_{LT}	TER trigger
BF 500-6	*Folsomia candida*	≥ 1000	0.008	≥ 125000	5
BF 500-7	*Folsomia candida*	≥ 800	0.005	≥ 160000	
Pyraclostrobin in BAS 516 07 F	*Folsomia candida*	16.8	0.015	1120	
total a.s. in BAS 516 07 F		83.8	0.260	322	
Pyraclostrobin in BAS 516 07 F	*Hypoaspis aculeifer*	≥ 33.5	0.015	≥ 2233	
total a.s. in BAS 516 07 F		≥ 167	0.260	≥ 642	

All long-term TER values exceed the Commission Regulation (EU) 546/2011 trigger value of 5, indicating that no unacceptable effects are expected for other non-target soil meso- and macrofauna (other than earthworms) when BAS 516 07 F is applied to potatoes according to the proposed use pattern.

CP 10.4.2.1 Species level testing

Report: CP 10.4.2.1/1
Friedrich S., 2006c
Effects of BAS 516 07 F on the reproduction of the collembolans Folsomia candida in artificial soil with 5% peat
2006/1015861
Guidelines: ISO 11267 (1999)
GLP: yes
(certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

The effects of BAS 516 07 F on mortality and reproduction of the collembolans *Folsomia candida* were investigated in a laboratory study over 28 days. Five application rates (62.5, 125, 250, 500 and 1000 mg BAS 516 07 F/kg dry soil) were incorporated into the soil (5% peat only) with 5 replicates per treatment (each containing 10 juvenile collembolans). An untreated control with 5 replicates was included. Assessment of adult springtail mortality and reproduction rate (number of juveniles) was carried out after 28 days.

Statistically significant mortality was observed at the two highest concentrations tested. In the treatment groups of 500 and 100 mg/kg dry soil mortality rates of 0% to 50% were observed, respectively, compared to 0% in the control. A mean of 775.2 juveniles was counted in the control. In the treatment groups the mean number of juveniles ranged from 637.6 to 786.6 at 62.5 to 500 mg/kg soil, respectively, and was not statistically significantly different compared to the control. The reproduction was significantly inhibited at the highest test concentration of 1000 mg/kg dry soil.

In a 28-d reproduction study on Collembola (*Folsomia candida)* with BAS 516 07 F the NOEC for mortality was 250 mg/kg dry soil and 500 mg/kg dry soil for reproduction. The LC_{50} was determined to be 955 mg BAS 516 07 F/kg dry soil and the EC_{50} (reproduction) was determined to be > 1000 mg/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 516 07 F, batch 1789, content of a.s.: pyraclostrobin (BAS 500 F; Reg. no.:304 428): 6.8% (nominal 6.7%); boscalid (BAS 510 F; Reg. no.:300 355): 26.7% (nominal 26.7%).
Test species:	Collembola (*Folsomia candida*), juveniles (10-12 days old); source: Biologische Bundesanstalt (BBA), Berlin-Dahlem.

B. STUDY DESIGN

Test design:	28-day test in treated artificial soil according to ISO 11267 (5% peat only); artificial soil filled in glass vessels was treated with different concentrations of the test item before collembolans were introduced; 6 treatment groups (5 test item concentrations, control); with 5 replicates each and each containing 10 juvenile collembolans. Assessment of adult collembolan mortality and reproduction rate (number of juveniles) after 28 days.
Endpoints:	Mortality, reproduction rate.
Reference item:	Betosip (phenmedipham, 114 g/L). The effects of the reference item were investigated in a separate study.
Test rates:	Control, 62.5, 125, 250, 500 and 1000 mg BAS 516 07 F/kg dry soil (nominal).
Test conditions:	Artificial soil according to ISO 11267 (with reduced content of peat: 5%); 20% kaolinite clay, 0.3% $CaCO_3$ and 74.7% quartz sand; pH 6.3 - 6.4 at test initiation and 6.3 - 6.4 at test termination; water content 24.4% - 25.9% at test initiation and 24.2% - 24.7% at test termination; temperature: 18C - 21C; photoperiod: 16 h light : 8 h dark, light intensity: 570 lux; food: 2 mg granulated dry yeast at the start of the test and after 14 days.
Statistics:	Descriptive statistics, Fisher`s Exact Test for mortality data, Dunnett-test for reproduction data (α = 0.05), Probit analysis for determination of the LC_{50} value.

II. RESULTS AND DISCUSSION

Statistically significant mortality was observed at the two highest concentrations tested (Fisher`s Exact Binominal Test, α = 0.05). In the treatment groups of 500 and 100 mg/kg dry soil mortality rates of 0% to 50% were observed, respectively, compared to 0% in the control. A mean of 775.2 juveniles was counted in the control. In the treatment groups the mean number of juveniles ranged from 637.6 to 786.6 at 62.5 mg to 500 mg/kg dry soil, respectively, and was not statistically significantly different compared to the control. The reproduction was significantly inhibited at the highest test concentration of 1000 mg/kg dry soil (Dunnett-test, α = 0.05). The results are summarized in Table 10.4.2.1-1.

Table 10.4.2.1-1: Effect of BAS 516 07 F on collembolans (*Folsomia candida)* in a 28-day reproduction study

BAS 516 07 F [mg/kg dry soil]	**Control**	**62.5**	**125**	**250**	**500**	**1000**
Mortality (day 28) [%]	0	0	0	0	22 *	50 *
No. of juveniles (day 28)	775.2	772.4	786.6	738.8	637.6	450.4 *
Reproduction (day 28) [%]	--	100	101	95	82	58
Endpoints [mg/kg dry soil]						
$NOEC_{mortality}$ (day 28)	250					
$NOEC_{reproduction}$ (day 28)	500					
LC_{50} (95% CL) [1)]	955 (774 - 1179)					
$EC_{50,\ reproduction}$	> 1000					

* Statistically significantly different compared to the control (Fisher`s Exact Test for mortality, Dunnett-test for reproduction, α = 0.05).

1) Median effect concentration calculated using probit analysis (with 95% Confidence Limits).

III. CONCLUSION

In a 28 d reproduction study on Collembola (*Folsomia candida*) with BAS 516 07 F the NOEC for mortality was 250 mg/kg dry soil and 500 mg/kg dry soil for reproduction. The LC_{50} was determined to be 955 mg BAS 516 07 F/kg dry soil and the EC_{50} (reproduction) was determined to be > 1000 mg/kg dry soil.

Report:	CP 10.4.2.1/2 Schulz L., 2014b Effects of BAS 516 07 F on the reproduction of the predatory mite Hypoaspis aculeifer 2014/1010834
Guidelines:	OECD 226 (2008)
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

The effects of BAS 516 07 F on mortality and reproduction of the soil mite *Hypoaspis aculeifer* were investigated in a chronic laboratory study over 14 days. The test item was mixed into artificial soil at rates of 31.25, 62.5, 125, 250 and 500 mg BAS 516 07 F/kg dry soil. Test item treatments were replicated four times each. As a control treatment, the soil was left untreated in eight replicates. Each treatment contained 10 adult female soil mites. Assessments of mortality and reproduction were carried out after 14 days of exposure.

Mortality rates of 2.5 - 7.5% were recorded in the test item treatment groups. In the control group the mortality rate was 5.0%. The observed mortality rates for adult mortality in the test item treatment groups compared to control were not statistically significantly different. Differences between the behavior and the morphology of the mites in the control and the test item treatment groups could not be observed.
Reproduction rates in the 31.25, 62.5, 125, 250 and 500 mg BAS 516 07 F/kg dry soil were 223.5, 220.8, 185.3, 211.8, 212.0 juveniles, respectively. The mean reproduction in the control reached 206.1 juveniles. BAS 516 07 F showed no statistically significantly differences on reproduction at all tested concentrations.

In a 14-day reproduction study with BAS 516 07 F on predatory soil mites (*Hypoaspis aculeifer*), the NOEC for mortality and reproduction was determined to be ≥ 500 mg/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 07 F, batch 12-000110, content of a.s.: pyraclostrobin (BAS 500 F; Reg. no.:304 428): 6.7% (nominal 6.7%); boscalid (BAS 510 F; Reg. no.:300 355): 27.1% (nominal 26.7%).

B. STUDY DESIGN

Test species: *Hypoaspis aculeifer* (CANESTRINI), adult mites with an age difference of 3 days; source: in-house culture.

Test design: 14-day chronic laboratory test (according to OECD 226) on effects of BAS 516 07 F on mortality and reproduction of soil mites. 5 different concentrations of the test item were homogenously mixed into artificial soil (5% peat) which was then filled in glass vessels before the soil mites were introduced on top of the soil; 6 treatment groups (5 test item concentrations, control); 8 replicates for the control and 4 replicates for test item treatments, each with 10 soil mites; assessment of adult mortality and reproduction effects (number of juveniles) after 14 days.

Endpoints: Mortality and reproduction rate after 14 days.

Reference item: Dimethoate (analysed purity: 99.8%, tolerance ± 1.0%). The effects of the reference item were investigated in a separate study.

Test rates: Control, 31.25, 62.5, 125, 250 and 500 mg BAS 516 07 F/kg dry soil.

Test conditions: Artificial soil according to OECD 226 (5% peat); pH 5.9 – pH 6.3 at test initiation, pH 5.8 - 5.9 at test termination; water content at test initiation 54.04% - 55.94% of maximum water holding capacity (WHC) and 52.95% - 55.71% of maximum WHC at test termination; temperature: 19.7°C - 20.5°C; photoperiod: 16 h light : 8 h dark; light intensity: 517 lux. Feeding of mites with *Tyrophagus putrescentiae* (SCHRANK) at the beginning and *ad libitum* in the course of the test.

Statistics: Descriptive statistics; Fisher's Exact Binominal Test with Bonferroni Correction for mortality ($\alpha = 0.05$, one-sided greater), Dunnett t-test for reproduction ($\alpha = 0.05$, one-sided smaller).

II. RESULTS AND DISCUSSION

Mortality rates of 2.5 - 7.5% were recorded in the test item treatment groups. In the control group the mortality rate was 5.0%. The observed mortality rates for adult mortality in the test item treatment groups compared to control were not statistically significantly different (Fisher's Exact Binomial Test with Bonferroni Correction, $\alpha = 0.05$, one-sided greater). Differences between the behavior and the morphology of the mites in the control and the test item treatment groups could not be observed.
Reproduction rates in the 31.25, 62.5, 125, 250 and 500 mg BAS 516 07 F/kg dry soil were 223.5, 220.8, 185.3, 211.8, 212.0 juveniles, respectively. The mean reproduction in the control reached 206.1 juveniles. BAS 516 07 F showed no statistically significantly differences on reproduction at all tested concentrations (Dunnett-t-test, $\alpha = 0.05$, one-sided smaller).

The results are summarized in table Table 10.4.2.1-2:

Table 10.4.2.1-2: Effects of BAS 516 07 F on predatory mites (*Hypoaspis aculeifer*) in a 14-day reproduction study

BAS 516 07 F [mg/kg dry soil]	**Control**	**31.25**	**62.5**	**125**	**250**	**500**
Mortality (day 14) [%]	5.0	2.5	7.5	7.5	5.0	5.0
No. of juveniles (day 14)	206.1	223.5	220.8	185.3	211.8	212.0
Reproduction [% of control] (day 14)	--	108	107	90	103	103
Endpoint [mg BAS 516 07 F/kg dry soil]						
$NOEC_{mortality}$	≥ 500					
$NOEC_{reproduction}$	≥ 500					
LC_{50}	> 500					
EC_{50}	> 500					

III. CONCLUSION

In a 14-day reproduction study with BAS 516 07 F on predatory soil mites (*Hypoaspis aculeifer*), the NOEC for mortality and reproduction was determined to be ≥ 500 mg/kg dry soil.

CP 10.4.2.2 Higher tier testing

Further studies are not triggered.

CP 10.5 Effects on soil nitrogen transformation

The new representative formulation BAS 516 07 F was not evaluated within a previous Annex I inclusion process. It is a water dispersible granule (WG) containing 67 g/kg pyraclostrobin and 267 g/kg boscalid.

The EU agreed endpoints for the soil metabolites of the active substance pyraclostrobin as described in the EU Review Report (SANCO/1420/2001-final, September 2004) plus endpoints from new studies with the new representative formulations BAS 500 06 F and BAS 516 07 F are used for the risk assessment on soil micro-organisms (see Table 10.5-1).

Table 10.5-1: Ecotoxicological endpoints for soil micro-organisms

Test substance	Test design [1)]	EU agreed endpoints	Endpoints used in risk assessment
Pyraclostrobin [2)]	C	NOEC = 3.33 mg a.s./kg dry soil, (equivalent to 2.5 kg a.s./ha)	--
	N	NOEC = 3.33 mg a.s./kg dry soil, (equivalent to 2.5 kg a.s./ha)	--
Pyraclostrobin [3)]	N	--	NOEC = 3.33 mg a.s./kg dry soil (equivalent to 2.5 kg a.s./ha)
BF 500-6	C	NOEC = 1.0 mg/kg dry soil, equivalent to 0.75 kg/ha	
	N	NOEC = 1.0 mg/kg dry soil, equivalent to 0.75 kg/ha	NOEC = 1.0 mg/kg dry soil, equivalent to 0.75 kg/ha
BF 500-7	C	NOEC = 0.5 mg/kg dry soil, equivalent to 0.375 kg/ha	
	N	NOEC = 0.5 mg/kg dry soil, equivalent to 0.375 kg/ha	NOEC = 0.5 mg/kg dry soil, equivalent to 0.375 kg/ha
BAS 516 07 F [4)]	N	--	NOEC = 24 mg/kg dry soil, equivalent to 18 kg/ha

1) C = Carbon transformation, N = Nitrogen transformation.
2) Study was conducted with the pyraclostrobin solo-formulation BAS 500 00 F (250 g pyraclostrobin/L).
3) Study was conducted with the pyraclostrobin solo-formulation BAS 500 06 F (200 g pyraclostrobin/L).
4) The study was performed with BAS 516 00 F, which is a minor change formulation of BAS 516 07 F (the detailed composition of both products is given in Document JCP 1.4.1).

Toxicity

The effects of the active substance, the relevant metabolites and the formulated product to soil micro-organisms are summarized in Table 10.5-2. Further details on the studies on nitrogen transformation with the formulated product are given in the summary provided below. According to Regulation 1107/2009 the study on carbon transformation was omitted from the formal data requirements. However, from previous submissions according to the former Directive EC 91/414 data on carbon transformation is available for BAS 516 07 F and is therefore presented at the end of this chapter as additional information without consideration in the risk assessment.

Table 10.5-2: Toxicity of BAS 516 07 F, BF 500-6 and BF 500-7 to soil micro-organisms

Test substance	Endpoint	NOEC	Reference (BASF DocID)
BF 500-6	Effects on nitrogen and carbon transformation	1.0 mg/kg dry soil	1999/11311 1999/11120
BF 500-7	Effects on nitrogen and carbon transformation	0.5 mg/kg dry soil	1999/11311 1999/11120
Pyraclostrobin [1)]	Effects on nitrogen transformation	3.33 mg a.s./kg dry soil (equivalent to 2.5 kg a.s./ha)	2012/1129443
BAS 516 07 F [2)]	Effects on nitrogen transformation	24.0 mg/kg dry soil (equivalent to 18.0 kg/ha)	2001/1005959
	Effects on carbon transformation [3)]	24.0 mg/kg dry soil (equivalent to 18.0 kg/ha)	2001/1005960

1) Study was carried out with BAS 500 06 F as a surrogate for pyraclostrobin. For the study summary please refer to the formulation dossier of BAS 500 06 F, M-CP 10.5.
2) The study was performed with BAS 516 00 F, which is a minor change formulation of BAS 516 07 F (the detailed composition of both products is given in Document JCP 1.4.1).
3) Not considered in risk assessment since not a formal data requirement according to Regulation 1107/2009

Exposure

Table 10.5-3: Critical use pattern of BAS 516 07 F

Crop	Application time (BBCH code)	Number of applications	Interval [d]	Application rate per treatment		
				Boscalid [g a.s./ha]	Pyraclostrobin [g a.s./ha]	BAS 516 07 F [g/ha]
potatoes	51 - 89	4	10	67	17	250

The predicted environmental concentrations of pyraclostrobin and relevant metabolites in soil (PEC_{soil}) were calculated as described in M-CP 9.1. The resulting maximum PEC_{soil} values are presented in Table 10.5-4.

Table 10.5-4: PEC_{soil} values for pyraclostrobin, relevant metabolites and boscalid

Test substance	$PEC_{soil, max}$ [mg/kg dry soil]	$PEC_{soil, plateau}$ [mg/kg dry soil]	$PEC_{soil, accu}$ [mg/kg dry soil]
Pyraclostrobin	0.015	--	--
BF 500-6	0.004	0.004	0.008
BF 500-7	0.003	0.002	0.005
Boscalid	0.069	--	0.245

Risk assessment for Soil Nitrogen Transformation

BAS 516 07 F (tested as minor change formulation BAS 516 00 F) had no significant effect on soil micro-organisms at 24 mg BAS 516 07 F/kg dry soil, corresponding to 1.6 mg pyraclostrobin/kg dry soil and 8.0 mg total a.s./kg dry soil. These concentrations are approximately 107-times higher than the maximum $PEC_{soil, max}$ of 0.015 mg pyraclostrobin/kg dry soil - and approximately 31-times higher than the sum of the highest PEC-values for both a.s., i.e. 0.260 mg total a.s./kg dry soil. This supports the conclusion that under field conditions, the use of BAS 516 07 F in potatoes at the recommended rates poses no unacceptable risk to non-target soil micro-organisms.

Furthermore, the NOEC values for the metabolites of 1.0 mg BF 500-6/kg dry soil and 0.5 mg BF 500-7/kg dry soil are 125- and 100-times higher than the maximum $PEC_{soil, accu}$ values of 0.008 mg BF 500-6/kg dry soil and 0.005 mg BF 500-7/kg dry soil, respectively.

It is concluded that the proposed use of BAS 516 07 F will not pose an unacceptable risk to non-target soil micro-organisms, when applied in potatoes according to the recommended use pattern.

Report:	CP 10.5/1 Wachter S., 2001a Assessment of the side effects of BAS 516 00 F on the activity of the soil microflora; nitrogen turnover 2001/1005959
Guidelines:	BBA VI 1-1 (1990)
GLP:	yes (certified by Ministerium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Executive Summary

The effect of BAS 516 00 F on nitrogen transformation was tested in a lucerne-enriched loamy sand soil and a loamy silt soil.
BAS 516 00 F was applied to samples of the soils, in a laboratory, at nominal application rates of 2.4 mg and 24 mg BAS 516 00 F/kg dry soil. The treated soils and untreated controls were incubated at 20 ± 2°C in the dark for 28 days. Triplicate samples of each treatment were removed for analysis of NH_4-nitrogen and NO_3-nitrogen, using calibrated ion-selective electrodes connected to an Orion expandable ion analyzer, 0, 14, 28 and 56 days after application.

No adverse effects of BAS 516 00 F on nitrogen transformation could be observed in both soils at both tested rates (single and ten-fold application rate) after 28 days (loamy silt soil) and 56 days (loamy sand soil).

Based on the results of this study, BAS 516 00 F caused no long-term effects (OECD 216) on the soil nitrogen turnover in both field soils tested at concentrations equivalent to field application rates of 1.8 kg BAS 516 00 F/ha (corresponding to 0.12 kg pyraclostrobin/ha and 0.48 kg boscalid/ha) and ten-fold that rate (i.e. 18 kg BAS 516 00 F/ha).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).

Test species: Biologically active agricultural soils: 1) loamy sand: pH 6.9, 1.06% C_{org}, 40.8% WHC. 2) loamy silt: pH 6.5, 2.78% C_{org}, 48.2% WHC.

B. STUDY DESIGN

Test design: Determination of the N-transformation in soil enriched with lucerne meal (concentration in soil 0.5%). Comparison of test item treated soil with a non-treated soil and a reference item treated soil. Three replicates per treatment and concentration. NH_4-nitrogen formed from organically bound nitrogen and NO_3-nitrogen from the nitrification process was determined by using calibrated ion-selective electrodes connected to an Orion expandable ion analyzer EA 940. Sampling scheme: 0, 14, 28 and 56 days after treatment, aliquots were withdrawn and subjected to the measurement.

Test concentrations: Control, 2.4 mg BAS 516 00 F per kg dry soil (corresponding to an application rate of 1.8 kg BAS 516 00 F/ha) and 24 mg BAS 516 00 F per kg soil (corresponding to an application rate of 18 kg BAS 516 00 F/ha) and reference item. The reference item was applied at a rate of 6.7 mg Dinoterb/kg dry soil (corresponding to an application rate of 5.0 kg Dinoterb/ha). Test concentrations related to a soil depth of 5 cm and a soil density of 1.5 g/cm^3.

Reference item: Herbogil liquide (Dinoterb, 250 g/L).

Test conditions: Soil moisture: 40% (loamy sand soil) to 60% (loamy silt soil) of its water holding capacity. Soil samples were incubated at 20°C ± 2°C while stored in glass bottles.

Statistics: Descriptive statistics.

II. RESULTS AND DISCUSSION

No adverse effects of BAS 516 00 F on nitrogen transformation could be observed in both soils at both tested rates (single and ten-fold application rate) after 28 days (loamy silt soil) and 56 days (loamy sand soil). The results are summarized in Table 10.5-5.

Table 10.5-5: Effects of BAS 516 00 F on soil micro-organisms (nitrogen transformation) on days 14 and 28 of incubation (additionally on day 56 for the loamy sand soil)

Soil (days)	Control	2.4 mg BAS 516 00 F/kg dry soil (equivalent to 1.8 kg/ha)		24 mg BAS 516 00 F/kg dry soil (equivalent to 1.8 kg/ha)	
	NO_3-N [mg/100 g dry soil]	NO_3-N [mg/100 g dry soil]	% Deviation from control [1)]	NO_3-N [mg/100 g dry soil]	% Deviation from control [1)]
Loamy sand (14 d)	1.88	2.87	+52.69	3.31	+75.97
Loamy sand (28 d)	3.39	4.10	+21.03	4.65	+37.26
Loamy sand (56 d)	4.99	4.69	-5.93	5.21	+4.42
Loamy silt (14 d)	7.83	7.70	-1.73	8.31	+6.07
Loamy silt (28 d)	8.54	8.44	-1.16	8.22	-3.73

[1)] Based on NO_3-nitrogen production; - = inhibition; + = stimulation.

A clear effect of the reference item Dinoterb was observed in both soils (54 and 29% increase).

III. CONCLUSION

Based on the results of this study BAS 516 00 F caused no long-term effects (OECD 216) on the soil nitrogen turnover in both field soils tested at concentrations equivalent to field application rates of 1.8 kg BAS 516 00 F/ha (corresponding to 0.12 kg pyraclostrobin/ha and 0.48 kg boscalid/ha) and ten-fold that rate (i.e. 18 kg BAS 516 00 F/ha).

Report:	CP 10.5/2 Wachter S., 2001c Assessment of the side effects of BAS 516 00 F on the activity of the soil microflora; short-term respiration 2001/1005960
Guidelines:	BBA VI 1-1 (1990)
GLP:	yes (certified by Ministerium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Executive Summary

The effect of BAS 516 00 F on carbon transformation was investigated in the field on a loamy sand soil and a loamy silt soil.

BAS 516 00 F was applied to samples of the soil, in a laboratory, at nominal application rates of 2.4 mg/kg and 24 mg/kg of dry soil. BAS 516 00 F treated soils and untreated controls were incubated at 20 ± 2°C in the dark for 28 days. Three replicate samples of each treatment were removed for analysis of carbon transformation (oxygen consumption), using an OxiTop® system, 0, 14 and 28 days after application.

No adverse effects of BAS 516 00 F on C-transformation could be observed in both soils at both tested rates (single and ten-fold application rate) after 28 days.

Based on the results of this study BAS 516 00 F caused no long-term effects (OECD 217) on the soil respiration in both field soils tested at concentrations equivalent to field application rates of 1.8 kg BAS 516 00 F/ha (corresponding to 0.48 kg boscalid/ha and 0.12 kg pyraclostrobin/ha) and ten-fold that rate (i.e. 18 kg BAS 516 00 F/ha).

I. MATERIAL AND METHODS

A. MATERIALS

Test item:	BAS 516 00 F; batch no. 2000-2; content of a.s.: boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%); pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%).
Test species:	Biologically active agricultural soils: 1) loamy sand: pH 6.9, 1.06% C_{org}, 40.8% WHC; 2) loamy silt: pH 6.5, 2.78% C_{org}, 48.2% WHC.

B. STUDY DESIGN

Test design:	Determination of C-transformation in soil after addition of glucose. Comparison of test item treated soil with a non-treated and a reference item treated soil. Three replicates per treatment and concentration. An OxiTop® system was used to measure the CO_2 production over a period of maximum 24 hours at different sampling intervals. Sampling scheme: 0, 14 and 28 days after treatment, aliquots were withdrawn and subjected to the measurement.
Test concentrations:	Control, 2.4 mg BAS 516 00 F per kg dry soil (corresponding to an application rate of 1.8 kg BAS 516 00 F/ha), and 24 mg BAS 516 00 F per kg soil (corresponding to an application rate of 18 kg BAS 516 00 F/ha) and reference substance. The reference item was applied at a rate of 6.7 mg dinoterb/kg dry soil (corresponding to an application rate of 5.0 kg dinoterb/ha). Test concentrations related to a soil depth of 5 cm and a soil density of 1.5 g/cm^3.
Reference item:	Herbogil liquide (dinoterb, 250 g/L).
Test conditions:	Soil moisture: 40% (loamy sand soil) to 60% (loamy silt soil) of its water holding capacity. Soil samples were incubated at 20°C ± 2°C while stored in glass bottles.
Statistics:	Descriptive statistics.

II. RESULTS AND DISCUSSION

No adverse effects of BAS 516 00 F on C-transformation could be observed in both soils at both tested rates (single and ten-fold application rate) after 28 days (see Table 10.5-6).

Table 10.5-6: Effects of BAS 516 00 F on soil micro-organisms (carbon transformation) on days 14 and 28 of incubation

Soil (days)	Control	2.4 mg BAS 516 00 F/kg dry soil (equivalent to 1.8 kg/ha)		24 mg BAS 516 00 F/kg dry soil (equivalent to 1.8 kg/ha)	
	O_2 consumption [mg/h/100 g dry soil]	O_2 consumption [mg/h/100 g dry soil]	% Deviation from control [1)]	O_2 consumption [mg/h/100 g dry soil]	% Deviation from control [1)]
Loamy sand (14 d)	0.43	0.41	-5.17	0.39	-10.41
Loamy sand (28 d)	0.44	0.43	-1.99	0.43	-1.60
Loamy silt (14 d)	2.33	2.12	-9.02	2.15	-8.05
Loamy silt (28 d)	1.84	1.71	-6.79	1.57	-14.53

[1)] Based on O_2 consumption; - = inhibition; + = stimulation

The reference item dinoterb produced in both soils the expected level of effect (26 and 16% inhibition).

III. CONCLUSION

Based on the results of this study, BAS 516 00 F caused no long-term effects (OECD 217) on the soil respiration in both field soils tested at concentrations equivalent to field application rates of 1.8 kg BAS 516 00 F/ha (corresponding to 0.48 kg boscalid/ha and 0.12 kg pyraclostrobin/ha) and ten-fold that rate (i.e., 18 kg BAS 516 00 F/ha).

CP 10.6 Effects on terrestrial non-target higher plants

The new representative formulation BAS 516 07 F was not evaluated within a previous Annex I inclusion process. It is a water dispersible granule (WG) containing 67 g/kg pyraclostrobin and 267 g/kg boscalid.

Endpoints from two studies with the new representative formulation BAS 516 07 F are used for the risk assessment on non-target higher plants (see Table 10.6-1).

Table 10.6-1: Ecotoxicological endpoints for non-target higher plants

Test substance	Test system	Test species	EU agreed endpoints	Endpoints used in risk assessment
BAS 516 07 F	Vegetative vigor	Carrot, lettuce, oilseed rape, cabbage, soybean, tomato, onion, ryegrass, wheat and maize	--	ER_{50} > 8.0 kg/ha
BAS 516 07 F	Seedling emergence	Carrot, lettuce, oilseed rape, cabbage, soybean, tomato, onion, ryegrass, wheat and maize	--	ER_{50} > 8.0 kg/ha

Toxicity

Studies on potential effects of BAS 516 07 F on vegetative vigour and seedling emergence have been carried out with ten plant species. Furthermore, a study on vegetative vigour of six plant species was conducted with the minor change formulation BAS 516 00 F (for the detailed composition of both products please refer to Document JCP 1.4.1). In conclusion there were no unacceptable effects on vegetative vigour and seedling emergence at rates up to and including 8.0 kg BAS 516 07 F/ha for all ten species and no unacceptable effects on vegetative vigour up to and including 5.4 kg BAS 516 00 F/ha for all six species tested (the latter study given only for completeness and not being used in the risk assessment). Further details of the studies are given in M-CP 10.6.2.

Table 10.6-2: Summary of effects on terrestrial non-target plants following exposure to BAS 516 07 F

Test substance	Test species	Test system	ER_{50} [kg/ha]	Reference (BASF DocID)
BAS 516 07 F [1)]	Carrot, sunflower, pea, cabbage, onion, oat	Vegetative vigor	> 5.4	2001/1005953
BAS 516 07 F	Carrot, lettuce, oilseed rape, cabbage, soybean, tomato, onion, ryegrass, wheat and maize	Vegetative vigor	> 8.0	2014/1010836
BAS 516 07 F	Carrot, lettuce, oilseed rape, cabbage, soybean, tomato, onion, ryegrass, wheat and maize	Seedling emergence	> 8.0	2014/1010835

1) Test was carried out with BAS 516 00 F, which is a minor change formulation of BAS 516 07 F (the detailed composition of both products is given in Document JCP 1.4.1).

Exposure

Table 10.6-3: Critical use pattern

Crop	Application time (BBCH code)	Number of applications	Interval [d]	Application rate per treatment		
				Boscalid [g a.s./ha]	Pyraclostrobin [g a.s./ha]	BAS 516 07 F [g/ha]
potatoes	51 - 89	4	10	67	17	250

Effects on non-target plants are of concern in the off-field environment, where they may be exposed to spray drift. The amount of spray drift reaching off-crop habitats is calculated using the 90th percentile estimates derived by the BBA [*BBA (2000) Bundesanzeiger Jg. 52 (Official Gazette), Nr 100, S. 9879-9880 (25.05.2000) Bekanntmachung über die Abtrifteckwerte, die bei der Prüfung und Zulassung von Pflanzenschutzmitteln herangezogen werden.*] from the spray-drift predictions of Ganzelmeier & Rautmann (2000) [*Ganzelmeier H., Rautmann D. (2000) Drift, drift-reducing sprayers and sprayer testing. Aspects of Applied Biology 57, 2000, Pesticide Application*]. Only a single application was considered, because factors like plant growth will reduce residues per unit area between multiple applications.
For a single application to vegetables (i.e. potatoes), 2.77% of the application rate was assumed to reach areas at 1 m from the edge of the crop (worst-case scenario). The highest single application rate of BAS 516 07 F is 0.250 kg product/ha, giving a maximum off-field predicted environmental rate ($PER_{off\text{-}field}$) of 0.007 kg product/ha.

Risk assessment for terrestrial non-target higher plants

BAS 516 07 F is a fungicide and therefore this product is not expected to have any significant herbicidal activity. Profiling studies of the effects on post- and pre-emergence of non-target higher plants were conducted and showed no effects on any of ten species tested at rates up to and including 8.0 kg BAS 516 07 F/ha.

According to the Terrestrial Guidance Document [*Anonymous (2002b). Guidance Document on terrestrial ecotoxicology under council directive 91/414/EEC. SANCO/10329/2002. 17 October 2002*], the risk to non-target plants should be considered acceptable if less than 50% effect on all ten species is seen at the maximum single application rate. Less than 50% effect on vegetative vigor and seedling emergence were observed on all tested species at the highest tested rate of 8.0 kg BAS 516 07 F/ha. The calculated maximum $PER_{off\text{-}field}$ of 0.007 kg product/ha is far below these test rates.

In conclusion, BAS 516 07 F poses no unacceptable risk to terrestrial non-target plants in off-crop areas following the intended use in potatoes.

CP 10.6.1 Summary of screening data

Tests on non-target plants have been conducted. The data point is covered by M-CP 10.6.2.

CP 10.6.2 Testing on non-target plants

Report:	CP 10.6.2/1 Oberwalder C., Schmidt O., 2001a BAS 516 00 F: Effects on non-target plants in the greenhouse - A limit test 2001/1005953
Guidelines:	EPA 850.4150, EPA 850.4000, OECD 208 B (Draft 1999), OECD 208 A (Draft 1999), EPA 712-C-96-163
GLP:	no

Executive Summary

In a vegetative vigor test four species of dicotyledonous plants (cabbage, carrot, sunflower, pea) and two species of monocotyledonous plants (oats, onion) were exposed to BAS 516 00 F. Nominal application rates tested were 1.8 and 5.4 kg BAS 516 00 F per ha. Following the application, the plants were cultivated for 14 days under greenhouse conditions. Assessment of phytotoxicity was carried out 7 and 14 days after application. Fresh weight was determined at study termination 14 DAA.

After treatment with BAS 516 00 F slight injuries could be seen in carrot plants (13% at 5.4 kg/ha) at study termination. Besides that, no clearly treatment related or only negligible visible phytotoxic effects were observed in the plant species tested. For all plant species the plant weight was at the same level as the weight of the control plants. No statistically significant differences were observed. Hence the observed plant damages were without impact on plant growth.

Based on the results of this study it can be concluded that BAS 516 00 F has only negligible phytotoxic potential to terrestrial non-target plants if applied at a rate of 5.4 kg BAS 516 00 F/ha. The ER_{50} value for all plant species is > 5.4 kg BAS 516 00 F/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 00 F; batch no. 2000-2; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.6% (nominal 6.7%); boscalid (BAS 510 F, Reg. No. 300 355): 27.9% (nominal 26.7%).

Plant species: Oats *Avena sativa*; onion *Allium cepa*; cabbage *Brassica oleracea*; pea *Pisum sativum*; carrot *Daucus carota*; sunflower *Helianthus annuus*.

B. STUDY DESIGN

Test design: Limit test; three treatment groups: two treatment rates plus a water treated control; 4 replicates/treatment group; 1 pot/replicate, 3-5 plants per pot (species dependent); greenhouse cultivation; BAS 516 00 F was applied post-emergence at growth stage BBCH 11-14 using a laboratory spray cabin at a water rate of 400 L/ha. Following the application, the plants were cultivated for 14 days in the greenhouse. Assessments for phytotoxicity (e.g. scorch, stunting, deformations) were done approximately 7 days after application (DAA) and 14 DAA. Immediately after the 14 DAA assessment the fresh weight of the plant biomass above ground was determined.

Test rates: 1.8 kg BAS 516 00 F/ha (equivalent to 121 g Pyraclostrobin/ha and 481 g Boscalid/ha) and 5.4 kg BAS 516 00 F/ha (equivalent to 362 g Pyraclostrobin/ha and 1442 g Boscalid/ha).

Test conditions: Greenhouse conditions: temperatures between 14°C and maximum 31°C; humidity: about 80%; photoperiod: 16 h light, 8 h dark; additional light when outdoor illumination was less than 4500 lux.

Statistics: Descriptive statistics, HSD test($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

After treatment with BAS 516 00 F slight injuries could be seen in carrot plants (13% at 5.4 kg/ha) at study termination. Besides that, no clearly treatment related or only negligible visible phytotoxic effects were observed in the plant species tested. For all plant species the plant weight was at the same level as the weight of the control plants. No statistically significant differences were observed (HSD test; $\alpha = 0.05$). Hence the observed plant damages were without impact on plant growth (see Table 10.6.2-1 below).

Table 10.6.2-1: Effect of BAS 516 00 F on plant biomass and plant condition (visible damage) 14 DAA

Treatment	Cabbage	Carrot	Sunflower	Pea	Oats	Onion
Mean plant weight [% of control]						
Control	100.0	100.0	100.0	100.0	100.0	100.0
1.8 kg/ha	98.1	92.0	86.8	100.6	99.8	99.4
5.4 kg/ha	99.1	76.9	100.9	90.6	91.1	138.8
Mean visible damage [% damage compared to control]						
Control	0	0	0	0	0	0
1.8 kg/ha	0	3	8	0	0	0
5.4 kg/ha	1	13	8	1	0	0

III. CONCLUSION

Based on the results of this study it can be concluded that BAS 516 00 F has only negligible phytotoxic potential to terrestrial non-target plants if applied at a rate of 5.4 kg BAS 516 00 F/ha. The ER_{50} value for all plant species is > 5.4 kg BAS 516 00 F/ha.

Report:	CP 10.6.2/2 Stroemel C., Brockmann A., 2014a Effect of BAS 516 07 F on vegetative vigour of ten species of terrestrial plants under greenhouse conditions 2014/1010836
Guidelines:	OECD 227 July 2006, EPA 850.4150, EPA 712-C-011
GLP:	yes (certified by Land Brandenburg Ministerium fuer Umwelt, Gesundheit und Verbraucherschutz, Potsdam, Germany)

Executive Summary

In a vegetative vigor test, six species of dicotyledonous plants (carrot, lettuce, oilseed rape, cabbage, soyabean, tomato) and four species of monocotyledonous plants (onion, rye grass, wheat, maize) were exposed to BAS 516 07 F to evaluate the phytotoxic potential of the test item. BAS 516 07 F was applied post-emergence at BBCH 12 – 14 in a dose-response design at test rates of 0.5, 1.0, 2.0, 4.0 and 8.0 kg BAS 516 07 F /ha. The plants were cultivated for 21 days after application under greenhouse conditions. Assessment of phytotoxicity was done 7, 14 and 21 days after application; plant length and dry weight was determined at study termination.

All tested species showed no phytotoxic symptoms after application of BAS 516 07 F up to and including 8.0 kg/ha. No plant mortality was observed for all tested plant species following the application of BAS 516 07 F up to and including the highest tested rate. No dose response for plant survival could be calculated for all tested species. Plant length was not substantially influenced by BAS 516 07 F up to and including 8.0 kg/ha for all tested plant species. However, a significant reduced plant length of 6% was found for carrot after application of 8.0 kg BAS 516 07 F/ha and between 3 and 5% in all treatments of wheat (except 2.0 kg/ha). Based on the actual data these reduced plant length can be considered as ecologically non-relevant. Therefore, based on expert judgement the NOER for all tested plant species determined to be equal to or higher than the highest testes rate of 8.0 kg BAS 516 07 F/ha. No reduction of plant dry weight was observed for all tested plant species after application of up to and including 8.0 kg BAS 516 07 F/ha.

Based on the results of this study, conducted under worst-case greenhouse conditions, it can be concluded that post-emergence application of BAS 516 07 F with rates up to and including 8.0 kg/ha did not cause adverse effects in terms of phytotoxicity, plant length and plant weight for carrot, lettuce, oilseed rape, cabbage, soybean, tomato, onion, ryegrass, wheat and maize. For all tested species, ER_{50} values for plant survival, plant length and plant weight was > 8.0 kg/ha.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 07 F; batch no. 12-000110; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.7% (nominal 6.7%); boscalid (BAS 510 F, Reg. No. 300 355): 27.1% (nominal 26.7%)

B. STUDY DESIGN

Test species: Carrot (*Daucus carota*), lettuce (*Lactuca sativa*), oilseed rape (*Brassica napus*), cabbage (*Brassica oleracea*), soybean (*Glycine max*), tomato (*Lycopersicon esculentum*), onion (*Allium cepa*), rye grass (*Lolium multiflorum*), wheat (*Triticum aestivum*) and maize (*Zea mays*).

Test design: Rate-response design; 6 treatments (5 test item rates, control) per plant species; 5 replicates per treatment, comprising 1-2 pot with 3 or 8 plants per replicate depending on species at application; BAS 516 07 F was applied post-emergence at BBCH 12 - 14 using a laboratory spray cabin (applied water volume 238 or 236 L/ha); greenhouse cultivation for 21 days after application; assessments of plant damage and plant survival were done 7, 14 and 21 days after application (DAA); Plant length and shoot dry weight was determined at 21 DAA.

Endpoints: NOER, ER_{25}, ER_{50}.

Test rates: Control (tap water), 0.5, 1.0, 2.0, 4.0 and 8.0 kg BAS 516 07 F/ha.

Test conditions: Greenhouse conditions: daily average temperature: 19.6°C to 24.4°C (extremes 11°C and 37°C only for short time); daily mean relative humidity: 37.1% to 74.5% (extremes 14% and 90% relative humidity, mean relative humidity lower than 45% for lettuce, oilseed rape, cabbage, tomato, wheat and maize for some days); photoperiod: day length ≥ 16 hours; additional light supply automatically when outdoor illumination was less than 10 klux.

Statistics: Descriptive statistics. Welch t-test for inhomogeneous variances with Bonferroni adjustment, Dunnett's t-test for homogenous variances.

II. RESULTS AND DISCUSSION

All tested species showed no phytotoxic symptoms after application of BAS 516 07 F up to and including 8.0 kg/ha. No plant mortality was observed for all tested plant species following the application of BAS 516 07 F up to and including the highest tested rate. No dose response for plant survival could be calculated for all tested species. Plant length was not influenced by BAS 516 07 F up to and including 8.0 kg/ha for all tested plant species. A statistically significant reduced plant length of 6% was found for carrot after application of 8.0 kg BAS 516 07 F/ha (Dunnett´s t-test, α=0.05). In wheat all treatments (except 2.0 kg/ha) are indicated as statistically significant different from untreated control with reductions between 3 and 5% (Dunnett´s t-test, α=0.05). Based on the actual data these reduced plant length can be considered as ecologically non-relevant. No negative influence of BAS 516 07 F on plant dry weight was observed for all tested plant species after application of 8.0 kg BAS 516 07 F/ha.

The results are summarized in Table 10.6.2-2 and Table 10.6.2-3.

[1)] Expert judgement

III. CONCLUSION

Based on the results of this study, conducted under worst-case greenhouse conditions, it can be concluded that post-emergence application of BAS 516 07 F with rates up to and including 8.0 kg/ha did not cause adverse effects in terms of phytotoxicity, plant length and plant weight for carrot, lettuce, oilseed rape, cabbage, soybean, tomato, onion, ryegrass, wheat and maize. For all tested species, ER_{50} values for plant survival, plant length and plant weight was > 8.0 kg/ha.

Report:	CP 10.6.2/3 Stroemel C., Brockmann A., 2014b Effect of BAS 516 07 F on seedling emergence and seedling growth of ten species of terrestrial plants under greenhouse conditions 2014/1010835
Guidelines:	OECD 208 (2006), EPA 850.4100, EPA 712-C-012
GLP:	yes (certified by Land Brandenburg Ministerium fuer Umwelt, Gesundheit und Verbraucherschutz, Potsdam, Germany)

Executive Summary

In a seedling emergence test, six species of dicotyledonous plants (carrot, lettuce, oilseed rape, cabbage, soyabean, tomato) and four species of monocotyledonous plants (onion, rye grass, wheat, maize) were exposed to BAS 516 07 F. The test item was applied pre-emergence in a dose-response-design with concentrations 0.5, 1.0, 2.0, 4.0 and 8.0 kg/ha in 234 L water/ha. Following the application, the plants were cultivated for 21 days (28 days for onion and carrot) under greenhouse conditions. Assessments on plant emergence, survival and length were carried out at 7, 14, 21 DAA (14, 21 and 28 DAA for onion and carrot) and on dry weight at 21 DAA (28 DAA for onion and carrot).

None of the tested plant species showed phytotoxic symptoms after application up to and including 8.0 kg BAS 516 07 F/ha pre emergence. No reduction of plant length was observed for all tested plant species following the application of BAS 516 07 F. The statistically significant difference found for oilseed rape at rates of 1.0 kg and 2.0 kg BAS 516 07 F/ha, but not at higher rates can be considered as not treatment related. No negative influence of BAS 516 07 F on plant dry weight was observed for all tested plant species up to and including 8.0 kg BAS 516 07 F/ha.

Based on the results of this study, conducted under worst-case greenhouse conditions, it can be concluded that pre-emergence application of BAS 516 07 F caused no unacceptable adverse effects up to and including the highest rate of 8.0 kg/ha to the seedling emergence and survival of all tested plant species.
The NOER for phytotoxicity of all tested plant species was determined to be ≥ 8.0 kg BAS 516 07 F/ha. The ER_{25} and ER_{50} values for plant length, plant dry weight and seedling emergence were determined to be > 8.0 kg BAS 610 06 F/ha for all tested plant species.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 516 07 F; batch no. 12-000110; content of a.s.: pyraclostrobin (BAS 500 F, Reg. No. 304 428): 6.7% (nominal 6.7%); boscalid (BAS 510 F, Reg. No. 300 355): 27.1% (nominal 26.7%).

B. STUDY DESIGN

Test species: Carrot (*Daucus carota*); lettuce (*Lactuca sativa*); oilseed rape (*Brassica napus ssp. napus*); cabbage *(Brassica oleracea. var. capitata f. alba);* soybean (*Glycine max);* tomato (*Lycopersicon esculentum);* onion *(Allium cepa*); ryegrass *(Lolium multiflorum);* wheat *(Triticum aestivum)*; maize (*Zea mays*)

Test design: Dose-response design; 6 treatment groups (5 test item rates, water-treated control) with 4 replicates; 1-2 pots/replicate with 5 or 10 seeds/pot; greenhouse cultivation; application pre-emergence with 234 L water/ha using a laboratory spray chamber. Following the application, all plants were grown for at least 21 days (28 for onion and carrot). Plant emergence, survival and length were assessed at 7, 14, 21 DAA (14, 21 and 28 DAA for onion and carrot), dry weight at 21 DAA (28 DAA for onion and carrot).

Endpoints: NOER, ER_{25}, ER_{50}.

Test rates: Control (tap water), 0.5, 1.0, 2.0, 4.0 and 8.0 kg BAS 516 07 F/ha.

Test conditions: Greenhouse conditions: daily average temperature ranged from 19.9°C to 24.9°C (extremes ranged from 13°C to 35°C, 35°C for maize and cabbage for one hour at one day, for oilseed rape and wheat for 1 hour at two days); daily mean relative humidity ranged from 36.9% to 59.2% (extremes 14% and 84% relative humidity, mean relative humidity lower than 45% for carrot, oilseed rape, soybean, tomato, onion and wheat at several days); photoperiod: day length ≥ 16 hours; additional light supply automatically when outdoor illumination was less than 10 klux.

Statistics: Descriptive statistics. Dunnett's t-test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

No control mortality > 10% and no other adverse effects on control plants were observed.

None of the tested plant species showed phytotoxic symptoms after application up to and including 8.0 kg BAS 516 07 F/ha pre emergence. No reduction of plant length was observed for all tested plant species following the application of BAS 516 07 F. The statistically significant difference found for oilseed rape at rates of 1.0 kg and 2.0 kg BAS 516 07 F/ha, but not at higher rates can be considered as not treatment related (Dunnett's t-test, $\alpha = 0.05$). No negative influence of BAS 516 07 F on plant dry weight was observed for all tested plant species up to and including 8.0 kg BAS 516 07 F/ha. The results are summarized in Table 10.6.2-4 and Table 10.6.2-5.

* Statistically significantly different to the untreated control (Dunnett´s t-test, α=0.05)

Table 10.6.2-5: NOER, ER_{25} and ER_{50} of BAS 516 07 F for non-target plants 21 DAA (28 DAA for onion and carrot)

Endpoints [kg/ha]	Carrot	Lettuce	Oilseed rape	Cabbage	Soybean	Tomato	Onion	Ryegrass	Wheat	Maize
Plant survival										
NOER	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0
Plant length										
NOER	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0
ER_{25}	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0
ER_{50}	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0
Plant dry weight										
NOER	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0
ER_{25}	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0
ER_{50}	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0
Seedling emergence										
NOER	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0	≥ 8.0
ER_{25}	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0
ER_{50}	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0	> 8.0

III. CONCLUSION

Based on the results of this study, conducted under worst-case greenhouse conditions, it can be concluded that pre-emergence application of BAS 516 07 F caused no unacceptable adverse effects up to and including the highest rate of 8.0 kg/ha to the seedling emergence and survival of all tested plant species.
The NOER for phytotoxicity of all tested plant species was determined to be ≥ 8.0 kg BAS 516 07 F/ha. The ER_{25} and ER_{50} values for plant length, plant dry weight and seedling emergence were determined to be > 8.0 kg BAS 610 06 F/ha for all tested plant species.

CP 10.6.3 Extended laboratory studies on non-target plants

Further tests on non-target plants are not triggered.

CP 10.6.4 Semi-field and field tests on non-target plants

Further tests on non-target plants are not triggered.

CP 10.7 Effects on other terrestrial organisms (flora and fauna)

Further studies are not triggered.

CP 10.8 Monitoring data

According to the knowledge of the applicant, there are currently no monitoring studies available, which are assessing ecotoxicological effects of BAS 516 07 F.

Table of Contents

CP 12 CLASSIFICATION AND LABELLING OF THE PLANT PROTECTION PRODUCT

Physico-chemical properties

Table 12-1: Physico-chemical data relevant for classification of BAS 516 07 F

Parameter	Findings (triggered risk phrase)	Reference (BASF DocID)
Explosive properties	The product has no explosive properties.	2005/1011601 2011/1065573
Oxidizing properties	The product has no oxidizing properties.	2005/1011601 2011/1065573
Flammability	Not easily flammable Auto-ignition temperature: 246°C	2005/1011601 2011/1065573
Content of hydrocarbons	< 10 %	Doc JCP 1.4.1
Viscosity	Not applicable	-
Surface tension	65.5 mN/m at 0.01%, 46.0 mN/m at 1.0% (both at 20°C)	2004/1024836

Remarks:
No classification is triggered for BAS 516 07 F by its physical/chemical properties.

Toxicology

Table 12-2: Toxicological data relevant for classification of BAS 516 07 F

Study type/species	Results	Classification		Reference
		EU Dir. 67/548/EEC 2001/59/EC	Reg. EC 1272/2008 (CLP)	(BASF DocID)
Acute oral toxicity, rat	LD_{50} > 2000 mg/kg bw	-	-	2008/1004838
Acute dermal toxicity, rat	LD_{50} > 2000 mg/kg bw	-	-	2001/1003723
Acute inhalation toxicity, rat	LC_{50} > 5.6 mg/L (both sexes)	-	-	2001/1001824
Skin irritation, rabbit	Non-irritating to rabbit skin	-	-	2007/1056989
Eye irritation, rabbit	Non-irritating to rabbit eye	-	-	2007/1056988
Skin sensitization LLNA assay, mouse	Non-sensitizing	-	-	2014/1001403

Remarks:
The acute dermal and inhalation toxicity studies have been conducted with BAS 516 00 F, a formulation that is very similar to BAS 516 07 F. Therefore studies performed with BAS 516 00 F are considered to be also valid for BAS 516 07 F. Information on the detailed composition of both formulations can be found in Doc JCP 1.4.1.
BAS 516 07 F is of low toxicity by the oral, dermal and inhalation route of exposure. It is non-irritant to the skin and the eye and does not cause skin sensitization.
Neither the classification of the active substances nor the classification of individual co-formulants has any further influence on the classification of the product BAS 516 07 F. Detailed information about the co-formulants is given in Documents JCP and JGH.

Ecotoxicology/Environment

Table 12-3: Ecotoxicological data relevant for classification of BAS 516 07 F

Study type/species	Results	Classification		Reference
		EU Dir. 67/548/EEC 2001/59/EC	Reg. EC 1272/2008 (CLP)	(BASF DocID)
Rainbow Trout (96 h)	LC_{50} = 0.088 mg/L	R50	H400	2000/1018726
D. magna (48 h)	EC_{50} = 0.120 mg/L	R50	H400	2007/1008605
Green alga (72 h)	E_RC_{50} = 10.8 mg/L	R52	-	2009/1117877
Biodegradation	Not readily biodegradable	R53	H410	1999/10655* 1999/10290**

* study conducted with pyraclostrobin
** study conducted with boscalid

Remarks:
The acute toxicity study in rainbow trout has been conducted with BAS 516 00 F, a formulation that is very similar to BAS 516 07 F. Therefore studies performed with BAS 516 00 F are considered to be also valid for BAS 516 07 F. Information on the detailed composition of BAS 516 00 F and BAS 516 07 F can be found in Doc JCP 1.4.1.
The statement on biodegradation has been derived from the properties of the active substances (both, pyraclostrobin and boscalid are not readily biodegradable). Neither the classification of the active substances nor the classification of individual co-formulants has any further influence on the classification of the product BAS 516 07 F. Detailed information about the co-formulants is given in Documents JCP and JGH.

Pyraclostrobin

DOCUMENT A

Statement of the context in which the dossier is submitted

Compiled by:

[redacted]

BASF SE
Agricultural Center
P.O. Box 120
67114 Limburgerhof
Germany

Telephone
Telefax
E-mail [redacted]

A supplementary dossier (Documents A to O) is herewith submitted as an application for the renewal of approval in accordance with Regulation (EC) No. 1107/2009 and Regulation (EU) No. 844/2012 for the active substance:

Pyraclostrobin (BAS 500 F)

Common name and chemical identity are shortly summarized below:

Common name:	Pyraclostrobin
Chemical names	
IUPAC:	Methyl N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxymethyl}phenyl)-(N-methoxy)carbamate
CA:	Carbamic acid, [2-[[[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxy]methyl]phenyl]methoxy-, methyl ester
CAS:	175013-18-0
CIPAC:	657
Empirical formula:	$C_{19}H_{18}ClN_3O_4$
Structural formula:	Molecular mass:	387.8 g/mol

Pyraclostrobin is a broad spectrum fungicide, which is active against fungal development stages both on the plant surface and within the tissues. It has a protective as well as an eradicative/curative action. Pyraclostrobin belongs to the group of active substances which is collectively known as strobilurins. The biochemical mode of action of the strobilurins is the inhibition of mitochondrial respiration.
In addition to the fungicidal effects plant physiology is also affected by the application of pyraclostrobin. Among these effects higher yield and better product quality in absence of diseases, improvement of the assimilation rate and delayed senescence have been reported. Furthermore, some studies showed better stress tolerance to abiotic stresses (e.g. drought or frost).
Pyraclostrobin is used world-wide in a large variety of crops including cereals, oilseeds, legumes, fruits and vegetables.

Pyraclostrobin was included in Annex I of Directive 91/414/EEC on 1 June 2004 (entry into force) under Inclusion Directive 2004/30/EC for the use as fungicide. This use was amended on 22 April 2009 (entry into force) by Inclusion Directive 2009/25/EC to the use as fungicide or plant growth regulator. Both Annex I inclusion decisions were based on the same endpoints and provisions.

The Review Report (Pyraclostrobin - SANCO/1420/2001-Final) is dated 08 September 2004 and provides endpoints agreed during first inclusion evaluation (Appendix II to the Review Report).

Member States were required to pay particular attention to the following areas:
- should pay particular attention to the protection of aquatic organisms, especially fish,
- should pay particular attention to the protection of terrestrial arthropods and earthworms

Due to the improvement of physical and chemical properties, the representative formulation will be changed to a 200 g/L EC solo formulation (coded BAS 500 06 F) representing the use in important and widely grown "row crops" (cereals and maize). In addition a second (new) representative formulation (coded BAS 516 07 F and containing boscalid as second active substance) has been chosen to represent the many uses in "specialty crops" were typically lower application rates are used.

The intended maximum application rate is 1.25 L product/ha for the EC solo formulation BAS 500 06 F corresponding to 250 g a.s./ha and 0.25 kg product/ha for the WG formulation BAS 516 07 F corresponding to 17 g pyraclostrobin/ha.

BASF SE makes this submission in good faith and is looking forward to working with Germany as Rapporteur Member State, as outlined in Commission Regulation (EU) No. 686/2012.

Pyraclostrobin is an existing active substance marketed by BASF SE. This application is submitted for the renewal of approval of pyraclostrobin in accordance with Regulation (EU) No. 1107/2009. BASF SE is the only applicant as stated in a letter of the Rapporteur Member State Germany (dated March 7, 2014) and owner of a complete data package regarding the active substance.

In agreement with the Rapporteur Member State (Germany) in this document general information is provided that is recommended to be contained on national product labels for BAS 500 06 F and BAS 516 07 F with focus on the representative uses. Furthermore, please consider that on the specific country labels additional detailed guidance for the use of the product is given considering the national requirements. These instructions will be covered by the dRRs to be submitted for the re-registration of the plant protection products BAS 500 06 F and BAS 516 07 F following the renewal of approval for the active substance pyraclostrobin.

General draft product label (”master label”) for BAS 500 06 F

Emulsifiable concentrate (EC) containing 200 g/L pyraclostrobin.

Classification and labelling

Causes serious eye irritation.
Causes skin irritation.
Harmful if inhaled.
Harmful if swallowed.
May cause an allergic skin reaction.
May be fatal if swallowed and enters airways.
Very toxic to aquatic life.
Very toxic to aquatic life with long lasting effects.
To avoid risks to human health and the environment, comply with the instructions for use.

Only for use as agricultural fungicide.

Instructions for the use in cereals

BAS 500 06 F is a fungicide with protectant and curative properties for disease control in winter and spring wheat, winter and spring barley, oats, rye and triticale.

Time of application:
Apply BAS 500 06 F at the start of foliar disease attack. Applications can be made starting from mid tillering (BBCH 25) until end of flowering (latest application at BBCH 69). The recommended spray interval is 21 days depending on disease pressure and the general spray program strategy.

Maximum number of applications: 2

Maximum individual application rate: 1.25 L per ha

Water volume: 100 – 400 L of water per ha

Instructions for the use in maize

BAS 500 06 F is a fungicide with protectant properties for disease control in maize (forage and grain).

Time of application:
Best results are achieved by an application of BAS 500 06 F before the start of foliar disease attack or at very early signs of infection. Application can be made after beginning of stem elongation (BBCH 30) and up to and including mid-flowering (BBCH 65).

Maximum number of applications : 1

Maximum individual application rate: 1 L per ha

Water volume: 100 – 400 L of water per ha

Resistance management
The general spray program strategy has to consider the use of other products providing a different mode of action.

Succeeding crops
No minimum waiting periods needs to be considered for succeeding crops.

Re-entry
Re-entry is possible after the spray deposits on the crops have dried given the worker is wearing adequate work clothing.

Personal precautions
Do not breathe vapour or spray. Use personal protective clothing. Avoid contact with skin, eyes and clothing. During use do not eat, drink or smoke. Hands should be washed thoroughly with soap and water before breaks.

Environmental precautions
Do not discharge into subsoil or soil. Do not discharge into drains, surface waters or ground-water.

Storage
Segregate from food and animal feed. Protect the product from heat, frost and direct sunlight. Storage temperature should not exceed 40 °C. Ensure ventilation of stores.

Mixing and spraying
Do not prepare more spray solution than required. Fill the tank half with clean water and start agitation. Shake container, add the required amount of product and the necessary additional amount of water. Continue agitation until spraying is complete. When tank mixes are used, add each product separately and consider any specific instructions given e.g. for the order of mixing. During spraying, buffer zones to surface water have to be respected.

Compatibility
BAS 500 06 F is at least compatible with the following products:
Basagran DP, Biathlon, Duplosan DP, Duplosan KV, Sumicidin Alpha, Fastac, Cycocel 720, Terpal C, Capalo, Adexar, Champion, Osiris, Diamant

Disposal
Any surplus spray solution containing BAS 500 06 F should be diluted with water at a ratio of 1:10 and sprayed onto the previously treated area according to the use instructions.
Empty packaging should be triple rinsed. The rinsing water must be added to the spray liquid.
Empty and rinsed containers should be delivered to local container collection stations or must be disposed according to local regulations.
The spray equipment should be cleaned thoroughly immediately after use by draining the system completely and by rinsing spray tank, boom and nozzles two to three times with clean water.

General draft product label (”master label”) for BAS 516 07 F

Water dispersible granule (WG) containing 6.7% w/w pyraclostrobin and 26.7% w/w boscalid.

Classification and labelling

Very toxic to aquatic life.
Very toxic to aquatic life with long lasting effects.
To avoid risks to human health and the environment, comply with the instructions for use.

Only for use as agricultural fungicide.

Instructions for the use in potatoes

BAS 516 07 F is a fungicide used in potatoes mainly for the control of Alternaria spp..

Time of application:
Apply BAS 516 07 F at the start of disease attack with Alternaria spp.. The last application should be done latest 3 days before harvest. The recommended spray interval is about 10 – 21 days depending on disease pressure and the general spray program strategy.

Maximum number of applications: 4

Maximum individual application rate: 0.25 kg per ha

Water volume: 150 – 400 L of water per ha

Resistance management

The general spray program strategy has to consider the use of other products providing a different mode of action.

Succeeding crops

No minimum waiting periods needs to be considered for succeeding crops.

Re-entry
Re-entry is possible after the spray deposits on the crops have dried given the worker is wearing adequate work clothing.

Personal precautions
Avoid dust formation. Use personal protective clothing. Avoid contact with skin, eyes and clothing. During use do not eat, drink or smoke. Hands should be washed thoroughly with soap and water before breaks.

Environmental precautions
Do not discharge into subsoil or soil. Do not discharge into drains, surface waters or ground-water.

Storage
Segregate from food and animal feed. Protect the product from heat, moisture and direct sunlight. Storage temperature should not exceed 40 °C. Ensure ventilation of stores.

Mixing and spraying
Do not prepare more spray solution than required. Fill the tank half with clean water and start agitation. Add the required amount of product and the necessary additional amount of water. Continue agitation until spraying is complete. When tank mixes are used, add each product separately and consider any specific instructions given e.g. for the order of mixing. During spraying, buffer zones to surface water have to be respected.

Compatibility
BAS 516 07 F is at least compatible with the following products:
Acrobat Plus, Polyram, Delan, Kumulus, Decis, Fastac, Stratos Ultra, Perfekthion, Rovral, Alverde, Forum, Aramo

Disposal
Any surplus spray solution containing BAS 516 07 F should be diluted with water at a ratio of 1:10 and sprayed onto the previously treated area according to the use instructions.
Empty packaging should be triple rinsed. The rinsing water must be added to the spray liquid.
Empty and rinsed containers should be delivered to local container collection stations or must be disposed according to local regulations.
The spray equipment should be cleaned thoroughly immediately after use by draining the system completely and by rinsing spray tank, boom and nozzles two to three times with clean water.

E-mail

The intended use patterns (GAPs) of the representative crops for which data and risk assessments will be provided in the supplemental dossier are already registered in several EU Member States for BAS 500 06 F and BAS 516 07 F. The intended maximum application rate is 1.25 L product/ha for the EC solo formulation BAS 500 06 F corresponding to 250 g a.s./ha and 0.25 kg product/ha for the WG formulation BAS 516 07 F containing pyraclostrobin and boscalid as active substances, corresponding to 17 g pyraclostrobin/ha.

In the following tables an overview of the GAPs is provided for all representative uses either already registered, or submitted and still under evaluation by the authorities, the latter being marked by "*". Tables showing only the already registered representative uses can be found in M-CP 3 of the supplemental product dossiers.

Germany

Telephone [redacted]
Telefax
E-mail

In agreement with the RMS Germany not all use patterns (GAPs) of all pyraclostrobin containing products currently registered in the EU are shown in this document, because a very long list of several hundred GAPs for all products, countries and crops will be not helpful for the evaluation of pyraclostrobin, which is in general based on selected representative uses, whose GAPs are shown in detail in Document D1.

However, in the following tables all registered crops or crop groups are listed for all currently registered products containing pyraclostrobin. [redacted] For each product-crop combination all EU member states with currently valid registrations are listed. Furthermore information is given on the general application method and whether a field, greenhouse or in-door use is registered.

Current practice is not known to considerably and/or consistently deviate from the registered uses as described on the approved labels. Consequently it is not necessary to compare the registered and actual use patterns in a table.

REGISTERED USES

PPP trade name: **Cabrio** **PPP code:** **BAS 500 00 F**

Formulation type: **EC (emulsifiable concentrate)**

Conc. of as: **250 g/L pyraclostrobin**

1	2	3	4	5	6
Use-No.	**Member state(s)**	**Crop or crop group**	**F G or I**	**Application method**	**Remarks:**
1	DE	Grapes	F	Spraying	[redacted]

PPP trade name: **Cabrio Olivio WG, Eland, Insignia** **PPP code:** **BAS 500 02 F**

Formulation type: **WG (water dispersible granules)**

Conc. of as: **20 % pyraclostrobin**

1	2	3	4	5	6
Use-No.	**Member state(s)**	**Crop or crop group**	**F G or I**	**Application method**	**Remarks:**
1	IT	Olives	F	Spraying	[redacted]
2	BE, FR, IT, LU, UK	Turf	F	Spraying	

PPP trade name: **Comet Pro, Comet 20 EC, Comet 200, Envelis 20 EC, Modem 200, Retengo, Retengo New, Solaram 200**

PPP code: **BAS 500 06 F**

Formulation type: **EC (emulsifiable concentrate)**

Conc. of as: **200 g/L pyraclostrobin**

1	2	3	4	5	6
Use-No.	**Member state(s)**	**Crop or crop group**	**F G or I**	**Application method**	**Remarks:**
1	DK, EE, ES, FI, FR, GR, IE, IT, LT, LV, PT, SE, UK	Cereals	F	Spraying	[redacted]
2	BG, GR, IT, SE	Maize (forage and grain)	F	Spraying	
3	FI, SE	Sugar beets	F	Spraying	

PPP trade name: **Cabrio, Cabrio EC, Comet 250 EC, Tucana, Varen**

PPP code: **BAS 500 13 F**

Formulation type: **EC (emulsifiable concentrate)**

Conc. of as: **250 g/L pyraclostrobin**

1	2	3	4	5	6
Use-No.	**Member state(s)**	**Crop or crop group**	**F G or I**	**Application method**	**Remarks:**
1	IT	Pome fruits	F	Spraying	[redacted]
2	ES, IT, PT	Grapes	F	Spraying	
3	IT	Cereals	F	Spraying	

PPP trade name: **Comet, Flyer, Ley, Modem, Platoon 250, Solaram, Tucana, Vivid**

PPP code: **BAS 500 14 F**

Formulation type: **EC (emulsifiable concentrate)**

Conc. of as: **250 g/L pyraclostrobin**

1	2	3	4	5	6
Use-No.	**Member state(s)**	**Crop or crop group**	**F G or I**	**Application method**	**Remarks:**

Germany

Telephone [redacted]
Telefax
E-mail

In agreement with the RMS Germany not all use patterns (GAPs) of all pyraclostrobin containing products intended to be registered in the EU after renewal of approval are shown in this document, because a very long list of several hundred GAPs for all products, countries and crops will be not helpful for the evaluation of pyraclostrobin, which is in general based on selected representative uses, whose GAPs are shown in detail in Document D1.

However, in the following table all crops or crop groups and their corresponding use patterns are listed, which are assumed to potentially represent a critical GAP (worse case) for the risk assessments that needs to be provided for intended product re-registrations following the renewal of approval for the active substance. The information is provided in a format close to the one used in the D1-Document. It is explicitly emphasized that currently not all GAPs for product re-registration are finally decided. Consequently the list of GAPs shown below can only represent the current status and changes are still possible.

Summary of critical GAPs per crop or crop group

1	2	3	4	5	6	7	8	10	11	12	13	14

EU MRLs set for the uses of pyraclostrobin

The list of current EU MRLs for pyraclostrobin (mg/kg) as of May 7, 2014 (source: DG Sanco website http://ec.europa.eu/sanco_pesticides/public/index.cfm?event=substance.resultat&s=1**),** is shown below. The residue definition is pyraclostrobin (parent only) for all matrices. * indicates the lower limit of analytical determination and (ft) that a footnote is given at the end of the table.

Code number	Groups and examples of individual products to which the MRLs apply (a)	Pyraclostrobin (F) EU MRL
100000	1. FRUIT FRESH OR FROZEN NUTS	
110000	(i) Citrus fruit	
110010	Grapefruit (Shaddocks, pomelos, sweeties, tangelo (except mineola), ugli and other hybrids)	1
110020	Oranges (Bergamot, bitter orange, chinotto and other hybrids)	2
110030	Lemons (Citron, lemon, Buddha's hand (Citrus medica var. sarcodactylis))	1
110040	Limes	1
110050	Mandarins (Clementine, tangerine, mineola and other hybrids tangor (Citrus reticulata x sinensis))	1
110990	Others	1
120000	(ii) Tree nuts	
120010	Almonds	0.02*
120020	Brazil nuts	0.02*
120030	Cashew nuts	0.02*
120040	Chestnuts	0.02*
120050	Coconuts	0.02*
120060	Hazelnuts (Filbert)	0.02*
120070	Macadamia	0.02*
120080	Pecans	0.02*
120090	Pine nuts	0.02*
120100	Pistachios	1
120110	Walnuts	0.02*
120990	Others	0.02*
130000	(iii) Pome fruit	0.5
130010	Apples (Crab apple)	0.5
130020	Pears (Oriental pear)	0.5
130030	Quinces	0.5
130040	Medlar	0.5
130050	Loquat	0.5
130990	Others	0.5

Code number	Groups and examples of individual products to which the MRLs apply (a)	Pyraclostrobin (F) EU MRL
140000	(iv) Stone fruit	
140010	Apricots	1
140020	Cherries (Sweet cherries, sour cherries)	3
140030	Peaches (Nectarines and similar hybrids)	0.3
140040	Plums (Damson, greengage, mirabelle, sloe, red date/Chinese date/Chinese jujube (Ziziphus zizyphus))	0.8
140990	Others	0.02*
150000	(v) Berries & small fruit	
151000	(a) Table and wine grapes	
151010	Table grapes	1 (ft)
151020	Wine grapes	2
152000	(b) Strawberries	1.5
153000	(c) Cane fruit	
153010	Blackberries	3
153020	Dewberries (Loganberries, tayberries, boysenberries, cloudberries and other Rubus hybrids)	2
153030	Raspberries (Wineberries, arctic bramble/raspberry, (Rubus arcticus), nectar raspberries (Rubus arcticus x Rubus idaeus))	3
153990	Others	2
154000	(d) Other small fruit & berries	
154010	Blueberries (Bilberries)	4
154020	Cranberries (Cowberries/redbilberries (V. vitis-idaea))	3
154030	Currants (red, black and white)	3
154040	Gooseberries (Including hybrids with other Ribes species)	3
154050	Rose hips	3
154060	Mulberries (Arbutus berry)	3
154070	Azarole (mediteranean medlar) (Kiwiberry (Actinidia arguta))	3
154080	Elderberries (Black chokeberry/appleberry, mountain ash, buckthorn/sea sallowthorn, hawthorn, serviceberries, and other treeberries)	3
154990	Others	3

Code number	Groups and examples of individual products to which the MRLs apply (a)	Pyraclostrobin (F) EU MRL
160000	(vi) Miscellaneous fruit	
161000	(a) Edible peel	0.02*
161010	Dates	0.02*
161020	Figs	0.02*
161030	Table olives	0.02*
161040	Kumquats (Marumi kumquats, nagami kumquats, limequats (Citrus aurantifolia x Fortunella spp.))	0.02*
161050	Carambola (Bilimbi)	0.02*
161060	Persimmon	0.02*
161070	Jambolan (java plum) (Java apple/water apple, pomerac, rose apple, Brazilean cherry, Surinam cherry/grumichama (Eugenia uniflora))	0.02*
161990	Others	0.02*
162000	(b) Inedible peel, small	0.02*
162010	Kiwi	0.02*
162020	Lychee (Litchi) (Pulasan, rambutan/hairy litchi, longan, mangosteen, langsat, salak)	0.02*
162030	Passion fruit	0.02*
162040	Prickly pear (cactus fruit)	0.02*
162050	Star apple	0.02*
162060	American persimmon (Virginia kaki) (Black sapote, white sapote, green sapote, canistel/yellow sapote, mammey sapote)	0.02*
162990	Others	0.02*
163000	(c) Inedible peel, large	
163010	Avocados	0.02*
163020	Bananas (Dwarf banana, plantain, apple banana)	0.02*
163030	Mangoes	0.05
163040	Papaya	0.07
163050	Pomegranate	0.02*
163060	Cherimoya (Custard apple, sugar apple/sweetsop, ilama (Annona diversifolia) and other medium sized Annonaceae fruits)	0.02*
163070	Guava (Red pitaya/dragon fruit (Hylocereus undatus))	0.02*
163080	Pineapples	0.02*
163090	Bread fruit (Jackfruit)	0.02*
163100	Durian	0.02*
163110	Soursop (guanabana)	0.02*
163990	Others	0.02*

Code number	Groups and examples of individual products to which the MRLs apply (a)	Pyraclostrobin (F) EU MRL
200000	2. VEGETABLES FRESH OR FROZEN	
210000	(i) Root and tuber vegetables	
211000	(a) Potatoes	0.02*
212000	(b) Tropical root and tuber vegetables	0.02*
212010	Cassava (Dasheen, eddoe/Japanese taro, tannia)	0.02*
212020	Sweet potatoes	0.02*
212030	Yams (Potato bean/yambean, Mexican yambean)	0.02*
212040	Arrowroot	0.02*
212990	Others	0.02*
213000	(c) Other root and tuber vegetables except sugar beet	
213010	Beetroot	0.1
213020	Carrots	0.5
213030	Celeriac	0.3
213040	Horseradish (Angelica roots, lovage roots, gentiana roots)	0.3
213050	Jerusalem artichokes (Crosne)	0.06
213060	Parsnips	0.3
213070	Parsley root	0.1
213080	Radishes (Black radish, Japanese radish, small radish and similar varieties, tiger nut (Cyperus esculentus))	0.5
213090	Salsify (Scorzonera, Spanish salsify/Spanish oysterplant, edible burdock)	0.1
213100	Swedes	0.02*
213110	Turnips	0.02*
213990	Others	0.02*
220000	(ii) Bulb vegetables	
220010	(a) Garlic	0.3
220020	(b) Onions (Other bulb onions, silverskin onions)	1.5
220030	(c) Shallots	0.3
220040	(d) Spring onions and welsh onions (Other green onions and similar varieties)	1.5
220990	(e) Others	0.02*

Code number	Groups and examples of individual products to which the MRLs apply (a)	Pyraclostrobin (F) EU MRL
230000	(iii) Fruiting vegetables	
231000	(a) Solanacea	
231010	Tomatoes (Cherry tomatoes, Physalis spp., gojiberry, wolfberry (Lycium barbarum and L. chinense), tree tomato)	0.3
231020	Peppers (Chilli peppers)	0.5
231030	Aubergines (egg plants) (Pepino, antroewa/white eggplant (S. macrocarpon))	0.3
231040	Okra (lady's fingers)	0.02*
231990	Others	0.02*
232000	(b) Cucurbits — edible peel	0.5
232010	Cucumbers	0.5
232020	Gherkins	0.5
232030	Courgettes (Summer squash, marrow (patisson), lauki (Lagenaria siceraria), chayote, sopropo/bitter melon, snake gourd, angled luffa/teroi)	0.5
232990	Others	0.5
233000	(c) Cucurbits-inedible peel	0.5
233010	Melons (Kiwano)	0.5
233020	Pumpkins (Winter squash, marrow (late variety))	0.5
233030	Watermelons	0.5
233990	Others	0.5
234000	(d) Sweet corn (Baby corn)	0.02*
239000	(e) Other fruiting vegetables	0.02*
240000	(iv) Brassica vegetables	
241000	(a) Flowering brassica	0.1
241010	Broccoli (Calabrese, Broccoli raab, Chinese broccoli)	0.1
241020	Cauliflower	0.1
241990	Others	0.1
242000	(b) Head brassica	
242010	Brussels sprouts	0.3
242020	Head cabbage (Pointed head cabbage, red cabbage, savoy cabbage, white cabbage)	0.2
242990	Others	0.02*

Code number	Groups and examples of individual products to which the MRLs apply (a)	Pyraclostrobin (F) EU MRL
243000	(c) Leafy brassica	1.5
243010	Chinese cabbage (Indian or Chinese) mustard, pak choi, Chinese flat cabbage/ai goo choi), choi sum, Peking cabbage/pe-tsai)	1.5
243020	Kale (Borecole/curly kale, collards, Portuguese Kale, Portuguese cabbage, cow cabbage)	1.5
243990	Others	1.5
244000	(d) Kohlrabi	0.02*
250000	(v) Leaf vegetables & fresh herbs	
251000	(a) Lettuce and other salad plants including Brassicacea	
251010	Lamb's lettuce (Italian corn salad)	10
251020	Lettuce (Head lettuce, lollo rosso (cutting lettuce), iceberg lettuce, romaine (cos) lettuce)	2
251030	Scarole (broad-leaf endive) (Wild chicory, red-leaved chicory, radicchio, curly leaf endive, sugar loaf (C. endivia var. crispum/C. intybus var. foliosum), dandelion greens)	0.4
251040	Cress (Mung bean sprouts, alfalfa sprouts)	10
251050	Land cress	10
251060	Rocket, Rucola (Wild rocket (Diplotaxis spp.))	10
251070	Red mustard	10
251080	Leaves and sprouts of Brassica spp, including turnip greens (Mizuna, leaves of peas and radish and other babyleaf crops, including brassica crops (crops harvested up to 8 true leaf stage), kohlrabi leaves)	10
251990	Others	10
252000	(b) Spinach & similar (leaves)	
252010	Spinach (New Zealand spinach, amaranthus spinach (pak-khom, tampara), tajer leaves, bitterblad/bitawiri)	0.5
252020	Purslane (Winter purslane/miner's lettuce, garden purslane, common purslane, sorrel, glassworth, agretti (Salsola soda))	0.02*
252030	Beet leaves (chard) (Leaves of beetroot)	0.5
252990	Others	0.02*
253000	(c) Vine leaves (grape leaves) (Malabar nightshade, banana leaves, climbing wattle (Acacia pennata))	0.02*
254000	(d) Water cress (Morning glory/Chinese convolvulus/water convolvulus/water spinach/kangkung (Ipomea aquatica), water clover, water mimosa)	0.02*

Code number	Groups and examples of individual products to which the MRLs apply (a)	Pyraclostrobin (F) EU MRL
255000	(e) Witloof	0.02*
256000	(f) Herbs	2
256010	Chervil	2
256020	Chives	2
256030	Celery leaves (Fennel leaves, coriander leaves, dill leaves, caraway leaves, lovage, angelica, sweet cisely and other Apiacea leaves, culantro/stinking/long coriander/stink weed (Eryngium foetidum))	2
256040	Parsley (leaves of root parsley)	2
256050	Sage (Winter savory, summer savory, Borago officinalis leaves)	2
256060	Rosemary	2
256070	Thyme (Marjoram, oregano)	2
256080	Basil (Balm leaves, mint, peppermint, holy basil, sweet basil, hairy basil, edible flowers (marigold flower and others), pennywort, wild betel leaf, curry leaves)	2
256090	Bay leaves (laurel) (Lemon grass)	2
256100	Tarragon (Hyssop)	2
256990	Others	2
260000	(vi) Legume vegetables (fresh)	0.02*
260010	Beans (with pods) (Green bean/French beans/snap beans, scarlet runner bean, slicing bean, yard long beans, guar beans, soya beans)	0.02*
260020	Beans (without pods) (Broad beans, flageolets, jack bean, lima bean, cowpea)	0.02*
260030	Peas (with pods) (Mangetout/sugar peas/snow peas)	0.02*
260040	Peas (without pods) (Garden pea, green pea, chickpea)	0.02*
260050	Lentils	0.02*
260990	Others	0.02*
270000	(vii) Stem vegetables (fresh)	
270010	Asparagus	0.02*
270020	Cardoons (Borago officinalis stems)	0.02*
270030	Celery	0.02* (ft)

Footnotes:

Pyraclostrobin (F)
(F) = Fat soluble

0151010 Table grapes
The European Food Safety Authority identified some information on residue trials as unavailable. When reviewing the MRL, the Commission will take into account the information referred to in the first sentence, if it is submitted by 13 July 2015, or, if that information is not submitted by that date, the lack of it.

0270030 Celery
The European Food Safety Authority identified some information on residue trials as unavailable. When reviewing the MRL, the Commission will take into account the information referred to in the first sentence, if it is submitted by 13 July 2015, or, if that information is not submitted by that date, the lack of it.

0620000 (ii) Coffee beans
The European Food Safety Authority identified some information on analytical methods as unavailable. When re-viewing the MRL, the Commission will take into account the information referred to in the first sentence, if it is submitted by 13 July 2015, or, if that information is not submitted by that date, the lack of it.

0840040 Horseradish
The applicable maximum residue level for horseradish (Armoracia rusticana) in the spice group (code 0840040) is the one set for horseradish (Armoracia rusticana) in the vegetables category, root and tuber vegetables group (code 0213040) taking into account changes in the levels by processing (drying) according to Art. 20 (1) of Regulation (EC) No 396/2005.

CODEX MRLs set for the uses of pyraclostrobin

The list of current CODEX MRLs for pyraclostrobin can be found on the CODEX ALIMENTARIUS website (http://www.codexalimentarius.net/pestres/data/index.html).

The list (as of May 2014) is given below in this document to allow for direct comparison with the EU-MRLs shown above. CODEX and EU have the same residue definition established.

Commmodity	Pyraclostrobin CODEX MRL [mg/kg]	Note
Alfalfa fodder	30	
Apple	0.5	
Artichoke, Globe	2	
Banana	0.02	(*)
Barley	1	
Beans (dry)	0.2

MRLs (worldwide, except EU) set for the uses of pyraclostrobin

The MRLs currently set in the EU can be found in Document E1.

1. Residue definitions

The metabolites are given in Table 1 according to the chemical names found in the internet on the official authority websites. The respective metabolite codes are shown in the footnotes at the end of the table.
In case no clear information on the residue definition could be found on the official authority websites, an expert judgment was done based on BASF-internal knowledge and the official MRL-values given. The residue definition is described in these cases as "Pyraclostrobin (assumed as 'parent only')".

Table 1: Residue definitions for pyraclostrobin

Active Substance: Pyraclostrobin		
Country	**Residue definition plant**	**Residue definition animal**
Argentina	Pyraclostrobin (assumed as 'parent only')	
Australia	Pyraclostrobin (parent only)	Sum of pyraclostrobin and metabolites hydrolysed to 1-(4-chloro-phenyl)-1H-pyrazol-3-ol ** expressed as pyraclostrobin
Brazil	Sum of pyraclostrobin and its metabolite N-[[1-(4-chlorophenyl) pyrazol-3-yl]oxy-o-tolyl]carbamate *	
Canada	All food crops: methyl *N*-[2-[[[1-(4-chlorophenyl)-1*H*-pyrazol-3-yl]oxy]methyl]phenyl]-N-methoxycarbamate, including the metabolite carbamic acid, *N*-[2-[[[1-(4-chlorophenyl)-1*H*-pyrazol-3-yl] oxy] methyl]phenyl]-methyl ester *	All livestock commodities, except poultry related: methyl *N*-[2-[[[1-(4-chlorophenyl)-1*H*-pyrazol-3-yl]oxy]methyl]phenyl*]*-*N*-methoxycarbamate, including the metabolites convertible to 1-(4-chlorophenyl)-1*H*-pyrazol-3-ol and 1-(4-chloro-2-hydroxyphenyl)-1*H*-pyrazol-3-ol ** Eggs, meat and meat byproducts of poultry: methyl *N*-[2-[[[1-(4-chlorophenyl)-1*H*-pyrazol-3-yl]oxy]methyl]phenyl*]*-*N*-methoxycarbamate, including the metabolites convertible to 1-(4-chlorophenyl)-1*H*-pyrazol-3-ol and 1-(3-chloro-4-hydroxyphenyl)-1*H*-pyrazol-3-ol ***
Chile	Pyraclostrobin (assumed as 'parent only')	
China	Pyraclostrobin (assumed as 'parent only')	

Active Substance: Pyraclostrobin		
Country	**Residue definition plant**	**Residue definition animal**
CODEX	Pyraclostrobin (parent only)	Pyraclostrobin (parent only)
Israel	Pyraclostrobin (assumed as 'parent only')	
Japan	Pyraclostrobin (assumed as 'parent only')	Pyraclostrobin (assumed as 'parent only')
New Zealand	Pyraclostrobin (assumed as 'parent only')	Pyraclostrobin (assumed as 'parent only')
Russian Federation	Pyraclostrobin (assumed as 'parent only')	Pyraclostrobin (assumed as 'parent only')
South Africa	Pyraclostrobin (parent) and includes the -desmethoxy metabolite (source: NZ MRL database)	
South Korea	Pyraclostrobin (assumed as 'parent only')	
Taiwan	Pyraclostrobin (assumed as 'parent only')	
USA	Tolerances are established for residues of the fungicide pyraclostrobin, including its metabolites and degradates. Compliance with the tolerance levels specified is to be determined by measuring only the sum of pyraclostrobin (carbamic acid, [2-[[[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxy] methyl]phenyl]methoxy-methyl ester) and its desmethoxy metabolite (methyl-N-[[[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxy] methyl] phenylcarbamate) *, calculated as the stoichiometric equivalent of pyraclostrobin	Tolerances are established for combined residues of the fungicide pyraclostrobin carbamic acid, [2-[[[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxy] methyl]phenyl]methoxy- methyl ester and its metabolites convertible to 1-(4-chlorophenyl)-1H-pyrazol-3-ol and 1-(4-chloro-2-hydroxyphenyl)-1H-pyrazol-3-ol **, expressed as parent compound

* Desmethoxy metabolite 500M07 (synonym: BF 500-3)
** Metabolites 500M04 (synonym: BF 500-5) and 500M85 (synonym: BF 500-8)
*** Metabolites 500M04 (synonym: BF 500-5) and BF 500-9

2. CODEX MRLs set for the uses of pyraclostrobin

The list of current CODEX MRLs for pyraclostrobin can be found on the CODEX ALIMENTARIUS website:

(http://www.codexalimentarius.net/pestres/data/index.html)

The list of current CODEX MRLs (as of May 2014) is given below.

Commmodity	**Pyraclostrobin CODEX MRL [mg/kg]**	**Note**
Alfalfa fodder	30	
Apple	0.5

Wheat	0.2	

(*) at or about the limit of determination
(fat) (for meat) The MRL/EMRL applies to the fat of meat.

3. Country MRLs set for the uses of pyraclostrobin

For collecting all current MRL data, different sources were used (country homepages, Homologa database, farmers´ associations and BASF-internal information), a complete reliability check is not possible. In case an official MRL source was identified, this information is given.

Argentina

The list of current MRLs set for pyraclostrobin in Argentina can be found on the following website:

(http://produccion.sanjuan.gov.ar/index.php?option=com_content&view=article&id=200%3A productos-fitosanitarios-registrados-en-argentina-x&catid=92%3Adestacados&Itemid=130).
MRL list: Activos Registrados y sus LMR, con actualizaciones posteriores (Res. 934/2010).
The National of MRLs is rarely updated, e.g. 2008 Resolution 934/2010. Due to this fact the commercial data base HOMOLOGA was checked in addition to the official website of the authority.
(http://www.homologa-new.com/pls/apex/f?p=550:1)

The list of MRLs currently set in Argentina is given below.

Commodity	Pyraclostrobin MRLs in Argentina [mg/kg]
Garlic	0.05
Blueberry	0.5
Peach	0.2
Lemon	1
Orange	1
Soybean (oil)	0.1
Soybean (seed)	0.05
Wheat (seed)	0.2
Peanuts (shelled)	0.05

Sweet Pepper/Bell pepper	0.5 *
Radicchio	2 *
Peas (seed, fresh)	0.2 *

* MRL of the commercial data base HOMOLOGA

Australia

The list of current MRLs set for pyraclostrobin in Australia can be found on the Australian pesticides and veterinary medicines authority (APVMA) website:

(http://www.apvma.gov.au/residues/standard.php#tables)
MRL list: comlaw website (external site) - Agricultural and Veterinary Chemicals Code Instrument No. 4 (*MRL Standard*) 2012 - prepared 11 April 2014

The list of MRLs currently set in Australia (as of May 2014) is given below.

Commodity	**Pyraclostrobin MRLs in Australia [mg/kg]**
Banana	* 0.02
Blackberries	T 3
Blueberries	T 5
Brassica leafy vegetables	T 3
Broccoli, Chinese	T 1
Cereal grains	* 0.01
Cherries	T 1
Cloudberry	T 3
Custard apple	T 3
Dewberries (including Boysenberry and Loganberry)	T 3
Dried grapes	5
Edible offal (Mammalian)	0.1
Eggs	* 0.05
Fruiting vegetables, other than Cucurbits	0.3
Grapes	2
Litchi	T 2
Mango	0.1
Meat [mammalian][in the fat]	* 0.05
Milks	* 0.01
Mung bean (dry)	T 0.2
Papaya [pawpaw]	T 0.5
Passion fruit	T 1
Pistachio nut	T 1
Pome fruits	1
Poppy seed	* 0.05
Potato	* 0.02
Poultry, Edible offal of	* 0.05
Poultry meat [in the fat]	* 0.05
Raspberries, Red, Black	T 3

Commodity	Pyraclostrobin MRLs in Australia [mg/kg]
Silvanberries	T 3
Sunflower seed	T 0.3
Tree nuts [except Pistachio nut]	* 0.01
Youngberry	T 3
Almond hulls	3
Apple pomace, dry	25
Cereal forage, green	5
Grape pomace, dry	10
Mung bean fodder	T 2
Mung bean forage	T 2
Oat forage (green)[fresh weight]	* 0.05
Oat straw and fodder, dry	* 0.05
Straw and fodder of cereal grains, dry	0.5

* The MRL or the ERL is set at or about the limit of analytical quantitation.

T The MRL or ERL, residue definition or use is temporary to enable further experimental work to be carried out in Australia or overseas, and will be reconsidered at some future date. This symbol is also used in cases where an MRL or ERL is being phased out.

Brazil

The list of current MRLs set for pyraclostrobin in Brazil can be found on the Brazilian food safety agency (ANVISA) website:

(http://portal.anvisa.gov.br/wps/content/Anvisa+Portal/Anvisa/Inicio/Agrotoxicos+e+Toxicologia/Assuntos+de+Interesse/Monografias+de+Agrotoxicos/Monografias)

The list of MRLs currently set in Brazil (as of May 2014) is given below.

Commodity	Pyraclostrobin MRLs in Brazil [mg/kg]
Cotton	0.2
Garlic	0.1
Peanut	0.1
Rice	0,02
Oat	1.0
Banana	0.5
Potato	0.01
Coffee bean	0.5
Sugarcane	0.1
Onion	0.5
Carrot	0.2
Barley	1.0
Citrus fruits	0.5
Bean	0.1
Apple	2.0
Papaya	0.1
Mango	0.1
Watermelon	0.1

China

China's National Health and Family Planning Commission (NHFPC) published the updated National food safety standard – Maximum residue limits for pesticides in foods, GB2763-2014. This updated standard, GB2763-2014, enters into force on **August 1, 2014**. Upon implementation, GB2763-2014 will override the current MRL standard, GB2763-2012.

The commercial data base HOMOLOGA (http://www.homologa-new.com/pls/apex/f?p=550:1) and the New Zealand Food Safety Authority Pesticide MRL Database (https://pxmrl.maf.govt.nz/) were checked in addition to the official document of the authority.

The list of MRLs currently set in China (as of May 2014) is given below.

Commodity	Pyraclostrobin MRLs in China [mg/kg]
Apple	0.5
Banana	0.02
Head Cabbage	0.5
Chinese Cabbage	5
Cucumber	0.5
Grape	2
Lychee {Litchi}	0.05
Mango	0.05

USA

The list of current MRLs set for pyraclostrobin in the USA can be found on the Electronic Code of Federal Regulations (e-CFR) website:

(http://www.ecfr.gov/cgi-bin/text-idx?c=ecfr&SID=07b96fcbec7602f5f0fbdc6dfe01a430&tpl=/ecfrbrowse/Title40/40cfr180_main_02.tpl)

The list of MRLs currently set in the USA (as of May 2014) is given below.

Commodity	Pyraclostrobin MRLs in USA [mg/kg]
Alfalfa, forage	10
Alfalfa, hay	30
Almond, hulls	7.0
Apple, wet pomace	8.0
Artichoke, globe	3.0
Avocado	0.6
Banana	0.04
Barley, grain	1.4
Barley, hay	25
Barley, straw	6.0
Bean, succulent shelled	0.5
Beet, sugar, dried pulp	1.0
Beet, sugar, roots	0.2
Beet, sugar, tops	8.0
Berry, low growing, subgroup 13-07G, except cranberry	1.2
Brassica, head and stem, subgroup 5A	5.0
Brassica, leafy greens, subgroup 5B	16.0
Bushberry subgroup 13-07B	4.0
Caneberry subgroup 13-07A	4.0
Canistel	0.6
Citrus, dried pulp	12.5
Citrus, oil	9.0
Coffee, green bean	0.3
Corn, field, forage	5.0
Corn, field, grain	0.1
Corn, field, refined oil	0.2
Corn, field, stover	17.0
Corn, pop, grain	0.1
Corn, pop, stover	17.0
Corn, sweet, forage	5.0

Commodity	Pyraclostrobin MRLs in USA [mg/kg]
Corn, sweet, kernel plus cob with husks removed	0.04
Corn, sweet, stover	23.0
Cotton, gin byproducts	30
Endive, belgium	4.0
Fruit, citrus, group 10-10	2.0
Fruit, pome, group 11-10	1.5
Fruit, small vine climbing, except fuzzy kiwifruit, subgroup 13-07F	2.0
Fruit, stone, group 12	2.5
Grain, aspirated fractions	2.5
Grape, raisin	7.0
Grass, forage	10
Grass, hay	4.5
Grass, seed screenings	27
Grass, straw	14
Hop, dried cones	23.0
Mango	0.6
Nut, tree, group 14	0.04
Oat, grain	1.2
Oat, hay	18
Oat, straw	15
Oilseed group 20	0.45
Papaya	0.6
Pea, succulent	0.2
Pea and bean, dried shelled, except soybean, subgroup 6C	0.5
Peanut	0.05
Peanut, refined oil	0.1
Peppermint, tops	8.0
Persimmon	3.0
Pistachio	0.7
Radish, tops	16
Rye, grain	0.04
Rye, straw	0.5
Sapodilla	0.6
Sapote, black	0.6
Sapote, mamey	0.6
Sorghum, grain, forage	5.0
Sorghum, grain, grain	0.60
Sorghum, grain, stover	0.80
Soybean, forage	11
Soybean, hay	14

Commodity	Pyraclostrobin MRLs in USA [mg/kg]
Soybean, hulls	0.06
Soybean, seed	0.04
Spearmint, tops	8.0
Star apple	0.6
Sugarcane, cane	0.20
Vegetable, bulb, group 3-07	0.9
Vegetable, cucurbit, group 9	0.5
Vegetable, foliage of legume, except soybean, subgroup 7A	25.0
Vegetable, fruiting, group 8-10	1.4
Vegetable, leafy, except brassica, group 4	29.0
Vegetable, leaves of root and tuber, group 2, except sugar beet	16.0
Vegetable, legume, edible podded, subgroup 6A	0.5
Vegetable, root, except sugar beet, subgroup 1B	0.4
Vegetable, tuberous and corm, subgroup 1C	0.04
Vegetables, foliage of legume, group 7	25
Wheat, grain	0.02
Wheat, hay	6.0
Wheat, straw	8.5
Cattle, fat	0.1
Cattle, liver	1.5
Cattle, meat	0.1
Cattle, meat byproducts, except liver	0.2
Goat, fat	0.1
Goat, liver	1.5
Goat, meat	0.1
Goat, meat byproducts, except liver	0.2
Hog, fat	0.1
Hog, liver	1.5
Hog, meat	0.1
Hog, meat byproducts, except liver	0.2
Horse, fat	0.1
Horse, liver	0.1
Horse, meat	0.1
Horse, meat byproducts, except liver	0.2
Milk	0.1
Poultry, eggs	0.10
Poultry, fat	0.10
Poultry, meat	0.10
Poultry, meat byproducts	0.10

Commodity	Pyraclostrobin MRLs in USA [mg/kg]
Sheep, fat	0.1
Sheep, liver	1.5
Sheep, meat	0.1
Sheep, meat byproducts, except liver	0.2

e-mail address:

2 Information to facilitate identification

2.1 Common name (proposed or ISO-accepted)

Pyraclostrobin (ISO-accepted)

2.2 Chemical name (IUPAC and CAS nomenclature)

IUPAC: Methyl N-(2-{[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxymethyl}phenyl) N-methoxy carbamate

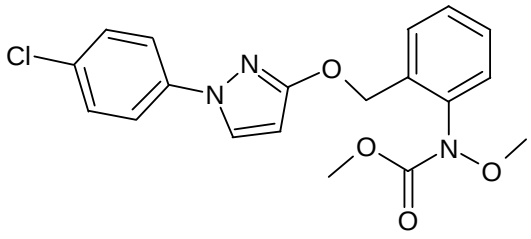
CAS: Carbamic acid, [2-[[[1-(4-chlorophenyl)-1H-pyrazol-3-yl]oxy]methyl]phenyl]methoxy-, methyl ester

2.3 CAS, CIPAC and EEC numbers (if available)

CAS: 175013-18-0
CIPAC: 657
EINECS: not assigned

2.4 Empirical and structural formula, molecular mass

Structural formula:



Molecular formula: $C_{19}H_{18}ClN_3O_4$
Molecular mass: 387.82

2.5 Specification of purity of the active substance in g/kg

Minimum purity: 975 g/kg

2.6 Classification and labelling

The classification and labelling according to Table 3.1 of Regulation (EC) No. 1272/2008 as amended by Commission Regulation (EC) No. 790/2009 is given as follows:

Classification:

Hazard class and Category:	Acute Tox. 3 Skin Irrit. 2 Aquatic Acute 1 Aquatic Chronic 1
H-statements:	H331, H315, H400, H410

Labelling:

Pictogram:	GHS06, GHS09
Signal word:	Danger
H-statements:	H331, H315, H410

3 New information

3.1 List of new information

References are given for the active substance pyraclostrobin (BAS 500 F), its metabolites and the representative formulations BAS 500 06 F and BAS 516 07 F.

These references are intended to be submitted together with a justification showing that they are considered necessary, in accordance with Article 15(2) of Regulation (EC) No 1107/2009.

As literature search is ongoing, only a few results are considered in the list.

Studies to determine the analytical profile of the active substance and the toxicity of its impurities are listed in a separate document, because for these studies confidentiality is claimed according to art 63 of 1107/2009.

3.1.1 Active substance pyraclostrobin (BAS 500 F)

Section 1: Identity of the active substance

New studies on the identity of the active substance are presented in the confidential part of the application.

Section 2: Physical and chemical properties of the active substance

Section 9: Fate and behaviour in the environment

A full set of exposure calculations will be provided for pyraclostrobin and its metabolites for which environmental risk assessments are triggered. The list of PEC calculation reports given below should thus be considered as preliminary. Additional PEC calculation reports might be provided as seen appropriate.

Data point	Author(s)	Year	Title Company Report No. Source (where different from company) GLP or GEP status Published or not	Vertebrate study Y/N	Data protection claimed Y/N	Justification for submission of study	Owner

KCP 5.1.1/5	Stegmaier W.	2012 a	Validation of an analytical method for the determination of dimethyl sulfate in BAS 516 07 F 2012/1213598 BASF SE - GMC Competence Center Analytics, Ludwigshafen, Germany Fed.Rep. Yes Unpublished	No	Yes	New representative formulation	BASF

Section 7: Toxicology

Data point	Author(s)	Year	Title Company Report No. Source (where different from company) GLP or GEP status Published or not	Vertebrate study Y/N	Data protection claimed Y/N	Justification for submission of study	Owner
KCP 7.1.1/1	[redacted]	2008 a	Acute oral toxicity in rats - Acute toxic class method 2008/1004838 [redacted] Yes Unpublished	Yes	Yes	New representative formulation	BASF
KCP 7.1.2/1	[redacted]	2001 a	BAS 516 00 F - Acute dermal toxicity study in rats 2001/1003723 [redacted] Yes Unpublished	Yes	Yes	New representative formulation	BASF
KCP 7.1.3/1	[redacted]	2001 b	BAS 516 00 F - Acute inhalation toxicity study in Wistar rats 4-hour dust exposure 2001/1001824 [redacted] Yes Unpublished	Yes	Yes	New representative formulation	BASF
KCP 7.1.4/1	[redacted]	2007 a	BAS 516 07 F: Acute dermal irritation / corrosion in rabbits 2007/1056989 [redacted] Yes Unpublished	Yes	Yes	New representative formulation	BASF
KCP 7.1.5/1	[redacted]	2007 b	BAS 516 07 F: Acute eye irritation in rabbits 2007/1056988 [redacted] Yes Unpublished	Yes	Yes	New representative formulation	BASF
KCP 7.1.6/1	[redacted]	2014	BAS 516 07 F: Skin Sensitization: Local Lymph Node Assay 2014/1001403 [redacted] Yes Unpublished	Yes	Yes	New data	BASF
KCP 7.3/1	Hassler S.	2014	BAS 510 F: Percutaneous Penetration of ^{14}C BAS 510 F formulated as BAS 516 07 F through human split-thickness skin membranes (in-vitro) 2014/1001401 Harlan Laboratories Ltd., Itingen, Switzerland Yes Unpublished	No	Yes	New data	BASF

Data point	Author(s)	Year	Title Company Report No. Source (where different from company) GLP or GEP status Published or not	Vertebrate study Y/N	Data protection claimed Y/N	Justification for submission of study	Owner
KCP 7.3/2	Hassler S.	2014	BAS 500 F: Percutaneous Penetration of ^{14}C BAS 500 F formulated as BAS 516 07 F through human split-thickness skin membranes (in-vitro) 2014/1001401 Harlan Laboratories Ltd., Itingen, Switzerland Yes Unpublished	No	Yes	New data	BASF

Section 9: Fate and behaviour in the environment

A full set of exposure calculations will be provided for pyraclostrobin and its metabolites for which environmental risk assessments are triggered. Exposure calculations will be also provided for the second active substance boscalid in formulation BAS 516 07 F. The list of PEC calculation reports given below should thus be considered as preliminary. Additional PEC calculation reports might be provided as seen appropriate.

Data point	Author(s)	Year	Title Company Report No. Source (where different from company) GLP or GEP status Published or not	Vertebrate study Y/N	Data protection claimed Y/N	Justification for submission of study	Owner
KCP 9.1.3/1	Eickler B.	2014	Predicted environmental concentrations in soil, groundwater, surface water and sediment of pyraclostrobin and its metabolites after application of its representative formulations 2014/1000685 No Unpublished	No	No	New exposure assessments according to newest guidelines and guidance documents	BASF
KCP 9.1.3/2	Eickler B.	2014	Predicted environmental concentrations in soil, groundwater, surface water and sediment of boscalid after application of BAS 516 07 F to potatoes 2014/1001461 No Unpublished	No	No	New exposure assessments according to newest guidelines and guidance documents	BASF
KCP 9.2.4/1	Eickler B.	2014	Predicted environmental concentrations in soil, groundwater, surface water and sediment of pyraclostrobin and its metabolites after application of its representative formulations 2014/1000685 No Unpublished	No	No	New exposure assessments according to newest guidelines and guidance documents	BASF
KCP 9.2.4/2	Eickler B.	2014	Predicted environmental concentrations in soil, groundwater, surface water and sediment of boscalid after application of BAS 516 07 F to potatoes 2014/1001461 No Unpublished	No	No	New exposure assessments according to newest guidelines and guidance documents	BASF
KCP 9.2.5/1	Eickler B.	2014	Predicted environmental concentrations in soil, groundwater, surface water and sediment of pyraclostrobin and its metabolites after application of its representative formulations 2014/1000685 No Unpublished	No	No	New exposure assessments according to newest guidelines and guidance documents	BASF

Data point	Author(s)	Year	Title Company Report No. Source (where different from company) GLP or GEP status Published or not	Vertebrate study Y/N	Data protection claimed Y/N	Justification for submission of study	Owner
KCP 9.2.5/2	Eickler B.	2014	Predicted environmental concentrations in soil, groundwater, surface water and sediment of boscalid after application of BAS 516 07 F to potatoes 2014/1001461 No Unpublished	No	No	New exposure assessments according to newest guidelines and guidance documents	BASF

Section 10: Ecotoxicology

Data point	Author(s)	Year	Title Company Report No. Source (where different from company) GLP or GEP status Published or not	Vertebrate study Y/N	Data protection claimed Y/N	Justification for submission of study	Owner
KCP 10.1.1.1/1	[redacted]	2006 a	BAS 516 07 F - Acute toxicity in the bobwhite quail (Colinus virginianus) after single oral administration (LD50) 2006/1030309 [redacted] Yes Unpublished	Yes	Yes	New representative formulation	BASF
KCP 10.2.1/1	[redacted]	2000 a	BAS 516 00 F - Acute toxicity study on the rainbow trout (Oncorhynchus mykiss WALBAUM 1792) in a static system (96 hours) 2000/1018726 [redacted] Yes Unpublished	Yes	Yes	New representative formulation	BASF
KCP 10.2.1/2	Janson G.-M.	2007 a	Acute toxicity of BAS 516 07 F to Daphnia magna STRAUS in a 48 hour static test 2007/1008605 BASF AG Agrarzentrum Limburgerhof, Germany Fed.Rep. Yes Unpublished	No	Yes	New representative formulation	BASF
KCP 10.2.1/3	Janson G.-M.	2009 a	Acute toxicity of BAS 516 07 F to Daphnia magna STRAUS in a 48 hour static test 2009/1117877 BASF SE, Limburgerhof, Germany Fed.Rep. Yes Unpublished	No	Yes	New representative formulation	BASF
KCP 10.2.1/4	Hoffmann F.	2007 a	Effect of BAS 516 07 F on the growth of the green alga Pseudokirchneriella subcapitata 2007/1005074 BASF AG Agrarzentrum Limburgerhof, Germany Fed.Rep. Yes Unpublished	No	Yes	New representative formulation	BASF

Data point	Author(s)	Year	Title Company Report No. Source (where different from company) GLP or GEP status Published or not	Vertebrate study Y/N	Data protection claimed Y/N	Justification for submission of study	Owner
